
COMMENTS ON CALIFORNIA STATE WATER RESOURCES CONTROL BOARD'S

PROPOSED AMENDMENTS TO THE WATER QUALITY CONTROL PLAN FOR ENCLOSED BAYS AND ESTUARIES – PART 1, SEDIMENT QUALITY FOR THE PROTECTION OF FISH AND WILDLIFE

JANUARY 2011

Submitted by: Date: March 15, 2011

California Business Properties Association
California Chamber of Commerce
Construction Industry Coalition on Water Quality
Southern California Contractors Association

Our organizations appreciate the opportunity to submit public comments to the California State Water Resources Control Board ("SWB"), in response to the issuance on January 28, 2011 of proposed amendments to the Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality for the Protection of Fish and Wildlife ("the Bays and Estuaries Plan").[1]

Our organizations support and encourage the SWB's efforts in developing sediment quality objectives and related implementation policies in the Bays and Estuaries Plan that are protective of benthic invertebrates, fish and wildlife, and human health. However, we believe the proposed amendments to the Bays and Estuaries Plan are not consistent with SWB's stated objectives, and, instead, propose excessively low concentrations for certain compounds which have no rational basis in science and do not correspond to any identifiable decrease in risk.

Specifically, we have serious concerns with SWB's proposed amendments to the Chemical Score Index ("CSI") because these amendments are contrary to real-world, scientifically-observed conditions. The proposed amendments also increase the risk that Regional Water Quality Control Boards may misuse concentration ranges by extracting these values from the Bays and Estuaries Plan and using them in an inappropriate manner to establish cleanup levels, in contravention of the integrated, multi-step process set forth in the Bays and Estuaries Plan. Indeed, staff for one such Regional Board already has done just this, as demonstrated by the California Regional Water Quality Control Board, Los Angeles Region's ("RWB") recent draft Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters total maximum daily load for toxic pollutants ("the Draft TMDL"). Accordingly, we request that the SWB revise its proposed amendments to be consistent with good science.

I. THE PROPOSED CSI AMENDMENTS FOR DDT ARE NOT SCIENTIFICALLY BASED

A. Benthic Organisms Are Not Affected By DDT Even At Levels Hundreds Of Times Higher Than Those In The Current Or Proposed CSI.

The proposed amendments to the Bays and Estuaries Plan would lower the category score concentration ranges for the CSI for DDE, DDT, and DDD. Under these amendments, the "high disturbance" thresholds for DDE, DDT, and DDD would be lowered from 154, 89.3, and 117 ug/kg, respectively, to 45.84, 34.27, and 26.37 ug/kg respectively. In addition, the DDE, DDT,

---

[1] These comments are based on SWB's report entitled, "Proposed Amendments to the Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality for the Protection of Fish and Wildlife" (January 28, 2011) (hereinafter "Staff Report"), and attachments thereto. We respectfully request that the cover letter, these public comments, appendices, and attachments submitted herewith be given appropriate consideration, be placed in the administrative record for the proposed Bays and Estuaries Plan amendments and be maintained in the agency's records.

and DDD values for the moderate, low, and reference disturbance categories would also change,[2] as would the weighting factors.[3]

These proposed amendments to the DDE, DDT, and DDD thresholds in the Bays and Estuaries Plan are unnecessary because the current thresholds are far too low in the first place, and do not correspond to any level of disturbance to benthic organisms. To be consistent with relevant published thresholds regarding potential effects of DDT on benthic organisms, the current CSI thresholds would need to be increased significantly – not lowered as proposed. There is a published no-observed-effect concentration ("NOEC") for total DDTs in the Southern California Bight of 8.51 mg/kg, or parts per million ("ppm") (equivalent to 8,510 ug/kg, or parts per billion ("ppb")).[4] A NOEC is the concentration below which there is no observed harm to the organisms at issue. This NOEC level indicates that DDT does not represent a threat to the benthic community at ambient levels prevalent throughout most of the water bodies to which the Bays and Estuaries Plan applies.[5] It is based on samples collected in 1994, and, since that time, DDT in the Southern California Bight has further aged, weathered, and been subject to other processes that would tend to make it less bioavailable. Thus, the NOEC today reasonably can be expected to be significantly greater than 8,510 ppb.

The published 8.51 mg/kg value corresponds to the concentration below which there were no observed effects on organisms in 1994, yet it is *hundreds of times greater* than the values currently in the CSI "disturbance" table and those proposed for the amended "disturbance" table. There is no scientific or evidentiary basis for SWB to conclude that sediment in bays and estuaries is in any way "disturbed" by DDT at levels below 8.51 mg/kg. We respectfully request that SWB set the threshold for "low disturbance" above 8.51 mg/kg, and that the moderate and high disturbance category scores are set even higher.

B. DDT Is Not A Risk To People; Any Threshold Concentration Based On Protecting Human Health Should Be Raised, Not Lowered.

SWB's legislative mandate to promulgate the Bays and Estuaries Plan states that the Bays and Estuaries Plan should be geared towards protecting against any health risk from the exposure

---

2 The upper thresholds for the moderate disturbance categories would go from (all in ug/kg) 154 to 45.84 (for DDE), 89.3 to 34.27 (DDT), and 117 to 26.37 (DDD). The upper thresholds for the low disturbance categories would go from (all in ug/kg) 4.15 to 6.01 (DDE), 1.52 to 2.79 (DDT), and 2.69 to 3.56 (DDD). Finally, the reference disturbance categories would go from (all in ug/kg) 0.50 to 1.19 (DDE), 0.50 to 0.61 (DDT), and 0.50 to 0.77 (DDD).

3 The weighting factors would change from 31 to 33 (DDE), 16 to 20 (DDT), and 46 to 45 (DDD).

4 Chapman, P.M. (1996). A Test of Sediment Effect Concentrations: DDT and PCB in the Southern California Bight. Env. Tox. and Chem., 15: 1197-1198.

5 See attached expert repot of Dr. Susan Kane Driscoll regarding bioavailability of DDT. This expert report was prepared in support of Montrose Chemical Corporation of California's ("Montrose") public comment letter on the Draft TMDL (discussed below).

of humans to pollutants through the food chain to edible fish, shell fish, or wildlife.[6] As such, the threshold values for pollutants in the Bays and Estuaries Plan should be based on values that pose a health risk to humans. As relevant here, this has not been done for DDT, as DDT does not present a risk to human health.

Numerous published studies have shown that DDT does not pose a risk to human health. In fact, discovery of DDT's insecticidal properties won Dr. Paul Mueller, the discoverer, the Nobel Prize in Physiology or Medicine in 1948.[7] These insecticidal properties have been used to improve human health throughout the world by saving lives that would otherwise be lost to malaria.[8] Multiple studies have demonstrated that there is a lack of connection between DDT and various cancers.[9]

Because DDT does not have adverse impacts on human health, any threshold value which is used in a process designed to protect human health should be raised from the current values, not lowered as contemplated by the proposed Bays and Estuaries Plan amendments to the CSI thresholds.

C. The Proposed Amendments To The Bays And Estuaries Plan Increase The Risk Of Misuse By Regional Boards.

The proposed amendments to the CSI disturbance table increase the risk of misuse by Regional Boards, as described below.

1. The Bays and Estuaries Plan is an integrated policy, where all steps are required to assess sediment quality.

It is our understanding that the Bays and Estuaries Plan is an integrated state-wide policy for the regulation of contaminated sediments. Specifically, the Bays and Estuaries Plan adopts a triad approach to assessing whether a particular sediment is impacted by toxic substances, and

---

6 Cal. Water Code § 13393(b) ("[t]he state board shall base the sediment quality objectives on a health risk assessment if there is a potential for exposure of humans to pollutants through the food chain to edible fish, shellfish, or wildlife.").

7 Expert Report of Donald Roberts, PhD from Garza v. Allied Chem. Corp., Case No. C-4885-99-F(10), 332d Judicial Dist., Hidalgo Co., Texas (describing the beneficial uses of DDT and the lack of negative human health effects).

8 Expert Report of Amir Attaran, PhD, LL.B from Garza v. Allied Chem. Corp., Case No. C-4885-99-F(10), 332d Judicial Dist., Hidalgo Co., Texas (describing the lack of negative human health effects of DDT and highlighting the extensive uses which improve human health and save lives that would otherwise be lost to malaria).

9 See, e.g., Expert Report of Seymore Grufferman, M.D., Dr. P.H. from Garza v. Allied Chem. Corp., Case No. C-4885-99-F(10), 332d Judicial Dist., Hidalgo Co., Texas (examining the lack of link between DDT and cancer); Expert Report of Marion J. Fedoruk from Garza v. Allied Chem. Corp., Case No. C-4885-99-F(10), 332d Judicial Dist., Hidalgo Co., Texas (examining the lack of link between DDT and non-Hodgkin lymphoma).

then employs a step-wise approach to identify the toxic agent and set a target for cleanup.[10] The triad approach uses multiple lines of evidence ("MLOE") to conclude whether sediment is impacted. These MLOE include sediment toxicity, benthic community condition, and sediment chemistry.[11] The Bays and Estuaries Plan makes it clear that no single line of evidence ("LOE") is a sufficient tool to assess sediment quality when used alone because no "individual LOE is sufficiently reliable when used alone to assess sediment quality impacts due to toxic pollutants."[12] Additionally, the Bays and Estuaries Plan states that "the chemistry LOE . . . shall not be used for setting cleanup levels or numeric values for technical TMDLs."[13]

It is clear that the Bays and Estuaries Plan requires the use of an integrated, multi-step process, including the use of the MLOE and step-wise processes, where each step is completed and all three of the LOEs are used concurrently to assess sediment quality.[14] Unfortunately, this is not what is happening at the Regional Board level, as demonstrated by RWB's recent development of the Draft TMDL.

2. RWB impermissibly uses portions of the Bays and Estuaries Plan in isolation, and fails to complete the required multi-step process.

In December 2010, the RWB released the Draft TMDL to address alleged impairments from toxic pollutants in waterbodies in the Dominguez Channel and Greater Los Angeles and Long Beach Harbor waters (collectively, "the Harbor Waters"). As part of the Draft TMDL, the RWB proposed "sediment targets" for several pollutants, including DDT.

The Draft TMDL ignores the integrated, multi-step process set forth in the Bays and Estuaries Plan. Instead, the Draft TMDL improperly excerpts portions of the Bays and Estuaries Plan and uses these provisions in isolation as targets for the individual LOEs. For example, the Draft TMDL Staff Report states that the target for the benthic community effects LOE is either "reference" or "low" disturbance.[15] The Draft TMDL Staff Report also sets the target for the toxicity LOE as "nontoxic."[16] For the sediment chemistry LOE, the Draft TMDL improperly utilizes the "Effect Range Low" ("ERL") screening values, which are not even a part of the Bays

11 Bays and Estuaries Plan at 3.

12 Id.

13 Id. at 20.

14 Indeed, Mr. Christopher Beegan, SWB's lead staff person and scientist for the Bays and Estuaries Plan testified to this very topic in an unrelated proceeding in October 2010. Specifically, Mr. Beegan testified in his deposition with respect to the importance of the step-wise approach in the Bays and Estuaries Plan and the risks involved in using individual LOEs apart from the integrated process. The full transcript of Mr. Beegan's deposition is being submitted with this comment letter.

15 Draft TMDL Staff Report at 47.

16 Id. at 49.

and Estuaries Plan, and uses these values in isolation to try to support sediment cleanup levels in the Harbor Waters.[17]

The Draft TMDL uses these targets and screening values to develop TMDL standards without completing the mandatory steps set forth in the Bays and Estuaries Plan, including the MLOE process, stressor identification, studies on the chemical linkage to impairment, identification of pollutant chemicals or classes of chemicals, source identification, and development of Sediment Management Guidelines ("SMGs") consistent with the course of action.[18]

The RWB's use of the ERL screening values is especially concerning because the ERL screening values were not developed through, or endorsed by, the Bays and Estuaries Plan process or any similar MLOE approach. Rather, the ERLs are screening values which are relevant only to the sediment chemistry LOE, as they do not predict sediment toxicity or benthic community effects. The study which developed the ERL screening values explicitly stated that the ERLs were not meant as indicators of toxicity or biologic effects.[19] This is especially true for mercury, nickel, total PCBs, total DDT, and DDE which were all identified in the ERL study as chemicals for which "there were relatively weak relationships between their concentrations and the incidence of effects."[20]

Two years after the ERLs first were published, government scientists from the United States Environmental Protection Agency ("EPA") and the National Oceanic and Atmospheric Administration ("NOAA") recognized the lack of utility for using the ERLs and the "effects range median" ("ERM") a higher, related screening value for purposes of setting sediment targets, stating:

> "The lack of even ER-L exceedance does mean that toxic effects are unlikely, but ER-M exceedances should only be taken to indicate that further analysis is in order. They should never be taken, by themselves, to mean that sediment is exerting a toxic

18 See attached expert report of Drs. D. Frederick Bodishbaugh and Charles Menzie regarding the misuse of the Bays and Estuaries Plan in the Draft TMDL. This expert report was prepared as a technical comment on the Draft TMDL.

19 "The [ERL and ERM] numerical guidelines should be used as informal screening tools in environmental assessments. They are not intended to preclude the use of toxicity tests or other measures of biological effects." Long, E.R., MacDonald, D.D., Smith, S.L., and Calder, F.D. 1995. Incidence of adverse biological effects within ranges of chemical concentrations in marine and estuarine sediments, Environmental Management 19(1): 81-97 at 95.

20 Id.

effect upon the environment or that there would be any benefit to decreasing its chemical content."[21]

Neither the ERLs nor the disturbance levels set out in the Bays and Estuaries Plan were intended to be directly used to develop TMDL standards or establish sediment cleanup levels, outside of the integrated process required by the Bays and Estuaries Plan. It is clear that the RWB's extraction of individual provisions of the Bays and Estuaries Plan in the Draft TMDL not only did not comply with the many requirements of the Bays and Estuaries Plan, including the MLOE and step-wise processes, but is also not related to the stated objectives of the Bays and Estuaries Plan to protect the benthic community and human health.[22]

3. Use of numeric thresholds separate from the fully integrated process risks a misallocation of resources, as demonstrated in the Draft TMDL.

Achieving compliance with the Draft TMDL would require implementation costs which RWB has estimated to exceed $900 million, including a dredging program with a cost estimated at nearly $700 million.[23] This estimate, however, is based on the low end of the sediment volume the Draft TMDL predicts will need to be dredged, and an unrealistically low value per cubic yard for the cost of remedial dredging. Applying the RWB's higher range for dredged material and a mid-range unit dredging cost, the actual cost of complying with the Draft TMDL could likely approach $7.0 billion.[24] Because the Draft TMDL has many flaws, some of which are pointed out in this comment letter, the cleanup program proposed by RWB is unwarranted, but this enormous estimated cost demonstrates the profound consequences which may occur if Regional Boards are allowed to improperly isolate numeric values out of studies and policies like the Bays and Estuaries Plan without completing the required integrated process.

22 See attached expert report of Drs. John Slocomb and Paul Mehrle regarding the use of the ERL screening values by RWB in the Draft TMDL. This expert report was prepared as a technical comment on the Draft TMDL.

23 Draft TMDL Staff Report at 125.

24 The roughly $700 million estimate for the dredging program supplied by RWB grossly underestimates the cost per cubic yard ("cy") to be dredged, estimating it at $60.84 per cy, when $200 per cy is a more reasonable estimate for remedial dredging based on prior remedial dredging projects in California. The $700 million estimate also uses an estimated volume to be dredged which does not correspond to the sediment targets proposed in the Draft TMDL. The estimated volume which corresponds with the TMDL targets proposed by RWB is over three times larger than the estimate RWB used. When this larger volume estimate and the $200 per cy estimate are used, the cost calculated for the dredging program is $6.9 billion. See attached expert report by Dr. David Sunding regarding the economics of the Draft TMDL. This expert report was prepared as a technical comment on the Draft TMDL.

The potential cost of compliance with future TMDLs may also be increased if the numeric threshold values for DDT are lowered as proposed here. Regional Boards may take this opportunity to extract these lowered disturbance levels and use these values as cleanup standards or sediment targets in other TMDLs, which may only increase the cost of compliance with the TMDL. Any future sediment standards or targets set with these lowered DDT "disturbance" values may thus result in the potential expenditure of tremendous resources to bring sediments into compliance with a value that is not based on any available science.

4. SWB should reemphasize that the numeric values in the Bays and Estuaries Plan are not to be extracted and used for sediment targets or cleanup values.

SWB should reemphasize to the Regional Boards that numeric values, and the individual LOEs, are not to be extracted and used independently of the fully integrated Bays and Estuaries Plan process. Such statements are in the current Bays and Estuaries Plan, but as demonstrated by the RWB's Draft TMDL, Regional Boards may not appreciate the import of these statements.

To prevent further misuse of the Bays and Estuaries Plan in the future, SWB should consider adding additional clarification to the Bays and Estuaries Plan to reiterate to the Regional Boards that the Bays and Estuaries Plan is an integrated process from which individual LOEs are not to be separated and used in isolation, risking a great expenditure of resources with no commensurate environmental benefit.

Short Communication

A TEST OF SEDIMENT EFFECTS CONCENTRATIONS: DDT AND PCB IN THE SOUTHERN CALIFORNIA BIGHT

PETER M. CHAPMAN
EVS Environment Consultants, 195 Pemberton Avenue, North Vancouver, BC V7P 2R4, Canada

(*Received* 14 *August* 1995; *Accepted* 2 *January* 1996)

Abstract—Independent efforts to determine concentrations of polychlorinated biphenyls (PCBs) and dichlorodiphenyltrichloroethanes (DDTs) along the Southern California Bight which result in adverse biological effects resulted in similar values. A correlative approach using historic data calculated the following likely sediment effects concentrations: total DDTs, 7.12 mg/dry kg (199 mg/kg organic carbon [OC]); and total PCBs, 0.592 mg/dry kg (30.4 mg/kg OC). Testing of field-collected sediments yielded the following no-observed-effect concentrations based on full life-cycle testing: total DDTs, 8.51 mg/dry kg (269 mg/kg OC); and total PCBs, 1.07 mg/dry kg (36.6 mg/kg OC).

Keywords—Sediment Toxicity tests DDT PCB

INTRODUCTION

As part of litigating damage claims for the injury or destruction of natural resources related to dichlorodiphenyltrichloroethanes (DDTs) and polychlorinated biphenyls (PCBs) deposited in the marine environment of southern California (the Southern California Bight Damage Assessment), a variety of independent studies were conducted. One of these studies involved determining the toxicity of spiked and field-collected sediments [1]. Another study involved using historic data to determine sediment effects concentrations [2]. When these studies were compared, the results of testing with field-collected sediments were determined to be consistent with predicted sediment effects values. This consistency is noteworthy and is reported herein.

METHODS

Sediment effects concentrations (SECs) for total DDTs (tDDT) and total PCBs (tPCB) in the Southern California Bight were determined to identify the concentrations of sediment-associated contaminants which are likely to cause, or to be associated with, adverse effects on sediment-dwelling organisms. The sum of *p,p′*-DDT, *o,p′*-DDT, *p,p′*-DDE (dichlorodiphenyldichloroethylene), *o,p′*-DDE, *p,p′*-DDD (dichlorodiphenyldichloroethane), and *o,p′*-DDD were defined as tDDT. All PCBs found in the Southern California Bight were defined as tPCB. Methodology involved a literature review with a weight-of-evidence approach to determine the ranges of chemical concentrations that were rarely, occasionally, or frequently associated with biological effects [3].

Full life-cycle (120-d) toxicity tests using the marine polychaete worm *Neanthes arenaceodentata* were conducted on Southern California Bight sediments contaminated with PCBs and DDTs. Full details of this testing, which is based on procedures adapted from Dillon et al. [4], will be the subject of a separate publication. Briefly, testing began with larvae and proceeded through to production of emergent juveniles. End points measured included survival, growth, fecundity, and reproduction.

Table 1. Predicted sediment effects concentration (SEC) compared to measured no-observed-effect concentration (NOEC)

Contaminant	SEC (mg/dry kg)	NOEC (mg/dry kg)	Ratio[a]	SEC (mg/kg OC)	NOEC (mg/kg OC)	Ratio[a]
tDDT	7.12	8.51	1.20x	199	269	1.35x
tPCB	0.592	1.07	1.81x	30.4	36.6	1.20x

tDDT = total dichlorodiphenyltrichloroethanes; tPCB = total polychlorinated biphenyls; OC = organic carbon.
[a] NOEC value divided by SEC value.

RESULTS AND DISCUSSION

The SECs and no-observed-effect concentrations (NOECs) for the two separate studies are provided and compared in Table 1. Effectively, though inadvertently, the measured polychaete NOECs serve to test the utility of the calculated SECs. Specifically, SECs were designed to provide a sediment value above which adverse effects would be expected to occur. The NOECs ranged from factors of 1.2 to 1.8 above the SECs, thus indicating that the SECs were appropriate.

Although neither method proves cause and effect, both are useful for determining screening level concentrations for individual contaminants. The utility of such concentrations does not include establishing rigorous sediment quality criteria but does include use as part of a burden-of-evidence approach to assessing the significance and extent of natural resource damage, a basis for identifying and delineating areas of concern, and a basis for identifying contaminants of concern.

Acknowledgement—I thank Don MacDonald for encouraging me to proceed with this publication. The manuscript was word processed by Vickie Duff.

EXTERNAL MEMORANDUM

TO: California Regional Water Quality Control Board, Los Angeles Region; U.S. Environmental Protection Agency, Region 9

FROM: Susan Kane Driscoll, Ph.D.

CC: Paul Singarella

DATE: February 17, 2011

SUBJECT: Site-Specific Bioavailability Has Not Been Considered in the TMDL Process for Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters

---

The TMDL report[1] presents a number of target levels for metals, PAHs, and bioaccumulative compounds such as PCBs and DDT. Bioavailability of chemicals is a critical aspect of understanding exposures and risks. However, the TMDL document does not consider this component of exposure. Instead, it presumes that chemicals are readily available. This assumption can yield target levels that are much lower than necessary for effective and wise water quality management. In this memorandum, we make the following points:

- Explicit consideration of bioavailability is a critical aspect of understanding exposures of biota to contaminants in water and sediments.
- The TMDL development is highly uncertain, because it does not factor bioavailability considerations into the development of target levels.

In this memorandum, we refer to Dominguez Channel and Greater Los Angeles and Long Beach Harbor waters as "The System."

Explicit Consideration of Bioavailability is Critical for Understanding Exposures

Since the early 1980s, when EPA began to attempt to establish sediment quality criteria, it became apparent that bioavailability of hydrophobic organic chemicals varies greatly among sediments. Whereas measured concentrations in water can generally be directly related to

[1] California Regional Water Quality Control Board, Los Angeles Region, and U.S. Environmental Protection Agency, Region 9. 2010. Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters Toxic Pollutants Total Maximum Daily Loads, Draft, December 2010.

adverse effects, measured concentrations of toxicants in sediment are often not at all directly related to expected adverse effects. This apparent difference between exposure and actual effect results from differences in bioavailability. EPA guidance acknowledges that toxicity may not be predicted accurately by simple bioaccumulation models, because properties of the sediments at the site may alter bioavailability (U.S. EPA 2003[2], 2008[3]).

Insights into the importance of considering the bioavailability of chemicals like DDT come from research on soils. For example, the effects of aging on the toxicity of DDT in soil were demonstrated in a study by Robertson and Alexander.[4] Mortality of insects exposed to soil spiked with DDT declined after aging the soil for 30 to 270 days. After 270 days, DDT-spiked soil was no longer toxic to one of three species tested, despite concentrations of DDT that were maintained at 84.7% of initial concentrations. In addition, Morrison et al. (2000[5]) documented extensive decline in bioavailability to earthworms as a result of aging DDT, DDE, DDD, in field soils. The authors of that study concluded that only 30%, 12%, 34%, and 20% of DDT, DDE, DDD, and total DDx were bioavailable in a soil treated in the field with DDT 49 years earlier. These studies highlight the importance of accounting for bioavailability when assessing exposure to residual compounds, the use of which ended decades ago. The presence of legacy compounds such as total DDT and PCBs in sediments means that they have been in the environment for a long time. This also means that the bioavailability of these chemicals is likely greatly reduced. The TMDL document makes no mention of this important time-dependent process.

The bioavailability of sediment-associated hydrophobic organic contaminants such as PCBs and DDT is a very important consideration in risk assessments and risk management. It is well established that the bioaccumulation of hydrophobic organic contaminants such as PCBs and DDT from sediment can be influenced by a variety of site-specific physical and chemical mechanisms, including adsorption, absorption, and ionic bonding, that act to reduce the concentration of toxic chemicals in sediment that is freely dissolved in sediment interstitial waters and is bioavailable (Di Toro et al. 1991[6]; U.S. EPA 2003[7], 2008[8]). Metals are also

influenced by physical and chemical mechanisms that must be considered in estimating exposure and associated risk (U.S. EPA 1999).[9] Bioavailability can also vary depending on how the chemicals are introduced into the system and in which environmental media they reside. For example, the bioavailability of chemicals that enter The System from atmospheric deposition is very different from that which enters from runoff of particulates. U.S. EPA recommends that bioavailability of hydrophobic organic contaminants be determined by estimating or measuring the freely dissolved chemical concentration in sediment interstitial water (U.S. EPA 2003).[10] This approach does not suggest that exposure to aquatic organisms is only from interstitial water, but rather that the interstitial water concentration is most closely correlated with the fraction of the total contaminant that is free to partition among all phases.

Approaches used to assess bioavailability typically assume that the contaminant is distributed into multiple phases: freely dissolved or associated with dissolved organic carbon in interstitial water, with natural sedimentary organic carbon, or with black carbon (discussed below). Recent research has made measurement of the bioavailable concentration feasible. The bioavailable concentrations can be determined in various ways: (1) estimated using a two-carbon model that takes into account the association of contaminants with black carbon, (2) extracted directly from interstitial waters, (3) estimated by passive sampling of whole sediments, and (4) estimated by passive sampling of interstitial waters (Hawthorne et al. 2007[11]; Kane Driscoll et al. 2009[12]; McArdle et al. 2010[13]). Standard methods for measuring bioavailable concentrations of certain hydrophobic organic compounds have been established (ASTM 2010[14]), and methods for other

hydrophobic organic compounds are in widespread use. Failure to incorporate approaches that are available to determine the bioavailability of sediment-associated hydrophobic organic compounds in the development of the TMDL are not consistent with current practice and contribute to the uncertainty and unreliability of the TMDL.

One parameter that is likely very important in The System is the presence of black carbon in sediments. Black carbon particles, such as soot and charcoal, are products of incomplete combustion that are ubiquitous in nearshore sediments, especially in areas of urban runoff, and can make up as much as 10%–30% of the total carbon in sediments of urban harbors (Middelburg et al. 1999).[15] This soot-like material will strongly bind DDT, PCBs, and other hydrophobic chemicals (Tomaszewski et al. 2007),[16] PCBs, and other hydrophobic chemicals, and reduces bioaccumulation of these chemicals by aquatic organisms (Rust et al. 2004).[17] Black carbon in field-collected sediments has been shown to reduce the bioavailable concentration of non-planar DDT/DDD by factors of 4 to 8, and planar DDE by factors as high as 50 to 250 (Bucheli and Gustafsson 2001). [18] Thus, black carbon reduces partitioning and bioavailability of DDT and PCBs. The reduction in bioavailability reduces the toxicity of these chemicals to benthic invertebrates and the potential for bioaccumulation into the food chain. The result is that the chemicals can be present in sediments at much higher levels without causing potentially harmful exposures.

The influence of black carbon on the bioavailability of hydrophobic chemicals has been shown to vary seasonally and spatially in an intertidal marsh in San Francisco Bay (Maruya et al. 1997).[19] The study demonstrated that bioaccumulation of hydrophobic organic chemicals by aquatic invertebrates was related to the concentration of soot particles, which increased during the local rainy season in areas affected by surface runoff. Therefore, the failure of the TMDL approach to account for seasonal and spatial variability in bioavailability of hydrophobic chemicals such as DDT and PCBs contributes greatly to the uncertainty of the method used to establish target sediment concentrations. The authors concluded that hydrophobic contaminants in the San Francisco Bay, and in general, may be approximately ten times less bioavailable than

expected, and that differences in bioavailability must be accounted for to improve the reliability of theoretical predictions.

The TMDL Process is Highly Uncertain, Because it Does Not Consider Bioavailability

The TMDL process for The System is highly uncertain, because it does not take into account bioavailability. The process relies on screening levels for sediments. An example is the 1.58-µg/kg target concentration for DDT in sediments. Screening levels such as the 1.58µg/kg value are typically used for *screening*, because there is confidence that no effect occurs at that concentration. EPA guidance described the types of conclusions that can be derived from screening-level assessments (U.S. EPA 2001).[20] In general, screening levels:

- "provide a general indication of the potential for ecological risk (or lack thereof)."
- "are conservative assessments in that they provide a high level of confidence in determining a low probability of adverse risk, and they incorporate uncertainty in a precautionary manner."
- "are not designed nor intended to provide definitive estimates of actual risk, generate cleanup goals and, in general, are not based on site-specific assumptions."
- "Upon completion of a conservative screen, if no materials (contaminants) are retained by the screen, one can confidently state that there is a minimal potential for ecological risk to exist. Alternatively, if materials (contaminants) are retained by the screen, one cannot conclude that an ecological risk "actually" exists; the characteristics of the material retained by the screen are unknown, other than its size is above some specified minimum values."

Thus, the screening level does not inform the assessment regarding the concentrations at which effects might occur. Those concentrations are governed by other factors, including bioavailability. By ignoring site-specific conditions, including those involving bioavailability, the TMDL process has derived target concentrations that may be off by orders of magnitude (e.g., by a factor of 10, 100, or even 1000). For example, the influence of organic carbon on bioavailability and toxicity of DDT and metabolites was demonstrated in a recent review of

[20] U.S. EPA. 2001. Eco Update. The role of screening-level risk assessments and refining contaminants of concern in baseline ecological risk assessments. Publication 9345.-014. EPA 540/F-01/014. U.S. Environmental Protection Agency, Office of Solid Waste and Emergency Response, Washington, DC.

historical data on the toxicity of sediment-associated DDT. Fuchsman et al. (2010)[21] considered multiple lines of evidence, including data from numerous laboratory and field studies, and demonstrated that an appropriate cause-effect screening value for total DDT is on the order of 50–100 mg/kg-organic carbon, which is equivalent to 2.5–10.0 mg DDT/kg (for sediment with 5% organic carbon).

The values determined by Fuchsman et al. (2010) are similar to independently derived values reported by Chapman (1996) for the Southern California Bight. Chapman (1996)[22] summarizes the results of two independent studies, one of which (EVS 1994)[23] reported a no-effect concentration (8.51 mg/kg or 269 mg/kg-organic carbon), and another (MacDonald 1994)[24] of which reported a sediment effects concentration (7.12 mg/kg or 199 mg/kg-organic carbon) for total DDT. The sediment effects concentration is intended to identify the concentration above which adverse effects to benthic-dwelling organisms would be expected to occur. The SEC is based on results of spiked sediment bioassay and field data. Field data were collected from four areas: seven sample locations in the vicinity of the Los Angeles County Sanitation District sewage outfalls on the Palos Verdes Shelf, four locations on the Palos Verdes shelf and Santa Monica Bay, seven locations in the vicinity of Palos Verdes, three locations in San Diego Harbor, and 12 locations in the vicinity of Palos Verdes Peninsula. Chapman (1996) concludes that the similarity of these independently derived threshold values supports their usefulness as screening values.

The comparison of the TMDL DDT sediment target 0.00158 mg/kg (1.58 μg/kg) to the values in the range of 2.5 to 10.0 mg/kg reported by Chapman (1996) and Fuchsman et al. (2010) indicates three orders of magnitude (1000×) uncertainty in the use of the screening level to represent a DDT direct-effects level for The System. This large uncertainty reflects the fact that bioavailability has not been considered in the TMDL process. Given this level of uncertainty and lack of any explicit consideration of uncertainty, the use of screening levels, such as that for total DDT, renders this aspect of the TMDL development process unreliable for management purposes. It is simply a screening-level analysis.

We have provided one example of the significance of not considering bioavailability. All the chemicals considered in the TMDL document are subject to the effects of bioavailability when

---

the goal is to derive meaningful target concentrations. In addition, the bioavailability of these chemicals varies among loading sources. Therefore, the fact that the TMDL document does not consider bioavailability for any contaminant or in relation to any source indicates that the process is highly uncertain, and the resultant TMDLs are not reliable and are not wise or effective management tools for The System.

Professional Profile: Susan B. Kane Driscoll

- Ph.D., Environmental Sciences, University of Massachusetts, 1994
- B.S., Natural Resources, University of Rhode Island, 1981

Dr. Driscoll is a Managing Scientist in Exponent's EcoSciences practice. She is an aquatic toxicologist, with 22 years experience in toxicology, specializing in ecological risk assessment, environmental chemistry, sediment toxicity testing, and the toxicity and bioavailability of sediment-associated contaminants to aquatic organisms and wildlife. Dr. Driscoll has directed or participated in numerous ecological risk assessments for RCRA, Superfund, and hazardous waste sites, serving a variety of industrial, utility, and governmental clients. She has extensive experience in designing and conducting laboratory and field aquatic toxicity and environmental fate studies in accordance with rigorous quality assurance practices. She has designed and contributed to numerous environmental programs that were used to develop technically defensible solutions to environmental problems and has negotiated their acceptance with state and federal authorities. Dr. Driscoll is a specialist in the field of sediment toxicology, and her original research and publications in the areas of bioavailability and toxicity of sediment-associated contaminants are widely cited. She has extensive knowledge of sediment toxicity testing, the technical basis and predictive ability of various sediment quality benchmarks, and has served as a reviewer for the development of emerging benchmarks.

Report of

Donald R. Roberts, Ph.D.

Garza v. Allied Chemical Corp., et al.
Cause No. C-4885-99-F(10)
District Court, Hidalgo County, Texas

September 30, 2009

Table of Contents

A. Introduction

I, Donald R. Roberts, Ph.D., was retained by Montrose Chemical Corporation of California in regard to *Guadalupe Garza. v. Allied Chemical Corp., et al.*, Cause No. C-4885-99-F(10), District Court, Hidalgo County, Texas.

Much of my professional life for the past three decades has been dedicated to studying DDT and its contributions to improved health and welfare of human beings, as well as evaluating the many accusations made against DDT. Based on my thirty-plus years of professional work on DDT, my education, scientific research, literature research, and experience, I conclude and can document the following to a reasonable degree of scientific certainty:

1. The discovery of DDT's insecticidal properties revolutionized the capacity of the global public health community to control major human diseases, such as malaria, typhus, and other diseases transmitted by insects. The public health impact was so great and so immediate that Dr. Mueller was awarded the Nobel Prize in Physiology or Medicine for his discovery of DDT's insecticidal properties.

2. The United States military used DDT extensively during World War II to prevent typhus in military forces and civilian refugee populations. Millions of lives were saved.

3. In the United States, federal, state, and local governments began spraying DDT inside homes to control malaria in the mid-1940s. During the next few years, DDT was used in large scale human health campaigns in 13 states, ultimately helping to quickly eradicate malaria from the United States. The large scale public health use of DDT also helped control murine typhus and other diseases through the 1960s.

4. In the 1940s and 50s, there was extensive public health use of DDT in Texas, including Hidalgo County and Mission, Texas. Public health use of DDT in Hidalgo County included spraying inner walls of houses and dusting DDT inside and outside of commercial buildings and houses to control insect-borne diseases. Even in the 1960s, DDT was sprayed in Hidalgo County as part of the national *Aedes aegypti* Eradication Program.

5. DDT also was used internationally in major public health campaigns to control malaria and other insect-borne diseases like dengue, yellow fever, and others. DDT's ability to prevent disease transmission and, in some cases, eradicate the disease vectors led a National Academy of Sciences committee to conclude: "To only a few chemicals does man owe as great a debt as to DDT...In little more than two decades, DDT has prevented 500 million human deaths, due to malaria, that otherwise would have been inevitable."[1]

---

[1] Herzog, A. An environmental failure: Restrictions on DDT. April 22, 2008. Townhall.com: http://www.townhall.com/Columnists/AshleyHerzog/2008/04/22/an_environmental_failure_restrictions_on_ddt

6. Throughout the 1950s, 1960s and early-1970s, DDT was heralded as a lifesaver and credited with saving millions of lives.

7. The period 1971-1973 marked the end of large scale DDT use in the United States. In June, 1972, the newly-formed EPA ruled against the continued use of DDT for agricultural uses. Preceding this EPA ruling, Administrative Law Judge Edmund Sweeney held 11 months of DDT hearings in 1971-72 and ruled not to de-list DDT for use in agriculture or public health. Two months later, and with no new data or evidence against DDT, EPA Administrator William Ruckelshaus overturned Judge Sweeney's ruling and de-listed the use of DDT for agricultural purposes.

8. Unsupported claims that DDT is harmful to human health have limited the effectiveness of disease control programs, allowing deadly diseases to re-emerge.

9. Even after DDT was de-listed for use in 1972, government officials and other users continued to obtain permission to employ DDT for certain public health, agriculture, forestry, and pharmaceutical uses in high-risk locations. In addition, DDT continued to be present in pesticide formulations and used widely in crops during the 1970s and 1980s, in the miticide Dicofol, also known as Kelthane.[2]

10. Today, the World Health Organization (WHO) and other U.N. bilateral and multilateral organizations have concluded that DDT is safe for humans and safely can be sprayed on house walls for disease control.

11. DDT is unequaled in its ability to control disease. It exhibits a complex of chemical actions to prevent disease transmission inside homes in three primary ways: (1) it is a powerful spatial repellent that stops mosquitoes from entering houses; (2) it is a strong contact irritant that causes mosquitoes to prematurely exit sprayed houses, often without biting; and (3) it kills mosquitoes that remain in prolonged physical contact with sprayed surfaces. DDT is the only insecticide presently recommended for spraying on house walls that actually stops a large proportion of mosquitoes from entering the house and transmitting diseases while residents are sleeping.

12. In the 1950s and 1960s, there were no adequate substitutes for major uses of DDT, such as cotton and public health. This was true even in 1972 when EPA de-listed all agricultural uses of DDT in the United States. Even today, there is no equally effective substitute for DDT in public health programs.

B. Professional Background and Experience

I hold a doctoral degree in medical zoology from the University of Texas School of Public Health in Houston, Texas. For 21 years, I was an Army officer. I retired as a Lieutenant Colonel from the Army Medical Service Corps in 1987. During my career, I earned the Legion of Merit with Oak Leaf Cluster, the Meritorious Service Medal with Oak Leaf Cluster, two Army Commendation Medals, and the Army Surgeon General's "A" designation for professional achievement. I led a team of American scientists that, along with Brazilian colleagues, discovered a biting midge was responsible for transmitting an important viral disease (Oropouche virus) to humans in the Amazon Basin of Brazil. After retiring from active duty, I served as a professor of tropical public health in this nation's only Department of Defense medical school, the Uniformed Services University of the Health Sciences in Bethesda, Maryland.

I retired from academic life on June 30, 2007. The Board of Regents of the Uniformed Services University of the Health Sciences awarded me the honorary title of Professor Emeritus in May 2007.

In September 2007, I was awarded the 2007 Frank Brown Berry Prize in federal healthcare. The prize is awarded for "...medical professionals who labor hard but reap little financial gain from their achievements, as they strive to make contributions in federal medicine."

Most of my professional life has been dedicated to the study of DDT and its use in disease control. I have worked with many different formulations, worked in many different houses sprayed with DDT, worked for prolonged periods of time among populations who lived continuously in DDT-sprayed houses, and I have slept and worked in such houses. I have observed spray operators spraying houses and have had malaria control operators spray experimental houses for purposes of my field research activities. My experiences include studies on effects of DDT on bees and mosquitoes. I have published over 100 peer-reviewed publications. Until my retirement, I served as reviewer of professional papers for several scientific journals, including the American Journal of Tropical Medicine and Hygiene.

The focal point of my research and work over the last thirty years has been DDT, including DDT's (1) history, (2) chemical actions, (3) role in control of human diseases, (4) influence on wildlife and the environment, and (5) action on mosquito behavior. I published a peer-reviewed probability model on DDT as a spatial repellent, a contact irritant and an agent to kill mosquitoes.[3] The probability model was the basis for a National Institutes of Health grant to test chemicals that might be used to replace DDT in malaria control programs.[4] I was the principal investigator for that grant until I retired in 2007.

I have provided testimony to Congressional committees and sub-committees on the subject of DDT's important role in public health, as follows:

- Testimony before the Senate Subcommittee on East Asian and Pacific Affairs on Neglected Diseases in East Asia: "Are Public Health Programs Working?," Washington, D.C., October 6, 2004.

- Testimony before the Senate Environment and Public Works Committee on the Misuse of Science in Environmental Policy Making: "Misrepresentations of Science During Decades of Environmental Campaigning against DDT," Washington, D.C., September 28, 2005.

- Testimony before the Senate Subcommittee on Federal Financial Management, Government Information, and International Security: "Bilateral Malaria Assistance: Progress and Prognosis," Washington, D.C., January 19, 2006.

- Testimony before the Senate Committee on Environment and Public Works: "Examining the Human Health Impacts of Global Warming," Washington, D.C., October 27, 2007.

I have been quoted and interviewed on the topic of DDT by print and broadcast news media, including Voice of America, British Broadcasting Corporation, Readers Digest, The Economist, The New York Times, The Washington Post, The Washington Times, and Public Broadcasting Service.

I am on the review board for the Integrated Vector Control Consortium. The Bill and Melinda Gates Foundation fund this program to produce new tools for disease control. The program is headquartered at the Liverpool School of Tropical Medicine and the London School of Tropical Medicine in the United Kingdom.

In December 2006 and again in Spring 2007, I served as a temporary adviser to World Health Organization ("WHO"). In that capacity, I chaired the Technical Advisory Group for Indoor Residual Spraying for Malaria Control. I also participated as a member of the Technical Research Advisory Committee of WHO. A copy of my curriculum vitae is attached.

In summary, my knowledge as to DDT comes from a lifetime of research, education, and work regarding DDT. My conclusions about DDT were reached and published long before Montrose contacted me about this litigation.

C. Opinions and Analysis

1. The discovery of DDT's insecticidal properties revolutionized the capacity of the global public health community to control major human diseases, such as malaria, typhus, and other diseases transmitted by insects. The public health impact was so great and so immediate that Dr. Mueller was awarded the Nobel Prize in Physiology or Medicine for his discovery of DDT's insecticidal properties.

DDT was first created in 1874 by a German graduate student, Othmar Zeidler. In the 1930s, Dr. Paul Mueller re-discovered DDT and also discovered its insecticidal properties.

Dr. Mueller was an employee of J. R. Geigy, a Swiss chemical company. The company was interested in finding a chemical that would control clothes moths, and Mueller worked on the clothes moth project. He found that flies died when he exposed them to DDT.[5]

The Swiss were using DDT to control beetles while others in Europe were fighting World War II. Historically, insect-borne diseases flourished during wars. Typhus is a leading example of such a disease. Body lice spread the disease and they thrive in crowded and filthy conditions of war. By 1942, the Swiss had discovered that DDT was effective against many insects. They also found that it killed fleas, mites, lice, mosquitoes and flies.[6] The Allies found that DDT was toxic to lice. Furthermore, it remained active against lice for many days after application, depending on personal hygiene. The Americans and the British conducted their own toxicity tests and confirmed the Swiss reports that DDT was safe for humans.[7]

Discovery of DDT gave the Allies a tool for preventing deadly outbreaks of typhus.[8] By early 1943, the U.S. military was working to greatly increase DDT production and was projecting even larger DDT requirements for 1944.[9] Thus, by late 1943, Geigy's subsidiary in the U.S., the Cincinnati Chemical Works, was producing DDT. By early 1944, fourteen other American chemical companies also were producing DDT, as were British corporations.[10] In a

reflection of the life-saving properties of DDT as an insecticide, Mueller ultimately won the Nobel Prize in Physiology or Medicine for his discovery in 1948.

2. The United States military used DDT extensively during World War II to prevent typhus in military forces and civilian refugee populations. Millions of lives were saved.

As early as WWI, the cycle of typhus transmission was known and delousing was performed in an attempt to get rid of lice and prevent typhus transmission. However, the chemicals of that time were not adequate. Under the squalid conditions of war, the disease still struck with spectacular ferocity. Thus, typhus killed more soldiers and civilians in WWI than all the shell-fire combined.[11] Human history tells many grim stories of wars and social instabilities that allowed typhus and other diseases to sweep through and lay waste to both military and civilian populations. The advent of DDT in 1943 forever changed the role of typhus in warfare.

The discovery and use of DDT during WWII contributed to an Allied victory. Allied Forces used DDT to protect deployed fighters and war refugees from typhus and other insect-borne diseases. DDT gained fame in 1943 by successfully stopping an epidemic of typhus in Naples, Italy, an unprecedented achievement.[12] The achievement was particularly remarkable because the Swiss had only released the formula for DDT in 1942. From WWII onward, DDT was in common use as a powder for spraying or sprinkling into clothing of soldiers and refugees for typhus prevention. Almost overnight, DDT went from being unknown to being a critical military necessity.

For many years after WWII, travelers commonly were provided a small container of DDT powder for sprinkling into underclothes to control body lice, other arthropods, and disease transmission. It became a standard issue for State Department officials.[13] In spite of extensive use over many years, there were no documented cases of harm from WWII soldiers or war refugees who were doused with DDT to prevent typhus or from officials who, in later years, also used DDT in their underclothes to prevent typhus. Critical uses of DDT during and immediately after the war set the stage for DDT to become a peacetime commodity.[14]

3. In the United States, federal, state, and local governments began spraying DDT inside homes to control malaria in the mid-1940s. During the next few years, DDT was used in large scale human health campaigns in 13 states, ultimately helping to quickly eradicate malaria from the United States. The large scale public

13 I have a small bottle of DDT powder, dated 1959, issued by the U.S. State Department with instructions for sprinkling in underclothing.

14 War time, domestic, and public health uses of DDT internationally, nationally, and in the state of Texas have been photographically documented.

health use of DDT also helped control murine typhus and other diseases through the 1960s.

In addition to extensive use of DDT for protecting deployed war fighters and travelers abroad, DDT also became an indispensable commodity for protecting the health and life of people in the United States. At the turn of the 20th Century, the continental United States was intensely malarious. The disease was an immense cause of human death, human illness, and economic loss. In 1916, malaria was estimated to reduce economic productivity in the U.S. by $100,000,000 (in 1916).[15] The economic loss from malaria in the state of California alone was estimated to be $3,000,000, and California was not even considered a highly malarious state.[16] A conservative estimate of malaria cases for the country as a whole was 1,000,000 or more cases per year.[17]

Malaria rates declined gradually in the United States through the first half of the 20th Century, with occasional increases as a result of war and other events. Regardless, by the 1940s, infectious diseases were still major public health problems throughout the country. Malaria remained a major public health problem in southeastern states. By the early 1940s, the ability of the United States to exert effective control over malaria was still limited in spite of growing wealth and improving standards of living. In fact, control was possible only in urban settings where draining and eliminating aquatic habitats for mosquitoes and using larvicide to kill mosquito larvae was cost-effective. In contrast, the only real progress in poor rural areas was to screen houses to prevent mosquitoes from entering and transmitting disease.[18]

The office of Malaria Control in War Areas (MCWA) was created right after the bombing of Pearl Harbor in 1942 "to prevent or reduce malaria transmission around Army, Navy, and essential war industry areas [in the United States] by extending the control operations carried on by military authorities within these reservations."[19] Spraying houses with DDT quickly became established within the program as the most effective method of stopping malaria transmission in and around military installations in the U.S.

Then, beginning in 1945, the MCWA launched its Extended Program of Malaria Control. The extended program was not limited to military posts, camps, and stations, but instead was

extended to more malarious civilian areas.[20] It consisted of spraying DDT on interior walls of homes and privies. The spraying program covered large areas of the southern U.S., including Texas. From January 1945 to September 1947, 3.2 million houses were sprayed.[21] This sum apparently did not include numbers of houses sprayed through use of local funds. As described in a 1946 report, "a number of larger cities have contributed sufficient funds to spray the cities in the 2,500-10,000 population group. The entire cost of this type of residual house spraying is paid from local funds."[22] After 1945, investigators discovered they could increase performance and get longer protection by spraying a greater concentration of DDT on house walls. Thus, as a result of a change in formulation, the number of sprayings per house varied from nearly two in 1945 to fewer than 1.5 in 1947.[23]

The MCWA was a war time organization and changes were needed when the war ended in 1945. With demobilization of military forces in 1945 and 1946, the MCWA went into a phase of rapid liquidation.[24] Liquidation of the MCWA led to creation of the Communicable Disease Center (CDC) of the United States Public Health Service on July 1, 1946.[25] The CDC was created to capture the unique resources and expertise of MCWA. The CDC was tasked to continue and expand MCWA programs in all areas of public health in the United States.[26]

The MCWA's Extended Program of Malaria Control already had been successful in reducing numbers of malaria cases in areas where houses were sprayed (Figure 1).

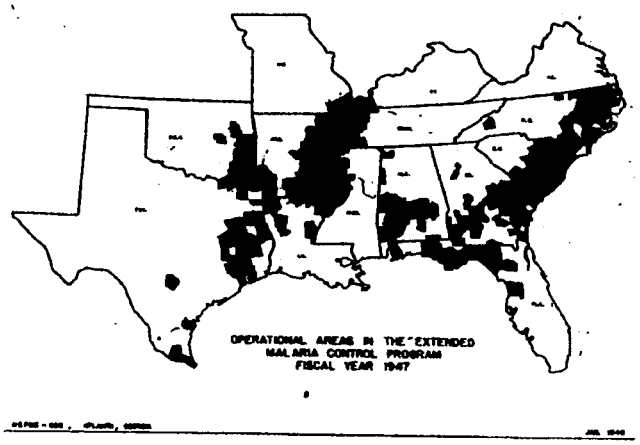

Figure 1. 1946-47 map of US counties where houses were sprayed with DDT for control of malaria.[27]

To build on early success, the CDC started a National Malaria Eradication Program, commencing operations on July 1, 1947. It was referred to as the Residual Spray Program. Spraying DDT on inner walls of rural homes in malaria-endemic counties was the key component of that program. From July 1947 to the end of 1949, the program sprayed over 4,650,000 houses. Based on surveys conducted in thirteen southeastern states, the CDC concluded that "over-all control (reduction in houses infested) was approximately 90 percent for the 5-year period [1945-1949]."[28]

Overall, beginning in 1945,[29] millions of houses were sprayed for malaria control throughout the southern U.S. DDT spraying broke the cycle of malaria transmission and, in 1949, the United States was declared free of malaria as a significant public health problem.[30]

However, spraying of houses did not end in 1949. DDT was used in many other public health endeavors:

a) Typhus - Control of murine typhus was one such endeavor. Murine typhus was an important public health problem in southern states. Control of typhus was achieved by dusting rat burrows and runways with DDT to kill fleas (oriental rat fleas) that transmit the disease (see

32 CDC Activities, 1946-1947. U.S. Public Health Service, Communicable Disease Center, Atlanta, Georgia. Page 11.

A total of 448,297 residences were dusted with DDT for typhus control in calendar year 1946.[34] Dusting of premises continued for several more years and declined only when risk of murine typhus had been greatly reduced or eliminated. Examples of extensive DDT use are 1) from September 1 to November 22, 1947, 91,083 premises were dusted;[35] and 2) from March 20 to July 2, 1949, 150,705 premises were treated.[36]

b) Housefly and dysentery control - Although houseflies eventually became resistant to DDT, it was used for a time to control them successfully. Control of houseflies also contributed to reducing problems of dysentery. Some housefly control was a byproduct of the residual spray program for eradicating malaria. As stated in a Missouri State Health Department publication (cited in a CDC report) in 1946:

> [L]ast year the U.S. Public Health Service sprayed 85,000 homes with DDT in the delta country of Mississippi. It was chiefly a malaria control project to kill mosquitoes. But so many flies died as a result of the spraying project that the infant death rate from fly-borne diseases such as dysentery, typhoid fever, diarrhea, and enteritis, was cut to less than one-third that of the year before.
>
> This means that approximately 50 children in Mississippi who otherwise would have died as a result of these diseases are alive today.[37]

c) *Aedes aegypti* control - For many years, DDT was sprayed in towns and cities for control of the mosquito that transmits dengue fever and urban yellow fever, *Aedes aegypti*. Sporadic efforts to control this important vector were converted into a national eradication program in the 1960s.

The United States, along with other countries of North, Central, and South America, first signed a resolution of the Pan American Health Organization to eradicate *Aedes aegypti* in 1947. The U.S. signed a similar resolution in 1961. Funds were appropriated to initiate a U.S. eradication program in 1963.[38] The CDC coordinated the program. This program, with rare

exception, was based on spraying DDT, as a matter of official public health policy, in urban residential areas and it was continued until 1969.[39]

d) Plague control – Eventually, DDT was used even in areas of western Texas and in a broad swath of the western U.S. for dusting prairie dog colonies and ground squirrel burrows to kill fleas as a means of plague control.[40]

None of the public health programs that made use of DDT, described above, were trivial in scope. The spraying and dusting of DDT in and around homes was carried out as critical components of national disease control programs. Extensive public health use of DDT brought great improvements in health for millions of Americans.

4. In the 1940s and 50s, there was extensive public health use of DDT in Texas, including Hidalgo County and Mission, Texas. Public health use of DDT in Hidalgo County included spraying inner walls of houses and dusting DDT inside and outside of commercial buildings and houses to control insect-borne diseases. Even in the 1960s, DDT was sprayed in Hidalgo County as part of the national *Aedes aegypti* Eradication Program.

The government and people of Texas participated heavily in public health use of DDT. Malaria in San Antonio, Texas in 1904 to 1908 caused a death rate of 17.5 per 100,000. In the interval from 1909 to 1913, the rate was 13.9 per 100,000 population.[41] To put these death rates into a modern framework, the rates for malaria infections alone were 2- to 4-fold higher than the modern death rate for all cancers combined in the 0 to 19 year age group in the United States.[42] However, malaria and other infectious diseases did more than just kill people. They also reduced their economic wherewithal.

In 1909, a malaria expert characterized the malaria problem in Texas and other southern states as follows:

> Texas, Georgia and Florida are badly infected in some portions with aestivo-autumnal malaria [falciparum malaria]; this form is also common along the southern portion of the Mississippi and its

> tributaries and there are regions in the delta of the Mississippi that are uninhabitable because of the prevalence of the most deadly forms of aestivo-autumnal infection.... Mexico and Central America are hot-beds of the most deadly forms of aestivo-autumnal [malaria] infection, and the low-lying coast lines of these countries are among the most dangerous of the lurking places of this form of disease.[43]

Malaria remained a formidable public health problem in Texas even in the 1940s. In 1941, the most malarious areas in Texas were "situated chiefly around the Rio Grande, Red and Sabine Rivers."[44] Public health officials believed in 1941 that malaria was "more widespread and probably more prevalent [in 1941] than in 1930."[45]

DDT was used extensively in Texas for disease control. Spraying houses with DDT to control malaria started at least by 1945. In that year, six counties, to include Hidalgo County, had county-wide residual house spraying programs.[46] During the latter half of 1945, a total of 75,850 Texas houses were sprayed with DDT.[47] Between July and October, 1946, 45,648 premises were sprayed, using 33,531 pounds of DDT, as part of the extended malaria control program.[48] This spraying included Hildago County.[49] For the period April through September, 1946 (corresponding to last half of fiscal year), a total of 46,184 houses were sprayed in Texas.[50] In addition, larviciding with DDT was carried out in nine cities in Hidalgo County, including McAllen and Mission, Texas.[51] From March 23 to June 28, 1947, a total of 455 houses were

sprayed in Hidalgo County.[52] From April 1 to June 28, 1947, a total of 41,934 Texas premises were sprayed.[53] During the same time period, Hidalgo County sprayed DDT as a larvicide.[54]

The CDC malaria eradication program continued beyond 1947, and houses in Texas continued to be sprayed to prevent disease transmission. For two half-year periods, July 1 to December 31, 1947 and January 1 through June 30, 1948, a total of 231 and 3,018 houses in Hidalgo County, respectively, were sprayed with DDT.[55]

The spray program in Texas was altered in 1948 from two spray cycles per year to just one spray cycle per year. The amount of DDT applied to house walls was 200 mg/ft^2, which sums to 2.15 grams per square meter of wall surface.[56] Two grams/m^2 of wall surface eventually became the international standard for malaria control treatments. The numbers of houses sprayed in Texas were 89,600, 94,905, and 71,870 in 1947, 1948, and 1949, respectively.[57] For part of 1948 and after, house spraying became less costly and better tolerated by residents. In 1950, a total of 85,355 houses in Texas were sprayed with DDT.[58] As stated in a CDC report for July, August and September, 1952, "...a total of 145,138 spray applications have been made this season."[59] Texas was one of the states that continued spraying houses in the 1950s. For example, 23,885 and 41,273 premises were sprayed in 1952 and 1953, respectively.[60]

Spraying continued in Texas from 1950-53 in part because malaria was still endemic in South Korea during the Korean War and several United States bases were located in Texas.

With the military returning from the Korean War, the United States had to maintain vigilance to prevent large re-introductions of malaria.[61]

DDT also was used in many other public health endeavors in Texas:

a) Murine Typhus - Texas started using DDT to control murine typhus in 1945.[62] A 1951 CDC report on murine typhus control in Texas stated: "In 1945, the Texas State Department of Health started an extensive typhus control program with operation policies based primarily on the incidence of murine typhus fever in humans. This program consisted of dusting rat runs and harborages with 10 percent DDT plus rat poisoning."[63] The program was effective because rats would pick up the DDT on their fur. DDT killed the rat fleas that were responsible for transmitting murine typhus to humans.

From July to December 1946, dusting of premises for control of murine typhus was performed in 47 Texas counties.[64] To illustrate the magnitude of the dusting program, from July to December, 1946, 31,502 premises were dusted.[65] A total of 3,804 pounds of DDT were used for dusting premises in Hidalgo County alone.[66] In addition, 835 premises were dusted in Hildago County during the next treatment interval from December 1946 to June 1947.[67] Given that there were potentially only about 21,000 houses for the whole county in 1940, many houses would have been dusted.[68] For all of fiscal year 1946, 90,300 premises in Texas were dusted with DDT.[69] In the first half of 1947, another 31,502 premises in 47 counties were dusted for

68 There were 106,059 people in Hidalgo County in 1940. Assuming five people per household Hidalgo County would have approximately 21,211 houses. See http://www.mcallen.lib.tx.us/city/population.htm.

69 Report from the Engineering Division of the Typhus Control Branch of the CDC to District, Directors, State Health Department and Others Concerned, dated August 23, 1946. Reported as tabular data, dated July 25, 1946.

murine typhus control.[70] Dusting of premises continued through the rest of the 1940s and into the 1950s.[71]

In the 1951 review of murine typhus control, public health officials concluded that "semiannual DDT dusting of rat runs and harborages in rat-infested business buildings and annual DDT dusting in the residential areas" attributed to reduction of rats and prevalence of murine typhus. All told, through those and other preventive measures, Texas reduced the incidence of murine typhus from 1,844 cases in 1945 to 222 in 1950."[72] This was an 88% reduction in disease.

b) *Aedes aegypti* - Texas and CDC initiated DDT spraying for control of *Aedes aegypti* in 1946.[73] In that year, Hidalgo County participated in a larviciding program, and DDT was one of the insecticides used.[74] The state of Texas combined the *Aedes aegypti* inspection and treatment programs with the typhus program. Activities for both programs were performed when teams visited to inspect houses. As part of *Aedes aegypti* control in 1946, 14,816 privies and dumps were sprayed in Texas, using 6,258 gallons of 5% DDT.[75] Spraying DDT for control of *Aedes aegypti* increased from that time forward and was performed by larviciding and eliminating *Aedes aegypti* larval habitats. As evidence of program evolution, in 1953, 1,704 Texas acres were sprayed for control of mosquito larvae and space spraying was performed over 54,164 acres.[76] Spraying DDT in and around the mosquito breeding sites in back yards and next to houses continued throughout the 1940s and 1950s.[77]

As stated in section 3, funds were appropriated for a national *Aedes aegypti* eradication program in the Fall of 1963.[78] The CDC-coordinated program got underway in 1964. As described in a 1964 annual report, the program had two objectives:

78 Schliessmann, D.J., "Initiation of the *Aedes aegypti* Eradication Programme of the USA," Bull Wld Health Org, 1967, Vol. 36; 604-609.

> It will protect this country against outbreaks of yellow fever and dengue, and it will eliminate this reservoir of *Ae. aegypti* as a possible source of reinfestation of countries that have rid themselves of the species.[79]

When the program was initiated, a total of 16 countries within the hemisphere had used DDT to successfully eradicate *Aedes aegypti*.[80] Thus, the second of the two objectives had great significance for many countries of the Americas. Simply stated, eradicating *Aedes aegypti* from the United States would have ended the export of the mosquito back into *Aedes aegypti*-free countries.

The United States *Aedes aegypti* eradication program was based on use of DDT. Southern Texas was one of several test sites for the program. In fact, Hidalgo County was one of four pioneer counties that participated in *Aedes aegypti* eradication efforts in Texas.[81] The startup of this program was reviewed in a 1965 publication, as follows:

> The *Aedes aegypti* eradication program was activated in FY 1964, and by the end of June was operational in southern Florida, southern Texas, Puerto Rico, and the American Virgin Islands. It is planned to have full-scale operations underway in all of the nine infested states in the southeastern United States and also in the State of Hawaii by 1967. This program meets U. S. commitments to participate with other member nations of the PAHO [Pan American Health Organization] in eradicating the *Aedes aegypti* species from the Western Hemisphere as a permanent solution for the prevention of urban yellow fever.[82]

The United States' *Aedes aegypti* eradication program was stopped in 1969.

c) Dysentery – Fly-borne dysentery was a huge problem in many southern states and was a particularly grave problem in Texas. As stated in a CDC report, Hidalgo County was a highly endemic area for fly-borne dysentery.[83] A project of spraying DDT in towns was started in 1945.

83 CDC Activities, 1946-1947. U.S. Public Health Service, Communicable Disease Center, Atlanta, Georgia. Page 23.

Fly control became a front-line defense against dysentery and spraying DDT was, in the early years, an important part of dysentery control. The dysentery control project was described as:

> ...a cooperative undertaking of the Communicable Disease Center and the National Institute of Health, with headquarters at Pharr, Texas. The primary objective is to determine whether or not the control of flies by insecticides will reduce significantly the prevalence of diarrheal disease.[84]

Early CDC reports document heavy experimentation and use of DDT in Texas for fly control during the 1940s and 1950s. For example, applications of DDT for fly control resulted in 30,022 premises being sprayed, residual spraying of 41,273 premises, and space spraying 74,614 acres in Texas.[85]

d) Encephalitis – On April 16, 1954, the Governor of Texas declared a state of emergency in Hidalgo County.[86] The cause of that state of emergency was an outbreak of St. Louise encephalitis (SLE). During the period April 22-May 8, under the Governor's state of emergency and with assistance of the CDC, (1) 1,784 acres were larvicided (insecticide sprayed on surface of water to kill mosquito larvae), (2) 13,942 acres space-sprayed with insecticide to kill adult mosquitoes, and (3) 304 premises residual-sprayed.[87] DDT was used for general larviciding, and DDT was also used to control adult mosquitoes. Dusting was done with gamma isomer BHC.[88] For space spraying and dusting operations, 3310 gallons of 5 percent DDT emulsion and 21,000 pounds of 3 percent gamma isomer BHC dust were applied to 20,225 acres.[89] DDT-diesel oil larvicide in the amount of 1,312 gallons was applied on 263 acres of both actual and potential mosquito breeding area.[90] A human population of approximately 72,000 within 12 cities and towns in Hidalgo County, Texas received protection by use of DDT and BHC to stop the outbreak of SLE.[91]

Data presented in sections a-d show the importance of public health uses of DDT to the disease prevention programs in Texas. These data also demonstrate that public health use of DDT reached down to the household level in many counties and towns in the Texas countryside. Clearly, the public health use of DDT at the household level was both extensive and intensive.

5. DDT also was used internationally in major public health campaigns to control malaria and other insect-borne diseases like dengue, yellow fever, and others. DDT's ability to prevent disease transmission and, in some cases, eradicate the disease vectors led a National Academy of Sciences committee to conclude: "To only a few chemicals does man owe as great a debt as to DDT...In little more than two decades, DDT has prevented 500 million human deaths, due to malaria, that otherwise would have been inevitable."[92]

The effectiveness of DDT for disease control stimulated various countries throughout the world to create national malaria control programs. Their successes eventually stimulated WHO to coordinate a global eradication program.

a) National Malaria Control Programs in South and Central America

In the mid-1940s, DDT was a new, effective, and exciting weapon in the battle against malaria. It was cheap, easy to apply, long-lasting once sprayed on house walls, and safe for humans. Wherever and whenever malaria control programs sprayed DDT on house walls, there were large reductions in malaria rates.

Almost all of the countries of the Americas started using DDT in their malaria control programs. For example, the experiences of countries like Venezuela and Guyana demonstrate the powerful benefit of spraying house walls with small amounts of DDT. In the mid-1940s and before, malaria rates in countries of the Americas were dangerously high. Venezuela had a national malaria program but was still reporting more than 800,000 cases per year.[93] Venezuela started spraying DDT in houses in 1946. The protection was immediate and malaria rates dropped precipitously in all sprayed areas. From the period 1941-45 (pre-spray period) to 1948,

DDT spraying dropped the number of malaria positive slides per 100,000 people from 1,083 to just 82, a 91.25% reduction in malaria.[94]

In the neighboring country of Guyana, the period from 1943 to 1945 was characterized with over 37% and 27% of rural and urban people, respectively, with malaria. Accompanying these high infection rates was a death rate of newborns of 126 per 1,000 live births. Guyana started experimental spraying DDT inside houses in 1945, expanded the program in 1946, and initiated country-wide spraying in 1947.[95] By the 1948-49 time period, as a result of house spraying alone, infant mortality declined by 39%.[96] In urban areas malaria declined by 99%. Even in the highly endemic rural areas malaria infections declined by a stunning 96%.[97]

By the early 1950s, both Venezuela and Guyana had used DDT to eliminate malaria from major geographical areas.[98] Soon malaria infections could be found only in sparsely populated forested areas of both countries. Malaria completely disappeared from heavily populated coastal regions and from much of the interior savannas.

Health workers in other countries also recognized the particular value of DDT. The head of malaria control in Brazil characterized the changes that DDT offered in the following statement:

> Until 1945-1946 [when DDT became available for malaria control], preventive methods employed against malaria in Brazil, as in the rest of the world, were generally directed against the aquatic phases of the vectors (draining, larvicides, destruction of bromeliads, etc....). These methods, however, were only applied in

the principal cities of each state and the only measure available for rural populations exposed to malaria was free distribution of specific drugs.[99]

In the late-1950s, under guidance of the World Health Organization and the Pan American Health Organization, most national malaria programs were converted into malaria eradication programs.

b) National Malaria Control Programs in Africa and Asia

Historical data from many countries outside the Americas also show the huge beneficial impact of spraying houses with DDT. Annex 1 to this report contains examples of what occurred in many countries around the world. Many countries started their own malaria control programs. These countries pioneered house spray methods, and laid the groundwork for what would become a WHO-coordinated global malaria eradication program. Over a third of a billion people were freed of endemic malaria even before the WHO-led eradication effort began.[100]

c) WHO's Global Malaria Eradication Program

The 8th World Health Assembly ("WHA") in 1955 directed WHO to coordinate a global program to eradicate malaria. As revealed in statistical reports of malaria eradication in the Americas, the program was fully underway in 1959. During the next nine years, another two-thirds of a billion people were freed of endemic malaria.[101]

Nepal was just one of several countries that benefited from malaria eradication. Some have opined that "dramatic, nationwide reduction of malaria [in Nepal] was perhaps the greatest technical and logistic triumph of the 1960s."[102] That triumph over malaria was based largely on use of DDT as the exclusive preventive measure of the eradication program.

Each year in the early 1950s, there were more than two million cases of malaria in Nepal, with a mortality rate of 10%. The burden of deaths fell most heavily on children. At that time, malaria was Nepal's most serious public health problem, and it contributed to increased deaths from other diseases as well. The U.S. Agency for International Assistance started the malaria

program in Nepal in 1959. Spraying of houses in the central zone began in 1960. Spraying in the eastern zone was underway in 1964 and in the western zone in 1965.[103]

From more than two million cases a year, only 2,468 cases were found in 1968. Before the malaria control program, life expectancy in Nepal was 28 years. By 1962, life expectancy was 33 years, and by 1970 it was 42.3 years.[104] Malaria in Nepal had been an enormous problem in many areas. Malaria had been so bad that it had stopped people from occupying land and producing crops. Once malaria was brought under control, previously unoccupied areas suddenly became available for agricultural productivity. As land became available there were large movements of populations into new areas. Total cost of the multi-year program in Nepal, which oversaw vast improvements in health, dramatically reduced death and increased population longevity and, ultimately, vastly increased agricultural productivity and wealth, was $13 million.[105]

All told, from the mid-1940s to 1969, almost one billion people worldwide were freed from endemic malaria by DDT-sprayed house walls.[106] This achievement is unequaled in the history of arthropod-borne disease control. DDT was used to change the global distribution of endemic malaria. In those countries that coupled malaria eradication with economic growth and development, the disease remained banished after spraying stopped.

d) Role of DDT in Combating Other Arthropod-Borne Diseases

Beginning in 1945, many countries around the world experimented with the use of DDT in the control of a variety of other human diseases, e.g., filariasis. As a successful example of these efforts, Bolivia was the first to employ DDT to eradicate *Aedes aegypti*, the vector of dengue viruses and the urban vector of yellow fever.[107] Both diseases were a frightening burden on populations of Central and South America. *Aedes aegypti* also was the cause of major outbreaks of both diseases in cities of the United States.

107 Severo, O., "Eradication of the *Aedes aegypti* Mosquito From the Americas," Yellow Fever: A Symposium in Commemoration of Carlos Juan Finlay, The Jefferson Medical College of Philadelphia: Philadelphia, PA (1955) Pages 32 and 49.

By 1947, Bolivia had eradicated *Aedes aegypti* mosquitoes.[108] Bolivia's quick success stimulated the Pan American Health Organization to begin a program using DDT to eradicate *Aedes aegypti* from the Americas.[109] By the early 1950s, many countries of the Americas had eradicated or greatly reduced the distribution of this dangerous mosquito. Through their successes, the risks of dengue and yellow fever epidemics largely disappeared from Central and South America. The countries maintained their *Aedes aegypti* free status for many years.

In summary, DDT reduced the burden of human disease and saved lives not only in Texas and throughout the United States, but also in countries around the world.

6. Throughout the 1950s, 1960s and early-1970s, DDT was heralded as a lifesaver and credited with saving millions of lives.

DDT was held in high regard by agriculture and public health officials in the United States and the world throughout the 1950s, 1960s and early-1970s, as reflected by the following statements:

- U.S. Public Health Service, Dr. S.W. Simmons (1959): "Except for the antibiotics, it is doubtful that any material has been found which protects more people against more disease over a larger area than does DDT."[110]

- World Health Organization (1969): "DDT has been the main agent in eradicating malaria in countries whose population total 550 million people. Of having saved about 5 million lives and prevented 100 million illnesses in the first 8 years of its use, of having recently reduced the annual malaria death-rate in India from 750,000 down to 1,500, and of having saved at least 2 billion people in the world without causing the loss of a single life by poisoning from DDT alone."

  "[I]t [DDT] is so safe that no symptoms have been observed among the spray men or among the inhabitants of the spray areas, which numbered respectively 130,000 and 535 million at the peak of the campaign."[111]

- Malaria Eradication Department of the Pan American Health Organization, Dr. Guzman Garcia-Martin, Chief (1969): "To date, there is no insecticide that could

effectively replace DDT which would permit the continuation of the eradication program or maintain the conquests made so far. The withdrawal of DDT will therefore represent a regression to a malaria situation similar to that in 1945."[112]

In addition, leading health organizations and officials stated that DDT did not pose a threat to public health.

- National Academy of Science (1969): "Available evidence does not indicate that present levels of pesticides in man's food and environment produce an adverse effect on his health."[113]

- Environmental Protection Agency, Samuel W. Simmons (1972): "Malaria control campaigns have extended over 2 decades, and no toxic effects have been reported among the hundreds of millions of people who live in houses that have been sprayed nor among the 200,000 or more spray-men applying the material."[114]

- Communicable Disease Center, Atlanta, Georgia (1969): "Although DDT has been studied more extensively in man than any other known insecticide, no concrete evidence has been presented that it presently constitutes any health hazard to man. Its use record with regard to human safety is unparalleled in the history of insecticides."[115]

- Assistant Attorney General of the United States, William Ruckelshaus, (1970): "DDT is not endangering the public health and has an amazing and exemplary record of safe use. DDT, when properly used at recommended concentrations, does not cause a toxic response in man or other mammals and is not harmful. The carcinogenic claims regarding DDT are unproved speculation."[116]

- United States Surgeon General Steinfield (1972): "The safety, long-lasting action, and low cost of DDT make it the only known insecticide that can be used on the scale required in malaria eradication programs within the resources currently available to

such programs or that can be reasonably expected to be available to them in the foreseeable future."[117]

- World Health Organization, (1970): "There had been no toxic effects recorded among the 200,000 spraymen employed and the 600 million population living in sprayed houses over a long period of time."[118]

Even as late as 1972, the U.S. Surgeon General stated: "We have no information on which to indict DDT either as a tumorigen or as a carcinogen for man and on the basis now available, I cannot conclude DDT represents an imminent health hazard."[119]

At the time of EPA's DDT hearings in 1972, national and international public health officials stood united against political and regulatory controls that would minimize availability, increase costs, or in any way jeopardize future uses of DDT in disease control programs. Public health professionals recognized the overwhelming benefit of using DDT for disease prevention.

7. The period 1971-1973 marked the end of large scale DDT use in the United States. In June, 1972, the newly-formed EPA ruled against the continued use of DDT for agricultural uses. Preceding this EPA ruling, Administrative Law Judge Edmund Sweeney held 11 months of DDT hearings in 1971-72 and ruled not to de-list DDT for use in agriculture or public health. Two months later, and with no new data or evidence against DDT, EPA Administrator William Ruckelshaus overturned Judge Sweeney's ruling and de-listed the use of DDT for agricultural purposes.

The anti-insecticide movement was a growing phenomenon during the 1960s. The overwhelming popularity of Rachel Carson's book, "Silent Spring," brought the movement political power over public health and agricultural programs that made use of insecticides. Claims were being trumpeted loudly that DDT was causing human health harm.

In spite of strong positions of the agriculture and public health communities in support of DDT, the stage was set for political action against DDT. The Nixon administration announced its intent to eliminate DDT and other pesticides.[120] When the Department of Agriculture and the public health service did not act precipitously against DDT, the Nixon administration removed

authority over insecticides from the Department of Agriculture and the public health service and transferred that authority to the newly-formed Environmental Protection Agency ("EPA"). Immediately following EPA's creation on December 2, 1970, the regulatory control of DDT was one of its first action items.[121]

EPA started its review of DDT in 1971 by appointing Administrative Law Judge Edmund Sweeney, as the Hearing Examiner to hold a hearing on the benefits and claims of harm from DDT use. The consolidated DDT hearing continued for eighty-one days from August 17, 1971 to March 16, 1972. Following the testimony of 125 witnesses, 365 exhibits, and 9,312 pages of transcripts, Hearing Examiner Edmund Sweeney presented his findings of fact, conclusions of law, and opinion on April 26, 1972.[122] In reaching his conclusions, Judge Sweeney noted:

> ... [N]o Hearing Examiner will ever enjoy the privilege that I had in listening to so many leaders in the field of scientific and medical achievement; from so many areas of expertise throughout the world, really; and including among them a Nobel Peace Prize winner, and the Surgeon General of the United States.[123]

After months of testimony, the judge found in favor of continued DDT use. The Hearing Examiner's 114-page opinion reached the following conclusions:

1. "DDT is not a carcinogenic hazard to man."[124]
2. "DDT is not a mutagenic or teratogenic hazard to man."[125]
3. "The uses of DDT under the registrations involved here do not have a deleterious effect on freshwater fish, estuarine organisms, wild birds, or other wildlife."[126]
4. "There is a present need for the continued use of DDT for the essential uses defined in this case."[127]

Reportedly, EPA Administrator William Ruckelshaus did not attend the hearings or read the transcript of the hearings.[128] However, just a few weeks later, the Administrator overruled

his own judge and de-listed all agricultural uses of DDT in the United States.[129] In ultimate findings of fact, Ruckelshaus found that DDT's chemical characteristics constitute a risk to the environment; an unknown, unquantifiable risk to man and lower animals; and a potential carcinogenic risk to humans.[130] His finding of basic fact that "DDT is a potential human carcinogen" was a newly formed opinion because he was the same person (William Ruckelshaus) who declared in 1970 that "[c]arcinogenic claims regarding DDT are unproven speculation." (See Ruckelshaus, Section 6, above). The Administrator's opinion was not based on any new evidence, because none was brought forward. The EPA Administrator ignored the national and international agencies that steadfastly defended DDT and opposed drastic and far-reaching actions to stop its use. Ultimately, the opinion was characterized as not being based on scientific evidence but rather on political pressure.

The Ruckelshaus decision was appealed to the United States Court of Appeals, District of Columbia Circuit.[131] On December 13, 1973, the D.C. Circuit Court affirmed the Administrator's decision to cancel DDT registrations for agricultural uses, concluding "...where questions involve a special expertise of an agency, such as in detailed scientific proceeding, the agency deserves special deference from the courts."[132] The Court noted that the hazardous nature of DDT was not "... proved beyond a reasonable doubt" and that the evidence "...might support contrary conclusions as well."[133]

To summarize this section, the 1972 decision was an amazing switch on the part of the United States government. No new scientific or medical evidence was brought forward to justify EPA's decision. There were no new insights or proofs of human health harm. In spite of official positions, as presented above, the misrepresentations of DDT science by the anti-insecticide movement brought about an abrupt change in government policy against DDT in 1972.[134]

Part I," Chemical Times and Trends, Oct. 1981, Pages 47-53; Ackerly, R.L., "DDT: A Re-evaluation. Part II," Chemical Times and Trends, Jan. 1982, Pages 48-55.

8. Unsupported claims that DDT is harmful to human health have limited the effectiveness of disease control programs, allowing deadly diseases to re-emerge.

In 1972, there was no equally safe, cheap, and effective chemical for replacing DDT in disease control programs. For that reason, public health officials around the world opposed delisting DDT for agriculture use. Those officials knew that delisting DDT would create pressures to stop its use to control human diseases and its production, distribution, sale, and use would become more expensive. Today, 36 years after the EPA decision, we can document how the fears of those public health officials became reality.

DDT production declined in the U.S. and other developed countries during the 1970s. Disease-endemic countries found it increasingly difficult to obtain supplies of DDT to meet their disease control requirements. Even before the 1972 EPA decision, this concern led a WHO official (James W. Wright, Chief, Vector Biology and Control, World Health Organization, Geneva) to state in 1970: "The prospects of maintaining the gains of the malaria eradication effort and protecting the 370 million people still unprotected from malaria depended essentially on the availability of an insecticide which was effective against the vector, inexpensive, and safe to man."[135] This official also noted: "[I]t could be categorically stated than any action limiting the availability or use of DDT for the control of malaria and other vector-borne diseases in developing countries could lead to a public health disaster."[136]

House spraying controlled malaria and even eradicated it in some regions of the world. The period of spraying and intensive control of malaria lasted for about 33 years, ending in 1979. By 1979, those who opposed use of insecticides had gained political leverage over malaria control policies and strategies. During the 1970s and 1980s, through the exercise of economic and political pressures, anti-insecticide activism brought huge changes in malaria control programs. Countries began experimenting with DDT substitutes and slowly stopped using DDT. Malaria re-emerged in many of those countries even as they switched to alternative insecticides. The trend of increasing disease was strong and revealed shortfalls of substitute insecticides.

Data from countries of the Americas clearly document changes in malaria rates that coincide with changes in house spray rates (Figure 4). As illustrated in Figure 4, malaria rates increased as the number of sprayed houses declined.

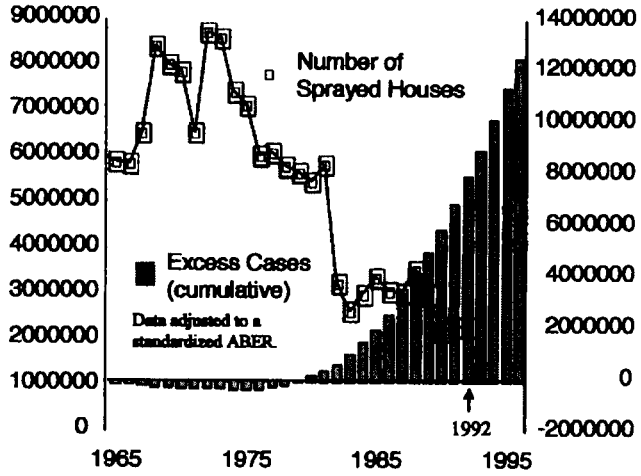

Figure 4.[137] Graph of increasing numbers of malaria cases, above baseline, with declining numbers of houses sprayed with DDT.

Similarly, before the advent of DDT, Mexico was a highly malarious country with 60% of its population living in endemic regions. During the 1940s and 1950s, malaria was responsible for as many as 24,000 deaths and 2.4 million infections each year.[138] Malaria was a huge health and economic burden.

DDT was used to bring malaria under control in Mexico until the mid-1980s. In the early 1980s, Mexico suffered a recession and reduced its house spray program. Numbers of infections increased to 133,698 cases per year. Mexico restarted its spray program and rapidly brought malaria back under control.[139]

---

137 Impact of de-emphasizing indoor spraying of house walls in 1979 and decentralization of malaria control programs beginning in 1985. (Line graph=numbers of sprayed houses.; bar graph= cumulative numbers of excess cases over average numbers per annum from 1965-1979; left axis is sprayed houses; right axis is excess cases). Data for Brazil, Colombia, Peru, Ecuador and Venezuela. Based on data from PAHO reports (see cite 139). Numbers of cases calculated by standardizing slide positive rates per 1000 population according to a standardized annual blood examination rate. Standardized rate was calculated as average for each country during period of 1965-1979. Adjustments were made for differences in size of population across 5 countries.

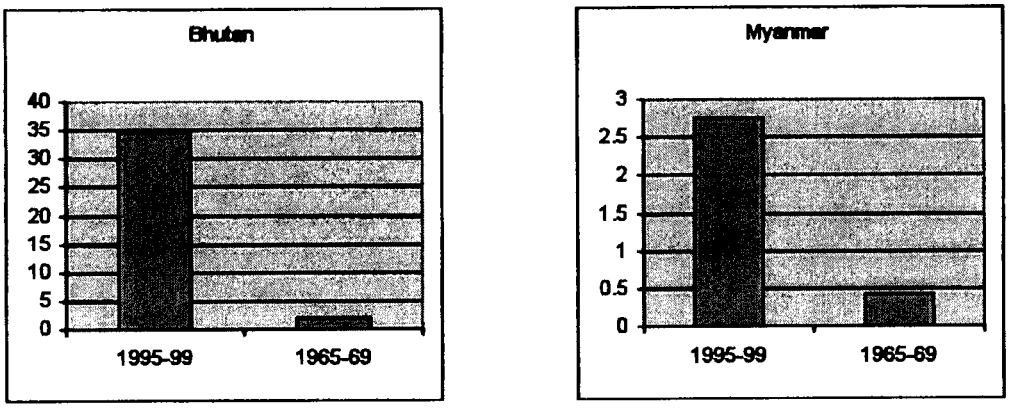
139 Pan American Health Organization, "Status of Malaria Programs in the Americas. XL Report." Washington (DC), 1991. Page 91.

In addition, house spraying with DDT brought spectacular reductions of malaria in many countries of Asia. Years later, when countries began gradually to abandon house spray programs, the numbers of malaria cases began increasing.[140] Figures 2-5 contrast malaria rates in recent years with the years when DDT was used. The data represent annual parasite indexes (a population-based index of malaria prevalence) during the period from 1995-99 compared with identical data from 1965-69. Differences in rates for the two performance periods are stunning.

Today, out of 30 countries in Asia, Bhutan, Myanmar, and Sri Lanka are the three most malarious.[141] In Bhutan, the malaria burden has grown 17.5-fold since the period when DDT was sprayed on house walls. For the countries of Myanmar, Sri Lanka, and India, malaria rates have grown 6.7-, 6.4-, and 807-fold, respectively.



Figures 5 and 6. Annual parasite indexes (APIs) for Bhutan and Myanmar for comparison periods of 1995-99 versus 1965-69.[142] The latter (1965-69) covers a period when DDT was used to spray house walls for malaria control. The period 1995-99 represents a period when DDT was not used to spray houses. Left axes represent API values, or the number of cases per thousand population.

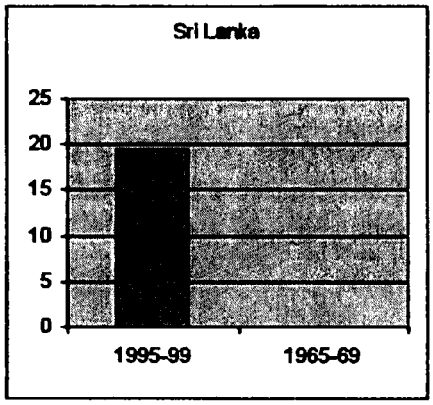

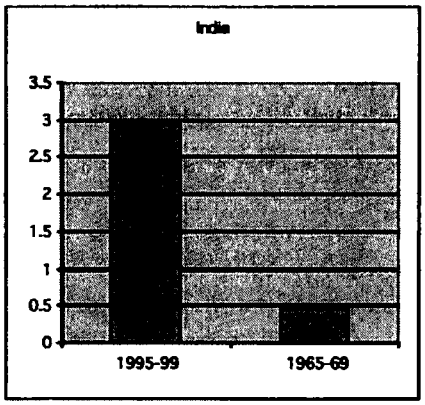

Figures 7 and 8. Annual parasite indexes (APIs) for Sri Lanka and India for comparison periods of 1995-99 versus 1965-69.[143] The latter (1965-69) covers a period when DDT was used to spray house walls for malaria control. The period 1995-99 represents a period when DDT was not used to spray houses (still used to a greatly reduced extent in India). Left axes represent API values, or the number of cases per thousand population.

In summation, anti-insecticide pressures caused countries to abandon use of DDT for control of malaria. The result, as illustrated by data presented above, has been a reversion to increasingly intense transmission of malaria and rapidly growing numbers of new infections each year.

The public health harm of anti-DDT advocacy was not limited to destruction of malaria control programs. The *Aedes aegypti* Eradication Program in the Americas was impacted. The use of DDT was phased out of use during the 1970s and the *Aedes aegypti* mosquito re-invaded all countries of the Americas, thereby bringing dengue and the risk of urban yellow fever back to all countries of Central and South America.

---

143 Data presented in graphs were extracted from WHO reports: WHO, Malaria Profile: http://w3.whosea.org/malaria/pdf/ino.pdf

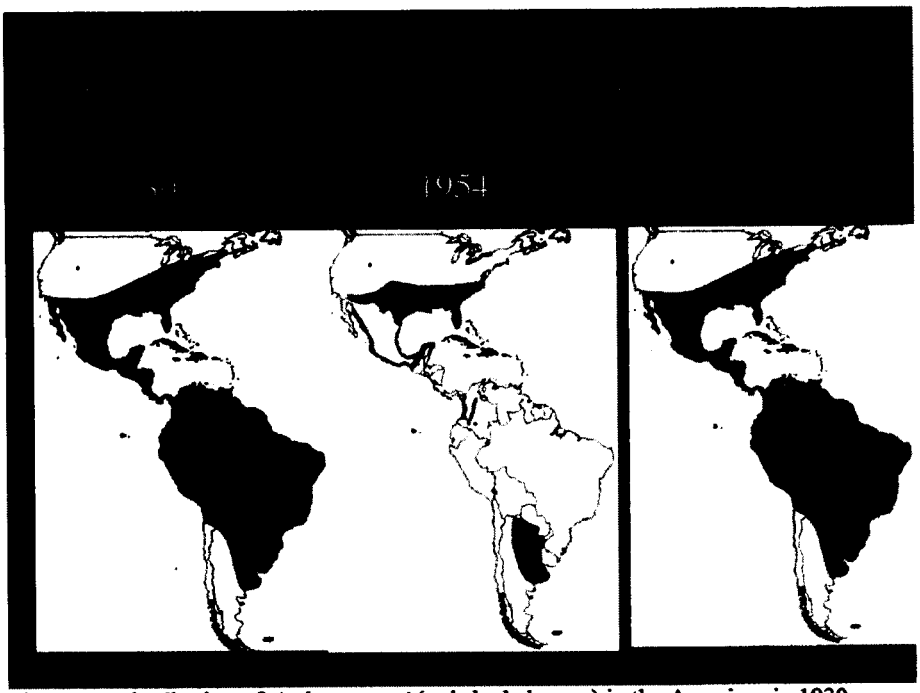

Figure 9. Distribution of *Aedes aegypti* (red shaded areas) in the Americas in 1930, during *Aedes aegypti* eradication in 1954, and in 1998 after the program had been stopped by anti-insecticide activism.[144]

The growing anti-DDT advocacy and de-listing of DDT in the United States ultimately resulted in the ramping down of eradication programs in Central and South America. The impact on other countries of stopping *Aedes aegypti* eradication in the United States was foreseen in the CDC's stated objectives for starting an eradication program in the United States:

> It will protect this country against outbreaks of yellow fever and dengue, and it will eliminate this reservoir of *Ae. aegypti* as a possible source of reinfestation of countries that have rid themselves of the species.[145]

Thus, when the United States stopped its own eradication program, Americans inadvertently harmed human health and economic growth in many other countries in the hemisphere. As programs in other countries were abandoned and *Aedes aegypti* returned to its old haunts in Central and South America, dengue fever went along.[146] Today, epidemics of dengue fever and dengue hemorrhagic fever are annual occurrences. Dimensions of the continuing catastrophe of dengue fever are growing. Each year there are millions of dengue cases and many deaths due to

---

145 CDC. Annual Report, F.Y. 1964, *Aedes aegypti* Eradication Branch, U.S. Department of Health, Education, and Welfare, Public Health Service, Communicable Disease Center, Atlanta, Georgia, Page 1.

146 CDC. Division of Vector-borne Infectious Diseases, http://www.cdc.gov/ncidod/dvbid/dengue/index.htm#current; PAHO, "Re-emergence of Dengue in the Americas," Epidemiological Bulletin, 1997, Vol. 18(2).

dengue hemorrhagic fever.[147] Given that most countries of the Americas had, for many years, eradicated the major vector of this disease, the modern burden of dengue for the people of Central and South America constitutes a colossal public health disaster. In 2008, Brazil suffered a devastating epidemic of dengue fever.[148] The 2008 epidemic may become the worst dengue outbreak in Brazil's history. Previous peaks in number of Brazilian cases for a given year occurred in 1998 with 500,000 cases, and 794,000 cases in 2002.[149] Devastating outbreaks of dengue are occurring each year in Mexico and other countries and regions of Central and South America.

Beyond the problems of a resurgent dengue fever problem, a silent but smoldering threat of urban yellow fever has accompanied the return of *Aedes aegypti* to countries of the Americas. Countries have had to redouble their yellow fever vaccination programs, at enormous costs, just to try and protect against a potential urban outbreak. Without the freedom to use DDT, the problems of dengue fever and risks of urban yellow fever are growing worse each year. Growing problems of yellow fever are illustrated by the national alerts that have been issued already in 2009. Yellow fever alerts, and in some cases multiple alerts, recently have been issued by Brazil, Argentina, Paraguay, Trinidad, and Venezuela.[150]

9. Even after DDT was de-listed for use in 1972, government officials and other users continued to obtain permission to employ DDT for certain public health, agriculture, forestry, and pharmaceutical uses in high-risk locations. In addition, DDT continued to be present in pesticide formulations and used widely in crops during the 1970s and 1980s, in the miticide Dicofol, also known as Kelthane.[151]

Even within the United States, the EPA decision to de-list agricultural uses of DDT in 1972 did not entirely close the book on issues of DDT use. Rather, EPA retained authority to make case-by-case determinations allowing use of DDT for experimentation, public health, and

quarantine purposes by public officials, and even crop infestations that could not be controlled with other insecticides.[152] EPA also enacted emergency exemption regulations to permit government agencies to use DDT for a variety of purposes.[153] Exemptions were granted for, among other things, control of the pea leaf weevil, Douglas fir moth, fleas, and plague.[154]

In addition, DDT continued to be present in pesticide formulations and used widely in crops during the 1970s and 1980s. DDT was a significant component (9-15%) of the miticide Dicofol, also known as Kelthane.[155] Regulations were passed only in the mid-1980s to require that levels of DDT in Dicofol be below 0.1%. Dicofol was used widely as a miticide on cotton and used heavily in Hidalgo County, Texas. The following map, prepared by the Department of the Interior, illustrates broad usage of Dicofol on cotton in 1992 (Figure 10).

Figure 10. Map for 1992 showing distribution of Dicofol use in the United States

DDT eventually was removed as a registered public health insecticide in the United States because of failure to pay fees to re-register DDT for public health in 1989. Use of DDT for quarantine, public health, and pharmaceuticals is still possible under the exemption process as long as it is consistent with EPA's 1972 order. Moreover, DDT is still eligible for registration as a public health insecticide.

10. Today, the World Health Organization (WHO) and other U.N. bilateral and multilateral organizations have concluded that DDT is safe for humans and safely can be sprayed on house walls for disease control.

Beginning in the mid-1990s, the United Nations Environment Program started efforts to eliminate public health use of DDT through negotiations for a persistent organic pollutants ("POPs") treaty. Treaty negotiations mobilized public health workers around the world in a campaign to prevent global elimination of DDT and restore the freedom of malaria endemic countries to use DDT in disease control programs. As a result of that campaign, DDT was

placed in Annex B of the Stockholm Convention, meaning that it is still available for use in public health programs, to include malaria control.[156]

Today, the United States Agency for International Development ("USAID") promotes indoor spraying for malaria control and supports the use of DDT.[157] WHO also endorses use of indoor spraying of insecticides, to include use of DDT.[158] As official policy, DDT is still approved for public health use by the WHO, USAID, UNICEF, the Global Fund, World Bank, Roll Back Malaria, and, as stated above, by the Stockholm Convention for Persistent Organic Pollutants.

Success of the campaign to prevent global elimination of DDT reflects certain fundamental facts about DDT and its long history of both intensive and extensive use, both in agriculture and public health. The facts are:

- There is still no concrete and replicated proof that DDT causes human cancer or other diseases.
- There is not even one documented human death from chronic or environmental exposure to DDT.
- Heavily DDT-sprayed areas do not exhibit the harmful effects activists claim (higher human mortality, more instances of cancer, lower fertility, etc.)

The new freedoms that now exist which allow countries to use DDT if they choose to do so has led to large reductions in disease and death in countries that have restarted house spraying and use of DDT.[159]

11. DDT is unequaled in its ability to control disease. It exhibits a complex of chemical actions to prevent disease transmission inside homes in three primary ways: (1) it is a powerful spatial repellent that stops mosquitoes from entering houses; (2) it is a strong contact irritant that causes mosquitoes to prematurely exit sprayed houses, often without biting; and (3) it kills mosquitoes that remain in prolonged physical contact with sprayed surfaces. DDT is the only insecticide presently recommended for spraying on house walls that actually stops a large proportion of mosquitoes from entering the house and transmitting diseases while residents are sleeping.

DDT is unmatched by other insecticides because of its low cost of production (no patent protections), effective duration of residual activity when sprayed on walls, and broad spectrum of chemical actions. No other insecticide can be produced and used as cheaply as DDT. DDT protects residents for as long as twelve months or more after it is sprayed on walls. No other recommended insecticide provides a comparable duration of residual activity. Other insecticides need to be sprayed in houses every two to four months and the need for frequent sprayings adds greatly to cost of the public health programs.

Although DDT is often thought of as a chemical that kills insects, it actually exerts a complex of chemical actions. It functions as a spatial repellent, a contact irritant and a contact poison. The spatial repellent and contact irritant actions function at concentrations of DDT that are far below concentrations needed for toxicity. DDT's actions of repellency, irritancy and toxicity intervene at specific points in the mosquito's sequence of malaria transmission behaviors. For instance, repellent action prevents the mosquito from entering the house altogether. If the mosquito does go indoors, then the contact irritant action causes the mosquito to exit, often before it even bites.[160] Lastly, with prolonged contact with a sprayed surface, the mosquito that enters the house in spite of repellant and irritant actions still may succumb to DDT's toxic action.[161]

In simple terms, the separate actions of DDT residues provide an interactive and cumulative benefit. For purposes of illustrating these interactions, imagine that the actions of repellency, irritancy, and toxicity each function at a level of 70 percent effectiveness. If one hundred mosquitoes enter a house not sprayed with DDT (see figure next page), then only thirty would enter if it were treated with DDT, as the other seventy would be repelled and not enter (see figure next page). Of the thirty mosquitoes that enter the house, twenty-one would be stimulated by contact irritant actions and exit, potentially without biting. This leaves nine mosquitoes that remain indoors and bite. Of these, six or seven would absorb a toxic dose of DDT and die, the other three or four would escape and survive. By summing the numbers of

---

160 However, a negative aspect of the contact irritant action would be to stimulate premature exiting after the mosquito bites, but before it absorbs a toxic dose of DDT.

161 Roberts, D.R., et al., "A Probability Model of Vector Behavior: Effects of DDT Repellency, Irritancy, and Toxicity in Malaria Control," J Vect Ecol, 2000, Vol. 25, Pages 48-61.

mosquitoes impacted by the three chemical actions of DDT, we find that although all of these actions function at equal levels of activity, spatial repellent and contact irritant actions together reduce the overall risk by 91 percent, while toxicity reduces risk by a maximum of only 6 to 7 percent. Overall, risk would be reduced by 95-96 percent.

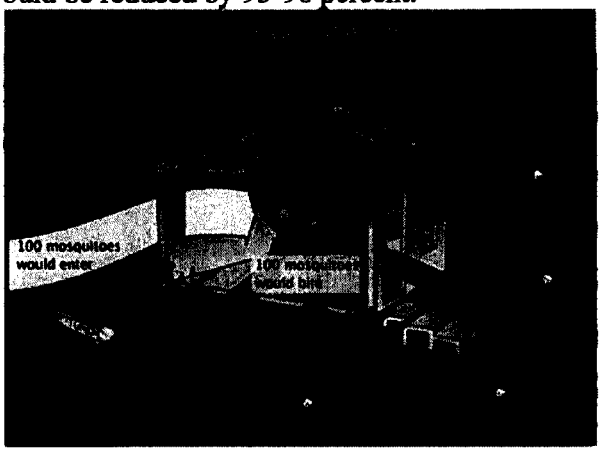

Figure 11. Behavior events for an idealized population of one hundred malaria mosquitoes that fly to a house that is not sprayed with DDT. All hundred mosquitoes would enter, bite, escape and survive if the house was not sprayed with DDT.

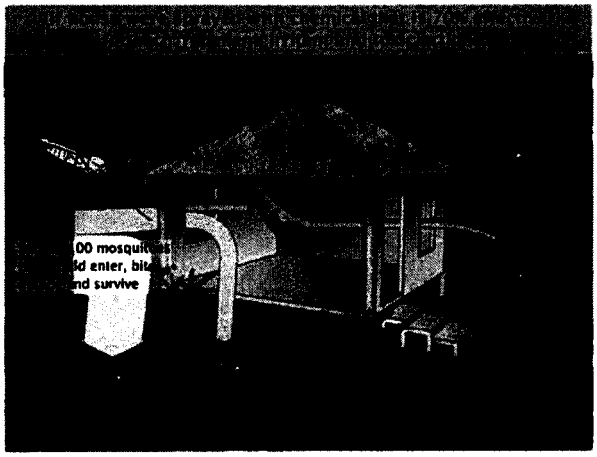

Figure 12. Behavior events for an idealized population of one hundred malaria mosquitoes that fly to a house that has been sprayed with DDT. In this model, we assume that each of the three chemical actions of DDT function at a 70% level of effectiveness. The model illustrates sequential behaviors of house entering, biting, and escaping the house.

The example above is based on repelling and irritating only 70 percent of the mosquitoes. Computer simulations of interactions between repellent, irritant and toxic actions show that an

insecticide would need to repel and irritate less than 30 percent each before toxicity would become the primary mode of chemical action against malaria vectors.[162] Yet in the real world, as demonstrated in different field studies, levels of DDT's repellent and irritant actions often function far above the 70% level of effectiveness.

Of the insecticides presently recommended for malaria control, only DDT has the complex of chemical actions described above. For this reason, no other insecticide is equally efficacious against most vector mosquitoes in most epidemiological settings. This profile of chemical actions goes far in explaining why DDT is still recommended and still needed for disease control programs in endemic countries.

12. In the 1950s and 1960s, there were no adequate substitutes for major uses of DDT, such as cotton and public health. This was true even in 1972 when EPA de-listed all agricultural uses of DDT in the United States. Even today, there is no equally effective substitute for DDT in public health programs.

The question of adequate DDT substitutes has been and continues to be polemic in the controversy over EPA's 1972 political action to stop agricultural uses of DDT in the United States. Statements presented by plaintiff's expert, Dr. Stanley Tocker, typify the controversy surrounding EPA's 1972 decision. Under the subheading of "Chlorinated hydrocarbon insecticide substitutes," Dr. Tocker states: "[L]ower persistence, efficacious technical chemicals were available as alternatives to the chlorinated hydrocarbons for virtually all insecticide markets." In the case of DDT, history and science have proven Dr. Tocker's assessment wrong – both during the 1950-1967 period and, for public health, even today.

a) Prior to 1972, prestigious study groups concluded that safer, adequate substitutes were not available for important DDT uses.

The lack of adequate substitutes for DDT was recognized even before EPA's precipitous action in 1972, as revealed in an article published in *Science* magazine in 1969:

> DDT substitutes, many experts say, are often potentially at least as dangerous as DDT, if not more so. In many cases no really adequate alternative is available.[163]

Such concerns were based on extensive deliberations of individual scientists, officials within major organizations, and important groups which had debated whether DDT was still needed. During the eight years leading up to the EPA decision to de-list DDT for agricultural uses, seven major groups met to consider whether DDT should continue to be used. The groups were:

c. The Committee on Persistent Pesticides of Biology and Agriculture, National Academy of Sciences
d. The Health, Education and Welfare Commission on Pesticides and their Relationship to Environmental Health, chaired by Dr. Emil Mrak, December, 1969
e. The Council on Occupational Health
f. The Council on Environmental and Public Health of the American Medical Association
g. The United States Congressional Committee on Agriculture, chaired by Congressman Poage, March, 1971.

The de-listing of DDT for agriculture was not recommended by a single one of these prestigious groups. In essence, each concluded that for some uses, no alternative insecticide is as cheap, effective, or as safe as DDT.[164]

The deliberations of committees affiliated with the American Medical Association have particular relevance to reports concerning whether or not DDT harms human health. In 1970, both the Council on Occupational Health and the Council on Environmental and Public Health of the American Medical Association ("AMA") made joint recommendations on continued use of DDT. The two committees, after noting that DDT accumulates in humans, reported:

> ...[T]here has been no significant increase in the storage of DDT by the general population in the United States since it was first measured in 1950. Pesticide handlers who have been studied with great care during the past 30 years have concentrations in fat as much as 50 times as high. Yet, careful research has shown no interference with their health despite long-continued exposure. Injuries to humans have been observed only in persons who accidentally received acute massive doses.[165]

The two councils jointly recommended:

> [T]he use of DDT should be continued for the control of pests on crops for which, at this time, no adequate alternative is available.[166]

Scientists and groups of scientists rather uniformly opined that DDT was safe to use, that environmental exposures had not been shown to be harmful to human health, and that precipitous

political actions against DDT would cause increased exposures of occupationally exposed workers to more highly toxic chemicals.

b) Potential DDT substitutes often have greater acute toxicities.

In his report dated February 8, 2008, Dr. Tocker incorrectly stated: "[L]ower persistence, efficacious technical chemicals were available as alternatives to the chlorinated hydrocarbons for virtually all insecticide markets." The implication is that formulators should have selected other insecticides for formulation and that the other chemicals would have safely met agriculture requirements in southern Texas. In making this statement, Dr. Tocker failed to consider how DDT-containing pesticides were being used by Hayes-Sammons' customers in southern Texas in the 1950s and 1960s.

Cotton and vegetables were important crops in southern Texas during the 1950s and 1960s. DDT was used on these crops from at least 1956 to 1964, and in 1965 and 1966, if not later.[167] In many areas, cotton producers depended on heavy use of DDT up to the time DDT was de-listed for use in agriculture in 1972. For example, as shown in an EPA document:

> Of the quantity of the pesticide [DDT] used in 1970-72, over 80 percent was applied to cotton crops, with the remainder being used predominantly on peanut and soybean crops.[168]

Given that a primary usage of DDT was on cotton, any suggestion that formulators should have (or could have) switched to safer, less persistent insecticides must take into account the options for alternative insecticides on cotton.

Dr. Tocker claims that carbamates (carbaryl), phosphonates (diazinon and malathion), soil fumigants and insect repellants were appropriate substitutes for DDT in the Hayes-Sammon's plant. None of these was as safe and cost-effective as DDT. Even the EPA formally recognizes that:

> Alternatives to DDT are not equally efficacious or economically feasible in all areas due to pest resistance and other factors.[169]

Similarly, in October 1970, the Texas Governor's Scientific Advisory Panel recognized that no "suitable alternative methods" were available to control certain agricultural pests,

including cutworms, cotton flea-hopper, carrot weevil, sweet potato weevil, and grape berry moth.[170]

D. General Conclusions

Decades of research show that DDT is safe for human exposure. This is not just my opinion, but also is reflected in the official positions of WHO, USAID, UNICEF, World Bank, and the Global Fund, all of which endorse the use of DDT in malaria control programs today. Over several decades, hundreds of millions of houses have been sprayed with DDT. Generations of people have lived in those houses and still no harm has been shown to result from those DDT exposures. The same conclusion can be drawn for spray operators and chemical plant workers who were occupationally exposed, sometimes for their whole adult lives, to very high levels of DDT. There is no disputing the fact that WHO itself consistently has opined that DDT, when used according to WHO guidelines, is safe for use in malaria control programs. What this means is that the world's premier organization for public health supports spraying DDT repeatedly **inside the homes** where people live.

The high efficacy, low cost, and large margin of safety for humans exposed to DDT are important reasons why DDT-sprayed house walls are so effective in control of malaria. Anti-insecticide pressures to stop spray programs, and to stop use of DDT in particular, are the main reasons malaria has re-emerged in many countries around the world. Anti-insecticide pressures and the damage they caused to the hemisphere-wide *Aedes aegypti* eradication program are also the primary reasons for the re-invasion of the Americas by the yellow fever mosquito. This re-invasion has been accompanied by the return of dengue fever, and presence of dengue hemorrhagic fever in the Americas. The return of *Aedes aegypti* to urban areas of the Americas is also the reason for a growing threat of urban yellow fever in countries of South America. Even today, there is no chemical that equals DDT's ability to safely protect the health and welfare of poor people in poor countries from major diseases like malaria and dengue.

ANNEX 1: National Malaria Control Programs in Africa and Asia

Historical data from many countries outside the Americas further evidence the huge impact of spraying houses with DDT. Selected examples are as follows:

a) South Africa

The vector control programs in southern Africa adopted DDT shortly after the end of WWII. Residual spraying with DDT brought rapid reductions in the number of malaria cases. In the Transvaal Province of South Africa, hospital admissions "fell from 1,177 cases during the 1945-46 transmission season to 601 in 1946-47 coinciding with the availability of DDT in 1946, and falling to 454 in 1948 and to a low of 61 cases in 1951."[171] Similar successes were echoed in other southern African countries where DDT was used.

b) Sri Lanka

After DDT was introduced for control of malaria in Sri Lanka (then Ceylon) in 1946, in a three-year period the spleen rate (malaria infections cause enlarged spleens) dropped from 77% to 2.7% and general infant mortality dropped by 62%.[172] By 1954, infections had declined from 413 per 1000 to 0.85 per 1000 people.[173] These statistics reveal reductions in millions of malaria cases per year.

c) Taiwan

The newly-formed Republic of China (Taiwan) adopted DDT use in malaria control shortly after the Second World War. In 1945, there were over 1 million cases of malaria on the island; however, by 1969 there were only nine cases.[174] Shortly thereafter, the disease was eradicated from the island (and remains eradicated today).[175]

174 Malaria Eradication in Taiwan, May 1991, Department of Health, The Executive Yuan, Republic of China.

175 Malaria Eradication in Taiwan, May 1991, Department of Health, The Executive Yuan, Republic of China.

In summary, extensive uses of DDT for malaria control preceded the global eradication program. As shown by the statistics presented above, countries used DDT to combat malaria and greatly improved the health of their residents.

ANNEX 2: Properties and Functions of DDT

A) Basic Biological and Environmental Relationships

DDT is an organic compound, which means it includes atoms of carbon. It is referred to as a chlorinated hydrocarbon. Many useful chemicals are chlorinated hydrocarbons. For example, chloroquine is a drug for treating malaria infections and it is a chlorinated hydrocarbon. DDT is an aromatic compound, meaning the DDT formula includes benzene rings.[176] Chloroquine is also an aromatic compound. The chemical formula of DDT also includes five atoms of chlorine.[177] Chlorine, like fluorine and bromine, is a halogen, so DDT is characterized as a halogenated compound. As with many chlorinated hydrocarbon compounds, DDT is hardly soluble in water and has low vapor pressure.[178] Thus, very few molecules of DDT will be present as vapor in a unit of air or as a solution in a unit of water. To illustrate this point, consider that water becomes saturated with DDT at a concentration of about two parts per billion. In other words, there will be two parts DDT to one billion (1,000,000,000) parts water.

DDT vapor in air or as a solution in water can be broken down quickly. DDT binds to organic particles so it also can be present in water and air as suspensions of organic materials that contain DDT. That is, DDT has adhered to an organic particle that become suspended in water or air. DDT is soluble in oils and organic solvents and is fat-soluble (or lipophilic).[179]

DDT can degrade rapidly in many environments. The processes of breakdown include chemical, biological, and photo-degradation. Recent studies show that uptake and degradation of DDT is complex.[180] In addition to degradative processes, the ebb and flow of DDT in both living organisms and the environment works through a process of partitioning. Partitioning helps explain DDT persistence. Partitioning occurs in different ways in the environment and living organism. In a living organism, DDT is partitioned into fat. Storage of DDT in fat cells can be referred to as compartmentalization in fat, and is not something that just happens. DDT is stored

---

176 The characteristic of aromaticity is related to specific chemical traits, as defined in a wikipedia, meaning "electrons are free to cycle around circular arrangements of atoms, which are alternately singly and doubly bonded to one another. (More properly, these bonds may be seen as a hybrid of a single bond and a double bond, each bond in the ring being identical to every other.)"; http://www.google.com/search?hl=en&defl=en&q=define:Aromaticity&sa=X&oi=glossary_definition&ct=title.

in fat by very specific biological or biochemical processes in which the living organism is an active participant, and it is a rate-limited process. Most organisms will accommodate only limited quantities of DDT.[181] This has proven to be true for humans, other mammals, and birds. Quantities of DDT beyond what the organism will accept are degraded and excreted. The major excretory product of DDT in humans is a water-soluble DDT metabolite known as DDA. As an excretory product, DDA is found in urine.

Through the processes of degrading and/or excreting DDT or by controlled partitioning of DDT into and out of fatty tissues, humans deal exceedingly well with chronic exposures to DDT. Findings from medical history, physical examination, routine clinical laboratory tests, and chest x-ray film of high occupational exposures to workers in DDT production did not reveal any ill-effects.[182] These findings are consistent with results of a CDC study conducted on human volunteers in the 1950s. In that study, humans were fed 32 mg of DDT per day for two years and then underwent an additional two years of medical follow-up. The people in this study suffered no medical harm from their high chronic DDT exposures.[183]

In the environment, DDT may be degraded to a point of disappearing. DDT is photo-degraded in sunlight. DDT in a solution of seawater has a half-life of about 10 days. Some fungi can mineralize DDT, white rot fungi for example.[184] Its half-life in the presence of some plants is only two to three days.[185] Natural sunlight quickly will degrade DDT in vapor phase.

Given the multiple pathways for DDT degradation and elimination, how is it possible that the chemical can persist in the environment? Actually, as stated above, environmental persistence is due mostly to the phenomenon of partitioning. That is to say, DDT can persist for long periods when partitioned into soil and organic materials and, to varying degrees, not be available for degradation. The term sequestered describes the condition of DDT being bound tightly to organic particles (soil particles for example). It is important to note that sequestration and long-term persistence means that DDT, in its long-term persistent or partitioned form, is not readily available for biological, chemical or photo-degradation.[186] If DDT is not bio-available, it

186 http://www.rosalindfranklin.edu/dnn/chicagomedicalschool/home/cms/biochem/faculty/walters/drugs.aspx As specified at this website: If a chemical is "too lipid-soluble, it may partition into fat stores and not reach the intended site of action. The balance between these two properties [solubility in octanol versus water] is measured roughly by the octanol-water partition coefficient. When octanol and water are mixed, they form

will not act against living creatures or be acted upon by living creatures (i.e., not inflict harm or be metabolized or degraded). If at some point the sequestered DDT becomes bio-available, then it will either be degraded or re-sequestered. In spite of these mechanisms for DDT persistence, once DDT is no longer applied to the environment, and as history has shown, DDT residue levels will rapidly decline. This is true for both animate and inanimate components of the global environment.

B) Routes of Exposure and Basic DDT Functions

Theoretically, DDT can be absorbed in three ways. These are (1) through the skin, (2) inhaled and absorbed through respiratory membranes, or (3) ingested and absorbed through the intestinal tract. The following general assessments relate to what might be expected from some typical environmental exposures. DDT absorption through skin is notoriously inefficient, so this is not a primary means of DDT exposure. As mentioned before, DDT has low vapor pressure and only exceedingly small concentrations of DDT vapors will be found in air. Particulate DDT can be found in air; but particulates are not absorbed through respiratory membranes. Instead, particulates actively are transported out of respiratory passages and eliminated. Thus, inhalation is not an effective means of DDT exposure. Since DDT is not very soluble in water (can be characterized as hydrophobic), imbibing DDT in water is not a primary means of DDT exposure. Basically, ingesting DDT in food is the primary method for humans to acquire DDT.[187]

---

a two-phase system (like an oil-and-vinegar dressing). Octanol roughly approximates the hydrophobicity of membrane lipids. So shake your drug in a mixture of octanol and water, let the layers separate, and measure the amount of your drug in each layer. The ratio [conc. in octanol]/[conc. in water] is the partition coefficient, P. The logarithm of P (log P) should ideally be less than 5.

CURRICULUM VITAE

DONALD R. ROBERTS, Ph.D
Professor Emeritus, The Uniformed Services University of the Heath Sciences in Bethesda, Maryland

Present Address: 118 First Street, Clifton Forge, VA 24422

Retirement Date: June 30, 2007

Post-retirement activities (June 2007 to present):

Member, Board of Directors, Africa Fighting Malaria (see: http://www.fightingmalaria.org)

Member, External Advisory Committee (EAC) for Sanaria, a company working to develop sporozoite-based malaria vaccines. The EAC is an advisory group for Safely Working with Plasmodium falciparum-infected mosquitoes, Address: Sanaria Inc., 9800 Medical Center Dr., Suite A209, Rockville, MD 20850

Member, Expert Scientific Advisory Committee for the Public Health Product development arm of the Innovative Vector Control Consortium (IVCC), The IVCC " is a Product Development Partnership developing vector control products and information systems. Bringing together expertise and technical resources with an initial award of $50.7 million from the Bill & Melinda Gates Foundation," (see: http://www.ivcc.com/organisation/index.htm)

I continue to write professional papers and editorials, make professional presentations at national meetings, review manuscripts for publication, and review research grant proposals.

Manuscript reviews:

American Journal of Tropical Medicine and Hygiene
Emerging Infectious Diseases
Journal of the American Mosquito Control Association
International Journal of Tropical Medicine
Acta Tropica
Environmental Entomology
Pest Management Science

Research grant reviews (2009 only):

U.S. Army Medical Research and Development Command
British Medical Research Council
Innovative Vector Control Consortium

EDUCATION:

Ph.D. - Medical Zoology, University of Texas School of Public Health, Houston, Texas. 1973.
M.S. - Entomology, University of Missouri, Columbia, MO. 1966.
B.S. - Zoology (Wildlife Conservation), University of Missouri, Columbia, MO. 1965.

ACADEMIC APPOINTMENTS:

1986-June 30, 2007: Professor, Division of Tropical Public Health, Department of Preventive Medicine and Biometrics, Uniformed Services University of the Health Sciences, Bethesda, MD 20814

1997-1999: Acting Director, Division of Tropical Public Health, Department of Preventive Medicine and Biometrics, Uniformed Services University of the Health Sciences, Bethesda, MD 20814

1984-1986: Associate Professor, Department of Preventive Medicine and Biometrics, Uniformed Services University of the Health Science, Bethesda, MD 20814

1978-1980: Visiting Professor, Nucléo De Medicina Tropical e Nutrição, Federal University of Brazil, Brasilia, Brazil and Chief, Department of Entomology, United States Army Medical Research Unit, Brasilia, Brazil.

SENATE TESTIMONY:

Roberts, DR. 2004. Senate Testimony before Senator Brownback's Subcommittee on East Asian and Pacific Affairs on Neglected Diseases in East Asia: Are Public Health Programs Working? October 6, 2004 at 2:30 p.m. in the Dirksen Building, Washington, D.C. 13 pp.

Roberts, DR. 2005. Senate Testimony before the full committee of the Environment and Public Works Committee on the misuse of science in environmental policy making. September 28, 2005. Specific topic was misrepresentations of science during decades of environmental campaigning against DDT. Presented in the Senate Building, Washington, D.C. morning of September 28, 2005.

Roberts, DR. 2006. Senate Testimony before Chairman Coburn's Subcommittee on Federal Financial Management, Government Information, and International Security. Title of hearing was "Bilateral Malaria Assistance: Progress and Prognosis." Hearing was held the afternoon of January 19, 2006. Presented views on malaria control and DDT use in public health programs.

Roberts, DR. 2007. Senate Testimony before Chairman Boxer, ranking member Inhofe and members of the Senate Committee on Environment and Public Works. Title of hearing was "Examining the Human Health Impacts of Global Warming". Hearing was held October 27, 2007. I presented views on the fear tactics used to stimulate pubic policy on

climate change-- drew parallels between fear tactics used in the anti-DDT campaign with those presently used in the global warming campaign.

LANGUAGES:
Portuguese

TEACHING:
USUHS: Courses taught:

Medical Acarology (course Director): 1988-present.
Aquatic Biology (Tutorial) (course Director): 1988-present.
Vector Biology (course Director): 1984-present.
Ecological Statistics (Tutorial) (course Director) 1998-present.

Participating instructor:
Environment and Health II: 1984-1986.
Tropical Medicine and Hygiene: 1984-1990.
Advanced Techniques in Medical Entomology: 1988-present.
Malaria Lectures in Diagnostic Parasitology: 1984-present.
Malaria Epidemiology and Control: 1989-present.

I have presented miscellaneous courses in Belize, Peru, Brazil, and Honduras. Topics include malaria, Disease control campaigns, Chagas disease, and applications of remote sensing and geographic information systems to public health.

Instructor, WRAIR Tropical Medicine Course (1982-1985)

Instructor, "Vector Biology and Control," WHO-sponsored course; International Center for Tropical Medicine Research, University of South Carolina (1986).

Instructor, National Academy of Science-sponsored "ELISA Workshop," USUHS (April 16-18, 1986)

Instructor, "Environmental Entomology and Pesticides Workshop," US Army Environmental Hygiene Agency, Aberdeen Proving Ground, Edgewood, MD (May 6-10, 1985 and April 20-24, 1987)

Instructor, "Vector Biology and Control," WHO-sponsored course taught in Portuguese at the University of South Carolina (1983).

Instructor, "Tropical Medicine for Health Care Professionals," WHO-sponsored international course conducted at the Nucléo de Medicina Tropical e Nutrição, UnB, Brasilia, Brazil (1979).

Instructor, "Extension Course in Tropical Medicine," Nucléo de Medicina Tropical e Nutricação, Universidade de Brasilia, Brasilia, Brazil (1978-1980).

Instructor, "Pest Control Operations and Equipment" Army Environmental Hygiene Agency, Edgewood Arsenal, MD (1970).

PROFESSIONAL ASSIGNMENTS:

1995-present: Director, Center for Applications of Remote Sensing and GIS in Public Health, a center within the Centers for Preventive Medicine and Public Health within the Department of Preventive Medicine/Biometrics, Uniformed Services University of the Health Sciences, Bethesda, MD.

1997-1999: Director, Division of Tropical Public Health, Department of Preventive Medicine/Biometrics, Uniformed Services University of the Health Sciences, Bethesda, MD

1980-1984: Chief, Department of Entomology, Walter Reed Army Institute of Research, Washington, D.C. 20307.

1978-1980: Deputy Commander, United States Army Medical Research Unit-Brasilia. Performed the duties of deputy commander and conducted malaria research in the Amazon Basin.

1976-1978: Commander, United States Army Medical Research Unit-Belém, Brazil. Performed the duties of unit commander and studied the mechanisms of epidemic and inter-epidemic transmission of Oropouche virus in the Amazon Basin of Brazil.

1975-1976: Deputy Commander, United States Amy Medical Research Unit-Belém, Belém, Brazil. Conducted multidisciplinary epidemiological surveillance of malaria and other diseases along the Transamazon Highway in Brazil. Conducted exploratory research on transmission of Oropouche virus.

1974-1975: Chief, Department of Entomology, United States Army Medical Research Unit-Belém, Belém, Brazil. Developed and conducted an integrated field and laboratory program of entomological surveillance along the Transamazon Highway in Brazil; investigated 3 urban epidemics of Oropouche virus; designed and supervised a malaria control program for migrant laborers near Paragominas, Para, Brazil. Also mounted epidemiological studies of malaria in the mirgrant laborers.

1969-1970: Entomologist, U.S. Army Environmental Hygiene Agency, Edgewood Arsenal, MD. Studied influence of insecticides on planktonic algae. Also conducted research on slow-release formulations of insecticides for control of mosquito larvae.

1968-1969: USARSUPTHAI Command Staff Entomologist, 712th Preventive Medicine Unit (SVC) (FLD), Korat, Thailand (Studied separate outbreaks of malaria and Japanese B encephalitis in American personnel).

1967-1968: Entomologist, First US Army Medical Laboratory, Fort Meade, MD. Studied influence of insecticides on survival and development of mosquito pupae.

EDITORIAL ACTIVITES:
I review manuscripts for:

American Journal of Tropical Medicine and Hygiene
Journal of Medical Entomology
Journal of the American Mosquito Control Association
Emerging Infectious Diseases
Bulletin of the Pan America Health Organization
Photogrammetric Engineering and Remote Sensing
Environmental Health Perspectives
The Lancet and other professonal journals.

AWARDS AND HONORS:

Delta Omega Honorary Society in Public Health.

Legion of Merit with Oak Leaf cluster for service in malaria vaccine development, Walter Reed Army Institute of Research and the Uniformed Services University of the Health Sciences.

Legion of Merit for service as Commander, United States Army Medical Research Unit-Belem, APO Miami 34030.

"A" Prefix awarded by the U.S. Army Surgeons General for the highest level of Professional Achievement.

Meritorious Service Medal (with Oak Leaf Cluster) for service as Chief, Department of Entomology, Walter Reed Army Institute of Research, Washington, D.C.

Meritorious Service Medal for service as Chief, Medical Entomology Section, United States Army Medical Research Unit-Brasilia, APO Miami 34040.

Examples of recent grants (up to time of retirement):
"Behavior-modifying compounds for disease vector control"
NIH Partnership Grant, Roberts (PI) 09/08/03-01/03/08
Goal is to develop new chemicals for vector control.

"Environmental determinants of Malaria in Belize, C.A."
NIH/NSF—Rejmankova (PI), UC-Davis 10/01/00-9/30/05
Roberts is PI for USUHS participation. Submitted in response to NIH RFA TW-00-002.

The major goal is to examine the role of anthropogenic change on the ecology of malaria and malaria vectors.

Partial Listing of Other Professional Activities:
1973-1978: Consultant in medical entomology and epidemiology to the World Health Organization, Pan American Health Organization in Brazil (consultant in Medical Entomology and Epidemiology).

1978-1980: Visiting Professor, Medical Entomology, University of Brasilia, Brasilia, D.F., Brazil.

1980-1981: Deputy Manager, Medical Entomology Study Group, USAMRDC.

1981: Chairman, Working Group on Surveillance, Attractants and Repellents. Workshop on Vector Control sponsored by the U.S. Agency for International Development,meeting site was Gainesville, FL.

1982: Consultant in arbovirology, World Health Organization, Pan Health Organization, worked in Bolivia.

1983: Member, Study Group for Vector Control, U.S. Agency for International Development, Washington, D.C.

1980-1984: Reviewer, Medical Entomology Study Group, USAMRDC

1980-1984: WRAIR Representative to the Armed Forces Pest Management Board (AFPMB)

1982-1984: Member, Medical Entomology Committee, Armed Forces Pest Management Board (AFPMB).

1984: Member, Ad Hoc committee for selection of meeting sites; American Society of Tropical Medicine and Hygiene.

1984: Chairman, Study Group for Vector Control, U.S. Agency for International Development.

1984: Consultant to the Minister of Health, Dominican Republic (consultant in malaria control).

1986: Member, Study Group of the U.S. Agency for International Development for Biological Control.

1986: Coordinator, "ELISA Workshop",sponsored by the National Academy of Sciences at USUHS, April 16-18, 1986.

1984-1988: Chairman, Local Arrangements Committee, 1988 Annual meeting of the American Society of Tropical Medicine and Hygiene. This annual meeting earned record profits, over $60,000.

1984-1988: Member, Advisory Council of the International Center for Public Health Research, University of South Carolina.

1989-1989: Member, AIBS review board for AID proposals in malaria vaccine development research

1988: Reviewer, Medical Entomology research proposals submitted to the Pan American Health Organization.

1989: Consultant, Pan American Health Organization, reviewed research program of the Center of Malaria Research, Tapachula, Mexico.

1986-1995: Chairman of "Admission Committee for the Ph.D. Program in Medical Zoology", DPMB, USUHS.

1995-1999 and 2003-present: Chairman, "Admission Committee for the Ph.D. Program in Medical Zoology," DPMB, USUHS.

1995-97: Member of Merit Review Board for the intramural grants program, USUHS.

1997: Chairman, "Ad hoc Committee to Evaluate Core MPH Curriculum," DPMB, USUHS.

1997-98. "Graduate Education Committee," DPMB, USUHS.

1997-99 "Executive Committee," DPMB, USUHS.

1999-2001: Member of the USUHS Committee for Advancement, Promotions and Tenure.

1999-present: Member of Department of Preventive Medicine's Committee for Advancement, Promotions and Tenure.

2002-2003: Member of Department of Military Medical History's Committee for Advancement, Promotions and Tenure.

2002-present: Member, Board of Directors, non-government organization "Africa Fighting Malaria."

2003-2005: Member of external committee for review of military medical research proposals (MIDRPs).

2003: Committee for review of Small Business Innovative Research proposals for the Army Medical Research Material Command.

Expert Report of Professor Amir Attaran

In the matter of *Garza v. Allied Chemical Corporation, et al,*
Cause No. C-4885-99-F(10), 332nd Judicial District, Hidalgo County, Texas

On behalf of the defendant Montrose Chemical Corporation of California

September 2009

My Qualifications:

I am Associate Professor in the Faculty of Law (Common Law Section) and the Faculty of Medicine (Department of Epidemiology and Community Medicine) at the University of Ottawa, where I currently hold the Canada Research Chair in Law, Population Health and Global Development Policy. My training is in both areas, having received a doctoral degree in the biomedical sciences (at Oxford University) and a degree in law (at the University of British Columbia).

My research is often oriented toward the combination or intersection of the biomedical sciences and the law. Universities increasingly encourage this sort of interdisciplinary scholarship, and the Canada Research Chair that I hold is intended for it. Prior to taking my current position at the University of Ottawa, I held research or teaching positions at both the Kennedy School of Government at Harvard University, the School of Public Health at Yale University, and the Royal Institute of International Affairs (now renamed Chatham House) in London. Global public health policy was a key scholarly interest of mine while in all these positions.

I have made careful studies of the claimed relationships between DDT exposure and human health, and historical and contemporary attitudes toward public policy on DDT. As an indication of my reputation in this field, my views on DDT and public health:

- have been published in some of the leading biomedical journals (e.g., *Nature Medicine*, the *British Medical Journal*);

- have been solicited as a member or invited guest in the committee deliberations of leading science policy organizations (e.g., the World Health Organization, and the Institute of Medicine of the US National Academy of Sciences);

- were adopted by the Government of South Africa in the drafting of a treaty on persistent organic pollutants (the Stockholm Convention), and specifically, the part which deals with the public health exemption;

- have been covered by the world's top press organizations (e.g., the *New York Times*, the *Economist*);

- have contributed to a reevaluation of DDT by the United States Senate, including in Senate committee hearings held in May 2005, where DDT was favorably discussed as among the options for malaria control; and

- have been presented in invited lectures at various universities.

(1) Summary opinion

Consistent with standards of good scientific scholarship, I cite the literature containing the evidence upon which my opinion rests throughout this report.

While I am acutely aware that no concise statement can fully capture the meaning of this report, subject to that caveat, here are my summary opinions as will be further elaborated herein:

1. At the present time, leading public health agencies at the national and international levels (such as DHHS, WHO and IARC) have concluded that the evidence does not support a causal association between DDT exposure and cancer in humans.
2. In contrast, there is abundant and non-controversial evidence that the public health use of DDT has avoided human death and illness from insect-borne diseases such as malaria or typhus. The savings are in the millions of lives historically.
3. Over a course of decades, and across a range of diseases, DDT delivered ascertainable improvements to Texans' health, including in Hidalgo County.
4. Since the 1990s, the use of DDT for public health purposes is experiencing a resurgence, with the support of agencies such as USAID, WHO and the World Bank, and the agreement of leading environmental groups.
5. The EPA did not "ban" DDT, but limited its registrations, principally for political reasons. Further, EPA's reasons did not include any finding that DDT is carcinogenic in humans.

Obviously, my opinion differs from those who (incorrectly) regard DDT as extremely dangerous. My views are shaped by the reality that DDT is unquestionably a life-saving agent: one that has saved millions of people from dying of malaria and other insect-borne diseases. With that reality comes an ethical reason to prepare this report: when in the past critics used faulty scientific reasoning to cast aspersions on DDT, history teaches that DDT was eliminated from malaria control programs in Africa, Asia, Latin America and elsewhere, with the result that many, perhaps millions, of people needlessly died. By letting faulty evidence go unchallenged, DDT could be wrongly sidelined again, with fatal consequences for some of the world's poorest or most vulnerable people.

As a sign that my views are genuinely held and not matters of convenience for this litigation, please note that all my peer-reviewed papers on DDT were published before I was aware of this litigation. I first formed my views on DDT while employed by one Canada's most prominent environmental conservation charities, and I later refined those views while employed by Harvard University, Yale University and the University of Ottawa.

(2) Historical uses of DDT around the world:

The identification of DDT as an effective insecticide was the work of a Swiss chemist, Paul Müller, in the late 1930s, as the Second World War was gathering steam. In the pragmatic mindset of that war, the positive health effects of Müller's discovery were immediately recognized. Insect-transmitted diseases such as typhus and malaria were familiar scourges in earlier wars, and continued to decimate troops and civilians in Southern Europe and the Asian Pacific theatres of the War.

Controlling these diseases became part of the war effort. City-wide programs were established to dust DDT and another insecticide, MYL, in neighborhoods, in homes—and even on the person. Finding a huge typhus epidemic tearing through Naples after its liberation from Nazi occupation, the Allies dusted up to 70,000 people *each day* with DDT or MYL.[1]

In those days, it was uncommon to *limit* peoples' exposure to DDT dust. On the contrary, with a ferocious epidemic underway, the Allies and their Italian counterparts exerted themselves to the fullest to douse as many Neapolitans in DDT as possible. In this sense, Naples makes an interesting counterfactual to the Hayes-Sammons situation, for in Naples the intention was to spray citizens' bodies with DDT, and to keep spraying whenever a case of typhus flared, right up to the 1950s. The fact that the DDT was applied not very judiciously, but directly on one's head, face and body at point-blank range, is readily apparent in photos of the Naples typhus campaign reproduced on next pages.[2]

The Allies' gambit with DDT worked: Naples brought an end to its typhus epidemic, which because of continued DDT operations was not to return.[3] Over 3,000,000 people were dusted (or re-dusted) between 1943-1945, and yet, scientists at the time observed "no evidence of sensitization or intoxication due to the DDT louse powder ... during the Naples control activities."[1] In other words, millions of Italians were doused with DDT at close range and scientists at the time did not observe any harm. Nor does it appear that scientists reported any long-term or delayed harm in later years. To the best of my knowledge, and having conducted a thorough search of the biomedical literature to the present day, there has been no reported epidemic of non-Hodgkin lymphoma (NHL) in the wake of this massive DDT campaign.

SIGN ON NAPLES ROAD WARNS SOLDIERS AGAINST LICE

TYPHUS IN NAPLES

AMG medical officers control an epidemic with tons of delousing powder and a preventive vaccine

When the Germans evacuated from Naples they dynamited the city's water system. Without water the Neapolitans could not wash their clothes or their bodies. As they became progressively more dirty they became better and better hosts for body lice which carry typhus fever. Somehow a few of these lice got a chance to bite a person suffering from typhus and thus picked up the disease. In the crowded slums of the half-homeless city these typhus-carrying lice crawled from one person to another spreading the infection as they went. When the Americans marched in last October they found an epidemic getting under way. But

Italian baby gets dusting while family undergoes examination. Each evening Italians, like the man at the left, undress themselves into squads of dozens. Paid 80 lire per night and supervised by U.S. Army doctors, they scatter all through the city, dusting everyone they can find.

U. S. Army doctor, Major C. M. Wheeler of Berkeley, Calif., pats over a little girl who looks as if she were going to cry. Major Wheeler is head of the Contact Delousing Service which, with Italian help, has the job of getting servant and dusting people in their homes and shelters.

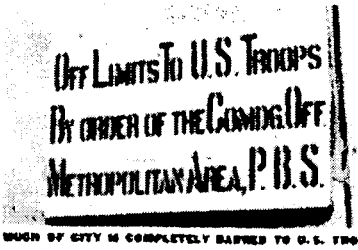
Cement mixer is used to mix the insecticide powder with Italian talc. This talc serves to prevent the powder from irritating the skin. The mixer holds half a ton of insecticide and talc at one loading and each 60-lb. bag (center) contains enough powder to delouse about 600 people.

Rockefeller Foundation worker examines the hair of a little girl. Head lice lay eggs which can be seen sticking to the individual hairs. Typhus is one of the great epidemic diseases of the world. In 1918 typhus spread through Russia, infecting 25,000,000 and killing some 3,000,000.

after four and a half months medical officers of the AMG last week seemed to be getting it under control.

Knowing that most of the population, after months of German oppression, had neither clean clothes nor clean bodies, U. S. doctors fought the epidemic by delousing 30,000 people a day with a new powder insecticide called DDT (dichlorodiphenyltrichloroethane). As a further preventive, Naples policemen and firemen were inoculated with an effective new vaccine. This same vaccine, developed by Bacteriologist Herald Rea Cox while he was at the Rocky Mountain Laboratory in Hamilton, Mont., has kept the typhus death rate of the U. S. troops stationed in the Naples area at zero.

Once a person develops typhus there is not much, aside from good nursing, that can be done for him. The incubation period lasts from eight to 12 days and the first symptoms are backache or headache and perhaps chills. By the third or fourth day the fever rises to 103° or 104°, a bumpy red rash breaks out and usually a muttering delirium sets in. Sometimes victims have terrifying, suicidal hallucinations. If infection has not become too extensive and there are no complications like bronchitis or pneumonia, fever drops abruptly after about two weeks and patient begins to recover.



MUCH OF CITY IS COMPLETELY BARRED TO U. S. TROOPS

Woman finishes as an Italian doctor gives her a blast of the powder. Most of the Italians like it, appreciating their delousing. This woman, who lives in a filthy tunnel under a road, is typical of the hundreds of people who were made homeless and miserable by the German occupation.

Squirt in the hair is added precaution. Typhus is generally carried by the body louse which never crawls above neck, but occasionally head lice become infected and transmit the disease. Body lice are the same as the cooties which tortured Americans in trenches of World War I.

Sky hits powder through the hair of his small brother. Naples has had to delouse everyone going to and coming from city to prevent spread of epidemic. Typhus, like Rocky Mountain fever, is caused by Rickettsia, a microorganism larger than a virus but smaller than bacteria.

Policemen are vaccinated by Captain Maxwell Reed of Immunization Service. Vaccine is made by infecting chick embryos and allowing Rickettsia to multiply. The infected matter is then diluted. Vaccination produces little reaction but must be repeated after about six months.

The success achieved with DDT against typhus naturally encouraged the thought that it could be useful against other insect-borne diseases. Of these, malaria was—and regrettably still is—the most significant as measured by the death or disability it causes.

In 1955, the Assembly of the World Health Organization passed a resolution committing to a global campaign of malaria eradication.[4] DDT was already the anti-mosquito insecticide of choice, and together with a highly effective malaria medicine (chloroquine), these constituted the keystones of the WHO's campaign from 1955 to (approximately) the early 1970s.

In WHO's standard technique, known as indoor residual spraying (IRS), DDT was applied once or twice yearly to the interior walls and eaves of family dwellings, at a dose of 1-2 grams per square meter.[5] The DDT so applied remains for 6-12 months as a highly effective mosquito-killing and mosquito-repelling residue. Since most species of malaria mosquitoes feed on their victims in the middle of the night as they sleep indoors, the indoor residual spraying technique could achieve a great reduction in cases of malaria.

Although the WHO campaign fell slightly short of the goal of total malaria eradication, the tactics it embodied achieved stunning results nonetheless and saved a vast number of people from the disease. After the introduction of DDT in 1945, WHO reports that transmission of malaria in Sri Lanka (then called Ceylon) was reduced from 2.8 million cases and 7,300 deaths, to 17 cases and zero deaths.[6,7] Similarly, a report from India commissioned for WHO reads that "the achievement in malaria control by DDT spraying was so spectacular that by 1965 malaria was wiped out in 373 million population ... [and] the incidence of malaria was drastically reduced from ... 75 million cases annually ... to about 0.1 million."[8] Succinctly put, in India and Sri Lanka, the malaria case rate fell by over 99%—an achievement which has not been matched by any technology since.

But a more dramatic achievement occurred in the southern United States, which totally eradicated malaria. Various social and sanitary measures such as swamp drainage or improved housing succeeded in lowering malaria cases from an estimated 600,000 cases in 1914 to 125,556 cases in 1934, but malaria remained a stubborn problem.[9] It was not until

---

[4] The original resolution of the Assembly is reproduced with further explanatory text in document WHO/Mal/162 of 1 February 1956, available at http://whqlibdoc.who.int/malaria/WHO_Mal_162.pdf (accessed 17 September 2009).

[5] To visualize how much DDT residue is used, imagine approximately a sugarcube of DDT, sprayed on a wall area equal in size to the front of a typical refrigerator door. That is, roughly speaking, about 2 grams per square meter. World Health Organization. Frequently asked questions on DDT use for disease vector control. Document WHO/HTM/RBM/2004.54 rev. 1 (2005). [9] When one speaks of eradicating an infectious disease, that means, as a public health concept, that there is no more stable transmission of the disease. There is today no stable transmission of malaria in the USA, although there are occasional cases of imported malaria, as by traveling persons or parasite-positive mosquitoes. The

the 1950s that, thanks largely to DDT, malaria was at last totally eradicated as a native disease of the southern United States—a major public health success.

(3) The use of DDT in Texas:

Texas has been a prime user—and Texans are beneficiaries—of DDT.

Starting after World War II, and with the success of controlling epidemics abroad ringing in their ears, the US Public Health Service, Communicable Diseases Center (USPHS-CDC), established anti-malaria and anti-typhus campaigns across the American South. Those campaigns normally involved overlapping efforts of federal, state and local level agencies, whose incomplete traces are spread across various archives today. This reality makes it difficult, if not impossible, to pinpoint exactly how much DDT was used for public health purposes. What I present here is at best a highly incomplete catalogue, which nevertheless makes clear that DDT was used in substantial quantities across the South for health protection—including in Texas.

Here is a tabular summary of the extent of DDT residual spraying in Texas for malaria control, as reported in contemporary documents of the USPHS-CDC:

Interval	Houses or Applications[10]	DDT (pounds)
1946 (Feb 23 – June 30 only)[11]	46,184	26,784
FY 1947[12]	101,350	91,215
FY 1948[13]	96,056	116,281
FY 1949[14]	71,870	72,225
FY 1950[15]	85,355	75,770
FY 1951[16]	39,789	31,014
FY 1952[17]	23,885	11,914

---

imported cases typically are a few dozen annually, and in the rare instance they re-establish community transmission, it is always short-lived and sputters out. *See* Zucker JR. Changing Patterns of Autochthonous Malaria Transmission in the United States: A Review of Recent Outbreaks. **Emerg Infect Dis** 1996;2:37-43. Available at ftp://ftp.cdc.gov/pub/EID/vol2no1/adobe/zucker.pdf (accessed 17 September 2009).

[10] Some of the original data reflected in the second column refer to the "number of houses sprayed," whereas other data refer to "number of house spray applications" or some similar term. There is no complete explanation found in the cited records for why the change in terminology occurred and whether it is meaningful as to a change in the statistical method. Regardless, it does not affect the conclusion for present purposes that a large number of houses in Texas were sprayed with DDT.

[11] USPHS. *Bulletin Communicable Disease Center: July, August, September 1946* (Federal Security Agency, USPHS; Atlanta), p. 13.

[12] USPHS. *CDC Activities* 1946-1947 (Federal Security Agency, USPHS; Atlanta), p. 6. Note that the calculation of pounds is subject to a footnote in the report which reads "second half of fiscal year only." In this and later footnotes in this section, note that the quantity of DDT may be approximated, as the total weight was not always reported by USPHS-CDC directly. A credible approximation can be made by multiplying the reported number of premises dusted with DDT by the reported average weight consumed per premises.

[13] USPHS. *CDC Activities 1947-1948* (Federal Security Agency, USPHS; Atlanta), p. 5.

[14] USPHS. *CDC Activities 1948-1949* (Federal Security Agency, USPHS; Atlanta), p. 76.

[15] USPHS. *CDC Activities 1949-1950* (Federal Security Agency, USPHS; Atlanta), p. 4.

[16] USPHS. *CDC Activities 1950-1951* (Federal Security Agency, USPHS; Atlanta), p. 47.

It can be seen from these data that tens of thousands of houses in Texas were sprayed with up to 58 tons of DDT annually for malaria control. Additional amounts of DDT were used for general mosquito larviciding, which while not exclusively directed to malaria mosquitoes would have had some beneficial impact: *e.g.* in FY 1948, 7,931 gallons of DDT oil emulsion were used in Texas for controlling malaria mosquito larvae.[18]

The DDT house spray operations were found in most parts of the state, including Hidalgo County. For instance, the USPHS-CDC reports that from July 1947 to June 1948, 3483 pounds of DDT were consumed to spray 3249 premises in Hidalgo County.[19] Hidalgo County is also shown in a map of USPHC-CDC malaria spray operations for the previous year (1946-1947).[20] A contemporaneous memo of the Texas State Health Officer notes that early in the history of the state's DDT use (winter 1946), "plans were formulated for presentation to the Commissioner's Court of each county calling for local participation, and agreements were signed."[21] Other memos by this same official note that DDT spraying, and also DDT larviciding, took place across Hidalgo County, including in Mission.[22]

Even larger quantities of DDT were used for typhus control in Texas. From 1941 to 1945, Texas had more cases of this potentially deadly disease than any other state.[23] When the effort to combat typhus reached full swing between FY 1948 to FY 1950, about 400,000 pounds—or 200 tons—of DDT were dusted in premises in Texas.[24] Again, contemporaneous maps published by USPHS-CDC confirm that these typhus control operations took place in Hidalgo County.[25]

Hidalgo County also resorted to DDT for other public health uses, aside from the customary malaria and typhus control uses. Starting in 1945, a scientific trial in Hidalgo County sought to reduce the highly endemic problem of dysentery (a severe, potentially life-threatening form of diarrhea) by spraying DDT to control fly populations.[26] The USPHS-CDC credits that trial with "a decreased dysentery rate" in those locales of Hidalgo County where DDT was used.[27] This trial appears to have achieved a marked reduction on the prevalence of *Shigella* infection in Hidalgo County while DDT spraying was underway.[28]

Texas also used DDT to combat mosquito-borne viral encephalitis. Such epidemics occurred from time to time in Hidalgo County and are always dangerous: e.g. Eastern equine

encephalitis kills about a third of its victims, and can brain damage survivors. A serious epidemic occurred in Hidalgo County in 1954, which led the Governor of Texas to declare a state of emergency there.[29] Both DDT spraying and larviciding were used in that epidemic.

In the 1960s, Texas also was part of a wider international program encouraged by the Pan American Health Organization (PAHO) to eradicate the *Aedes aegypti* mosquito, which is particularly dangerous because it can transmit yellow fever. While countries such as Brazil had eradicated *Aedes aegypti* in the 1950s, the mosquito remained in Texas. The USPHS-CDC strategy for *Aedes aegypti* eradication called for DDT spraying, which was successful in short order.[30] Two maps published by USPHS-CDC tell the story: the first map shows that Hidalgo County was "infested" in 1964, but just two years later, the southern tip of Texas is "uninfested or presumed uninfested."[31] The USPHS-CDC *Aedes aegypti* eradication branch records that 26,985 gallons of DDT concentrate were supplied to Texas in 1964, in anticipation of such operations.[32]

In sum, even with the often incomplete archival records available today, it is possible to draw this conclusion: over a course of decades, and across a range of diseases, DDT delivered ascertainable improvements to Texans' health, including in Hidalgo County. Of greatest significance, malaria was eradicated, and typhus is now rare. DDT brought about these health benefits, and was transformational.

(4) DDT is of overall benefit to human health:

Some critics of DDT may be tempted to view these decades-old results and brush them aside, by a sort of "that was then; this is now" reasoning. Doing so is equally unscientific as it is factually incorrect. The consensus of contemporary scientific thought is that, correctly used, DDT remains a beneficial and safe intervention against vector-borne disease.

The World Health Organization, which is the leading health agency in the United Nations system, and which counts the USA as a member, currently supports DDT as a safe and effective public health intervention. In 2005, WHO wrote:

> *"WHO recommends indoor residual spraying of DDT for malaria vector control."*[33]

In September 2006, WHO reassessed the scientific evidence on DDT, and amplified its recommendation, after finding fault with its earlier assessments that caused DDT use to decline. As WHO wrote of its 2006 reassessment:

> *"WHO actively promoted indoor residual spraying for malaria control until the early 1980s when increased health and environmental concerns surrounding DDT caused*

[33] See WHO, Frequently asked questions on DDT use for disease vector control, cited above at footnote 5.

the organization to stop promoting its use and to focus instead on other means of prevention. Extensive research and testing has since demonstrated that well-managed indoor residual spraying programmes using DDT pose no harm to wildlife or to humans."[34]

It should be emphasized that by giving approval to DDT indoor residual spraying, WHO today sanctions the practice where DDT is intentionally and directly sprayed on the interior walls of homes, into the spaces where people live. The quantity of DDT that is used (recall it is 1-2 grams per square meter) leaves a visible crust of DDT on the walls. With time, the DDT crumbles off the walls, and some is inhaled or ingested by the homes' inhabitants. Further, this exposure pattern is repeated indefinitely, since the standard practice is to respray homes once or twice yearly. All this is consistent with WHO's current guidelines.

Other global authorities have followed WHO's lead in this regard. For example, in 2006 the World Bank states:

"...[T]here has been no scientific evidence that indoor spraying with DDT for malaria has resulted in negative health or environmental consequences. So the Bank's position is very pragmatic on its use. We will use insecticide, and that includes but is not limited to DDT. There is no room for dogma on this issue..."[35]

The United States Agency for International Development (USAID), which is the main implementing agency for the President's Malaria Initiative (under both President Bush and President Obama) currently says this about DDT:

"USAID supports indoor residual spraying (IRS) with DDT as an effective malaria prevention strategy in tropical Africa in those specific situations where it is judged to be the best insecticide for IRS both epidemiologically and entomologically and based on host-country policy..."[36]

"If used correctly for [indoor residual spraying], it poses no known risk to human health..."[37]

The world's leading foreign aid donors such as the Global Fund to Fight AIDS, TB and Malaria, the World Bank, and USAID now provide (or are preparing to provide) funding to several developing countries to use DDT for malaria control. While there appears to be no fully comprehensive list, the scientific literature discloses that Mozambique, South Africa, Swaziland, Eritrea, Ethiopia, Madagascar and India are some of the countries which have

used DDT in the last decade.[38] [39] The United Nations Environment Programme currently lists 15 countries using or reserving the right to use DDT for disease control.[40]

The widespread recognition by leading development or health institutions that it can be used without harm to humans invites this question: What is correct to think about the DDT exposure of the persons whose homes are sprayed in malaria control operations, relative to the DDT exposure of persons such as Ms. Garza?

In my opinion, it is very unlikely that Ms. Garza received a greater dose of DDT than the many millions of people whose homes were regularly sprayed with DDT for malaria control. Recall that in the WHO-sanctioned technique, DDT is sprayed actively and directly into one's home at frequencies sufficient to keep a constant residue on the walls—and this implies an exposure greater than what one might receive passively through the environment in the neighborhood or community of a pesticide plant. As WHO finds "no harm to ... humans" occasioned by DDT in the indoor residual spraying situation, one would not expect harm to humans in the neighborhood or community situation.

Further, and to the best of my knowledge after having conducted a thorough search of the biomedical literature to the present day, there is no reported epidemic of non-Hodgkin lymphoma (NHL) in the wake of DDT indoor residual spraying for malaria, anywhere in the world. The head of India's national malaria control program, writing for WHO, has made a similar observation:

> *"This insecticide [DDT] has been used extensively in the country for over 40 years in Public Health, especially for the control of vectors of malaria, but there has not been a single instance of its acute or chronic toxicity hazard on human being[s] or domestic pets & cattle, reported from any corner of the country."*[41]

This view—that DDT had public health benefits inuring to millions, and risks observed in precisely no one—prevailed worldwide, including in the United States. Within living memory, it was not uncommon for great leaders and persons of stature to consider DDT a good thing (see some of their quotes collected in Appendix One). Then the tide began to turn: environmental campaigners in the 1960s, notably Rachel Carson, lobbied vigorously to shift public opinion against DDT and to cancel DDT's product registration. The campaigners too often forgot the very substantial good that DDT had done for less fortunate multitudes living

at risk of vector-borne diseases—including people in Texas. As the US National Academy of Sciences estimated in 1970:

> *"To only a few chemicals does man owe as great a debt as DDT. In little more than two decades DDT has prevented 500 million human deaths due to malaria that would have otherwise have been inevitable."*[42]

Of course, one may quibble with the National Academy of Sciences estimate for being only that—an estimate, which by definition lacks exact precision. But even so, I have never heard the following fact challenged or contested, even by DDT's most ardent opponents: DDT has saved a very large number—indeed, millions—of lives from typhus, malaria and other causes. Having once been a prime producer of DDT for agencies such as the US Public Health Service, WHO and UNICEF, and for countries such as Brazil and India, Montrose Chemical Corporation of California's products contributed to this humanitarian success to some extent.[43]

DDT continues to save lives in countries such as South Africa, which experienced a very serious resurgence of malaria in the 1990s when, because of environmentalists' pressure, it forsook DDT for other insecticides (the rise in malaria cases and deaths forced South Africa's return to DDT in 2000).[44] Having traveled full circle from DDT use, to non-use, and back to DDT use again, the public perception in South Africa about DDT has advanced to such an extent that the country's former president is seen publicly toting a spray can (see Figures 1 and 2).

The South African history with DDT is so compelling that even environmental campaigners have had pause to reconsider and to consider DDT's health-protecting virtues. As a World Wildlife Fund spokesman on toxins stated to the *New York Times* in 2005:

> *"South Africa was right to use DDT... If the alternatives to DDT aren't working, as they weren't in South Africa, geez, you've got to use it. In South Africa it prevented tens of thousands of malaria cases and saved lots of lives."*[45]

Environmental Defense, the organization which led the successful campaign to have DDT "banned" (a misnomer; more on that later in this report) from use in the United States, also has come to the conclusion that DDT has redeeming features. When in 2004 the US Agency for International Development was weighing the resumption of DDT use, Environmental Defense wrote:

> *"While Environmental Defense sees absolutely no justification for re-introducing use of DDT in the US, we believe that indoor spraying of small quantities of DDT in developing countries areas [sic] where malaria is spread by indoor-dwelling mosquitoes is an important tool given the limited alternatives now available."*[46]

Elsewhere, WHO mentions the Sierra Club and Endangered Wildlife Trust as other environmental groups that have rethought the matter and that now endorse DDT for malaria control.[47]

Thus on a comprehensive view of the scientific developments and the evolution of public perception, the decision to award Paul Müller, who discovered DDT's remarkable insecticidal properties, with the Nobel Prize in medicine in 1948 can be said to have withstood the test of time.

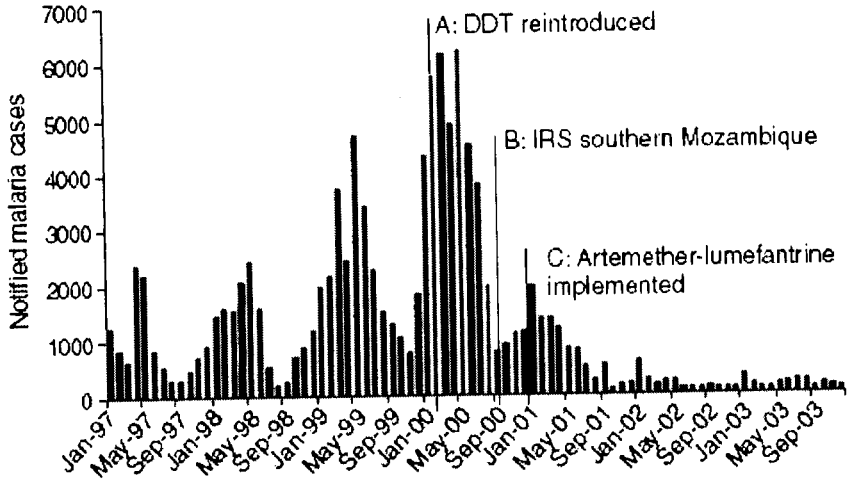

Figure 1 Number of notified malaria cases in KwaZulu-Natal by month in relation to timing of significant malaria control interventions. Source: South African National Department of Health Notification Data.

Figure 1: Time-trend observation of malaria cases in KwaZulu-Natal, the largest malaria-endemic province of South Africa. Following the failure of pyrethroid-class insecticides to quell seasonal outbreaks of malaria in the late 1990s, the authorities reverted to the use of DDT indoor residual spraying in March 2000 (point "A"). That measure, plus other insecticidal measures in neighbouring Mozambique (point "B") and the introduction of a new malaria medicine (point "C"), stopped further epidemics almost totally. As the researchers in this area write, "the reintroduction of DDT is considered to have contributed substantially to the recent decline in malaria in this province."

(Graph reproduced from Muheki C et al, cited at footnote 44.)

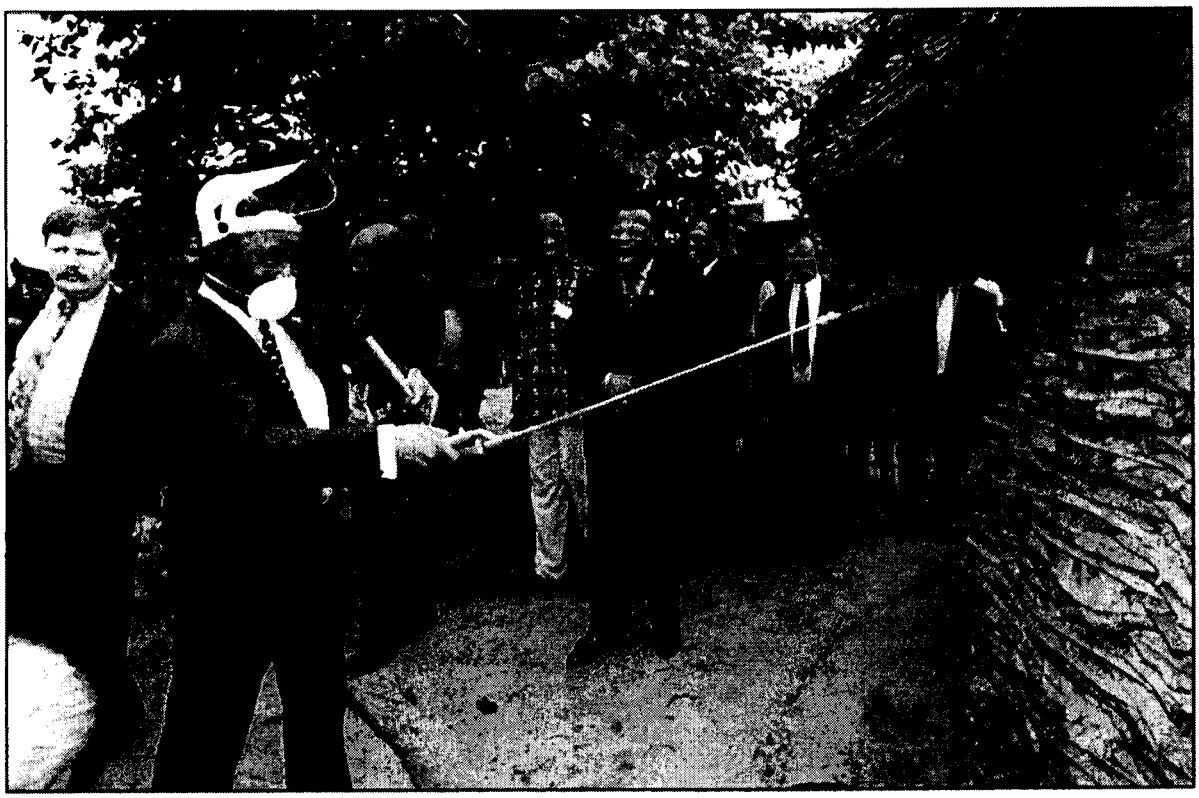

Figure 2: President Thabo Mbeki of South Africa, shown spraying a house. (But note the incorrect method, better suited to a politician's photo opportunity than the WHO technique of malaria control: he is spraying the outside, not the inside, of the house.)

(5) Leading health agencies do not link DDT to cancer in humans:

As alluded to in the previous sections, there is a misperception that DDT causes human cancers. Yet top health protection agencies in the USA and internationally have unambiguously stated that the available scientific evidence does not support the conclusion that DDT causes cancer in humans. I excerpt some of their statements in this section.

The World Health Organization wrote in 2004:

> *"[T]here is currently no direct link between DDT and any negative human health effect."*[48]

To say DDT has no direct link to "any" negative human health effect is, of course, also to mean that there is also no direct link between DDT and human cancers—including NHL. WHO's pronouncement in 2004 updates an earlier (1979), more in-depth expert consensus published by WHO and the United Nations Environment Programme, which similarly read that "there is no evidence that DDT is carcinogenic in man."[49]

The US Department of Health and Human Services (DHHS) is the leading federal government agency with responsibility for the health of Americans. DHHS basically agrees with WHO, though is more precise in its use of language. DHHS's Agency for Toxic Substances and Disease Registry carried out an evaluation of DDT in 2002, which reads:

> *"Studies have monitored human tissue and blood for DDT and its metabolites, but no correlation has been made between the levels found in these tissues and specific disease states."*[50]

In plain language, this statement means that DHHS has reviewed the available studies, and finds that people whose bodies absorbed more or less DDT from the environment are not, respectively, more or less likely to have disease. There is, as DHHS puts it, "no correlation."

The International Agency for Research on Cancer (IARC), a specialized branch of the WHO, also has done an evaluation of DDT. The IARC assessment of DDT, last updated online in 1997 (IARC has a policy of updating its assessments when needed, but apparently has found no need for DDT) states bluntly: "there is *inadequate evidence* in humans for the carcinogenicity of DDT."[51] In turn, IARC defines "inadequate evidence" to mean that:

> *"The available studies are of insufficient quality, consistency or statistical power to permit a conclusion regarding the presence or absence of a causal association between exposure and cancer, or no data on cancer in humans are available."*[52]

---

[48] See WHO, Frequently asked questions on DDT use for disease vector control, cited above at footnote 5.
[49] World Health Organization. DDT and its Derivatives. Environmental Health Criteria series volume 9. Geneva, 1979. Available at http://www.inchem.org/documents/ehc/ehc/ehc83.htm (accessed 17 September 2009).
[50] DHHS Agency for Toxic Substances and Disease Registry (2002). *2002 Toxicological Profile for DDT, DDE, and DDD*, page 206. Available at http://www.atsdr.cdc.gov/toxprofiles/tp35.pdf (accessed 17 September 2009).
[51] IARC. "DDT and Associated Compounds," available at http://www.inchem.org/documents/iarc/vol53/04-ddt.html (accessed 17 September 2009).
[52] See http://www.inchem.org/documents/iarc/monoeval/eval.html (accessed 17 September 2009).

Based on this assessment, IARC categorizes DDT as a Group 2B substance, or in plain terms, a substance that is no more than "possibly carcinogenic to humans"—a fairly low category, and well below the category of substances that are outright "carcinogenic to humans".[53] The "possibly carcinogenic" category contains numerous other industrial chemicals, prescription medicines, and foods such as coffee or pickled vegetables.[54] In IARC's assessment, all of these are possibly able to cause cancer in humans.

(6) DDT and the US Government – Regulatory History and Current Usages:

The foregoing sections invite the question of why DDT, being so effective in controlling insect-borne epidemic diseases and apparently not harming human health, had most of its registrations cancelled (sometimes called "deregistration") in the United States during or shortly after 1972.[55]

It is not accurate to state that DDT was "banned" in the United States; this is a misnomer which incorrectly implies that the US government acted to forbid all instances of DDT use. A more historically accurate statement is that US government decisions cancelled most uses of DDT, so as to narrow but not to wholly eliminate the remaining approved uses. Later, a number of approved uses were voluntarily cancelled, not as a result of US government action. Most recently, the US government (through USAID) finances the use of DDT overseas, in countries where malaria still exists.

According to the EPA's official history of events, a number of administrative actions between 1967 and 1972 resulted in canceling most household and agricultural uses in the USA.[56] Certain emergency or military uses of DDT for public health and agricultural purposes remained, and EPA approved applications for those on a case-by-case basis after 1972. Cited below are some cases documented in the *Federal Register*, where dispensation to use DDT was granted on the dates shown:

- March 19, 1974 – For the pea leaf weevil in Washington and Idaho[57]
- March 5, 1974 – For the Douglas-fir tussock moth in Oregon, Idaho and Washington.[58]
- June 8, 1976 – For fleas transmitting the plague in California.[59]

Thus DDT continued to be used in the US on an as-needed basis, for crop or forest pests or disease control, well after the 1972 decision cancelling certain DDT usages. Texas benefitted

---

[53] See http://monographs.iarc.fr/ENG/Classification/crthgr02b.php (accessed 17 September 2009).
[54] Ibid.
[55] The administrative decision which cancelled most of DDT's uses was issued in 1972, but because of its terms, and subsequent appeals, it did not take effect immediately, and perhaps not until 1973. For ease of reference I adopt the convention of citing the earlier date, and those in need of a more precise timeline will find it in footnote 56, below.
[56] EPA. DDT Regulatory History: a brief survey (to 1975). Available at: http://www.epa.gov/history/topics/ddt/02.htm (accessed 17 September 2009).
[57] Page 10322.
[58] Page 8377.
[59] Page 22979.

from these uses in later years, and appears to have used DDT as late as 1980.[60] Such as-needed uses of DDT came to an end after October 1989, when all the remaining registrations of DDT were voluntarily cancelled by reason of a failure to pay maintenance fees.[61]

However, even as DDT experiences disuse in the US, it still is not banned. The Commission for Environmental Cooperation, an intergovernmental organization of the NAFTA countries (the US is a member), writes that "the United States does not have the legislative authority to prohibit production of DDT if a manufacturer wanted to initiate such production in the future"[62] The EPA Administrator retains the discretion to allow the use of DDT, either by way of a hearing to reverse DDT's cancellation, or on an emergency basis without a hearing.[63] The EPA has a duty to act expeditiously on applications claiming an emergency,[64] and can in the case of public health, stipulate an exemption of up to a year allowing DDT to be used.[65] In cases of true crisis, the option still exists in law for a federal or state branch of government to use DDT immediately on that basis, with notification to EPA later.[66] As already mentioned, Texas made use of DDT for public health purposes, even after the EPA's cancellation of general agricultural uses.

Fortunately, today there is no need for DDT use in the US, as the public health challenges that might necessitate it are limited and solvable with other techniques. But that is not true overseas, where the US government currently supports the use of DDT in malaria-affected countries. A current page on EPA's website indicates that agency is helping foreign countries to use DDT safely:

> *"DDT is one of 12 pesticides recommended by the WHO for indoor residual spray programs. It is up to countries to decide whether or not to use DDT. EPA works with other agencies and countries to advise them on how DDT programs are developed and monitored, with the goal that DDT be used only within the context of Integrated Vector Management programs, and that it be kept out of agricultural sectors."*[67]

USAID also is involved in advancing the use of DDT abroad. As the USAID website reads:

> *"USAID is currently supporting IRS with DDT in Zambia.*
>
> *This year, pending completion and satisfactory results of all necessary entomological and environmental assessments, USAID plans to support IRS with DDT in Ethiopia*

and Mozambique (including purchase of the insecticide); and also in Madagascar (using DDT purchased by another donor)."[68]

As of 2009, the US government's efforts have grown, such that it is a leading financier of DDT for malaria control. For example in Ethiopia, the President's Malaria Initiative plans to spend $1.6 million in FY 2009 to purchase DDT and perhaps other insecticides (the exact amount of DDT that the US government will purchase in 2009 is not known at this writing, but as an indication American support is ongoing, in Ethiopia in FY2009, US government funds have been provided with the intention of purchasing 1.6 million kilograms of 75% DDT).[69]

(7) The EPA's decision-making processes, circa 1972:

The EPA arrived at its decision in 1972 to cancel the non-emergency civilian DDT registrations in two stages: (i) a decision of administrative law Judge Edmund Sweeney, before whom an extensive hearing took place on DDT's safety, and; (ii) a decision of EPA Administrator William Ruckelshaus, overturning Judge Sweeney without further hearing.

The hearing that Judge Sweeney conducted was extensive: seven months, 125 witnesses, and 365 exhibits, after which he wrote "the pros and cons of DDT have been well aired."[70] Judge Sweeney reached this terse and unqualified finding:

"DDT is not a carcinogenic hazard to man."[71]

Administrator Ruckelshaus reversed Judge Sweeney's decision three months after it was delivered. He did so not because of disagreement with Judge Sweeney's finding of fact on carcinogenicity, but rather because as Administrator Ruckelshaus wrote in his reasons:

"The possibility that DDT is a carcinogen is at present remote and unquantifiable; but if it is not a siren to panic, it is a semaphore which suggests that an identifiable public benefit is required to justify the continued use of DDT."[72]

Unable to find that DDT was carcinogenic, Administrator Ruckelshaus hinged his decision on there being a "*possibility* that DDT is a carcinogen." He then proceeded to ask if there were satisfactory alternatives to DDT. Since he also concluded that "safer alternatives exist[ed] to achieve the same benefit" for DDT's principal agricultural uses, he cancelled those uses.[73]

[71] Ibid, page 93.

[72] *In re. Stevens Industries, Inc., et al (Consolidated DDT Hearings)*, I.F.&R. Docket nos. 63 et al., 2 June 1972, per Administrator William Ruckelshaus, page 29.

[73] Ibid., page 28.

Where there were not safer alternatives, as for public health, he declined to cancel those DDT uses.[74]

There are differing explanations of why Administrator Ruckelshaus reversed Judge Sweeney's decision. One is that Administrator Ruckelshaus acted on the basis of what later came to be known as the "precautionary principle". That is, where there were good alternatives to DDT for a particular use, it was a feasible precaution to cancel DDT in that use even absent proof that it was a human carcinogen. (A difficulty with such precautionary reasoning is that one may not always have evidence to establish that the alternatives are actually any safer.)

Another, not necessarily incompatible, explanation is that Administrator Ruckelshaus acted for political reasons. Administrator Ruckelshaus was the inaugural head of EPA, at a time when that newly-created agency was under organized pressure from groups such as Environmental Defense Fund. Some insight into the political effect of that pressure is gained by comparing Administrator Ruckelshaus's decision, to this advice he received from a young lawyer who had worked on a DDT court case:

> *"The safety record of DDT is phenomenal. Billions of pounds of DDT have been used in anti-malaria programs during the past quarter of a century, and there is no record of human illness attributable to DDT resulting directly from the normal spraying operations among either the 130,000 spraymen or the 535 million occupants of DDT treated houses... Human volunteers and employees working in DDT formulating plants have been exposed to inordinately large quantities of DDT without incurring any illness attributable to DDT... [M]edical and scientific research and investigation fail to indicate any adverse clinical effect upon human health."*[75]

The "young lawyer" who wrote this passage was actually William Ruckelshaus! He was promoted to EPA Administrator only months after penning this passage; it seems that the expectations in his new post reformed his point of view quite considerably.

In summary, EPA's reasoning in 1972 as regards carcinogenicity is fully concordant with the US government's *status quo* in 2009, and fully concordant with the WHO, DHHS and IARC statements published in intervening years—an unbroken thread connects them all.

(8) Conclusion

Based on my education, research, policy work and other career experiences, I conclude as follows:

1. At the present time, leading public health agencies at the national and international levels (such as DHHS, WHO and IARC) have concluded that the evidence does not support a causal association between DDT exposure and cancer in humans.

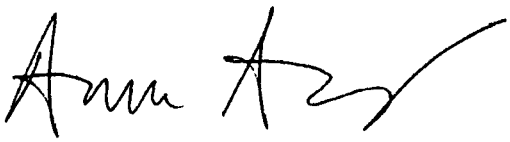
---

[74] Administrator Ruckelshaus emphasized that the EPA's "hearings... never involved the use of DDT by other nations in their health control programs," and so the benefits of DDT for controlling malaria and other diseases simply were not considered in EPA's decision: see Ibid., page 31.

[75] Brief for the Respondents, *Environmental Defense Fund et al v. Clifford M. Hardin, Secretary of Agriculture et al.*, file 23813, U.S.C.A. (DC Cir.). Mr. Ruckelshaus was Assistant Attorney General and his name appears as such on the Brief, dated 31 August 1970.

2. In contrast, there is abundant and non-controversial evidence that the public health use of DDT has avoided human death and illness from insect-borne diseases such as malaria or typhus. The savings are in the millions of lives historically.
3. Over a course of decades, and across a range of diseases, DDT delivered ascertainable improvements to Texans' health, including in Hidalgo County.
4. Since the 1990s, the use of DDT for public health purposes is experiencing a resurgence, with the support of agencies such as USAID, WHO and the World Bank, and the agreement of leading environmental groups.
5. The EPA did not "ban" DDT, but limited its registrations, principally for political reasons. Further, EPA's reasons did not include any finding that DDT is carcinogenic in humans.

Signed at Ottawa, Ontario, on 22 September 2009.



Professor Amir Attaran, D.Phil. (Oxon), LL.B. (UBC)
Canada Research Chair in Law, Population Health and Global Development Policy

Appendix One – Historical Public Attitudes Approving of DDT:

The Right Honourable Sir Winston Churchill:

"The excellent D.D.T. powder, which has been fully experimented with and found to yield astonishing results, will henceforward be used on a great scale by the British forces in Burma and by American and Australian forces in the Pacific and, indeed, in all theatres, together with other remedies consistently improving, and these will make their effect continually manifest... These remedies will be a help to all the Allies; indeed they have been a help. The eradication of lice in Naples by the strict hygienic measures taken may be held to have averted a very grievous typhus epidemic in that city and neighbourhood when we occupied it."

Winston Churchill (1945). *The Dawn of Liberation.* Boston: Little, Brown, p. 243.

Dr. Albert Schweitzer:

"We are often reminded that ours is a jungle Hospital by the natives who arrive after being wounded by wild animals. The white ants too are a constant reminder. We are continually being stirred up by them, and their presence is only discovered when they have already done considerable damage. Then everything has to be cleared out in order to find out just where they made their entrance. How much labor and waste of time these wicked insects do cause! Nothing so far has been effective in keeping them out, but a ray of hope, in the use of DDT, is now held out to us."

Albert Schweitzer (1949). *Out of My Life and Thought: an autobiography.* New York: Henry Holt, p. 261-262.

The Nobel Prize Presentation Committee (the presentation speech)

"Towards the end of the Second World War, typhus suddenly appeared anew. All over the world research workers applied their energies to trying to discover an effective delousing method. Results, however, were not very encouraging. In this situation, so critical for all of us, deliverance came. Unexpectedly, dramatically practically out of the blue, DDT appeared...

Since those days DDT has been used in large quantities in the evacuation of concentration camps, of prisoners and deportees. Without any doubt, the material has already preserved the life and health of hundreds of thousands."

Professor G. Fischer, member of the Staff of Professors of the Royal Caroline Institute, on awarding the Nobel Prize in Physiology or Medicine 1948 to Paul Hermann Müller "for his discovery of the high efficiency of DDT as a contact poison against several arthropods". Expert Report of Seymour Grufferman, M.D., Dr.P.H., on Behalf of Montrose Chemical Corporation of California

Guadalupe Garza v. Allied Chemical Corp., et al.

October, 2009

TABLE OF CONTENTS

Page

I.

INTRODUCTION

I have been retained by Montrose Chemical Corporation of California in connection with the *Guadalupe Garza v. Allied Chemical Co., et al.* litigation. My areas of scientific expertise include cancer epidemiology in general, the epidemiology of the hematologic malignancies and the epidemiology of non-Hodgkin lymphoma (NHL). I have reviewed the medical records, deposition testimony, and other documents related to the claim that DDT exposure was the cause or a contributing factor to Ms. Guadalupe Garza's NHL. I have reviewed the reports and claims of plaintiff's experts, Dr. Richard W. Clapp, Dr. Frank H. Gardner, Dr. William R. Sawyer and Dr. Theodore M. Farber, on NHL causation. In addition, I have reviewed (1) scientific literature on the causation of NHLs, and (2) the 40 reports in the published scientific literature that consider whether or not DDT is a cause of NHL.[1]

I will render an opinion on whether or not DDT is a scientifically established cause of NHL or a contributing factor. I also will render opinions on whether or not Ms. Garza's NHL was caused by her alleged exposure to DDT, and whether or not DDT was a contributing factor to her NHL. Finally, I will render an opinion on whether or not Drs. Clapp, Gardner, Sawyer and Farber used accepted scientific methodology in reaching their causation opinions on DDT and NHL.

[1] Unless otherwise specified, reference to "DDT" in this report also includes its metabolites.

II.

SUMMARY OF OPINIONS

Based on my years of education, training, research and peer review work on the lymphomas, together with my review of all of the materials listed above, I conclude to a reasonable degree of medical and scientific certainty that DDT is not a cause of NHL in humans. In fact, DDT has been shown to be a safe product for humans and one that has great public health value for the control of malaria. In 2006, the World Health Organization and the U.S. Agency for International Development recommended the use of DDT inside homes for malaria control and eradication in countries with endemic malaria. The epidemiologic evidence as well as human experimental evidence simply does not support the notion that DDT is a scientifically established cause of NHL. This opinion is also shared by leading scientists, not involved in this litigation, who have reviewed the scientific literature and authored review chapters on the epidemiology of NHL for leading textbooks in the field. This opinion that DDT is not a cause of NHL is accepted scientific knowledge in agreement with the scientific literature.

The published epidemiologic literature on DDT and NHL covers an extensive array of scientific research. It includes two human experiments, 36 analytic study reports (seven cohort studies, eight case-control studies employing multivariate analyses, 21 case-control studies employing univariate analysis) and two ecologic study reports. Despite searching for over two decades for evidence of a causal association between DDT and NHL, at the cost undoubtedly of millions of dollars, researchers have been unable to demonstrate any such link. In fact, the absence of any such causal link is evidenced by the overwhelming number of published studies that either have no statistically significant findings or results that center around the null value of 1.0.

At the request of Montrose, I undertook an exercise in which I aimed to identify study reports that had findings of a statistically significant doubling of the risk. The results are notable:

1. In the seven cohort study reports, *none* has a finding with a statistically significant doubling of the risk.
2. In the eight case-control study reports with multivariate analyses, *none* has a finding of a statistically significant doubling of the risk after controlling for potential chemical and other confounders.
3. In the two ecologic study reports, *neither* had a finding of a statistically significant doubling of the risk.
4. In the two DDT experiments where humans were fed extremely large amounts of DDT, *neither* evidenced an increase in cancer risk.
5. In the 21 case-control reports with only univariate analysis—reports that failed to control for confounding exposures using sophisticated, modern epidemiologic methods—just three of the 21 reports contain statistically significant DDT findings that evidenced a doubling of the risk, among numerous findings resulting from a multitude of subset analyses. Thus, in 18 of the 21 reports, there is not one finding which shows a statistically significant doubling of risk, despite the fact that these 18 studies do not control for critical confounders like other exposures. In the other three reports, each performs numerous subset analyses, increasing the likelihood of findings being due to chance and/or confounding, and/or conducts

analyses that are of questionable relevance to Ms. Garza, i.e., risk estimates for EBV EA antibodies.

Based on this evidence and my years of study relating to the causation of the lymphomas, DDT is not a cause of NHL in humans. Ms. Garza's experts have, among other things, failed to consider all 40 studies, failed to document and report their analyses of these 40 studies, and also failed to reach a conclusion through application of proper scientific methodology. Therefore, the opinions they reach are unscientific and unreliable.

I also have reviewed the epidemiologic literature regarding DDT and NHL to determine whether there is any evidence of DDT being a contributing cause for NHL. None of the papers I found in the literature on DDT and NHL provide scientific data on DDT as a contributing factor for the disease. Thus, DDT is not a contributing factor to NHL, since there is no scientific evidence to support this notion.

Lastly, to a reasonable degree of medical and scientific certainty, Ms. Garza's NHL was not caused by her claimed exposure to DDT as alleged by certain plaintiff's experts. Since the scientific evidence does not show that DDT causes NHL in humans, it could not have caused Ms. Garza's NHL. Moreover, Ms. Garza has had no history of employment that would entail occupational exposure to DDT. Occupationally exposed workers and volunteers who ingested extremely high levels of DDT had no increased risk of NHL. Whatever the level of Ms. Garza's alleged exposure to DDT, assuming she was even exposed to greater than ambient U.S. levels, and based on the scientific literature, it certainly is not the cause of her NHL. Furthermore, there is no scientific evidence in the literature to suggest that DDT was a contributing cause to Ms. Garza's NHL.

III.

EXPERT'S BACKGROUND

My education, training and experience are detailed below. I hold a B.S. degree from C.C.N.Y., where I majored in biology and chemistry. I obtained my M.D. degree from the State University of New York Upstate Medical Center in Syracuse where I received an award for the student showing the most promise for a career in medicine or surgery. I received an M.P.H. degree in 1968, an M.S. degree in 1974, and a Dr.P.H. degree in 1979, all in epidemiology, from the Harvard University School of Public Health. My doctoral dissertation at Harvard was on the possible transmissibility of Hodgkin's disease, a type of lymphoma. I was a recipient of the annual Student Prize Paper Award of the Society for Epidemiologic Research for my thesis and two papers from my thesis were published in the New England Journal of Medicine.

In addition to my medical and epidemiologic education, I also have completed clinical training in medicine. I completed a rotating internship at the University of Illinois Research and Educational Hospitals in 1965, following graduation from medical school. I then completed residency training in pediatrics at the New York Hospital – Cornell Medical Center in 1967. As part of my residency, I received training in pediatric oncology at the Memorial-Sloan Kettering Cancer Center. I am board-certified in Pediatrics, a Diplomate of the National Board of Medical Examiners, and hold active state medical licenses in North Carolina and Pennsylvania. Following completion of my clinical training and obtaining an M.P.H. degree, I served in the U.S. Air Force from 1968-71. I was Chief of Pediatrics and Military Public Health at the USAF Hospital in Tachikawa, Japan, which was a large Air Force referral and training hospital. I was also 5th Air Force Consultant in Pediatrics and provided supervisory care at bases in Japan and

Okinawa. Following this experience, I took a position as Assistant Professor and Chairman of the Department of Public Health at the Gondar Public Health College (of the then Haile Sellassie I University) in Gondar, Ethiopia. In addition to teaching epidemiology and biostatistics, I also taught organic chemistry and tropical medicine.

I returned to the United States in 1973 to resume my education in epidemiology at Harvard. Following completion of my education at Harvard, I joined the faculty at the Duke University Medical Center as Assistant Professor of Community Health Sciences and later, Pediatrics and Medicine. I was also Associate Director for Cancer Epidemiology and Prevention at the Duke Comprehensive Cancer Center. I taught epidemiology and biostatistics to third-year medical students and ran a special training program in epidemiology for medical students. While at Duke, I received a Preventive Oncology Academic award from the National Cancer Institute and a large grant in clinical epidemiology from the A.W. Mellon Foundation. These allowed me to run a large training program in epidemiology at Duke for medical students, residents, medical subspecialty fellows and faculty. While at Duke, I was awarded peer-reviewed, National Institutes of Health grants for research on rhabdomyosarcoma (a soft tissue sarcoma of children), multiple myeloma (bone marrow cancer), NHL and Hodgkin's disease. Thus, I am rendering opinions in this case on a cancer on which I personally have conducted peer-reviewed, NIH-funded, etiologic research. While at Duke, I was promoted to Associate Professor, was awarded tenure, and became Chief of the Division of Clinical Epidemiology in the Department of Pediatrics. I taught and practiced pediatrics at Duke and held admitting privileges to the Duke University Hospital.

I moved to the University of Pittsburgh in 1987 as Professor of Epidemiology in the Graduate School of Public Health and Associate Director for Cancer Epidemiology and Control of the Pittsburgh Cancer Institute. Shortly thereafter, I was appointed as Chairman of the Department of Clinical Epidemiology and Preventive Medicine in the School of Medicine. This Department evolved over the years into a Department of Family Medicine and Clinical Epidemiology. The Department did all of the medical school teaching of epidemiology and biostatistics. While I was Chairman, I served on the Executive Committee of the School of Medicine. I was elected President of the University Physicians Practice Association and performed a variety of functions related to the restructuring of the Medical Center to incorporate a network of community hospitals and physicians throughout western Pennsylvania. I stepped down as Department Chair in 1998, and retired from the University of Pittsburgh in 2004. I taught and practiced family medicine at the University of Pittsburgh and had admitting privileges to the Children's Hospital and Presbyterian-University Hospital.

I relocated to the University of New Mexico (UNM) in 2004, where I held the rank of Research Professor in the Epidemiology Division of the Department of Internal Medicine. I moved a large NIH research grant for research on Hodgkin's disease to UNM and this and rhabdomyosarcoma remain my major research activities. I retired from UNM at the end of June, 2007, and continue to hold an appointment as Adjunct Research Professor.

I have considerable experience in performing peer review work for government and non-governmental organizations. I served four-year terms on a National Cancer Institute (NCI) Review Committee that reviewed all NIH cancer center grants, a National Institute

of Allergy and Infectious Diseases committee that reviewed AIDS-related epidemiology research grants (which I chaired for four years), an NCI committee that reviewed all training and career development grants (I served two consecutive terms on this committee) and a review committee of the American Cancer Society (ACS) that reviewed research grants in the areas of cancer prevention, detection and treatment. I recently completed a term as a charter member of the Cancer Biomarkers Study Section of the NIH. This Study Section reviews all NIH grant applications that relate to biomarkers of cancer, which are mostly of a molecular biologic nature. Even though I completed my term on this Committee, I continue to serve on it as an ad hoc member. In total, I have over 20 years of service in the formal review of research grants for the NIH and ACS. In addition, I perform numerous special reviews of grants for NIH and other funding agencies in the U.S. and other countries. For example, I have served for the past five years on an annual NCI review committee to evaluate grant applications for repayment of educational loans for new investigators. I also assisted the Associazione Italiana per la Ricerca sul Cancro (Torino, Italy) in reviewing cancer research grants. I continue to perform peer review of manuscripts for leading medical and public health journals.

In summary, I have extensive experience in medical and public health practice and education, academic and medical administration, peer review work on behalf of the U.S. National Institutes of Health (NIH), American Cancer Society, and international agencies, and in the conduct of peer-reviewed NIH (and other agencies) funded research on many cancers. I have extensive experience in peer review of all aspects of cancer research, as well as of epidemiologic and biostatistical research in general, for a wide variety of governmental and private funding agencies worldwide. This equips me

particularly well for critical review of the scientific literature on the subject of DDT and NHL.

I also have extensive experience in teaching epidemiology and biostatistics. I organized and taught courses on these subjects at the Gondar Public Health College, Harvard and Duke Universities and the University of Pittsburgh. I taught in a series of International Agency for Research on Cancer (IARC) courses on Cancer Epidemiology and Biostatistics all over the world (in the former GDR and USSR, Pakistan, Thailand, Poland and Zambia). I was usually the course director for these courses that were focused on the use of epidemiology and biostatistics for cancer research. I also taught in several courses at the U.S. National Cancer Institute on cancer epidemiology and prevention and covered the topic of the hematopoietic malignancies (leukemias, lymphomas and multiple myeloma). This extensive teaching experience also equips me well for dealing with the scientific literature on DDT and NHL.

In addition, I personally have conducted peer-reviewed, NIH-funded research on NHL as well as on the possibly related diseases of Hodgkin lymphoma and multiple myeloma. I have published peer-reviewed papers on the epidemiology of NHL and have written chapters on this topic for one of the leading textbooks on hematologic malignancies. I am currently revising this chapter for the next edition of this textbook (Neoplastic Diseases of the Blood, 4th Ed., in preparation). One of my NHL papers was published in the New England Journal of Medicine and received extensive public media attention including an article in Time magazine. I am co-author of the chapter on Hodgkin lymphoma, a disease whose scientific literature overlaps with that of NHL, in the newly released third edition of the leading textbook on cancer epidemiology and

prevention. I am a Fellow of the American College of Epidemiology and an elected Fellow of the American Association for the Advancement of Science (AAAS). My election as a Fellow of the AAAS was on the basis of my contributions to research on the leukemias and lymphomas.

In summary, my expertise on the causation of NHL is not generated by this litigation. Rather, my expertise in this case derives from a lifetime of research and experience on the lymphomas (and their medical literature).

IV.

THE UNIQUE ROLE OF EPIDEMIOLOGY IN ASSESSING POTENTIALLY HARMFUL EXPOSURES

A. Scientists Presently Are Not Allowed to Conduct Experiments in Humans of Potentially Harmful Substances

In this report, I will be relying primarily on my epidemiologic expertise and my review of the epidemiologic and related medical literature. Often, the best evidence upon which scientists can rely to determine disease causation is from human experiments. Such experiments and the analogous clinical trials in humans allow for the control of many confounding factors. An experiment can be defined as a study in which the investigator allocates an "exposure" (i.e., a drug) to human subjects, typically in a random manner, and uses a comparison group of very similar, but unexposed, subjects. The exposed and unexposed groups are followed over time for occurrence of an outcome (clinical improvement in the case of a drug trial or adverse effects in a toxicology study). Rates of occurrence of the outcomes then are compared for the exposed and unexposed groups. Such trials generally provide reliable and unbiased evaluations of treatment modalities and often are considered to be the "gold standard" of clinical research.

While experiments and the experimental approach are held in high regard as generally providing definitive answers to many therapeutic and toxicologic questions, there is one major limitation. This limitation is that it is unethical and scientifically unacceptable to conduct experiments in humans of potentially toxic substances. Clinical trials can only be done ethically (and legally) to evaluate potentially beneficial exposures (usually drug treatments). There are almost no human clinical trials in the literature of potentially harmful exposures. Thus, there are usually no experimental scientific data available on the potentially adverse health effects of pesticide exposures in humans.

However, in the 1960s and 1970s, the United States government studied the possible health effects of feeding human volunteers DDT. As described below, two of these studies involved the use of prison inmates and no adverse health effects of ingesting DDT were found. By today's standards, such research would not be permissible under international and U.S. regulations, but revisions to these rules are being considered currently. Thus, there are no experimental scientific data, other than the feeding studies, on any health effects of DDT (and other pesticide) exposure in humans. While there are animal experiments on these and other similar chemical exposures, the data from such experiments cannot be extrapolated reliably to humans. For example, in addition to different susceptibilities of various animal species, the exposure doses used in most animal studies are usually quite high and typically several orders of magnitude higher than that which humans might encounter environmentally.

B. Epidemiology Allows Researchers to Approximate Experiments in Humans

It is because of this inability to obtain experimental data in humans regarding possibly harmful environmental exposures that epidemiology comes to play a central role. Methods used in epidemiology allow researchers to approximate human

experiments. Such epidemiologic approaches rely on observations of potentially toxic exposures in humans that were "allocated" to individuals by natural factors and not by a scientific investigator. In a clinical trial or experiment, the investigator determines who is given the drug or possibly harmful agent. In an epidemiologic study, natural factors or individual choices and opportunities determine who is exposed and not exposed. For example, in a study of disease occurrence in a cohort of workers in an industry or plant, the workers' exposures essentially are determined by factors such as the availability of jobs, their decision to seek employment in that industry, or their assignment to jobs in a particular plant location or process area of a company. This gets around the ethical dilemma of determining exposures, but the methods used in epidemiology cannot duplicate an experiment and provide similarly precise information. The epidemiologic approach uses a body of methods to approximate experimental results in "free-living" human populations and the approach has proven to be extremely useful and reliable. The results of epidemiologic studies have provided very valuable and important health information over the long history of the field.

V.

EPIDEMIOLOGIC APPROACHES

A. Epidemiology Studies How a Disease Occurs or is Distributed in Human Populations and Tests Disease-Related Hypotheses

Epidemiology can be defined as the scientific study of the distribution and determinants of disease occurrence in human populations (MacMahon and Pugh). The "distribution" of a disease refers to how a disease occurs or is distributed in a population. This realm of the field has often been referred to as "descriptive epidemiology" and deals with such issues as the distribution of disease occurrence in terms of time, person and

place characteristics. For example, an investigator might assess whether there is variation in occurrence of a disease by season, age or gender of those affected, or by area of residence. From such information, the investigator might derive clues as to possible causes of the disease. Such clues might lead to hypotheses (basically, educated guesses) regarding the cause of the disease.

The second part of the definition above, the "determinants" of disease occurrence, deals with the testing of such hypotheses in studies of human populations. A well-developed body of epidemiologic methods has been developed for the generation and testing of disease-related hypotheses in humans.

B. There Are at Least Two Broad Categories of Epidemiologic Studies – "Descriptive Studies" and "Analytic Studies"

For purposes of this report, I will group the commonly used epidemiologic methods into two broad categories: "descriptive studies" and "analytic studies".

1. Descriptive Studies

So-called descriptive epidemiologic studies generally are used to develop new hypotheses about the occurrence, natural history or causation of a disease or condition. They tend to focus on the first part of the MacMahon and Pugh definition of epidemiology – the distribution of diseases in human populations. Typically, an epidemiologic investigator would assess the occurrence of a disease in terms of the distribution of cases by time, place and person characteristics. For example, an investigator in the 1940s might have noticed that there was an unusually high recent occurrence of what previously had been a very rare disease, primary lung cancer. On paying closer attention to these new cases, he might have noticed that almost all of the cases were cigarette smokers. Such an observation might lead to the development of an

hypothesis that cigarette smoking is a cause of lung cancer. This type of epidemiologic investigation has proven particularly useful in gaining knowledge about the natural history and possible causes of new diseases. For example in recent years, much was learned about the possible causes of SARS (severe acute respiratory syndrome), its spread and its natural history by the simple approach of observing the occurrence of cases in small residential areas (Tsang, et al., 2003; Yu, et al., 2004). The major limitation of the descriptive epidemiologic approach is that it has not been useful for proving disease causation.

One type of descriptive study is the so-called "ecologic study." In this study method, the occurrence of a disease is related to levels of certain suspected harmful (or beneficial) exposures in a community. The notion is that if there were a true association between some disease and community levels of exposure to a putative cause, it would suggest a causal relationship. An example of this approach was the observation that people who resided in regions with high naturally occurring levels of fluoride in their water supplies had fewer decayed teeth. While this did not prove that fluoridation protected against dental cavities, it led to the more formal testing of the hypothesis via a community trial of fluoridation of water supplies (an experimental approach). Unfortunately, most such ecologic findings prove to be false leads.

The major problem with ecologic studies is that there is no information on what any individual person with disease or healthy person might have been exposed to or at what levels. This is a particular problem when ecologic studies are done of large geographic areas, such as whole states. These studies also are particularly prone to the effects of confounding (discussed below), which can severely distort results.

A second type of descriptive study is the "cross-sectional study." Subjects with a disease or health condition are studied for some current characteristic or marker. An example of this would be a survey of serum cholesterol levels in men admitted to the hospital for an acute myocardial infarction (a heart attack). While cholesterol levels in these men may be higher than the population norms, one cannot say whether the elevated cholesterol levels preceded the heart attack, let alone say that it was a cause of the heart attack. Typically, cross-sectional studies are even less clear-cut than this example and suffer from the "chicken and egg" dilemma of which came first. Such studies rarely are done nowadays because of this limitation.

These examples of descriptive epidemiologic approaches illustrate the major limitations of such studies for assessing disease causation. They are useful, however, for suggesting causes or means of prevention of disease that could be tested by more precise methods.

2. Analytic Studies

Much of modern epidemiologic research falls within the realm of analytic studies. The two main research approaches used for analytic epidemiologic studies are the case-control and cohort studies.

a. Case-Control Studies

In a case-control study, a group of people with a disease or health condition is selected for research after the disease or condition has been diagnosed. The subjects are studied for their prior history of "exposure" to potential causes of their disease, such as their occupations, their family history of the disease and a variety of other antecedent suspected "risk factors." Findings in the "cases" typically are compared to findings of antecedent events in a comparable group of people without the disease at issue –

"controls." The basic features then of case-control studies are the selection of subjects for research after they have been diagnosed with the disease being studied and the search for potentially causal events prior to their diagnosis.

By way of an example, in a typical case-control study, a researcher might identify a group of 150 persons with newly diagnosed NHL. A similar number of control subjects might be identified from cases' neighborhoods by use of random digit-telephone dialing (a method based on a case's home telephone number to call other homes in the same calling area to identify a comparable person who does not have NHL). Cases and controls then would be interviewed regarding a long list of antecedent potential "risk factors" (a suspected factor that appears to be associated with risk of a disease) such as occupational history and exposures, diet, past medical history, family history, etc. All of these factors will have occurred prior to the cases' diagnosis. Typically, in a case-control study, a very large number of risk factors are queried, often 100 or more. Comparisons then are made between the frequency of assessed risk factors in the cases and controls. In the analysis of such studies, the frequencies (odds) of exposure in the two groups are compared. Thus, the relative frequencies of exposures are determined, but case-control studies cannot provide direct measures of what the rates of disease occurrence are in exposed and unexposed individuals. Rather, the investigator obtains an "odds ratio" (the ratio of the odds of exposure in the two groups). For most diseases, the odds ratios from case-control studies prove to be comparable to the more precise relative risks (the ratio of actual risk in the exposed and not-exposed groups) from cohort studies.

Case-controls studies have several advantages over cohort studies:

1. Case-control studies have greater efficiency in the study of rare diseases. When a disease is rare, cohort studies would have to be extremely large to produce adequate numbers of cases of the rare disease to be studied. In many cohort studies of limited size, for example, there may be very few cases of NHL as an outcome since it is a relatively uncommon diagnosis. In such instances, cohort studies might lump together several of the hematologic malignancies (leukemias and the lymphomas, and occasionally multiple myeloma as well) for purposes of analysis. Such results are of limited utility for assessing risk of any specific member of the group, such as NHL. On the other hand, in case-control studies, one can assemble a sufficiently large number of cases for most analyses;
2. Another advantage of the case-control study is its ability to assess many potential causal factors, whereas in a cohort study one can assess one (or a limited number of) exposure(s), but study several possible diseases in relation to that exposure;
3. Case-control studies are generally more quickly done than cohort studies since there is no lengthy follow-up period needed between the exposure and disease outcome; and
4. A fourth advantage of case-control studies is that diagnosis of cases is generally more accurate than in cohort studies which frequently use diagnoses from death certificates rather than from pathology reports as is commonly done in case-control studies.

The disadvantages of the case-control study include:

1. No direct measure of relative risk can be obtained usually;
2. The investigator frequently relies on subjects' recall of past "exposure" history; and
3. By assessing many potential risk factors, the investigator is likely to frequently encounter chance associations. This latter disadvantage can be dealt with by use of analytic techniques for assessing the role of chance and by the application of methods for evaluating whether an observed association might be causal rather than chance (see the Hill criteria discussion below).

b. Cohort Studies

The other major research approach in this domain is the cohort study. In a cohort study, research subjects are chosen on the basis of their "exposure" status, not on the basis of whether they have the disease being studied. In most such studies, subjects with an exposure of interest, for example cigarette-smoking, are identified and followed over time for the occurrence of a suspected associated disease or group of diseases. A comparable cohort of people without the exposure of interest is identified and followed simultaneously over time to observe their disease risk. Comparison is later made between the risks of disease in the exposed and not-exposed groups. The ratio of the disease rate in the exposed group and that in the unexposed group provides a measure of risk termed the relative risk. The basic features of cohort studies are the selection of subjects for research based on their exposure status (not their disease status as in case-control studies) and their ability to prospectively determine health risks of an exposure.

An example of this type of study is the now classic cohort study of smoking in British physicians. The investigators were able to assemble large cohorts of cigarette

smokers and non-smokers among British physicians as the exposed and non-exposed groups. Physicians were studied because of the relative ease with which they could be followed reliably. These groups were then followed over time for the occurrence of lung cancer and related diseases. Rates of lung cancer in the two groups then were compared.

Unfortunately, the majority of modern cohort studies are not this well-designed. Much of cohort study research is now done in occupational settings. For example, an investigator might wish to study the risks of various diseases in an occupational group (cohort) such as farmers. A group of farmers is selected and then followed over time. For issues of feasibility, occurrence of cancer in the cohort might be assessed from death certificates rather than from medical records of affected farmers. Again for issues of feasibility, comparisons of disease occurrence in the exposed cohort will be made with occurrence of the disease(s) of interest in the general population in the region where the farmers reside. In this example, the specific exposures of the individual farmers may not be known and may have to be imputed. The use of mortality as a study endpoint is fraught with difficulty for those diseases where survival is good. Mortality endpoints would provide only a partial picture for NHL where the majority of patients survive. Factors such as access to medical care, local availability of the newest therapies, health knowledge of the groups studied, etc., could greatly skew the results of mortality studies. Another problem with cohort studies is that they frequently assess deaths (or less commonly disease incidence) from many diseases. Just on the basis of chance, many associations can be observed because of the large number of disease (mortality) endpoints assessed. This is analogous to the criticism of case-control studies in which the evaluation of multiple exposures often lead to many chance associations.

4. Temporality of the association;
5. Demonstration of a biologic gradient;
6. The plausibility of the association;
7. The coherence of the association;
8. Experimental evidence; and
9. Analogy to the association.

The first of these criteria (Hill called them "viewpoints") is an evaluation of the **strength of an association (1)**. It is good common sense that the stronger an observed association (for example, the higher the relative risk) the more likely the association is to be a causal one. Weak associations, for example, an odds ratio or relative risk of less than 2.0 are unlikely to be causal. Weak associations are often the product of bias, confounding or chance, and tend not to be reproducible in other studies. Observed statistical associations due to confounding factors generally tend to have relative risks less than 2.0, and to be highly inconsistent from study to study. Strong associations, for example, an odds ratio of 3.0-3.5 or higher, are much more likely to be valid and causal. The stronger the observed association, the more likely the finding is to be reproducible and to stand the "test of time" (i.e., to be consistent and reproducible in different studies involving different populations).

Consistency of an association (2) is a very persuasive strut for establishing causality of an association. The scientific method involves the establishment of an hypothesis and then the testing and retesting of the hypothesis in different and/or multiple settings. Only after the hypothesis has been tested and confirmed several times does it enter the realm of established science. The consistent demonstration of an association in

different studies is a strong piece of evidence that a finding is valid and likely to be causal.

The **specificity of an association (3)** is another consideration in assessing whether or not an observed association is a causal one. The more specific an association is between a given exposure and a single disease, the more likely the exposure is to be a causal one. The specific exposure of interest should be found to be associated with the specific disease of interest only. This criterion must be interpreted cautiously, since some factors have been found to be causally associated with more than one disease. For example, cigarette smoking has been found to be causal not only for lung cancer, but also laryngeal cancer and several other cancers. On the other hand, for many infectious diseases, very specific associations have been observed between an infectious agent and a single disease, and this specificity has been useful in establishing causality.

The **temporality** (4) of an association is of course essential to establishing causality. To be a causal association, the cause always should precede the disease. It is simple common sense that the cause should precede the outcome if the association is a causal one.

Demonstration of a **biologic gradient** (5) (i.e., a dose-response relationship) is suggestive of an association being valid and causal. Again, it is simple common sense that if something causes a disease, the greater the dose the greater the risk of disease should be. While the absence of a demonstrable dose-response gradient does not rule out causality, finding a strong biologic gradient is suggestive of an association being causal.

An association is more likely to be a causal one if the finding is **biologically plausible (6)**, which means it makes sense in light of what is known about the biology of the disease and the suspected cause. It is another common sense criterion.

Along these same lines of reasoning is the criterion of the **coherence of an association (7)**. What Hill meant by this is that an observed cause-effect relationship should be coherent with what is known about the biology and natural history of the disease.

One of the most persuasive of the criteria for establishing causation is the availability of supporting **experimental evidence (8)**. An example I use in teaching relates to the hypothesis that fluorides protect against dental cavities. There were many descriptive studies of the association of naturally occurring fluorides in water supplies and risk of dental disease. The causal association was proven and accepted into the mainstream of established science after a community experiment was performed that demonstrated a protective effect of adding fluorides to a city water supply.

The demonstration that **analogous associations (9)** exist is perhaps the weakest of the criteria. The demonstration of analogous causal studies is limited only by the imagination of investigators.

While there is no magic scoring formula for how well these criteria apply to a given finding, and not all of them need to be met to establish causality, they have proven highly useful to generations of epidemiologists and other scientists. In most cases, an investigator can apply these criteria and make a reasonable judgment about how well they are met and how likely the association tested is to be a valid and causal one. The only criterion that is absolutely necessary to prove causality is that of temporality - the cause

always should precede the outcome. In essence, these criteria provide common sense assessments of an association. For example, if an association is valid and causal, investigators ought to be able to demonstrate the association consistently. Most scientific papers published today will include an assessment of the consistency of their findings in the paper's discussion section. The observation of a dose-response relationship between an exposure and an outcome is usually highlighted in a paper and makes it more likely to be accepted for publication. While typically these discussions in scientific papers are not specifically labeled as applications of the Hill criteria, they are thoroughly accepted and ingrained in current generally accepted scientific methodology and are considered strongly in the peer-review process.

It should be pointed out also that the "scientific method," dating back to the times of Pasteur and Koch, involves the need to replicate observations and demonstrate consistency of such observations before they can be established as causal. Some of the "Hill criteria" antedate Hill and have been accepted scientific methodology for well over a century. Hill simply updated scientific methodology for assessing causality of observed associations.

VII.

STATUS OF CURRENT KNOWLEDGE ON CAUSATION OF THE NON-HODGKIN LYMPHOMAS

A. The NHLs are Forty or More Different Diseases with Different Characteristics, Pathology, Treatment and Prognosis

While HL and NHL are sometimes grouped together under the rubric "lymphomas," they are very different diseases with different presentations at diagnosis, different clinical courses, different treatments, different incidence and survival rates,

different risk factors and very different patterns of occurrence (i.e., descriptive epidemiology). It is likely that they will be shown to have different etiologies in the future and that the two diseases will be found to have viral etiologies.

The NHLs are actually 40 or more different diseases with different microscopic anatomical features and different immunologic characteristics. Additionally, the component lymphomas have different natural histories, prognoses, treatments and risk factors. Probably as a result of this important issue, relatively little is known about the causes of NHL and the uncertainty regarding the causes of NHL is widely recognized. Researchers in the lymphoma field increasingly are recognizing this and, as a result, therapies are being tailored individually to specific subsets of lymphomas identified by cancer biomarkers. Epidemiologists also are recommending that future studies divide the lymphomas into subgroups based on biologic features that may define homogeneous, separate component types of lymphomas. Some studies of NHL subtypes have been done utilizing relatively crude biomarkers such as chromosomal translocations. This is in contrast to recent clinical studies that use more complex and sophisticated lymphoma biomarkers for subclassification of the disease. The use of sophisticated biomarkers for lymphoma classification is a very active area of new research.

It increasingly is being recognized that the general failure to find causes of the NHLs may be due to the artificial lumping together of different diseases with different biologic features and different risk factors. As a result, associations for one subgroup may be masked by finding no associations for other different subgroups merged into the overall category of NHL. A problem with proposed studies of subgroups of NHLs is

that the individual component diseases are each uncommon to rare. This poses significant problems for conduct of case-control studies where case accrual becomes difficult and usually requires multi-center studies, and also for cohort studies where cohorts will need to be extremely large to find sufficient numbers of specific component NHL diagnoses as outcomes.

B. <u>DDT is Not One of the Established Causes of NHL</u>

The established causes of NHL include:

1. Severe immunodeficiency (congenital, iatrogenic or acquired);
2. Infectious agents:

   A. Viruses: The Epstein-Barr virus (EBV); the human T-lymphotropic virus, type one (HTLV-1); Kaposi's sarcoma herpes virus (KHSV); human immunodeficiency virus, type one (HIV-1); hepatitis C virus (HCV)

   B. Bacteria: Helicobacter pylori
3. Family history of NHL and to a lesser degree, Hodgkin lymphoma or multiple myeloma;
4. Iatrogenic factors such as chemotherapy;
5. Certain rare medical conditions (such as Sjogren's syndrome, Felty's syndrome, Crohn's disease).

No causes beyond these factors have been established to a reasonable degree of scientific certainty, and the cause of most NHLs is unknown and can be considered to be spontaneous occurrences. While the literature is replete with other risk factors for the NHLs, none of these observations has been consistent or has demonstrated strong associations, let alone demonstrating any consistent dose-response for their observations. Beyond these five broad categories of established NHL, and some reported associations of NHL with rare genetic syndromes, there are no scientifically

established or accepted known causes of NHL. Obesity and diabetes are increasingly being recognized as potential causes for NHL, and as discussed in Section XI, these factors should have been considered by the plaintiff's experts in light of the biased methodology they employed.

There is a voluminous scientific literature on associations between various occupations and specific occupational exposures and risk of NHL, but this literature is characterized by an almost total lack of consistency of results from study to study and typically weak associations. Scherr and Mueller make this point very well in a chapter on the epidemiology of NHL in a leading textbook on cancer epidemiology (Schottenfeld & Fraumeni, 2nd ed.). They present two tables that run for 6 ½ pages that summarize the literature on NHL and various occupations and occupational exposures. The most striking features of the tables include: (1) The large number of diverse occupations and exposures that have been reported as associated with NHL; (2) The lack of consistency of these results; and (3) The general lack of statistical significance and the weakness of these associations, with few relative risks or odds ratios above 2.0. (see the extensive review by Alexander, et al. 2007).

This summarizes what is currently known about the causes of NHL. For most patients with the disease, there is no established cause and their disease is considered to be of spontaneous origin. Comprehensive reviews of the literature on the epidemiology and causation of NHL have been written by leading scientists in the field (Melbye and Trichopoulos, 2002; Hartge and Wang, 2004; Grufferman, 2003; Scherr and Mueller, 1996; Hartge, et al., 2006; Alexander, et al., 2007). Importantly, none of these authoritative textbook chapters or comprehensive reviews reaches a conclusion that

DDT is a cause of NHL. Most of these reviews do not even mention DDT. Leading scientists in the field of NHL research simply do not recognize DDT as a cause of or contributing factor to NHL.

VIII.

DDT AND NHL IN HUMANS – A REVIEW OF THE SCIENTIFIC LITERATURE

Against this backdrop of what are the known causes of NHL, I will next review the scientific literature on the topic of DDT and NHL in humans. There are 40 scientific papers in total on this topic—a very large and comprehensive data set. The 40 papers can be characterized as follows:

1. Reports of Experiments/Human Feeding Studies (N = 2);
2. Reports of Analytic Studies (N = 36);
    a. Case-control study reports (N = 29)
    b. Cohort study reports (N = 7)
3. Descriptive/Ecologic Study Reports (N = 2)

The 40 papers represent all of the scientific literature that I have located to date and evaluated in connection with developing my opinions. In my efforts to identify all pertinent epidemiologic literature relating to DDT and NHL, I have searched the PubMed and other scientific literature databases and reviewed bibliographies of numerous scientific articles on related topics. Epidemiologic studies included in my analysis are restricted to those where specific information and data on DDT exposure and NHL occurrence were provided. These epidemiologic studies relating to the question of whether or not DDT is associated with NHL are identified here and discussed in detail in Attachments 1 and 2; no studies are excluded based on the magnitude of their risk

estimates. After an extensive analysis of this literature, I conclude that DDT is neither a cause nor a contributing factor to NHL, including follicular lymphoma, in humans.

All human experiments involving DDT are included. With the exception of the experimental studies, my discussion of the literature is confined to the topics of DDT and NHL—Montrose's sole product was DDT, and Ms. Garza has NHL. Studies examining occupational groups with presumed DDT exposure, or evaluating pesticides as a group, or evaluating hematopoietic malignancies as a group, without specific findings as to DDT and NHL, are excluded generally. For example, papers involving farmers as an occupational group, but providing no specific information on individual farmer's exposure to DDT, are not included. Farmers are exposed to a multitude of fuels, solvents pesticides, herbicides, viruses, etc., and it is not possible in most studies to tease apart the individual role of each exposure. The failure of such papers, as well as papers on pesticide applicators, to identify the specific and actual exposure of subjects to DDT, makes them inevaluable as to whether DDT is a cause of NHL. Similarly, papers that fail to specifically identify NHL as an outcome are inevaluable and were excluded. For example, papers that only report findings for the overall group of hematopoietic malignancies and not NHL specifically were excluded. Proper scientific evaluation of the literature requires that specific information on DDT and NHL be provided in the papers considered.

In Section A below, I first discuss the two human feeding studies that were conducted on DDT in the 1960-70s. Then, in Section B, I summarize my conclusions as to DDT and NHL after a full evaluation of the 36 analytic reports and two ecologic studies.

A. Experiments: The Feeding Studies of DDT to Humans Provide Evidence that DDT is Safe for Humans Even at High Doses

The pesticide DDT was for many years the single most widely used chemical for insect control and was particularly valuable for mosquito control in the management of malaria and typhus. It was believed to be safe for humans. DDT was presumed so widely to be harmless to humans that the U.S. Government conducted human feeding studies with the results published in leading medical journals.

The first study was conducted by the Communicable Disease Center of the U.S. Public Health Service, which was the precursor to the current U.S. Centers for Disease Control and Prevention, beginning in 1954 (Hayes, et al., JAMA, 1956). This research was conducted on U.S. prison inmates who volunteered to ingest two different types of DDT at differing doses on a daily basis for up to 18 months. Three different doses were administered ranging from 0 to 35mg per day (equivalent to 0.5 mg/kg/day, a dose estimated to be 200 times that to which the general population at the time was exposed). None of the subjects developed any symptoms or developed any sign of illness. The study concluded: "The study results indicate that a large safety factor is associated with DDT as it now occurs in the diet." Thus, the feeding of DDT on a daily basis to human volunteers over an 18-month period resulted in no apparent symptoms or illness and some of the subjects received very high doses of DDT.

A second study also was done by the Communicable Disease Center and started in 1956 (Hayes, et al., Arch Env Health, 1971). This study also used prison inmate volunteers who received the same three dosages as in the earlier study (0, 3.5 mg and 35 mg per day). This research was intended to reevaluate the findings of the first report and assess the storage and loss of DDT over a longer period of time. Twenty four subjects

ingested technical or *p,p'*-DDT at doses up to 35 mg per day for 21.5 months with no laboratory or clinical evidence of injury after lengthy follow-up (ranging from 25.5 months to five years after cessation of their DDT ingestion). The researchers concluded that "...these factors indicate a high degree of safety of DDT for the general population." The authors point out that the average dose of DDT administered was 555 times that ingested by comparably aged men in the general population.

What these two papers suggest is that DDT ingestion in humans was believed by U.S. government researchers in the 1950s to be safe, even at high doses, and their research results support this notion. Follow-up for up to five years after DDT feeding showed no adverse health effects, and there is no mention of cancer occurrence, let alone NHL specifically, in the study subjects. Here, we have one of the few scientific examples of experimental administration of DDT to humans and no harm was demonstrated. This argues strongly against DDT being a cause of lymphomas and other cancers in humans. In fact, it demonstrates that DDT, even at high doses, is safe for humans.

B. Analytic Studies: Case-Control and Cohort Studies of DDT and NHL Show That DDT Is Neither a Cause of Nor a Contributing Factor to NHL

It is important to point out that most epidemiologic studies, both case-control and cohort studies, identify broad occupational categories as suspected risk factors. However, such broad categories usually entail exposure to a very wide range of occupational exposures. Additionally, many such studies use univariate analyses (i.e., analyses that consider only a single variable or exposure at a time) to identify a single exposure as a suspected risk factor when the individuals studied may have been exposed at the same time to a multitude of other factors. As a result, a specific finding could easily be the result of confounding by other environmental exposures. To deal with such problems of

confounding, i.e., an observed association being due to another risk factor to which subjects were also exposed, biostatistical methods have been developed to tease apart the separate effects of multiple exposures in the same individual. Such methods typically involve multivariate analyses that can separate out the individual exposures for the disease being studied. These methods are particularly necessary for proper evaluation of occupational groups such as farmers with their multitude of different occupational exposures. Modern epidemiology increasingly uses multivariate analyses to deal with the important scientific issue of confounding. Thus, I have specifically identified those studies that employed multivariate analyses and have accorded them greater importance than univariate analysis studies in arriving at my causation opinions. Similarly, I have accorded substantial weight to the cohort studies on DDT and NHL, given their ability to estimate DDT exposures more precisely.

1. Case-Control Studies

a. Case-Control Studies Performing Multivariate Analyses

There are eight case-control studies on DDT and NHL that employed multivariate analyses and published results of these analyses (Baris, et al., 1998; De Roos, et al., 2003; Engel, et al., 2007; Hardell, et al., 1994; Hardell, et al., 2002; McDuffie, et al., 2001; Persson, et al., 1993; Rothman, et al., 1997). Each of these papers is summarized and discussed in detail in Attachments 1 and 2, respectively.

As shown, each report controls for other chemical exposures in their analyses. The multivariate analyses in all eight papers demonstrate no causal association between DDT exposure and NHL.

Baris, et al., 1998 demonstrated no association between DDT exposure and risk of NHL in an important multivariate analysis. My interpretation is consistent with the

authors' own concluding statement: "No strong consistent evidence was found for an association between exposure to DDT and risk of non-Hodgkin's lymphoma." De Roos, et al., 2003 similarly found no association between DDT and NHL after adjustment for all other pesticides—OR = 1.0 (95% CI = 0.7-1.3). The Baris, et al., 1998 and De Roos, et al., 2003 studies are important and compelling because of the large number of subjects and controls in their pooled analyses, which provided opportunities for proper statistical evaluation of confounding exposures.

Rothman, et al., 1997, which controlled for confounding exposures, is an excellent example of the importance of collecting pre-diagnosis blood samples and therefore avoiding potential bias and confounding. This study found no evidence of an association with DDT and NHL after controlling for PCBs (non-significant ORs ranged from 1.0-1.2). Engel, et al., 2007, which also used biologic specimens, is another large, pooled case-control study that, after performing multivariate analyses, found no significant associations between NHL risk and DDE in blood samples collected well in advance of NHL diagnosis. The four other studies employing multivariate analyses—Hardell, et al., 1994; Hardell, et al., 2002; McDuffie, et al., 2001; Persson, et al., 1993—also demonstrate no evidence of a statistically significant association between NHL and DDT following multivariate analyses. Thus, the eight studies employing sophisticated, modern epidemiologic methods produced very specific findings, all of which show no statistically significant association between DDT and NHL. Together, this is powerful scientific evidence that DDT is not a cause of NHL.

b. <u>Case-Control Studies Performing Univariate Analyses Only</u>

In addition to the eight reports above with multivariate analyses, there are 21 scientific papers considering DDT and NHL that perform univariate analyses and do not

control for other chemical exposures. Each of these papers is summarized and discussed in detail in Attachments 1 and 2, respectively. As noted in these Attachments, the failure to control for other chemical exposures is a significant limitation of the studies. Nevertheless, an evaluation of these reports further supports the conclusion that there is no valid association between exposure to DDT and risk of NHL, including follicular NHL.

Among the 21 studies are seven case-control studies that examined levels of DDT and its metabolites in biologic specimens (blood or fat samples) as indirect measures of past DDT exposure. Two Swedish studies (Hardell, et al., 1996; Hardell, et al., 2001) found no statistically significant association, while a third study (De Roos, et al., 2005) conducted by NCI showed a statistically significant protective effect in one of their analyses. Additional studies (Cocco, et al., 2008; Hardell, et al., 2009; Quintana, et al., 2004; Spinelli, et al., 2007) showed various and inconsistent results, including non-statistically significant associations. The odds ratios in all of these studies were below 2.0 for DDT and NHL, including follicular NHL. In the aggregate, the results of these seven studies provide no evidence of a causal association between DDT exposure and NHL, including specifically follicular NHL.

In addition to the seven case-control studies in the preceding paragraph, there are 12 case-control studies of DDT and NHL that do not have biologic specimen data, and instead assess exposure by history through questionnaires or interviews. This collection of studies includes several reports examining the same set of subjects, i.e., mid-western farmers and their families from a large NCI study (Cantor, et al., 1992; Cantor, et al., 1993; Lee, et al., 2004; Schroeder, et al., 2001; Zahm, et al., 1993). As pointed out in the

first study by Cantor, et al., 1992, farmers experience a multitude of occupational exposures (i.e., animal viruses, fertilizers, gasoline and diesel fuels, etc.) and multivariate analyses to control for these potentially confounding variables is critical. However, only univariate analyses were done in this group of studies.

These NCI farmer studies and additional studies employing univariate analyses (Colt, et al., 2005; Eriksson, et al., 2008; Hardell, et al., 1999; Persson, et al., 1989; Persson, et al., 1999; Woods, et al., 1987; Woods, et al., 1989) produced remarkably inconsistent results that are largely weak and not statistically significant. The weak findings generally centered around the null value of 1.0, suggesting that the weak associations between DDT and NHL were confounded by other environmental exposures. This was borne out by the multivariate analysis studies which showed uniformly that DDT was no longer associated with NHL when other exposures were controlled for in the analyses. Thus, based on a critical review and analysis of these 12 studies along with the multivariate studies, there is no basis for concluding that a causal association exists between DDT exposure and NHL risk. On the contrary, the evidence suggests otherwise.

Additionally, there are two case-control studies (Miligi, et al., 2003; Nanni, et al., 1996) that assess DDT exposure and risk of a combined category of NHL and chronic lymphocytic leukemia (CLL). Although CLL is currently considered one of the lymphoid malignancies in the new WHO classification, on clinical and epidemiologic grounds, it is a separate disease from NHL. For purposes of completeness, they are included in my review. Like the case-control studies discussed previously, these two studies do not demonstrate a causal association between DDT exposure and NHL. In

fact, Miligi, et al., 2003, found a statistically significant protective effect of DDT exposure in women (OR = 0.3, 95% CI = 0.1-0.8).

In conclusion, the results of all 29 case-control studies, particularly those studies that employed multivariate analyses, show no consistent or conclusive evidence of a causal association between DDT exposure and NHL. Rather, this collection of studies that span over two decades and were conducted in different populations by different investigators using different designs provide compelling evidence that DDT is not a cause of NHL.

2. Cohort Studies of DDT and NHL in Humans

The seven cohort reports studying DDT and NHL also present strong evidence that DDT is not a cause of NHL. See Attachments 1 and 2 for full discussion of these seven studies. As discussed previously, one notable strength of cohort studies is their ability to estimate more precisely exposure to DDT. The cohort studies each studied groups of persons who had high levels of occupational exposure to DDT. Three of the cohort studies, Laws, et al., 1967, Ditraglia, et al., 1981 and Brown, et al., 1992, are particularly important because they studied workers at plants that exclusively manufactured DDT; these workers were very heavily and specifically exposed to DDT. For example, Brown, et al., 1992, reported that the average daily intake of DDT in plant workers ranged from 438 to 450 times that of the general population. Although the sample sizes in these three reports were small, no cases of NHL were observed among DDT plant workers.

No increase in NHL was observed in studies of licensed DDT pesticide applicators or workers exposed to DDT as part of a public health malaria eradication program (Purdue, et al., 2006; Cocco, et al., 1997(a); Cocco, et al., 1997(b); Cocco, et al.,

2005). Again, both of these occupational groups were heavily and directly exposed to DDT. If a causal association between NHL and DDT existed, one would expect to see evidence of it in such heavily-exposed workers. Yet, the four reports of these groups failed to provide any support for a causal association between DDT and NHL.

Thus, the seven cohort reports—which examined the highly-exposed DDT workers and DDT pesticide applicators—each evidence no statistically significant association between DDT and NHL in these groups. There was not one exception, despite these cohorts being extremely heavily exposed to DDT. Together, this is powerful evidence for lack of any causal relationship between DDT and NHL.

C. Ecologic Studies

Finally, consistent with appropriate scientific methodology, where one must consider all relevant literature, I also evaluated the two ecologic studies regarding DDT and NHL (Cocco, et al., 2000; Pavuk, et al., 2004). See Attachments 1 and 2 for full discussion of these studies. While ecologic studies are of limited value in determining risk or causation, they nevertheless also do not support the claim that DDT causes or contributes to NHL, finding no excess of NHL with DDT exposure. In fact, one of the two studies (Cocco, et al., 2000) found a significantly protective effect between tissue DDE levels (DDE is a major metabolite of DDT) and NHL mortality in three of the four groups they studied.

D. In Summary, the Epidemiologic Literature Provides Strong and Consistent Evidence that DDT is Neither a Cause of NHL Nor a Contributing Factor

In summary, the voluminous body of scientific literature addressing DDT exposure and NHL specifically, provides strong and compelling evidence that DDT is neither a cause of nor a contributing factor for NHL. I analyzed all of the experimental

studies, analytic epidemiologic studies and ecologic studies that I was able to locate concerning DDT exposure and NHL, including follicular NHL (Attachments 1 and 2). This totaled 40 scientific papers. As an epidemiologist, I find that both the case-control studies with multivariate analyses and the cohort studies as a whole to be the most persuasive. Following the use of multivariate analyses to control for confounding exposures, not one of these eight case-control studies and none of the cohort studies showed a statistically significant association between DDT and NHL. Based on my extensive review of all relevant literature, together with my professional experience, education, training and background, I conclude to a reasonable degree of medical and scientific certainty that DDT is not a cause of NHL in humans.

My conclusion is consistent with those reached by leading governmental and public health organizations, including IARC (IARC, 1991), the U.S. Environmental Protection Agency (U.S. EPA, 1991), Agency for Toxic Substances and Disease Registry (ATSDR, 2002), and the National Toxicology Program (NTP, 2005), none of which conclude that DDT is a human carcinogen. Leading scientists in published, peer-reviewed literature (see the extensive review by Alexander, et al., 2007) also are in agreement with my conclusion.

In addition, none of the papers that I located in the literature on the subject of DDT exposure and NHL provide any evidence on DDT being a contributing factor to NHL. While plaintiff's experts may claim that there is some interaction or additive effect that occurs when a person is exposed to DDT, BHC/lindane, dieldrin and/or toxaphene in some combination, I have identified no evidence in the literature supporting such an assertion. De Roos, et al., 2003 was the only paper that considered interactions among

any of these chemicals, including the potential interactions between DDT and aldrin, chlordane, and lindane. The authors reported their findings for chlordane and DDT, which showed no significant interaction. The authors did not present data for their other DDT interaction analyses, suggesting no interaction among these pesticides. This report therefore provides no specific evidence of interaction between DDT, aldrin and lindane. Thus, it is also my opinion, to a reasonable degree of medical and scientific certainty, that DDT has not been proven to be a contributing factor to NHL in humans.

E. The DDT and NHL Epidemiologic Literature Fails to Meet the Causation Criteria

Finally, Montrose requested that I consider whether or not well-designed, properly conducted DDT and NHL studies overall report a risk estimate greater than 2.0 that is statistically significant at the 95% level such that the confidence limits do not include 1.0. I understand these specific criteria for assessing causation are based on a judicial decision, Merrell Dow Pharmaceuticals, Inc. v. Havner, Texas Supreme Court (1997). These criteria are consistent with the approach that I and the epidemiologic community typically use in the evaluation of research results.

As noted previously, the DDT and NHL literature set contains 40 different reports. In epidemiology, this constitutes a large study set from which we can draw definitive conclusions. Despite this considerable body of literature:

- There is not one cohort study report that evidences a statistically significant doubling of the risk. (0/7 reports);
- There is not one case-control study that evidences a statistically significant doubling of the risk following multivariate analysis. (0/8 reports);

- There is not one ecologic study that found a statistically significant doubling of the risk. (0/2 reports)
- The DDT experiments, where humans were fed large amounts of DDT, also found no increase in cancer risk. (0/2 reports)
- There are 21 case-control reports with only univariate analysis (i.e., they fail to control for relevant confounding exposures by using more sophisticated statistical analyses). Yet, just 3 (Cantor, et al., 1992; Eriksson, et al. 2008; K. Hardell, et al., 2009) of the 21 reports contain any statistically significant finding above 2.0 among their multitude of findings on DDT. Thus, in 18 reports, there is not one finding which evidences a statistically significant doubling of the risk, despite not controlling for critical confounders. In the three reports referenced above, each performs numerous analyses, making it likely that results reported may be due to chance and/or confounding. The authors of Cantor, et al., 1992 recognize and discuss this problem in their paper. Consequently, when Baris, et al., 1998 and De Roos, et al., 2003 evaluated the same data as Cantor, et al., 1992 using multivariate analyses, they found no significant association between DDT and NHL. Hardell, et al., 2009 and Eriksson, et al. 2008 suffer from similar deficiencies in that they perform numerous subset analyses that increase the likelihood of chance findings and/or are of unknown relevance to Ms Garza, i.e., risk estimates for EBV EA antibodies. In sum, the vast majority of findings as to DDT and NHL within these 21 reports also do not meet these criteria. (3/21 reports).

In my 42 years of professional experience as an epidemiologist, I have rarely seen a literature set as large as DDT and NHL which has such overwhelmingly negative results. There are 40 total studies—37 of which fail the "doubling of the risk" test completely, and the other three of which are not only obvious outliers, but also need to be interpreted cautiously due to their failure to control for confounders and their performance of multiple subset analyses. Thus, despite decades of scientific research, DDT has neither been proven to be a cause of NHL in humans nor a contributing factor to NHL in humans.

IX.

REPORTS OF THERAPEUTIC USE OF DDT AND/OR ITS ANALOGS

Also of interest are two additional studies (three reports) that demonstrate the safety of administration of DDT and/or its analogs to treat human patients. The first study is a case report in the Lancet from 1969 that reported the use of dicophane, which contains no less than 70% of DDT, in the successful treatment of a young man with unconjugated hyperbilirubinemia (a type of jaundice) (Thompson, et al., Lancet, 1969). DDT was considered to be extremely safe and its use was widespread in the 1960s, and even led to the use of DDT as a treatment for jaundice.

Interestingly, the use of a DDT compound for treatment of disease in humans continues to this day. A second, very recent paper in the prestigious New England Journal of Medicine (Terzola, et al., 2007) reported on the use of mitotane ("a synthetic derivative of the insecticide dichlorodiphenyltrichloroethane (DDT)") in the successful treatment of adrenocortical carcinoma. Mitotane is chemically termed *o,p'*-DDD which is important since DDT is metabolized in humans to DDD. DDD is further broken down in the body and does not persist very long, so it does not accumulate in human tissues.

The major adverse effects of mitotane treatment were gastrointestinal symptoms and neurologic symptoms in patients receiving high-dose therapy. Patients on lower dose therapy had none of these symptoms.

This is a modern-day clinical study of a DDT derivative for treatment of cancer in humans that was considered ethical to conduct. An accompanying commentary (Schteingart, N Engl J Med, 2007) states that the study "provides a compelling rationale for the use of low dose mitotane as adjuvant therapy" in adrenocortical carcinoma. Thus, it is likely that a DDT derivative will become part of the standard treatment of this rare human malignancy. Neither of these two New England Journal papers, written by oncologists, raises any concern about risk of NHL in patients receiving mitotane.

These three papers demonstrate that the administration of DDT analogs is considered safe for treatment of medical patients and has therapeutic value.

X.

REVIEW OF PLAINTIFF'S MEDICAL HISTORY

A. Ms. Garza's NHL Has Had A Typical And Uncomplicated Course And She Has Survived Ten Years Since Diagnosis

I have reviewed the available medical records, deposition testimony, replies to interrogatories, etc., that were provided to me for the plaintiff, Guadalupe Garza, who has alleged that she developed NHL as the result of environmental exposure to DDT from the Hayes-Sammons facility in Mission, Texas. I have had extensive experience in reviewing patient medical records as a practicing physician, having conducted NIH-funded, peer-reviewed epidemiologic research using medical records (on the hematologic malignancy, multiple myeloma), and having served for ten years as a member of the Medical Records Committee of the Duke University Medical Center.

Ms. Guadalupe Garza was born on February 19, 1943, and was diagnosed with NHL on December 2, 1998, at the age of 55 years. This is a common age for the diagnosis of NHL in adults.

Ms. Garza reports the following residential history: She was born in Mission, Texas and lived there for most of her life. During the period 1969-1975, she lived in Wheeling, Illinois. She returned to Mission in 1975 and she still resides there. From 1943 to 1957, she states in her interrogatories that she resided at 506 Nicholson, in Mission. From 1957 to 1967, she further indicates that she lived at 423 Canal Avenue and, from 1975 to the present, she has resided at 1015 Nicholson in Mission.

Ms. Garza reported that she assisted her husband in cleaning offices while they lived in Illinois. She reported having used ordinary household cleaning products in the work. Upon returning to Mission in 1974, she stated that she worked at Kenneth White Junior High School and kept this job until the 1990s. She was next employed by the La Joya School in La Joya, Texas. Her job duties at both schools were selling snacks to students. This appears to be the extent of her occupational history. Her husband worked for the post office in Illinois and cleaned offices as a second part-time job.

Ms. Garza's medical history reveals that she has had a typical and uncomplicated course of her NHL and has survived almost ten years since diagnosis. Moreover, she has problems with morbid obesity, diabetes, hypertension and dyslipidemia, all of which antedate her NHL. The history of her NHL is as follows: In August, 1998, she underwent mammography and a moderately enlarged left axillary lymph node was detected. A follow-up breast ultrasound examination was done one month later, and multiple hypoechoic masses were observed in the left axilla. A biopsy was

recommended. A needle biopsy was performed on November 10, 1998, at Rio Grande Regional Hospital, and the specimen was felt to be benign, but due to the small amount of biopsied material examined, an excisional biopsy was recommended.

On December 2, 1998, Ms. Garza underwent an excisional biopsy of left axillary lymph nodes, also at Rio Grande Regional Hospital. This tissue was diagnosed as a malignant lymphoma, follicular (nodular), of B-cell type, after immunophenotyping the specimen. She was referred to Dr. Suresh Ratnam, currently with the South Texas Cancer in McAllen, for further evaluation, staging and treatment. She underwent a bone marrow biopsy and was found to have marrow involvement by her lymphoma, which was confirmed to be a B-cell tumor of probable follicular center cell origin and thus a follicular lymphoma. A history of sweats and fatigue was obtained making her disease of the "b-type." Extensive staging examinations were done, and she was classified as having stage IV-b disease.

She was started on combination chemotherapy (FND) on January 6, 1999, and completed six cycles of this course of treatment on May 7, 1999. She had a "good response" to the chemotherapy, and she was next started on Rituxan therapy on May 24, 1999. Ms. Garza completed eight weekly doses of Rituxan and then was placed on maintenance alpha-interferon therapy in July, 1999. On September 22, 1999, she was found to be in complete remission from her disease. The alpha-interferon therapy was discontinued in August, 2001, and she had no evident disease at her last follow-up whole body PET scan evaluation in March, 2002. At this point, she was in complete remission, and remained in complete remission as of March, 2004.

In August, 2004, she was found to have recurrent active lymphoma and was restarted on Rituxan therapy. By September, 2005, her oncologist (Dr. Ratnam) reported no convincing evidence of active disease. In January, 2006, she was again noted to have active NHL and her oncologist switched her treatment from maintenance Rituxan to a full course of the drug. In January, 2007, she was also placed on high dose prednisone therapy. At that time her physician noted that she had mildly progressive, low volume Stage IV-B follicular lymphoma. In March, 2007, she was found to be responding to her therapy. PET and CAT scans performed in June, 2008, showed evidence of increased lymphadenopathy consistent with progressive lymphoma. A new course of Rituxan and CVP therapy as well as monthly IVIG for hypogammaglobulinemia was prescribed. As of December 18, 2008, she was responding well to her chemotherapy. She was on chemotherapy at the time of her last available medical record.

She is currently alive 10 1/2 years after her diagnosis. Ms. Garza's clinical course is typical of a well managed adult follicular NHL patient. She has had responses to therapy (remissions) and relapses of her disease with few clinical symptoms. Her relapses have responded to therapy and it is likely that she will continue to do well. She does not appear to be in imminent danger of death as a plaintiff's expert has opined. The last medical records of Ms. Garza that I reviewed were dated January 9, 2009. I reserve the right to supplement this report if and when any additional medical records are provided.

A review of her general medical history is as follows: Her past medical history and review of systems are marked by a history of extreme obesity, with body weights up to 270 pounds (on 7/2/05 and 5/11/06), with a height of 63-65 inches, even after

chemotherapy. Her last recorded body mass index (BMI) was 52.33 on 11/14/05. This was after chemotherapy and before her diagnosis of Type II diabetes. A body mass index over 40 is classified as extreme or "morbid" obesity. Her severe obesity antedated her diagnosis of NHL, with weights as high as 241 lbs. on 4/1/98. Her height at that time was 65 inches, resulting in a calculated BMI of 40, which is the lower bound of extreme obesity. She was diagnosed with Type II diabetes on 5/1/06, although she had borderline to frankly abnormal blood glucose levels for two years before diagnosis. Severe obesity, as Ms. Garza has had for many years, is a major risk factor for Type II diabetes. She additionally has a long history of treated hypertension and osteoarthritis, which are also associated with extreme obesity. Well before her NHL diagnosis she was noted to have dyslipidemia (2/20/89). The combination of obesity, particularly abdominal obesity, dyslipidemia, and hypertension has been termed the "metabolic syndrome," a condition that markedly increases the risk of atherosclerosis and its complications. At her last medical visit on 12/18/08, her weight was 258 lbs. Her morbid obesity is an important consideration in understanding the potential causes of Ms. Garza's NHL given that obesity is a potential risk factor for NHL (Alexander, et al., 2007; Hartge, et al., 2006).

Ms. Garza has no history of prior malignancies, kidney disease, hepatitis, HIV infection, infectious mononucleosis, tuberculosis, or asthma. She has had two TIAs (transient ischemic attacks), the first on 3/31/97 and the second on 6/5/08. Evaluation of her carotid arteries on 4/7/97 revealed mild plaques of both carotid arteries with no stenosis. A TIA is similar to a mild stroke of short duration (less than one hour) and is typically due to emboli from stenotic carotid or vertebral arteries. In 1985, she complained of shortness of breath, chest pain and palpitations, and underwent a cardiac

stress test and 24-hour cardiac monitoring both of which were normal. She was placed on Inderal therapy at that time and her symptoms subsided. She reports that she does not smoke or drink alcoholic beverages. She has undergone a prior hysterectomy. There is a positive family history of heart disease and her paternal grandmother died of stomach cancer. She was on atenolol, Clinoril and Premarin therapies at the time of her diagnosis.

As part of routine re-evaluation of her lymphoma status, she underwent a CT examination of her abdomen on 8/19/08. A mass was noted in her left kidney that was enlarged since first noted on 1/3/07. As a result, she underwent a biopsy on 9/23/08 that revealed renal cell adenocarcinoma, clear cell type. She underwent radioablation therapy for this tumor and the mass was stable on repeat CT examination on 1/09/09.

B. <u>DDT Did Not Cause or Contribute to Ms. Garza's NHL</u>

Because DDT is not a cause of or a contributing factor to NHL, Ms. Garza's NHL was not caused by DDT. In fact, using the occupational studies that I evaluated in this report as a reference point, it is evident that Ms. Garza's alleged exposure could not possibly have caused NHL. Specifically, Ms. Garza alleges exposure to DDT while residing in proximity to the Hayes-Sammons facility, thus she claims to have had only residential exposure. There is no evidence that Ms. Garza was a farmer, pesticide applicator, chemical plant employee or that she experienced any type of occupational exposure to DDT. Furthermore, it should be emphasized that there are no direct measurements of Ms. Garza's alleged exposure levels from the actual time of these purported exposures.

We know from the occupational cohort studies that extremely high levels of exposure to DDT, which are orders of magnitude higher than any type of residential exposure that Ms. Garza might have experienced, do not cause NHL. Therefore, even

assuming she had levels of exposure equivalent to those experienced by members of the occupational cohorts, which she did not, such exposure would not have caused her NHL. Consequently, Ms. Garza's claim that her NHL was caused by presumably much lower levels of exposure is scientifically unfounded.

Furthermore, my conclusion that DDT is not a cause of Ms. Garza's NHL is consistent with studies performed by the Texas Department of Health (TDH). Starting in 1998, TDH performed a series of surveillance studies in Mission, Texas. Specifically, in addition to various other cancers, TDH evaluated NHL incidence and mortality in the Mission, Texas zip code (78572). Based on their most recent evaluation from March 31, 2005, NHL incidence and mortality for men and women during the period 1993 - 2002 were all below the rates expected in the general Texas population (TDH Report, 2005). The standardized incidence ratios (SIR) were 0.76 in men and in women and the standardized mortality ratios (SMR) were 0.69 in men and 0.76 in women. These data clearly show that not only were there no increases in NHL incidence and mortality in the Mission, Texas zip code, but that there were fewer than expected cases and deaths. If the plaintiff's allegations regarding the Hayes-Sammons facilities were correct, we would expect to see increased cancer rates in the area around the plant. In fact, the most salient findings of the TDH surveillance studies showed statistically significant deficits of incidence and mortality for many cancers.

XI.

PLAINTIFF'S CAUSATION EXPERTS HAVE NOT USED ACCEPTED SCIENTIFIC METHODOLOGY IN REACHING THEIR OPINIONS

I have reviewed the reports and deposition testimony of plaintiff's experts, Drs. Richard Clapp, Theodore Farber, Frank Gardner, and William Sawyer. In sum, I find

that their reports and testimony completely fail to demonstrate a causal relationship between DDT exposure and the development of NHL—much less show that Ms. Garza's alleged exposure to DDT caused or contributed to her development of NHL. Plaintiff's experts have a serious flaw in common—the failure to use accepted scientific methods in reaching their opinions. More specifically, plaintiff's experts have: (1) failed to systematically search for and analyze the relevant literature; and (2) failed to systematically and critically review even the narrow subset of literature they do cite.

Not surprisingly, these limitations in methodology have resulted in seriously misleading expert reports and opinions. The four Plaintiff's experts rely on a biased and narrow selection of the relevant epidemiologic studies to support their opinions; further, they selectively cite and mischaracterize findings within this narrow range of studies. Plaintiff's experts have also cited numerous studies that are simply irrelevant. Finally, Drs. Gardner and Sawyer have ignored potential alternative risk factors that may have caused or contributed to Ms. Garza's development of NHL.

With these concerns in mind, I discuss the reports and testimony of each of these experts in turn.

A. Dr. Richard W. Clapp Has Not Used Accepted Scientific Methodology in Arriving at His Opinion on DDT and NHL

Dr. Clapp authored a curious report in 2005 to support his opinion that the organochlorine pesticides at issue are capable of causing the development of NHL. Foremost, of the 26 pages of text in Dr. Clapp's report, more than 19 pages are devoted to a lengthy philosophical discussion in which Dr. Clapp eschews traditional reliance on statistical significance and p-values and purports to follow the "Hill guidelines" for assessing causal relationships (Richard Clapp's Expert Report ("2005 Clapp Report"),

February 8, 2005, pages 1-19). Dr. Clapp's opinion regarding statistical significance is not surprising, given that the bulk of epidemiologic evidence in this case does not reach statistical significance. The overwhelming majority of the scientific community views statistical significance much differently than Dr. Clapp. Indeed, in any leading scientific journal—such as the highly-regarded New England Journal of Medicine—the authors of virtually every scientific article present p-values and/or confidence intervals. Despite his denigrating the use of p-values, Dr. Clapp himself relied on p-values in his evaluation of the scientific literature presented in his report (2005 Clapp Report, pages 24-26).

Dr. Clapp has completely failed to employ any scientific methodology. Though Dr. Clapp engages in lengthy philosophical discussion and interpretation of the Hill criteria in his report, he failed to explain how he employed the Hill criteria to reach his opinions (2005 Clapp Report at 20-26). The supplemental report Dr. Clapp filed in 2008 is similarly devoid of any explanation of his methodology (Supplemental Report of Dr. Richard Clapp ("Clapp Supplemental Report"), December 5, 2008). During deposition, Dr. Clapp claimed that he employed the Hill guidelines in excluding studies, but admitted that he did not document this process with respect to any individual pesticide or group of pesticides (Deposition of Dr. Richard W. Clapp ("Clapp Deposition"), pages 189:1-190:16).

Dr. Clapp has employed no consistent or precise methodology in his review of the literature. Dr. Clapp claimed that he has excluded "animal studies," older studies employing dated methods, and studies that have been questioned or deemed unreliable (Clapp Deposition, pages 74:4-75:1). Dr. Clapp purports to have conducted Medline searches to identify literature on NHL and pesticide exposures. Despite this

methodology, he inexplicably ignores nearly two-thirds of the studies relevant to assessing the possible relationship between DDT and NHL. Simply put, Dr. Clapp has selected epidemiologic literature that supports his conclusions. For example, I have identified 40 studies relevant to whether or not there is a causal connection between exposure to DDT and NHL development; Dr. Clapp has cited only 13 of these studies. Furthermore, regarding the 13 studies Dr. Clapp does cite, he omits the findings for DDT at least six times (2005 Clapp Report, pages 20-26; Supplemental Report of Dr. Richard Clapp, dated December 5, 2008, pages 1-2). When questioned about several of the DDT/NHL studies he ignored during deposition, Dr. Clapp admitted their relevance and—not surprisingly—had difficultly explaining his failure to consider them in reaching his opinions in this case (Clapp Deposition, pages 79:12-23; 80:24-81:3; 107:21-109:2; 81:7-18).

Dr. Clapp's biased selection of results within studies is equally problematic, especially given the narrow range of studies he cites. He seemingly recognizes that, in studies that adjusted for exposure to other potential risk factors—performing, in other words, a multivariate analysis—odds ratios regress towards the null and become statistically insignificant for DDT and NHL (for example where he discusses Hardell, et al., 1994 and Baris, et al., 1998) (2005 Clapp Report, pages 21-22). Yet, in several instances, Dr. Clapp failed to cite the results of multivariate analyses. As an example, he ignores the multivariate analysis findings in De Roos, et al., 2003 and McDuffie, et al., 2001 (2005 Clapp Report, pages 20-26). Similarly, Dr. Clapp has routinely selected only the highest odds ratios from within particular studies, ignoring many other findings. For example, with respect to De Roos, et al., 2003, he cites the findings for chlordane,

lindane, and toxaphene, but ignores the DDT findings that show no association (2005 Clapp Report).

Dr. Clapp also cites several studies that are simply not relevant to whether or not a causal association exists between a particular disease and a specific agent like DDT. For instance, he cites a study in Utah linking farming occupations to development of NHL, apparently relying on farm work as a "surrogate" for exposure to organochlorine pesticides (Schumacher, et al., 1985) (Clapp Report, page 20; Clapp Deposition, pages 147:6-148:1). Of course, farm-workers are exposed to a host of potential exposures, including animal viruses, gasoline, fertilizers, herbicides, and non-organochlorine pesticides. Thus, farm work cannot be used reliably as a surrogate for DDT exposure when trying to assess whether or not a causal relationship exists between DDT and NHL.

Finally, Dr. Clapp purportedly relies on five studies to meet the Havner criteria for demonstrating causation between DDT and NHL (Clapp Deposition, Exhibit 42). First, a proper scientific analysis and methodological evaluation should have considered all 40 studies in reaching a conclusion—not simply the five that Dr. Clapp claims support his opinion. Second, contrary to Dr. Clapp's contention, the five identified studies do not meet the criteria outlined in the Havner decision:

- Dr. Clapp cited Baris, et al., 1998 and culled one finding from dozens of non-elevated, non-significant findings; when a multivariate analysis was performed, as Dr. Clapp admits, the same finding was neither elevated nor significant—the authors themselves concluded that there was no strong consistent evidence of an association between DDT and NHL;

- Dr. Clapp cites only one of dozens of findings in Cantor, et al., 1992, though the same subjects were evaluated in two subsequent studies that used more sophisticated, multivariate analysis and found no associations (Baris, et al., 1998, and De Roos, et al., 2003);
- He cites Colt, et al., 2005 for its T-cell lymphoma findings, though (1) T-cell lymphoma is not the type of NHL Ms. Garza has, (2) the follicular lymphoma findings, which Ms. Garza has, were not significant and close to the null, and (3) the authors found no association for women;
- He cites Hardell, et al., 1994 for a single univariate finding, and ignores (1) the non-significant results of the multivariate analysis that controlled for other chemicals, and (2) the authors' conclusion that DDT was not associated with an increased risk for NHL; and
- He cites Engel, et al., 2007 for a single unadjusted DDE finding out of many analyses, and then fails to note that the significance of this one finding disappeared when adjusted for exposure to PCBs and also ignores the numerous other findings in the paper itself and its extensive supplement. Dr. Clapp's use of the Engel paper is an extreme example of highly selective use of one finding out of a multitude of findings to arrive at a causation opinion.

(Clapp Deposition, pages 149:3-150:8; 159:16-25).

In sum, Dr. Clapp has not used accepted scientific methodology to arrive at his opinions regarding DDT. He has omitted dozens of relevant studies and even ignored the conclusions in his own writings. Indeed, though Dr. Clapp has published several papers or chapters discussing the purported causes and risk factors for cancers (including NHL),

he has never claimed in his published work that DDT causes NHL. Given his incomplete, selective and distorted review of the scientific literature, Dr. Clapp's opinions are unscientific, unreliable and insufficient to demonstrate any link between DDT and NHL.

B. Dr. Theodore M. Farber Presents No Scientific Basis for His Conclusory Statements Concerning DDT and Cancer Causation

Seemingly, Dr. Farber has drafted a general causation report on DDT. On page 40 of his report, he states the following: "Long term health effects [of DDT] may include cancer, liver damage, and fertility problems" (Dr. Theodore Farber's Expert Report ("Farber Report"), February 8, 2005, page 40). However, he identified no specific cancers, liver damage, or fertility problems and provided no scientific references to support his statements. Dr. Farber goes on to list a litany of government regulations and guidelines for DDT use (Farber Report, pages 3-76). Yet, nowhere has he presented any scientific evidence that DDT is capable of causing cancer, let alone NHL. The regulations and guidelines Dr. Farber cites cannot be used to support his general causation opinion—they are government policy, not scientific evidence. Undoubtedly, regulators may elect to enact cautious policies whether justified by science or not. Dr. Farber has made no effort to review the scientific basis for such regulations or, more broadly, the literature regarding the purported relationship between DDT exposure and NHL. Thus, Dr. Farber has not even attempted to use scientific methodology to support his general causation opinions—rendering them wholly unreliable.

C. Dr. Frank H. Gardner Has Not Used Valid Scientific Methodology In Arriving at His Opinions on NHL Causation

Initially, Dr. Gardner submitted a brief five page letter comprised largely of his opinions that pesticides exert a mutagenic effect in humans (Dr. Frank Gardner's

February 14, 2005 Letter ("2005 Gardner Report")). These opinions were conjecture and largely unsupported by any scientific references. Similarly, Dr. Gardner expressed the opinion that pesticides cause or contribute to the development of NHL without providing any explanation or specific references to support his views—rather, he cited to an appendix of incomplete epidemiologic literature (2005 Gardner Report, page 5). Despite his lack of epidemiologic training or expertise, Dr. Gardner purportedly relied on this appendix without any discussion or interpretation of the studies.

On December 9, 2008, Dr. Gardner submitted an updated report, titled Affidavit of Frank H. Gardner, M.D. ("2008 Gardner Report"). In this report, Dr. Gardner provides an appendix that he claims contains studies that "indicat[e] a significant association between individual organochlorides [sic] and [NHL]." He identifies *only* nine papers relating to DDT and admits that this chart was intended to satisfy the Havner criteria (2008 Gardner Report, Appendix III; Deposition of Dr. Frank Gardner ("Gardner Deposition"), pages 242:13-17). Like Dr. Clapp, however, Dr. Gardner has failed to specify any clear, consistent parameters for defining and analyzing the relevant literature set. He then reached conclusions that were not based on any clearly articulated methodology.

During his deposition, Dr. Gardner admitted that he culled studies purporting to satisfy Havner (Gardner Deposition, pages 246:10-247:3). When pressed about his methodology, and—particularly—his exclusion of negative studies, he asserted that he eliminated studies that had insufficient numbers of cases and controls (Gardner Deposition, pages 246:4-9; 346:25-347:4). However, if he had in fact used his stated selection process, he would have included additional relevant studies. For instance, Dr.

Gardner ignored Hardell, et al., 1999 though it contained cases (66) and controls (107) with DDT exposure, outnumbering those in other studies he cited. As an example, Gardner cited a single DDT finding from Baris, et al., 1998 based upon only 11 exposed cases and 15 exposed controls (2008 Gardner Report, Appendix III). This comparison demonstrates the rule, rather than the exception. With respect to the 40 studies that I evaluated, Dr. Gardner relies on only nine of those studies for DDT; furthermore, he ignores DDT findings in at least four other studies (De Roos, et al., 2003; Lee, et al., 2004; Purdue, et al., 2006; Schroeder, et al., 2001) that he relies upon or otherwise references in his reports (2005 Gardner Report; 2008 Gardner Report, Appendix III).

Indeed, even within the studies Dr. Gardner cited, he paid little heed to case and control numbers—instead again culling individual results in an effort to satisfy Havner. For example, Gardner cited a dieldrin result from a 2001 Schroeder, et al. study with seven cases and 33 controls, ignoring two non-elevated, non-significant DDT findings based on, respectively, 13 and 22 cases, and 216 controls with a DDT exposure (2008 Gardner Report, Appendix III). As this example illustrates, he repeatedly ignored negative DDT findings in the studies he cites—instead citing only those significant findings that supported his opinion. Dr. Gardner could not explain why he cited only the statistically significant finding for DDT (Gardner Deposition, pages 263:25-270:5). Like Dr. Clapp, Dr. Gardner's approach to reviewing the literature is not accepted scientific methodology.

Finally, Dr. Gardner admits that he has not considered other potential risk factors for the development of NHL in Ms. Garza. He also has ignored other chemicals processed by Hayes-Sammons (Gardner Deposition, pages 325:2-328:16). He claims to

have briefly considered, then disregarded, potential causal associations between animal viruses and NHL, as well as organophosphate pesticides and NHL (Gardner Deposition, pages 131:5-133:1; 325:2-328:16).

Thus, Dr. Gardner has not used any systematic approach for defining the relevant literature set, assessing that literature, and then using it to reach his conclusions. By admission, Dr. Gardner has ignored "negative" studies in his attempt to only identify studies that would "come up to the Havner concepts or near them" (Gardner Deposition, pages 39:25-40:8). Even within these studies, Dr. Gardner has selected only findings favorable to his position. Moreover, Dr. Gardner admittedly has failed to consider several potential risk factors relevant to the development of Ms. Garza's NHL. For all of the above reasons, Dr. Gardner's approach and resulting opinions regarding DDT and NHL are unscientific and unreliable.

D. Dr. William R. Sawyer Presents No Scientific Basis for His Opinions Regarding NHL and DDT

Dr. Sawyer's opinions center largely on Ms. Garza's purported exposures to DDT and other organochlorines processed at the Hayes-Sammons facility. Other defense experts will comment on Dr. Sawyer's exposure opinions; here, I consider only his opinion regarding DDT and NHL. Similar to Dr. Clapp, Dr. Sawyer expounds upon the use of the Hill criteria, their application to general causation, and his supposed use of the "weight of the evidence" approach (Dr. Sawyer's "Residential, Medical History & Toxicological Causation Assessment," December 9, 2008 ("2008 Sawyer Report"), pages 10-16). A review of his report and testimony quickly shows that he failed to apply any of these methods that he admits are important in arriving at a causation opinion. Indeed, Dr. Sawyer cites to a narrow sub-set of the relevant epidemiologic literature without

specifying his selection criteria, then states his conclusions in summary fashion (2008 Sawyer Report, pages 20-30). Furthermore, Dr. Sawyer has written a lengthy discussion of Ms. Garza's medical history—which he is unqualified to do since he is not a physician.

In Dr. Sawyer's initial report, titled "Environmental Exposures and Dose Calculations" ("2005 Sawyer Report"), dated February 9, 2005, Dr. Sawyer states that "human epidemiological studies have demonstrated statistically significant increased rates of NHL associated with DDT . . . .." (2005 Sawyer Report, page 16). Dr. Sawyer did not provide a single scientific reference to support his position. In his 2008 report, Dr. Sawyer makes a similar claim, this time citing risk estimates from 15 studies that, purportedly, support this opinion (2008 Sawyer Report, pages 20-29).

When questioned about the narrow range of literature he selected to support his general causation opinions, Dr. Sawyer maintained that he had reviewed all the available literature relating to organochlorines and NHL (Deposition of Dr. William Sawyer ("Sawyer Deposition"), pages 162:24-163:4). He claimed that nearly all the "negative studies" (i.e., those studies showing no association between pesticide exposure and NHL development) "were irrelevant" (Sawyer Deposition, page 164:1-4). Yet, Dr. Sawyer had no plausible explanation for why these "negative studies," including the many studies finding no association between DDT and NHL, were irrelevant. Dr. Sawyer cites only six of the 40 studies that I rely on and then ignores the DDT findings in three of the studies he does cite (2008 Sawyer Report). Furthermore, Dr. Sawyer like the other plaintiff's causation experts, cites studies that rely on surrogate measures of exposure or

lack any clear exposure data for specific chemicals, like Merhi, et al., 2007, Orsi, et al., 2007 and Flower, et al., 2004 (2008 Sawyer Report, pages, 22-25).

Dr. Sawyer, like Drs. Clapp and Gardner, selected a narrow subset of the relevant scientific literature and then cites only findings that support his opinions, while ignoring the bulk of other results and authors' conclusions. For example, he cites findings from Quintana, et al., 2004, but omits the authors' conclusions that (1) there was "no clear association between exposure to DDT and NHL," and (2) the association between DDE and NHL was confounded by other pesticides (2008 Sawyer Report, pages 26-27). He also cites Hardell, et al., 2001 for several non-DDT findings, and ignores near null, non-significant findings for a DDT metabolite (2008 Sawyer Report, pages 23-24).

Finally, Dr. Sawyer states that his "review of [Ms. Garza's] historical medical records, direct personal interview and inspection of her 1015 Nicholson Street home failed to provide any other significant occupational or environmental exposures contributing to the onset of her NHL" (2008 Sawyer Report, page 30). Although by this statement Dr. Sawyer suggests that he examined alternative causes, there is no evidence that he in fact ruled out potential risk factors for NHL. If one used Dr. Sawyer's biased methodology for selecting and reviewing scientific literature, he would conclude that such possible risk factors as obesity, arthritis, and blood transfusions caused Ms. Garza's NHL and thus should have been considered in his analysis.

In conclusion, Dr. Sawyer has failed to systematically review the total relevant body of literature and fairly interpret the studies he cites. He did not follow the methodology he claims to use (i.e., "weight of the evidence"), and instead provides a biased and limited analysis of a highly selected subset of the scientific literature.

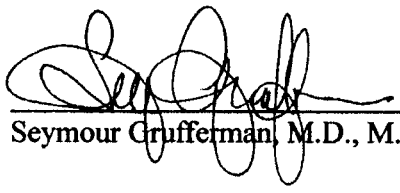
Moreover, he failed to properly consider alternative risk factors for NHL. Thus, his approach is unscientific and his resulting opinions are unreliable.

XII.
SUMMARY OF OPINIONS

In summary, based on my review of the scientific evidence in the medical and epidemiologic literature and my years of research and study of the causation of the lymphomas, I conclude:

1. To a reasonable degree of medical and scientific certainty, DDT is neither a direct nor a contributing cause of NHL in humans.
2. To a reasonable degree of medical and scientific certainty, Ms. Garza's NHL was not caused by her alleged exposure to DDT, nor did DDT contribute to the cause of her NHL. The scientific literature as a whole demonstrates very clearly and persuasively that DDT is not a cause of NHL and does not contribute to NHL causation, even at extremely high exposure levels. The vast majority of NHLs are considered to be spontaneous occurrences and Ms. Garza's NHL is highly likely to fall within this category.
3. Drs. Clapp, Gardner, Sawyer and Farber have not used accepted scientific methodology in reaching their causation opinions regarding DDT and NHL.

I reserve the right to modify and/or supplement my opinions and this report if and when new information becomes available.



Seymour Grufferman, M.D., M.P.H., S.M., Dr.P.H.

Non-Hodgkin Lymphoma Epidemiologic Studies Involving DDT (38 Studies)

Case–Control Studies Performing Multivariate Analyses (8 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Baris, D., et al., Agricultural Use of DDT and Risk of Non-Hodgkin's Lymphoma: Pooled Analysis of Three Case-Control Studies in the United States, Occup. Environ. Med. 55:522-7 (1998)	Pooled data from three population-based case-control studies. Exposure data from interviews.	993 cases and 2,918 controls interviewed. 161 cases and 340 controls exposed to DDT.	OR=1.2 (1.0-1.6), unadjusted. Adjusted OR = 0.9 (0.4-1.8). When analyses adjusted for other chemicals, ORs ranged from 0.3 to 1.9 (Table 5). 36 total analyses reported in Table 6.	N.S.
2.	De Roos, A., et al., Integrative Assessment of Multiple Pesticides as Risk Factors for Non-Hodgkin's Lymphoma Among Men, Occup. Environ. Med. 60:E11 (2003)	Pooled data from three population-based case-control studies. Exposure data from interviews.	870 cases and 2,569 controls interviewed. For analyses of multiple pesticides, 650 cases and 1,933 controls.	OR for DDT = 1.0 (0.7-1.3), based on 98 DDT-exposed cases and 226 DDT-exposed controls.	N.S.
3.	Engel, L., et al., Polychlorinated Biphenyl Levels in Peripheral Blood and Non-Hodgkin's Lymphoma: A Report from Three Cohorts, Cancer Res. 67:5545-5552 (2007)	Nested case-control study in 3 prospective cohorts in which blood samples previously had been collected.	Cohort 1 (Janus): 190 cases and 190 controls. Cohort 2 (CLUE 1): 74 cases and 147 controls. Cohort 3 (Nurses' Health): 30 cases and 78 controls.	Adjusted ORs for p,p'-DDE in highest quartile of exposure = 1.4 (0.7-2.9) in Janus cohort and 1.5 (0.7-3.2) in CLUE 1 cohort. Adjusted ORs for p,p'-DDE in highest quartiles = 4.3 (1.2-15.0) in Janus 2-16 years of follow-up group and 2.1 (0.7-6.3) in CLUE 1 0-12 year follow-up. Adjusted ORs for p,p'-DDE in highest quartiles = 0.8 (0.3-2.0) in Janus 17-25 year follow-up and 1.1 (0.3-3.4) in CLUE 1 13-19 year follow-up groups. In analyses adjusted for total PCBs, the ORs for p,p'-DDE in highest quartiles of exposure were 3.4 (0.9-12.7) for Janus and 0.9 (0.2-3.4) in CLUE 1 for "short" follow-ups and 0.7 (0.3-2.1) in Janus and 0.9 (0.3-3.0) in CLUE 1 for "long" follow-ups. Similar analysis for the Nurses' study in terms of the highest tertile yielded	N.S. (Analysis for only 1 of hundreds of strata was statistically significant but became N.S. when adjustment was made for both individual and all PCBs.)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
				an OR = 1.4 (0.4-4.6).	
4.	Hardell, L., et al., Exposure to Phenoxyacetic Acids, Chlorophenols, or Organic Solvents in Relation to Histopathology, Stage and Anatomical Location of Non-Hodgkin's Lymphoma, Cancer Res. 54:2386-89 (1994)	Combination of self-administered and interviewer administered, telephone questionnaires.	105 cases and 335 controls. (Cases from a single hospital and controls from population-based registries.)	Unadjusted OR = 2.4 (1.2-4.9). Adjusted for other chemicals OR = 1.5 (0.6-3.6), based on 17 exposed cases and 26 exposed controls.	N.S.
5.	Hardell, L., et al., Exposure to Pesticides as Risk Factors for Non-Hodgkin's Lymphoma and Hairy Cell Leukemia: Pooled Analysis of Two Swedish Case-Control Studies, Leuk. Lymph. 43:1043-49 (2002)	Data from two previous case-control studies. Includes data on NHL and hairy cell leukemia. Mailed, self-administered questionnaires.	515 cases and 1,141 controls.	Univariate analysis: OR = 1.27 (0.92-1.73), based on 77 cases and 138 controls with DDT exposure. "In the multivariate analysis no risk was found."	N.S.
6.	McDuffie, H., et al., Non-Hodgkin's Lymphoma and Specific Pesticide Exposures in Men: Cross-Canada Study of Pesticides and Health, Cancer Epidemiol. Biomarkers Prev. 10:1155-63 (2001)	Multi-center study. Information from mailed questionnaires followed by telephone interview.	517 cases and 1,506 community controls.	Unadjusted OR = 1.63 (1.03-2.57), based on 32 exposed cases and 59 exposed controls. DDT was "found not to contribute significantly to the risk of NHL" in multivariate analyses.	N.S.
7.	Persson, B., et al., Some Occupational Exposures as Risk Factors for Malignant Lymphomas, Cancer 72: 1773-78 (1993)	Exposure data from mailed, self-administered questionnaires.	93 cases and 204 controls. (Cases from a regional cancer registry and controls from another study.)	Crude OR = 3.0 (no CI provided) Adjusted OR = 2.0 (90% CI = 0.3-13), based on 4 exposed cases and 3 exposed controls.	N.S.
8.	Rothman, N., et al., A Nested Case-Control Study of Non-Hodgkin Lymphoma and Serum Organochlorine Residues, Lancet 350:240-44 (1997)	Nested case-control study using pre-diagnostic serum samples from a prospective cohort study.	74 cases and 147 matched-controls.	The OR for DDT in the highest quartile level vs. the lowest was 1.9 (0.8-4.5). In an analysis adjusted for PCBs, the OR for this analysis was reduced to 1.2 (0.5-3.0).	N.S.

Case–Control Studies Performing Univariate Analyses Only (21 Studies)

1. Case–Control Studies of DDT and NHL Without Biologic Specimens (12 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Cantor, K., et al., Pesticides and Other Agricultural Risk Factors for Non-Hodgkin's Lymphoma Among Men in Iowa and Minnesota, Cancer Res. 52:2447-55 (1992)	Population-based case-control study. Interviewer administered questionnaires.	622 white male cases and 1,245 matched community controls.	The study's findings regarding DDT included: • The OR for having ever handled DDT as an animal insecticide was 1.2 (95% CI = 0.9-1.7). • The OR for having handled DDT as an animal insecticide prior to 1965 was 1.3 (0.9-1.8). • The OR for having ever handled DDT as a crop insecticide was 1.7 (1.2-2.6). • The OR for having ever handled DDT as a crop insecticide prior to 1965 was 1.8 (1.1-2.7). • The OR for having ever handled DDT as an animal insecticide with protective equipment was 1.2 (0.9-1.7). • The OR for having ever handled DDT as an animal insecticide without protective equipment was 1.3 (0.9-1.8). • The OR for having ever handled DDT as a crop insecticide with protective equipment was 1.7 (1.2-2.6). • The OR for having ever handled DDT as a crop insecticide without protective equipment was 2.0 (1.3-3.1). • The OR for Iowa subjects who ever used DDT prior to 1965 as an animal insecticide was 0.9 (0.5-1.5). • The OR for Minnesota subjects who ever used DDT prior to 1965 as an animal insecticide was 1.7 (1.1-2.7). • The OR for Iowa subjects who ever used DDT prior to 1965 as a crop insecticide was 1.5 (0.9-2.6).	Some findings statistically significant; some N.S.

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
				• The OR for Minnesota subjects who ever used DDT prior to 1965 as a crop insecticide was 2.3 (1.1-4.8). • When analyses were stratified by state, the DDT results were not statistically significant for Iowa subjects and were statistically significant for Minnesota subjects. In summary, ORs ranged from 0.9 (0.5-1.5) to 2.3 (1.1-4.8) based on numerous subset analyses.	
2.	Cantor, K., et al., Letter to the Editor: Correspondence Re: K. P. Cantor, et al., Pesticides and Other Agricultural Risk Factors for Non-Hodgkin's Lymphoma Among Men in Iowa and Minnesota, Cancer Res. 53:2421 (1993)	Population-based case-control study. Interviewer administered questionnaires. Addendum to Cantor, et al., 1992.	110 white male cases and 211 matched community controls, a subset of subjects from the prior Cantor, et al., 1992 paper.	• The ORs for DDT use as a crop insecticide were 1.2 (0.5-2.8) for 1-4 days per year of use; 1.6 (0.4-5.6) for 5-9 days per year of use; and 1.7 (0.6-4.8) for 10+ days per year of use. • The ORs for DDT as an animal insecticide were 0.3 (0.1-0.8) for 1-4 days per year of use; 0.5 (0.1-1.8) for 5-9 days per year of use; and 0.9 (0.4-2.0) for 10+ days per year of use.	Statistically significant protective effect for 1 stratum. The other analyses were N.S.
3.	Colt, J., et al., Organochlorines in Carpet Dust and Non-Hodgkin's Lymphoma, Epidemiology 16:516-525 (2005)	Population-based case-control study using data from SEER Program. Exposure data from analysis of carpet dust.	603 cases and 443 frequency-matched controls who could provide vacuum cleaner dust samples.	The OR for DDE in dust samples was 1.6 (1.1-2.2) for the highest vs. lowest tertile and the p-value for trend was 0.02. The reported association was stronger in men (OR = 1.6, 1.1-2.3) than in women (OR = 1.1, 0.7-1.5). The OR for DDT in dust samples was 1.2 (0.8-1.6) for the highest vs. lowest tertile. A trend test for DDT yielded a p-value of 0.09.	N.S. for all DDT tertiles. Statistically significant result for highest DDE dust tertile only.
4.	Eriksson, M., et al., Pesticide Exposure as Risk Factor for Non-Hodgkin Lymphoma Including Histopathological Subgroup Analysis, Int. J. Cancer, 123:1657-1663 (2008)	Population-based case-control study. Self-administered mailed questionnaires supplemented by telephone interviews.	910 cases from university hospitals and 1062 controls from a national population registry.	OR for DDT = 1.46 (0.94-2.28) based on 50 exposed cases and 37 exposed controls. Subjects were subdivided into two exposure categories, ≤37 days (OR = 1.17, 0.62-2.22) and >37 days (OR = 1.76, 0.97-3.20). The authors also found an OR of 2.14 (1.05-4.40) for DDT and follicular, grade I-III NHL, based on 165 such cases.	Overall OR for DDT, N.S. Significant for only one of several subgroup analyses.
5.	Hardell, L., Eriksson, M., A Case-Control Study of Non-Hodgkin Lymphoma and Exposure to Pesticides, Cancer, 85:1353-60 (1999)	Population-based case-control study. Self-administered mailed	404 cases from a regional cancer registry and 741 controls from a national population registry.	OR for DDT = 1.1 (0.7-1.7), based on 66 exposed cases and 107 exposed controls.	N.S.

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
		questionnaires supplemented by telephone interviews.			
6.	Lee, W.J., et al., Non-Hodgkin's Lymphoma Among Asthmatics Exposed to Pesticides, Int. J. Cancer 111:298-302 (2004)	Pooled, population-based case-control study. Interviewer administered questionnaires.	872 cases and 2,381 frequency-matched controls from the Cantor, et al., 1992 study and another study by Zahm, et al., in 1990.	The ORs for DDT in non-asthmatics was 1.2 (0.9-1.5), based on 158 exposed cases and 313 exposed controls, and 1.2 (0.6-2.4) in asthmatics, based on 11 cases and 24 controls.	N.S.
7.	Persson, B., et al., Malignant Lymphomas and Occupational Exposures, Brit. J. Indus. Med. 46:516-20 (1989)	Hospital-based case-control study with population-based controls from another case-control study. Exposure levels imputed from self-administered questionnaires.	106 cases and 275 controls.	OR for DDT = 0, based on 0 exposed cases and 3 exposed controls.	--
8.	Persson, B. and Fredrikson, M., Some Risk Factors for Non-Hodgkin's Lymphoma, Int. J. Occup. Med. Environ. Health 12:135-142 (1999)	Population-based case-control study using data from 2 other studies (Persson, et al., 1989; Persson, et al., 1993).	199 cases and 479 community controls.	The OR for DDT was 1.4 (0.3-5.9), based on 4 exposed cases and 6 exposed controls.	N.S.
9.	Schroeder, J., et al., Agricultural Risk Factors for t(14;18) Subtypes of Non-Hodgkin's Lymphoma, Epidemiology 12:701-9 (2001)	Population-based case-control study using data from Cantor, et al., 1992.	182 cases studied for t(14;18) translocations and 1,245 controls.	The OR for DDT and t(14;18) positive cases vs. controls was 1.1 (0.6-1.9), based on 13 exposed positive cases and 216 exposed controls. The OR for DDT and t(14;18) negative cases vs. controls was 1.2 (0.8-1.7), based on 22 exposed negative cases and 216 exposed controls. The OR for t(14;18) positive cases vs. negative cases was 0.9 (0.4-1.9).	N.S.
10.	Woods, J., et al., Soft Tissue Sarcoma and Non-Hodgkin's Lymphoma in Relation to Phenoxyherbicide and Chlorinated Phenol Exposure in Western Washington, J. Natl. Cancer Inst. 78:899-910 (1987)	Population-based case-control study. Interviewer administered questionnaires.	576 cases from a population-based tumor registry and 694 community controls selected by random-digit telephone dialing.	OR for DDT = 1.82 (1.04-3.2), based on an overall 4.0% exposure in the study population.	Statistically significant.
11.	Woods, J., et al., Non-Hodgkin's Lymphoma Among Phenoxy Herbicide-Exposed Farm Workers in Western Washington State, Chemosphere 18:401-406 (1989)	Population-based case-control study. A subset of same subjects from Woods, et al., 1987 study who had	181 cases and 196 controls.	OR for DDT = 1.68 (0.9-3.3).	N.S.

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
		ever been farmers. Interviewer administered questionnaires.			
12.	Zahm, S., et al., The Role of Agricultural Pesticide Use in the Development of Non-Hodgkin's Lymphoma in Women, Arch. Environ. Health 48:353-58 (1993)	Population-based case-control study. Interviewer-administered telephone questionnaires.	119 female cases and 471 frequency-matched controls.	The OR for DDT was 1.7 based on 16 exposed cases and 36 controls. No confidence interval was provided, but the paper states that the results were non-significant.	N.S.

2. Case–Control Studies of DDT and NHL/Chronic Lymphocytic Leukemia (2 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Miligi, L., et al., Non-Hodgkin's Lymphoma, Leukemia, and Exposures in Agriculture: Results from the Italian Multicenter Case-Control Study, Am. J. Industrial Med. 44:627-636 (2003)	Population-based case-control study. Data collected by personal interviews.	1,145 combined NHL and CLL cases and 1,232 randomly sampled general population controls.	An OR of 0.6 (0.3-1.1) was found for DDT in men based on 21 exposed NHL and CLL cases. An OR of 0.3 (0.1-0.8) was found in women based on 5 exposed NHL and CLL cases.	Statistically significant protective effect in women. N.S. in men.
2.	Nanni, O., et al., Chronic Lymphocytic Leukaemias and Non-Hodgkin's Lymphomas by Histological Type in Farming-Animal Breeding Workers: A Population Case-Control Study Based on A Priori Exposure Matrices, Occup. Environ. Med. 53:652-57 (1996)	Population-based case-control study of CLL and NHL. Data from interviews and a priori exposure matrices.	187 combined NHL and CLL cases and 977 matched population controls.	The OR for DDT and combined NHL and CLL was 1.74 (0.93-3.27), based on subjects' recall of exposure (recall by 27 cases and 61 controls). The OR for DDT and combined NHL and CLL was 1.70 (0.91-3.17), based on job matrix estimation of exposure (28 cases and 65 controls exposed). The ORs for CLL and low grade NHL were 2.33 (0.93-5.85) in a recall analysis and 2.16 (0.86-5.43) in the job matrix analysis of subjects with exposures via farming-animal breeding. When cumulative dose was compared in CLL and low grade NHL cases and controls, an OR of 1.22 (0.95-1.57) was found.	N.S.

3. Case-Control Studies of DDT Levels in Biologic Specimens and NHL (7 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Cocco, P., et al., Plasma polychlorobiphenyl and organochlorine pesticide level and risk of major lymphoma subtypes, Occup. Environ. Med. 65:132-140 (2008)	Case-control study of plasma levels for six DDT isomers. Blood samples obtained pre-treatment for a subset of cases. Information on potentially confounding covariates based on "personal interviews."	174 NHL cases from the Epilymph study (France, Germany, and Spain) and 203 controls. Methods for selection of cases and controls are not specified.	OR for highest quartile of serum p,p'-DDE (≥ 1431.08 ppb) = 1.2 (0.7-2.4). For diffuse large B-cell lymphoma, the OR for the highest quartile of serum levels = 1.3 (0.5-3.6); for CLL/SLL the corresponding OR was 1.0 (0.4-2.5).	N.S.
2.	De Roos, A., et al., Persistent Organochlorine Chemicals in Plasma and Risk of Non-Hodgkin's Lymphoma, Cancer Res. 65:11214-226 (2005)	Population-based case-control study using data from SEER Program and from another study. Analysis of plasma samples for persistent organochlorine chemicals. Blood samples obtained after diagnosis.	100 cases and 100 controls from a large N.C.I. study of 1,321 cases and 1,057 controls.	For p,p'-DDE, the OR for the highest plasma concentration quartile was 0.85 (0.37-1.94). For the second highest quartile, the OR was 0.33 (0.14-0.80). For p,p'-DDT, the OR for the highest quartile level was 1.20 (0.39-3.70). Trend tests for both these sets of analyses were non-significant. For "extreme levels of exposure" the OR for p,p'-DDT was 3.3 (0.7-15.9).	Statistically significant protective effect for the third quartile of p,p'-DDE levels. All other values N.S.
3.	Hardell, K., et al. Concentrations of Organohalogen Compounds and Titres of Antibodies to Epstein-Barr Virus Antigens and the Risk for Non-Hodgkin Lymphoma, Oncology Reports 21:1567-1576 (2009)	Population-based case-control and cross-sectional study. Subset of cases and controls from Eriksson, et al., 2008. Analysis of blood samples from a subset of subjects obtained after cases' diagnosis	100 cases and 100 controls from a subset of subjects with available blood samples.	For all NHL, there was no significant difference between cases and controls with regard to blood concentrations of p,p'-DDE (p = 0.11). For follicular lymphoma, OR = 1.2 (0.4-3.5) for p,p'-DDE. From the numerous subgroup analyses: • For follicular NHL only (n = 20): For > the median p,p'-DDE level and EA >40, OR = 1.2 (0.3-4.3). • All NHL: For > the median p,p'-DDE level and EA >40, OR = 3.3 (1.4-7.7).	N.S. for all NHL and blood concentrations of p,p'-DDE. N.S. for follicular NHL.

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
4.	Hardell, L., et al., Higher Concentrations of Specific Polychlorinated Biphenyl Congeners in Adipose Tissue from Non-Hodgkin's Lymphoma Patients Compared with Controls Without a Malignant Disease, Int. J. Oncol. 9:603-608 (1996)	Case-control study of adipose tissue.	28 cases and 17 surgical controls.	The mean concentration of p,p'-DDE in adipose tissue was 1,420 for NHL and 1,068 for controls (p = 0.29).	N.S.
5.	Hardell, L., et al., Case-Control Study on Concentrations of Organohalogen Compounds and Titers of Antibodies to Epstein-Barr Virus Antigens in the Etiology of Non-Hodgkin Lymphoma, Leuk. Lymph. 42:619-29 (2001)	Case-control study of adipose tissue and blood samples. (Includes subjects from Hardell, et al., 1996 study.)	50 cases and 47 surgical controls for the adipose tissue portion of the study. 32 cases and 36 controls for the blood sample portion of the study.	For p,p-DDE, an OR of 1.2 (0.60-2.5) was found based on 44 cases and 41 controls. In multivariate analysis of organohalogen compounds, the OR for p,p-DDE was unchanged (OR = 1.2, 0.44-3.5). Case control analyses of p,p-DDE in relationship to EBV antibody titers yielded ORs of 2.0 to 2.9 with none of the values statistically significant.	N.S.
6.	Quintana, P., et al., Adipose Tissue Levels of Organochlorine Pesticides and Polychlorinated Biphenyls and Risk of Non-Hodgkin's Lymphoma, Environ. Health Perspect. 112:854-61 (2004)	Nested case control study using adipose samples from cadavers (> 96%) and surgical patients collected previously by the EPA.	175 cases and 481 controls selected from 2 groups: subjects with accidental injury or death and subjects with myocardial infarction.	For p,p'-DDT, the OR for the highest vs. lowest quartile was 1.39 (0.78-2.47). A trend test for these strata was statistically significant (p = 0.04). For p,p'-DDE, the OR was 1.99 (1.14-3.47) for the highest vs. lowest quartiles. A trend test for these strata was statistically significant (p = 0.002). In an analysis that used "two-pesticide models," when joint exposure to other pesticides was considered, the ORs for the highest vs. lowest quartiles of p,p'-DDE were lower and no longer statistically significant.	N.S. for DDT and DDE.
7.	Spinelli, J., et al., Organochlorines and risk of non-Hodgkin lymphoma, Int. J. Cancer 121:2767-2775 (2007)	Subset of participants in a larger NHL case-control study. Self-administered questionnaires and CATI. Blood samples obtained from cases (after diagnosis) and controls.	422 cases and 460 community controls.	For "p',p'-DDT," the OR for the quartile level > 3.24 ng/g versus no level was 0.91 (0.68-1.20). For p,p'-DDE, the OR for the highest vs. lowest quartile was 1.42 (0.92-2.19). A trend test for the quartiles of DDE levels yielded a p-value of 0.027, yet there was no statistically significant finding for any of the quartiles. For follicular lymphoma, the ORs were 0.7 (0.5-1.1) for p,p'-DDT and 1.8 (0.9-3.3) for p,p'-DDE.	N.S.

Cohort Studies of DDT and NHL (7 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Brown, D., Mortality of Workers Employed at Organochlorine Pesticide Manufacturing Plants – An Update, Scand. J. Work Environ. Health 18:155-61 (1992)	An update of the Ditraglia, et al., 1981 study, of workers at 4 organochlorine pesticide manufacturing plants.	328 exposed workers at Plant 4 with 9,797 person-years of observation.	The SMR for all malignant neoplasms among Plant 4 workers was 0.87 (0.52-1.39). There were no deaths from lymphatic/hematopoietic neoplasms in Plant 4 workers.	N.S.
2.	Cocco, P., et al., Cancer Mortality among Men Occupationally Exposed to Dichlorodiphenyltrichloroethane, Cancer Res. 65: 9588-94 (2005)	A mortality follow-up study of deaths among men who used mainly DDT in an anti-malarial campaign in Italy during the 1940s. (A follow-up of subjects from the Cocco, et al., 1997a and 1997b studies.)	4,552 male workers exposed to DDT. Of these, 2,726 died and had death certificate information available.	For the total cohort, the SMR for lymphatic cancer was 115 (87-151). For the applicator group, the lymphatic cancer SMR was 101 (65-157). For unexposed workers, the SMR for lymphatic cancers was 174 (112-271).	N.S. for applicators. Statistically significant excess in lymphatic cancer mortality for unexposed workers.
3.	Cocco, P., et al., Long-term Health Effects of Occupational Exposure to DDT; A Preliminary Report, Ann. N.Y. Acad. Sci. 837:246-56 (1997b)	A proportional mortality study of deaths among men who used mainly DDT in an anti-malarial campaign in Italy during the 1940s. (Uses the same data from the Cocco, et al., 1997a study.)	1,043 deaths between 1956 and 1992.	PMR = 81 (9-294) for NHL in the DDT exposed group, based on two NHL deaths. For all cancers of the lymphohemopoietic system, there were SMRs of 136 (36-347) for those exposed for less than 75 days and 146 (39-375) for those exposed for 150 days or more. (These results are identical to the Cocco, et al., 1997a paper.)	N.S.
4.	Cocco, P., et al., Proportional Mortality of Dichloro-Diphenyl-Trichloroethane (DDT) Workers: A Preliminary Report, Arch. Environ. Health 52:299-303 (1997a)	A proportional mortality study of deaths among men who used mainly DDT in an anti-malarial campaign in Italy during the 1940s.	1,043 deaths between 1956 and 1992.	PMR = 81 (9-294) for NHL in the DDT exposed group, based on two NHL deaths. For all cancers of the lymphohemopoietic system, there were SMRs of 136 (36-347) for those exposed for less than 75 days and 146 (39-375) for those exposed for 150 days or more.	N.S.

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
5.	Ditraglia, D., et al., Mortality Study of Workers Employed at Organochlorine Pesticide Manufacturing Plants, Scand. J. Work Environ. Health 7:140-46 (1981)	Workers at 4 organochlorine pesticide manufacturing plants. Only 1 of the plants produced DDT (Plant 4), and this plant produced only DDT.	Approximately 2,100 men who worked at manufacturing plants for at least 6 months prior to December 31, 1964.	For workers at Plant 4, mortality for all malignant neoplasms, based on 6 observed deaths, yielded an SMR of 68 (25-247). There were no observed deaths from lymphatic and hematopoietic system cancers in workers at Plant 4. In workers employed for 20 or more years at Plant 4, the SMR for deaths due to malignant neoplasms was 132 (43-309), based on 5 observed deaths.	N.S.
6.	Laws, E., et al., Men With Intensive Occupational Exposure to DDT, Arch. Environ. Health 15:766-775 (1967)	Volunteers from a DDT-manufacturing facility (a study of workers from Montrose Chemical Corporation of California by the U.S. Public Health Service).	35 men with more than 5 years of occupational exposure to DDT.	No cases of cancer or blood dyscrasia in the 35 men studied and in the 63 men at the plant with more than 5 years of DDT exposure (data obtained from medical record review).	N.S.
7.	Purdue, M., et al., Occupational Exposure to Organochlorine Insecticides and Cancer Incidence in the Agricultural Health Study, Int. J. Cancer 120:642-649 (2006)	A prospective cohort study of licensed applicators enrolled in the Agricultural Health Studies (in Iowa and North Carolina). Initial data from self-administered questionnaires.	A sample of 22,409 workers from the total of 51,011 male AHS applicators.	For NHL, a RR of 0.9 (0.6-1.5) was found for DDT based on 37 NHLs in 12,305 exposed workers.	N.S.

Ecologic Studies of DDT and NHL (2 Studies)

	Document Description	Source of Data	Number of Subjects	Findings	Statistical Significance
1.	Cocco, P., et al., Cancer Mortality and Environmental Exposure to DDE in the United States, Environ. Health Perspect. 108:1-4 (2000)	Adipose tissue DDE levels in 1968 in population samples from 22 U.S. states and mortality rates from 1975-1994. Data on DDE tissue concentrations were obtained from an EPA report in 1968.	No information is provided on the number of tissue samples or on the number of malignancies observed.	The data are difficult to interpret. The authors state that their study showed no evidence of a consistently significant increase in mortality with increasing adipose DDE levels. They further state that mortality from NHL was inversely related to DDE levels in 3 of the 4 study groups.	NA.
2.	Pavuk, M., et al., Environmental Exposure to PCBs and Cancer Incidence in Eastern Slovakia, Chemosphere 54:1509-1520 (2004)	Population-based cross-sectional study of serum levels of pesticides in 2 districts in Slovakia. An ecologic study was performed to compare cancer incidence in the same 2 districts. One of the 2 districts produced PCBs.	225 subjects in one district and 207 subjects in the second district.	In the PCB-producing district, levels of p,p'-DDT in males and females were significantly different from the second district ($p = 0.003$ for males and females). For p,p'-DDE, levels in the PCB- producing district were also significantly higher for both men and women ($p = 0.05$ for men and $p = 0.001$ for women). In the ecologic study of cancer incidence, the SIR for NHL in males was 1.12 (0.80-1.52) in the PCB-producing district and 1.11 (0.62-1.84) in the second district. The SIR for NHL in females was 1.04 (0.70-1.49) in the PCB-producing district and 0.56 (0.22-1.28) in the second non-PCB-producing district.	N. S. for NHL results.

ATTACHMENT 2

I. DETAILED ANALYSES OF CASE-CONTROL STUDIES PERFORMING MULTIVARIATE ANALYSES

(1) Baris D, Zahm SH, Cantor KP, Blair A. Agricultural use of DDT and risk of non-Hodgkin's lymphoma: pooled analysis of three case-control studies in the United States, 1998. This is a pooled study of three population-based case-control studies of NHL in four mid-western states, including the study reported by Cantor, et al., 1992 and discussed below. As stated by the authors, the "main motivation for the pooled analysis was to conduct a more detailed analysis than was possible for individual studies, and to adjust ORs for possible confounding effects from exposure to other pesticides."

The study involves subjects from four states with a relatively high proportion of farmers. The pooled subjects constituted 993 NHL cases and 2,918 controls that were interviewed to obtain information on agricultural pesticides and other risk factors. An OR of 1.2 (1.0-1.6) for any use of DDT was found, based on 161 cases and 340 controls who were exposed. Farmers who had used DDT for 15 years or more had an OR of 1.5 (1.0-2.3). Farmers who had used DDT for 5 days/year or more had an OR of 2.6 (1.1-5.9). These were the results, out of many, that the authors chose to include in the paper's abstract.

When these analyses were adjusted for use of other pesticides and herbicides, the odds ratios were all closer to 1.0 (ranging from 0.3 to 1.9) and none was statistically significant. In Table 5, the authors present the findings of analyses that adjust for the following: 1.) use of other groups of pesticides; 2.) other individual pesticides; and 3.) organophospates and 2,4-D simultaneously. The analyses were performed by duration and frequency of DDT use as well as in terms of ever/never use. Table 6 in this paper presents odds ratios for use of DDT stratified by use of 2,4-D and organophosphates. This adjustment procedure, combined with stratification by

duration and frequency of DDT use, yielded odds ratios ranging from 0.0 to 2.9. Of the 36 analyses reported, 3 were statistically significant and 3 were of borderline significance (i.e., CI lower bound was 1.0.). Interestingly, the highest observed OR (2.9) was for the stratum of farmers who used DDT for 5-9 years and never used 2,4-D or organophosphates. This is likely to be a chance observation for two reasons. First, the results in this table generally show higher risks for combined use of DDT and 2,4-D or organophosphates than for DDT alone. Second, this OR of 2.9 was found for use of DDT for 5-9 years, but the OR for use of DDT for ≥10 years was lower at 1.0. The fact that this value was an outlier was recognized by the authors; however, the authors' discussion of it suggests an apparent error in Table 6 or in the discussion. The authors state on page 526 that the finding of an OR of 2.9 was for those farmers who used DDT for ≥10 years and never used 2,4-D or organophosphates. This does not jibe with the data presented in Table 6.

To summarize, this study shows clearly that there are no associations between DDT exposure and risk of NHL when other chemical exposures can be controlled for in multivariate analyses. This study suggests that previous observations of associations between DDT and NHL likely were confounded by exposures of study subjects to other chemicals. The authors are in agreement with my assessment and state: "No strong consistent evidence was found for an association between exposure to DDT and risk of non-Hodgkin's lymphoma." It seems that the excess risk initially found may be explained by other confounding variables. Furthermore, this study is important because, as the authors state in their conclusion, "[t]he relatively large number of exposed cases and controls in this pooled analysis provided analytic opportunities which were not available in individual studies." Such analytic opportunities particularly allow for proper

statistical evaluation of confounding. As this study and the next demonstrate, the effects of confounding by other chemicals are substantial when such analyses are possible.

(2) De Roos AJ, Zahm SH, Cantor KP, et al. Integrative assessment of multiple pesticides as risk factors for non-Hodgkin's lymphoma among men, 2003. This is a pooled study of data from three NCI-conducted, case-control studies of NHL in the Midwestern U.S. done in the 1980s, which includes data from the earlier Cantor, et al., 1992 study. These are the same three studies analyzed in the previously discussed Baris, et al., 1998 paper. Using newer, highly sophisticated statistical methodology, De Roos, et al., used the data again to assess pesticide exposures in farming as NHL risk factors and shed new light on the subject.

A total of 870 cases and 2,569 controls were studied. For the analyses of multiple pesticides, 650 cases and 1,933 controls were studied. The very large sample size allowed for the analysis of 47 pesticides simultaneously, controlling for potential confounding by other pesticides. Adjustment also was made based on a pre-specified variance to make estimates more stable. After adjusting for exposures to all other pesticides, the OR for DDT exposure was 1.0 (0.7-1.3) using logistic regression. When hierarchical regression (the method based on pre-specified variances) was used, the OR for DDT was also 1.0 (0.7-1.3). These results were based on 98 DDT-exposed cases and 226 DDT-exposed controls.

This is an important study for several reasons. First, the pooled studies provided large numbers of subjects so that there was adequate statistical power for simultaneous consideration of a large number of pesticides as risk factors for NHL. Second, sophisticated biostatistical methods were employed to carefully assess confounding by multiple chemical exposures. Third, they clearly showed that the ORs for DDT and NHL risk were 1.0 when other confounding

chemical exposures were controlled in the analyses. Thus, it appears that all of the previously noted weak associations with agricultural pesticides were confounded by other exposures.

This is yet another example of a study that was able to assess associations of NHL with DDT and other agricultural chemicals such as herbicides and other pesticides in a multivariate manner. As was found in other such adequately sized multivariate analyses of herbicides and pesticides, there was little or no association between DDT and NHL when other chemical exposures were adjusted for in the analyses.

In conclusion, control of confounding exposures is essential for proper assessment of whether DDT is associated with NHL, particularly when weak associations are observed. My opinion is supported by De Roos, et al., who conclude that, "[c]onsideration of multiple exposures is important in accurately estimating specific effects and in evaluating realistic scenarios." Thus, as newer statistical methods have been developed, they have been applied to the NCI multi-site case-control study data by successive investigators. The newer statistical approaches used by De Roos, et al., effectively have controlled for potential confounders and demonstrate that DDT exposure is not associated with NHL risk.

(3) Engel L, Laden F, Anderson A, et al. Polychlorinated Biphenyl Levels in Peripheral Blood and Non-Hodgkin's Lymphoma: A Report from Three Cohorts, 2007. This is a nested case-control study in 3 prospective cohorts in which blood samples previously had been collected. The first cohort was the Janus cohort that included 87,600 Norwegian men and women who provided blood samples between 1972 and 1978. The second cohort was the CLUE 1 cohort that included 23,938 residents of Washington County, MD. Blood samples for this cohort were provided in 1974. The third cohort was the Nurses' Health Study that included 121,700 female registered nurses. Blood samples for 32,826 nurses were provided between 1989

and 1990. Cancer diagnoses for the first two cohorts were ascertained by cancer registries. Cancer diagnoses in the Nurses' cohort was by self-report on a biennial follow-up questionnaire.

Cases for the nested case-control study had a confirmed NHL diagnosis. Controls were individually matched to cases and were cohort members without cancer diagnoses. The Janus cohort provided 190 cases and 190 controls. The CLUE 1 cohort provided 74 cases and 147 controls. The Nurses' Health Study provided 30 cases and 78 controls.

The adjusted ORs for p,p'-DDE in the highest quartile of exposure were 1.4 (0.7-2.9) in the Janus cohort and 1.5 (0.7-3.2) in the CLUE 1 cohort. The adjusted ORs for p,p'-DDE in the highest quartiles were 4.3 (1.2-15.0) in Janus 2-16 years of follow-up group and 2.1 (0.7-6.3) in CLUE 1 0-12 year follow-up. The adjusted ORs for p,p'-DDE in the highest quartiles were 0.8 (0.3-2.0) in Janus 17-25 year follow-up and 1.1 (0.3-3.4) in CLUE 1 13-19 year follow-up groups.

In analyses adjusted for total PCBs, the ORs for p,p'-DDE were 1.2 (0.6-2.7) and 0.9 (0.4-2.1) for the highest quartiles in the Janus and CLUE 1 cohorts, respectively (Supp. Table 10). Similar analysis for the Nurses' study in terms of the highest tertile yielded an OR of 1.4 (0.4-4.6) (Supp. Table 10). In analyses based on time from blood draw to diagnosis and adjusted for total PCBs, the ORs for p,p'-DDE in the highest quartiles of exposure were 3.4 (0.9-12.7) and 0.9 (0.2-3.4) in Janus and CLUE 1, respectively, for "short" follow-ups and 0.7 (0.3-2.1) and 0.9 (0.3-3.0) in Janus and CLUE 1, respectively, for "long" follow-ups (Supp. Table 11). Additional values are provided in Supplementary Tables 12 and 13, but they are not adjusted for PCBs.

These data again demonstrate that initial univariate analyses of DDT metabolites and NHL typically are confounded by other exposures. The single finding of a significantly elevated

OR was attenuated and was no longer statistically significant when the confounding effect of other exposures (total PCBs) was controlled by multivariate analysis.

As the authors state: "The main *p,p'*-DDT metabolite, *p,p'*-DDE, showed a slightly increased risk of NHL across the three cohorts, which was stronger in the earlier follow-up period. However, there were no apparent exposure-response trends in most analyses, and the *p,p'*-DDE effect was attenuated more by adjustment for PCBs than vice versa. Although several epidemiologic studies have found modest increases in NHL risk related to measured or self-reported *p,p'*-DDT/*p,p'*-DDE exposure (20-24), this effect has tended to decrease substantially in those studies in which adjustment was made for other chemical exposures (21, 25)."

This conclusion by the authors is in complete agreement with my opinions regarding the need for performing multivariate analyses of data of DDT and DDE to rule out the confounding effects of other chemical exposures. In the Engel, et al., 2007 study, the only statistically significant finding from multiple analyses was no longer significant when other confounding exposures were controlled for in multivariate analyses.

In summary, this very large, pooled, nested case-controlled study showed no significant associations between NHL risk and p,p'-DDE in blood samples collected well in advance of NHL diagnosis. This study again illustrates the importance of multivariate analyses for assessing DDT and NHL.

(4) Hardell L, Eriksson M, Degerman A. Exposure to phenoxacetic acids, chlorophenols, or organic solvents in relation to histopathology, stage and anatomical localization of non-Hodgkin's lymphoma, 1994. This is a reanalysis of an earlier reported case-control study of NHL and Hodgkin lymphoma in Sweden conducted by the same group of investigators. The study is based on 105 NHL cases from a single Swedish hospital and 335

matched controls selected from population-based registries. Exposure information was obtained by a combination of self-administered questionnaires and interviewer administered questions. This paper reports an unadjusted OR for DDT and NHL of 2.4 (95% CI = 1.2-4.9). However, when multivariate analysis controlling for other chemicals was done, the OR for DDT dropped impressively to 1.5 (0.6-3.6).

This paper focused primarily on phenoxyherbicides and organic solvents. This study demonstrates well that when initial associations are observed between DDT and NHL, they usually are confounded by other chemical exposures. In this case, an OR of 2.4 that was statistically significant was reduced to 1.5 and was no longer statistically significant when other chemical exposures were adjusted for in the analyses.

In summary, this paper shows no evidence of a clear association between NHL and DDT exposure. Although the authors provide brief details of the methods used for analyses and pay little attention to DDT exposure, they did employ multivariate analyses to control for potential confounding "between exposures of interest." As in other studies that assessed the association between NHL and DDT exposure, they found that an initially elevated odds ratio that was statistically significant was lowered remarkably by controlling for confounding by other chemicals and was no longer significant. The consistency of the demonstration of confounding, when it is possible, of initially observed DDT-NHL associations by other chemical exposures is remarkable.

(5) Persson B, Fredriksson M, Olsen K, et al. Some occupational exposures as risk factors for malignant lymphomas, 1993. This is a report of a case-control study of 93 cases of NHL (and 31 cases of Hodgkin lymphoma) obtained from a regional cancer registry in Sweden and 204 community referents. The same referents were from a series of three other studies by

Flodin, et al., which makes this and the other studies overlapping and not independent. They found 4 cases and 3 controls with exposure to DDT for a crude OR of 3.0 and a logistic (adjusted) OR of 2.0 (90% CI = 0.3-13). The adjustment criteria are poorly defined only in a table footnote.

Note that the authors used a 90% CI rather than the conventional 95% CI. A 90% CI is less stringent for assessing statistical significance than a 95% CI and still the DDT results were far from significant and the interval was extremely broad. Most studies finding fewer than 5 exposed cases would not even try to estimate risk or statistical significance, let alone attempt to do meaningful multivariate analyses. Thus, the major problem with this study was that it was too small to properly assess associations with uncommon exposures such as DDT. Although the authors were less stringent than usual by employing 90% CIs rather than 95% CIs, they still did not find a statistically significant association between DDT and NHL.

(6) Hardell L, Eriksson M, Nordstrom M. Exposure to pesticides as risk factors for non-Hodgkin's lymphoma and hairy cell leukemia: Pooled analysis of two Swedish case-control studies, 2002. This is another study from Sweden that uses data from previous studies for re-analyses in an attempt to "enlarge the study size thereby allowing more precise risk estimates." Results are presented in the paper for the combined group of NHL and hairy cell leukemia cases. Subjects were 515 cases and 1141 controls, with 77 cases and 138 controls reporting DDT exposures. Exposure information was obtained via mailed, self-administered questionnaires supplemented by telephone queries if the data were "unclear." They found an OR of 1.27 (95% CI = 0.92-1.73) for DDT using univariate analysis. When latency from first exposure to diagnosis was considered, the OR for the >10-20 year latency period was higher than that for the longest (>30 year) latency period, although none of the ORs was statistically

significant. Specific data for the multivariate analysis of DDT is not provided, but the authors state that "[i]n the multivariate analysis no risk was found." The paper is unclear as to what variables were considered in the multivariate analyses.

This is another analysis of previous study data by this group of authors (data from the Hardell, et al., 1999 study were included in this study) to assess associations between NHL and pesticides and again only a slight, non-significant association with DDT was found. When multivariate analyses were done of DDT and NHL, "no risk was found." In conclusion, this is a reanalysis of previous studies that adds no new information on a relationship between DDT and NHL. Again, the study shows that weak associations between DDT and NHL tend to disappear when multivariate analyses are done, though in this case the nature of the multivariate analysis is not fully described.

(7) McDuffie HH, Pahwa P, McLaughlin JR, et al. Non-Hodgkin's lymphoma and specific pesticide exposures in men: Cross-Canada study of pesticides and health, 2001. This is a large, multi-center, case-control study of 517 NHL cases and 1,506 community controls. Cases were identified from Provincial cancer registries except in Quebec. Controls were identified via health insurance records, voter registration records and telephone listings. Exposure information was obtained by mailed questionnaires followed by a telephone interview for those reporting 10 hours/year or more of pesticide exposure, as well as for a 15% random sample of respondents. While the study was large, the number of DDT-exposed subjects was half that reported in a smaller case-control study reported by Hardell, et al., in 1999.

An unadjusted OR of 1.63 (1.03- 2.57) was found for DDT exposure based on 32 exposed cases and 59 exposed controls. The OR adjusted for medical variables and a family history of cancer was 1.73 (1.08-2.76). A dose-response relationship for DDT exposure was

reported. An OR of 1.75 (0.96-3.21) was found for the category of >0 and <2 days per year of DDT exposure compared to no exposure. An OR of 1.5 (0.77- 2.91) was found for the comparison of the >2 days per year group versus the never exposed group. No trend test result was reported. Curiously, in the paper's abstract, DDT is listed as one of the chemicals statistically significantly associated with NHL, but no odds ratio or confidence interval is provided as for the other chemicals listed as being associated with NHL.

However, when conditional logistic regression analyses were done on "individual chemical pesticides and important covariates" that were found to be statistically significant in univariate analyses ($p < 0.05$), DDT was included in the multivariate model and was **"found not to contribute significantly to the risk of NHL"** (Table 7). Thus, when the confounding effects of other pesticides and risk factors were considered in the analysis, DDT was not a significant risk factor for NHL. Interestingly, in Table 3, results are presented after adjustment for observed statistically significant medical variables and the OR for the association between DDT and NHL is slightly higher than the unadjusted OR. When adjustment was done for these same medical variables and for other chemical pesticide exposures together (Table 7), the results for DDT were no longer significant (no point estimate of the OR was presented for this analysis of DDT). This suggests that it was the other chemical pesticide exposures, per se, that were the underlying confounders in the previously observed DDT association.

In conclusion, this is a potentially misleading paper in terms of the authors' presentation of findings and conclusions. Although the authors suggest a statistically significantly increased NHL risk in DDT-exposed subjects, results of their multivariate analyses that control for confounding effects of other chemical exposures and non-chemical risk factors show that DDT

was "not found to contribute significantly to the risk of NHL." This finding is glossed over and not reported in the abstract or the paper's discussion section.

The study results for DDT are typical of what one would expect to find in an association that is confounded by other associations. In such situations, odds ratios are typically below 2.0, indicating a weak association. They also highlight another problem found in studies of DDT exposure and that is that people with DDT exposure often will have had multiple other chemical exposures. Unless one can tease apart the independent effects of DDT exposure, particularly in the face of observed weak associations, reported associations with DDT must be considered questionable and treated with skepticism. The authors performed analyses to assess DDT as an independent risk factor. When analyses were controlled for other pesticide exposures, no association with DDT remained. My interpretation of this paper and its analyses leads me to conclude that DDT is not a risk factor for NHL.

(8) Rothman N, Cantor KP, Blair A, et al. A nested case-control study of non-Hodgkin lymphoma and serum organochlorine residues, 1997. This paper reports result of a case-control study of 74 cases of NHL and 147 matched controls nested within the Washington County, MD, cohort study that has been conducted for many years by investigators at the Johns Hopkins University. In this present study, blood samples were collected when the subjects were first enrolled, an average of 12.1 years before diagnosis of cases' NHL. Serum levels of lipid-corrected concentrations of DDT, its metabolites and other organochlorines were determined for cases and controls. They found no significant differences in total lipid-corrected concentrations of DDT between cases and controls. Risk of NHL increased weakly and non-significantly with increasing DDT serum concentrations. The matched odds ratios by quartile of serum DDT levels ranged from 1.0 in the lowest group to 1.9 (95% CI = 0.8-4.5) in the highest group in univariate

analyses. When the DDT findings were adjusted for PCB levels, the ORs for DDT ranged from 1.0 to 1.2 (0.5-3.0) creating an almost flat trend with increasing levels.

This is an interesting and important study in that serum DDT levels were measured in cases and matched controls many years before the NHL cases were diagnosed. Thus, results were not confounded by disease-related weight loss and fat mobilization in cases. The Washington County cohort study is very well conducted and has yielded many important research findings that have stood the test of time. This study is persuasive and again demonstrates the important results of controlling analysis of DDT results for other confounding chemical exposures. It demonstrates clearly that blood levels of DDT found in the blood of healthy donors are not associated with the development of NHL in later years.

II. CASE-CONTROL STUDIES PERFORMING UNIVARIATE ANALYSES ONLY

A. Detailed Analyses of Case-Control Studies of DDT and NHL Without Biologic Specimens

(1) Hardell L and Eriksson M. A case-control study of non-Hodgkin lymphoma and exposure to pesticides, 1999. This is a study that obtained exposure data by self-administered mailed questionnaires and then was supplemented by telephone interview "if the information was unclear regarding specific exposures." Cases (N = 404) were from regional Swedish cancer registries and controls (N = 741) were from the Swedish National Population Registry. Specific data are provided for exposure to DDT and an unadjusted OR of 1.1 (0.7-1.7) was found based on 66 exposed cases and 107 exposed controls. This is a relatively large number of exposed subjects and provides a stable estimate of risk. No other analyses of DDT exposure were reported. While multivariate analyses are presented in Table 7, no data are presented for DDT since there were no striking or significant elevations of NHL risk associated with DDT in univariate analysis.

In conclusion, this study did not find any association between occupational exposure to DDT and NHL risk. An OR of 1.1 with a 95% confidence interval that includes the null value of 1.0 is a finding of no association and is not statistically significant. This finding is based on large numbers of DDT-exposed cases and controls and there is a very narrow confidence interval. This is a persuasive finding as a result. No multivariate analyses of DDT were reported, but were not necessary since no overall association was observed for DDT.

(2) Woods JS, Polissar L, Severson R, et al. Soft tissue sarcoma and non-Hodgkin's lymphoma in relation to phenoxyherbicide and chlorinated phenol exposure in Western Washington, 1987. This is a population-based case-control study of 576 NHL cases and 694 randomly selected community controls. Cases were identified from a population-based tumor registry in Western Washington State. Exposure data were collected by personal interviews. Four percent of the overall study population (cases and controls) was exposed to DDT. This translates into a total of 51 DDT-exposed total subjects which is far less than in other similarly sized studies.

The paper reports the results of several different analyses. An OR of 1.46 (0.8-2.8) was found among farmers who reported working with "the specific organochlorine insecticides DDT and chlordane." This provides no direct information on the NHL risk in farmers of exposure to DDT per se. Table 5 reports NHL risks "for potential chlorophenol exposure" in various wood working occupations and includes the manufacturing of chlorophenols (for which they found an OR of 1.72, 95% CI = 0.9-3.4, based on a 3.0% frequency of this exposure in the overall study population, which translates into 38 exposed subjects). "When all of these occupations involving potential exposure to chlorophenols were considered together," the risk of developing NHL was

0.99 (0.8-1.2). A pooled OR for specific DDT exposure among men with many occupational factors was 1.82 (1.04-3.2) based on 4.0 % exposure in the study population (Table 7).

The authors attempted to assess interactions between the various chemicals that were being assessed in the study using logistic regression analysis. Unfortunately, relatively crude analyses were done to assess interactions between phenoxyherbicides or chlorophenols and "organochlorine pesticides (DDT + chlordane)" and several other chemicals and risk factors. They report that "none of the interactions between chlorinated phenol or phenoxyherbicide exposure and these variables was statistically significant, with the exception of that between phenoxyherbicides and organic solvents as a risk factor for NHL." The authors state that the logistic regression analysis used "confirmed the magnitude of risks shown in Tables 6 and 7". No specific results of this analysis are presented. This analysis appears to have primarily assessed interactions rather than providing adjusted risk estimates for specific chemicals such as DDT.

So what does all this mean? This paper reports the results of a very large case-control study of NHL (576 male cases) with a very low number of cases and controls exposed to the chemical of interest, DDT. Based on their report of 4.0% of subjects having been exposed to DDT, only a total of 51 subjects – cases and controls – were exposed. Such small numbers are apt to result in unstable estimates of risk. Also, as a result, several analyses lump together DDT exposure with chlordane exposure. Results for the lumped category are non-significantly elevated for NHL in farmers. Risk of NHL was not elevated for the sum of the other occupational categories in Table 5. For the stratum of the occupational category of "manufacturer of chlorophenols" in Table 5, an OR for NHL of 1.72 (0.9-3.4) is found. This is an occupational group with presumed high exposure to these chemicals and yet the odds ratio is

low and not statistically significant. The only information on the specific NHL risk for DDT exposure is found in Table 7, an OR of 1.82 (1.04-3.2). While multivariate analysis to assess the possibly confounding effects of other chemical exposures were done, they were done for the lumped category of chlordane and DDT and only statistical significance was used to assess the interaction when exposed subject numbers were very small. Much more sophisticated multivariate analyses are done today than were done 20 years ago.

In summary, this is a study that was very limited in terms of the number of subjects with DDT exposure. Many analyses were done and only one sub-analysis found a statistically significant, weak association (OR less than 2.0) between DDT and risk of NHL. The more analyses that are done, the more likely the study is to find a chance association, particularly when the numbers of exposed subjects are small. Crude attempts to control for confounding of this association were made and no specific DDT information was provided in the text. Thus, it is quite likely that the weak results reported could be due to the confounding effects of other chemical exposures. As a result, the finding of a single variable showing a weak, but borderline statistically significant association between DDT exposure and NHL risk must be treated with scientific skepticism, as it is likely to be the result of confounding.

(3) Woods JS, Polissar L. Non-Hodgkin's lymphoma among phenoxy herbicide-exposed farm workers in western Washington State, 1989. This paper is a report of a case-control study of NHL conducted in Washington that was primarily focused on phenoxy herbicides and NHL risk. Subjects were NHL cases and their matched controls from the first study by Woods, et al. (1987). The paper is brief and is unclear, but appears to have only included cases and controls who were ever employed as farmers (N = 181 cases and 196 controls) as subjects. Thus, it is a subset analysis of a prior, larger study. An OR of 1.68 (95%

CI = 0.9-3.3) was found for DDT exposure and there is no indication of the number of exposed subjects on which the OR is based. There was no further elaboration on DDT beyond this OR presented in one of the tables. Curiously, in the first study by Woods et al. (1987), they report an OR of 1.46 (0.8-2.8) for the combined category of DDT and chlordane exposure (p. 902) in farmers. In the second study, they found ORs of 1.56 for NHL and chlordane and an OR of 1.68 for DDT. Both of these values are higher than the combined result.

While interactions between phenoxy herbicides and other agricultural chemicals were assessed, there was no attempt to assess confounding of the DDT finding by other agricultural exposures. Thus again, a weak association between DDT and NHL is observed with no attempt made to adjust for confounding by other exposures. In this paper, however, the weak elevation of the OR was not statistically significant.

This paper is an apparent second analysis of the first Washington study, and it is unclear as to how many of the analyses differ from those in the first study. However, this paper illustrates that the conduct of many analyses of the same data set will lead to disparate results simply on the basis of chance. In this sub-analysis of the same data set from the first study by Woods, et al., an elevated risk of NHL was found for farmers and exposure to DDT, but this finding was even weaker than the previously reported DDT association and was not statistically significant. No further attempts were made this time to assess the confounding effects of other chemical exposures even though farmers are a group with highly varied exposures to a multitude of different chemicals – ranging from pesticides and herbicides to motor fuels and fertilizers.

In summary, this new paper by Woods, et al., uses the same data set and many of the same analyses from their first paper (discussed previously). However, this time for a subset of the same NHL cases from the first study, they found a non-significant, weak elevation of NHL

risk in farmers exposed to DDT. No further attempt was made to deal with confounding of this finding by other chemical exposures. Thus, it adds little new information other than to illustrate the likely occurrence of chance and/or confounding in studies such as this and Woods, et al. (1987) where small numbers of subjects are exposed to the risk factor at issue.

(4) Persson B, Dahlwander A-M, Fredriksson M, et al. Malignant lymphomas and occupational exposures, 1989. This is a Swedish, hospital-based, case-control study of 106 NHL cases and 275 controls. The community controls were from two other case-control studies (Flodin, et al., 1987 and 1988). Exposure information was obtained by mailed questionnaires completed by the study subjects. The researchers imputed levels of exposure from the responses. Specific data on DDT exposure are presented with an OR of 0, based on no exposed NHL cases and 3 exposed controls.

It should be pointed out that this is the third study utilizing the same control group. All of these studies found exposure excesses in cases relative to the common set of controls, raising the possibility that the controls were a relatively underexposed group of subjects with regard to occupational exposures. Nevertheless, while the study is relatively small and can provide only limited information, more controls than cases had exposure to DDT with an OR of 0 for the association between DDT and NHL. Thus, the results of this study are completely negative for DDT.

(5) Cantor KP, Blair A, Everett G, et al. Pesticides and other agricultural risk factors for non-Hodgkin's lymphoma among men in Iowa and Minnesota, 1992. This is a report of a very large case-control study of NHL in two states with large populations of agricultural workers. The study was designed to assess agricultural risk factors for NHL and numerous analyses of suspected risk factors were done. In-person interviews were used to

collect exposure histories from 622 white men with NHL and 1,245 population-based controls in Iowa and Minnesota. Cases were ascertained from the Iowa State Health Registry and from a special surveillance of Minnesota hospital and pathology laboratory records from 1981-1983. Population-based controls were similarly interviewed.

The study's findings regarding DDT exposure were as follows:

- The OR for having ever handled DDT as an animal insecticide was 1.2 (95% CI = 0.9-1.7).
- The OR for having handled DDT as an animal insecticide prior to 1965 was 1.3 (0.9-1.8).
- The OR for having ever handled DDT as a crop insecticide was 1.7 (1.2-2.6),
- The OR for having ever handled DDT as a crop insecticide prior to 1965 was 1.8 (1.1-2.7).
- The OR for having ever handled DDT as an animal insecticide with protective equipment was 1.2 (0.9-1.7)
- The OR for having ever handled DDT as an animal insecticide without protective equipment was 1.3 (0.9-1.8).
- The OR for having ever handled DDT as a crop insecticide with protective equipment was 1.7 (1.2-2.6).
- The OR for having ever handled DDT as a crop insecticide without protective equipment was 2.0 (1.3-3.1).
- The OR for Iowa subjects who ever used DDT prior to 1965 as an animal insecticide was 0.9 (0.5-1.5).

- The OR for Minnesota subjects who ever used DDT prior to 1965 as an animal insecticide was 1.7 (1.1-2.7).
- The OR for Iowa subjects who ever used DDT prior to 1965 as a crop insecticide was 1.5 (0.9-2.6).
- The OR for Minnesota subjects who ever used DDT prior to 1965 as a crop insecticide was 2.3 (1.1-4.8)
- When analyses were stratified by state, the DDT results were not statistically significant for Iowa subjects and were statistically significant for Minnesota subjects.

This paper reports numerous analyses of DDT and other agricultural chemical exposures. While the observed ORs for DDT exposure were almost all greater than 1.0, only two reached the level of 2.0. Of the twelve DDT findings, six were statistically significant. Thus, numerous stratified analyses were done and all ORs were 2.3 or less and only half were statistically significant.

An important limitation of this study was its inability to control for other chemical exposures in farmers exposed to DDT. The authors themselves recognize this problem and state: "Interpretation of results regarding individual pesticides is fraught with difficulties, including the problems of interpreting risk of individual factors in the multiple exposure setting of modern agriculture as well as the chance occurrence of finding positive associations with multiple comparisons." I agree fully with the authors' statement. As later studies have found, even those using the same data set as this study, when multiple chemical exposures are controlled for in analyses, the associations between DDT and NHL are lessened, no longer statistically significant

and frequently are reduced to the null value of one. These later studies demonstrate the tremendous impact of confounding by other agricultural chemicals.

In summary, this is a large case-control study that performed a very large number of analyses of their data. Of the 12 results reported, all but one OR was above 1.0, with two above 2.0. Half of the reported ORs were statistically significantly elevated. There is no mention of how many more analyses were done that found no association and were not reported. Taken by itself, this paper suggests that there are weak, but consistent, associations between DDT exposure and NHL risk. However, this paper did not attempt to assess or control for the effects of confounding variables on the study results, a concern raised by the authors themselves. This concern is validated by the results of later more sophisticated statistical analyses of the same data (Baris, et al., 1998; De Roos, et al., 2003). These later studies found that when other chemical exposures were adjusted in multivariate analyses, DDT was no longer associated with risk of NHL. Thus, the Cantor, et al., findings do not hold up in later studies of the same data and confirm Canter, et al.'s stated suspicions that their findings were due to confounding or chance.

(6) Cantor KP, Blair A, Brown LM, et al. Letter to the Editor: Correspondence Re: K. P. Cantor, et al., Pesticides and Other Agricultural Risk Factors for Non-Hodgkin's Lymphoma Among Men in Iowa and Minnesota, Cancer Res. 52:2447-2455, 1992, (1993). This letter to the editor includes new data that supplements the data provided in Cantor, et al., 1992. After the initial interviews for the project reported in the Cantor, et al., 1992 paper, another study evaluated NHL risk in relation to the annual number of days of pesticide use. As a result, the authors conducted a supplemental interview of Iowa residents to obtain similar data. This portion of the study involved 107 cases and 203 controls from Iowa (or their next of kin). Data were collected by a supplemental telephone interview. Many subjects from the Cantor, et

al., 1992 study had died, and proxies were the respondents for 55% of cases and 28% of controls. These findings originally were included in the first Cantor, et al., 1992 manuscript, but were removed at the suggestion of journal peer reviewers.

The authors found an OR of 1.2 (0.5-2.8) for NHL and DDT use of 1-4 days per year as a crop insecticide. The OR for 5-9 days per year of DDT use was 1.6 (0.4-5.6) and for 10+ days of use per year, the OR was 1.7 (0.6-4.8). The ORs for DDT use as an animal insecticide were 0.3 (0.1-0.8) for 1-4 days per year of use; 0.5 (0.1-1.8) for 5-9 days per year of use; and 0.9 (0.4-2.0) for 10+ days per year of use. Because "time delay, different method of data collection, and participation of more proxies likely introduced substantial exposure misclassification that is likely to mask exposure-response gradients," the authors "consider these findings to be very weak evidence either for or against the possibility of a causal association with any single pesticide exposure."

I agree with the authors' conclusion that these data provide very little support for a causal association between DDT and NHL. There was a statistically significant protective association between NHL and DDT use as an animal insecticide for 1-4 days per year. Aside from this protective effect, none of the other DDT findings were statistically significant.

(7) Lee WJ, Cantor KP, Berzofsky JA, et al. Non-Hodgkin's lymphoma among asthmatics exposed to pesticides, 2004. This is a study based on two NCI, population-based case-control studies of NHL conducted in three mid-western states, Iowa, Minnesota and Nebraska. Exposure data were collected by interviews. Cases were derived from State Tumor registries and hospitals and pathology laboratories. Community controls were frequency matched to cases by random-digit telephone dialing and Medicare records. This study utilizes the same data as other case-control studies (Baris, et al. 1998; De Roos, et al. 2003). Using the

same merged study base, this study found an OR for DDT of 1.2 (0.9-1.5) in non-asthmatics (based on 158 exposed cases and 313 exposed controls) and an OR of 1.2 (0.6-2.4) in asthmatics (based on 11 cases and 24 controls exposed). There was no discussion of DDT and NHL risk in the paper.

The Lee, et al., study uses univariate analyses that are adjusted only for age, vital status and State. This is in contrast to the 1998 and 2003 studies that were able to adjust simultaneously for the confounding effects of other chemical exposures. Unfortunately, this study did not perform multivariate analyses adjusting for the confounding effects of exposures to other chemicals. This is probably due to the very small number of asthmatics with DDT exposure and NHL (N = 11). Furthermore, this study focuses on only a subset analysis of subjects in the farmer studies, namely asthmatics. Such multiple subset analyses of a single database increase the likelihood of finding chance associations.

In conclusion, this study found very weak, non-significant associations between DDT and NHL that did not differ between asthmatics and non-asthmatics. This lack of difference runs counter to the paper's other findings regarding pesticides, NHL and asthma. Given the weakness of the association found (OR = 1.2, a value very close to the null value of 1.0), it is quite likely that the DDT finding is due to chance or confounded by other chemical exposures, as was demonstrated in the studies by Baris, et al. (1998), and De Roos, et al. (2003) using data from the same study.

(8) Zahm S, Weisenburger DD, Saal RC, et al. The role of agricultural pesticide use in the development of non-Hodgkin's lymphoma in women, 1993. This is a report of a case-control study of 119 women with NHL and 471 controls who resided in Nebraska. This paper relies on data used in several other studies covered in this report (Baris, et al., 1998; De Roos, et

al. 2003), but only analyzes a subset of the data, i.e., data for women. Community controls were selected by random-digit dialing and Medicare records. Telephone interviews were used for exposure information.

No data for DDT and NHL are presented in the paper's tables. However, the text states that there was an OR for DDT exposure of 1.7 based on 16 exposed cases and 36 controls. No confidence interval or p-value for this finding is provided and there is no further discussion of DDT in the paper. The authors conclude: "No individual insecticide was associated with a significant risk of NHL among women." Thus, this paper provides little information regarding NHL and DDT beyond there being a weak association that was not statistically significant, and for which there was no evaluation of confounding by other exposures. Additionally, this study is yet another example of a subset analysis being performed on the same database, the NCI farmers' studies.

(9) Schroeder JC, Olshan AF, Baric R, et al. Agricultural risk factors for t(14;18) subtypes of non-Hodgkin's lymphoma, 2001. This is a re-analysis of data from a previous case-control study of NHL and farm exposures (Cantor, et al. 1992). Data are from the NCI farmers' studies that are the basis of many of the papers discussed in this review. Tumor specimens were obtained for 40% of the 622 original Iowa and Minnesota study cases and only 29% (182) were assayed successfully for the t(14;18) translocation. Of these, 68 cases were positive for the translocation and 114 cases were negative. Previously collected interview data for these cases and their controls served as the basis for the new study's analyses. In Table 5, the OR for DDT and NHL in the t(14;18)-positive NHL cases and their controls was 1.1 (95% CI = 0.6-1.9). The OR for DDT in the translocation-negative cases was 1.2 (0.8-1.7).

In the methods section, the authors discuss the problem with the fact that, "over 70% of the FARM study could not be classified as t(14:18)-positive or –negative." Because the authors were concerned that "ignoring unclassified cases may have biased estimates for case-subtypes compared with controls," they used elaborate statistical methods to include exposure data from unclassified cases. As an example, the authors "constructed pseudo-data with observations missing case-subtype data apportioned to case-subtypes according to the probabilities for their covariate substratum," and they then "modeled these data to determine new maximum likelihood probabilities, which were used to assign new pseudo-data." It is unclear from this extremely confusing text as to how these and other statistical manipulations of the data impinge on the results presented in Table 5.

This study was an interesting attempt at sub-classifying NHL on a biologic basis for analysis of risks associated with agriculture. Unfortunately, histologic materials only could be obtained for 29% of NHL cases, a proportion that could lead to significant bias, and this study's authors recognize this. The use of arcane methods to create expected numbers for missing subjects' data does not improve the quality of this study.

Based on the small proportion of cases for whom tissues were available, for DDT, there was no difference in those NHL cases with or without the t(14;18) chromosomal translocation. The study did not assess whether or not these weak, non-significant associations were the result of confounding by other exposures ("Weak associations may have resulted from confounding, since we were unable to model individual agricultural exposures simultaneously."). The weak, non-significant ORs of 1.1 and 1.2 in this study suggest little or no association and are likely the results of confounding by other exposures. Moreover, this is another example of the many sub-

set analyses performed on the NCI farmer studies data. For all of the reasons above, at best, the study could be viewed as hypothesis generating, rather than as hypothesis testing.

(10) Persson B, Fredrikson M. Some risk factors for non-Hodgkin's lymphoma, 1999. This paper merges data from two other studies discussed above (Persson, et al., 1989, 1993). The merger was done to deal with the problem of limited sample sizes: "To overcome some of the problems with limited numbers, the present study was set up as a pooled analysis of two previously published case-referent studies, focusing on some rare exposures which could not be studied before." Thus, it is not a separate and independent study. Nevertheless, the merged study was still very limited in size with regard to numbers of subjects with DDT exposure. They studied 199 NHL cases and 479 referents and found an OR for DDT and NHL of 1.4 (95% CI = 0.3-5.9) based on 4 exposed cases. Although DDT data are presented in the tables, there is not a single mention of DDT in the text. This underscores the lack of any meaningful elevation of NHL risk associated with DDT in this pooled analysis.

This study is a pooled analysis of two very small studies that adds no independent new information on DDT. The study uses cases from two other studies and compares exposures with a group of controls used in many other studies by these authors. Moreover, no attempt was made to adjust the DDT finding for exposures to other chemicals and the slight elevation in OR for DDT may well be due to confounding. In conclusion, the pooling of results brings the OR for DDT closer to 1.0. The attempt to shed new light on the authors' previous studies shows that with larger subject numbers, the OR for DDT and NHL only comes closer to the null value, i.e., a finding of no association.

(11) Colt JS, Severson RK, Lubin J, et al. Organochlorines in carpet dust and non-Hodgkin lymphoma, 2005. This is a population-based case-control study using four

Surveillance, Epidemiology, and End Results (SEER) reporting sites to identify cases. Controls were selected by random-digit telephone dialing or for older subjects, Medicare files. Organochlorine concentrations were measured in vacuum cleaner bag dust in the carpets of 603 cases and 443 controls. There were many missing values for carpet dust levels of chemicals and multiple statistical estimations were made. Only Caucasian subjects were studied and subjects had to have owned their carpets for at least five years.

No association with DDT was found, the overall OR was 0.9 (95% CI = 0.7-1.2), and an OR of 1.3 (1.0-1.7) was found for DDE. NHL risk was 1.6 (1.1-2.2) for the top tertile of DDE concentration and there was a statistically significant trend with increasing concentration (p=0.02), but the dose-response was not monotonic, i.e., there was no consistent increase in ORs with increasing DDE levels. Thus, for the middle tertile of DDE levels, the OR declined to 1.1 (0.7-1.6) from an OR of 1.3 for the lowest tertile. Additionally, the DDE results were different for men and women. For men, the OR for DDE was 1.6 (1.1-2.3) and for women, it was 1.1 (0.7-1.5). If there was a true association, it seems paradoxical since women are likely to spend more time in the home and to do more of the vacuum cleaning in the household. Importantly, the authors failed to provide similar results for DDT. The authors fully recognize the oddness of their results and state: "Our results for DDE were less consistent. An association was observed only in men, the dose-response relationship was not monotonic, and the concurrent finding of no association for DDT is difficult to explain." I agree fully with the authors' interpretation of their results.

In summary, this is a rather odd case-control study using carpet dust as a surrogate measure of past exposures to a variety of chemicals. It is like a cross-sectional study in that levels of chemicals in carpets are measured after the time of cases' diagnosis. While no one

knows whether dust levels are valid measures of past exposure, particularly remote past exposures, the authors assume in this study that levels are a valid surrogate of past household exposure levels. Further, in determining carpet dust levels of chemicals, there were many problems with missing values or measurement of specific chemicals. As a result, numerous imputations and other estimations of levels had to be computed. Thus, it is likely that results of the study were affected by imprecise estimates of specific chemical levels. Further concern about the credibility of this study is generated by some paradoxical findings regarding DDT and DDE levels in carpet dust. The study found a weak association for NHL and DDE, but not for DDT. The trend for NHL risk and DDE exposure, while statistically significant, was odd in that the OR for the middle tertile of DDE levels was 1.1. The very large sample sizes in this study make small increases in risk statistically significant. Equally puzzling is their observation of an association between DDE levels and NHL for men, but not for women.

In conclusion, no association was found between DDT in carpet dust and NHL, and the DDE findings were inconsistent with the DDT findings. The authors had no explanation for the inconsistencies observed. Nevertheless, this was an extremely large study with more than adequate statistical power to detect an association with DDT if it existed; yet they found no such association.

(12) Eriksson M, Hardell L, Carlberg M, et al. Pesticide exposure as risk factor for non-Hodgkin lymphoma including histopathological subgroup analysis, 2008. This is a report of a population-based case-control study of 995 NHL cases and 1,016 population registry controls in Sweden. Cases were identified from participating university clinics and controls from the Swedish population registry. Controls were frequency-matched in 10-year age and sex group categories. The study was designed to evaluate exposures to pesticides as risk factors for NHL.

Exposure data were collected by self-administered questionnaires supplemented by telephone interviews "if important data were lacking, incomplete or unclear." The telephone interviewers were blinded as to case/control status of the subjects.

Fifty cases and 37 controls reported exposure to DDT for an OR of 1.46 (95% CI = 0.94-2.28). These subjects were subdivided into two exposure categories, ≤37 days (OR = 1.17, 0.62-2.22) and >37 days (OR = 1.76, 0.97-3.20). The authors also found an OR of 2.14 (1.05-4.40) for DDT and follicular, grade I-III NHL, based on 165 such cases. Multivariate analyses were not performed for any DDT finding because DDT did not meet the authors' criteria for performing a multivariate analysis, which was done only for "agents with statistically significant increased OR, or with an OR > 1.50 and at least 10 exposed subjects." The authors state that "[s]ince mixed exposure to several pesticides was more a rule than an exception, and all single agents were analyzed without adjusting for other exposures, a multivariate analysis was made to elucidate the relative importance of different pesticides." The authors point out that results from multivariate analyses were "in general lower" than those from univariate analyses.

In conclusion, the study found a weak association between reported DDT exposure and NHL that was not statistically significant. It also found a moderate association between reported DDT exposure and follicular NHL that was statistically significant. However, no multivariate analyses of the DDT-NHL associations were performed despite the authors' observation that ORs were generally lower in multivariate analyses than univariate analyses and that mixed exposure to several pesticides was frequent. Based on their findings, the authors conclude as follows: "The organochlorine DDT has shown suggestive but rarely significant association with NHL in some studies. Our study showed a moderately but not significant increase OR for

exposure to DDT." No mention is made of DDT and NHL in the paper's abstract. I agree with the authors' conclusion that the study found no significant OR for exposure to DDT.

B. Detailed Analyses of Case-Control Studies of DDT and NHL /Chronic Lymphocytic Leukemia

Until recently CLL and NHL were considered to be different pathologic entities, with CLL being included in the broad category of leukemias. The new WHO classification of lymphomas includes CLL in the category of lymphomas on pathologic and immunologic bases. Most epidemiologists still consider CLL to be a disease entity separate from NHL. However, to be complete in my literature review, I am including those papers that lump CLL and NHL together in their analyses.

(1) Miligi L, Constantini AS, Bolejack V, et al. Non-Hodgkin's lymphoma, leukemia, and exposures in agriculture: Results from the Italian Muticenter Case-control Study, 2003. This is a report of a multi-site, very large, case-control study from Italy. The study was done in 11 areas, five of which had a high prevalence of agricultural activities. They accrued 1,145 NHL cases, 430 leukemia cases and 1,232 general population controls that were interviewed. For the combined groups of NHL and chronic lymphocytic leukemia (CLL), they found an OR of 0.6 in men (0.3-1.1) and 0.3 in women (0.1-0.8) for DDT exposure. These ORs were based on 21 DDT-exposed male cases and 5 exposed female cases. There is no discussion of these DDT findings anywhere in the paper and, curiously, the significantly protective effect of DDT exposure in women is ignored. The authors state: "Table V shows ORs for NHL for exposures to major classes of insecticides. No exposures were found to be significantly associated with NHL ..." Yet the ORs for women and DDT, as well as the category of diphenylethanes, were 0.3 (95% CI = 0.1-0.8) in Table V, two statistically significant values demonstrating a protective effect.

This large case-control study lumps together NHL and CLL and presents findings only for the combined category. Despite the large number of study subjects, only 21 male cases and 5 female cases were reportedly exposed to DDT in the combined disease group. The study found protective effects for DDT for both men and women, with the value for women being statistically significant, findings the authors ignore. In summary, this study combines NHL and CLL to generate a study with a very large sample size that finds that DDT protects against NHL (and CLL).

(2) Nanni O, Amadori D, Lugaresi, et al. Chronic lymphocytic leukaemias and non-Hodgkin's lymphomas by histologic type in farming-animal breeding workers: A population case-control study based on a priori exposure matrices, 1996. This was an Italian, population-based, case-control study of 187 cases of CLL and NHL (which included 162 NHL cases, 23 CLL cases and 2 mycosis fungoides cases) and 977 controls from the general population. All cases were from a single province in Northeast Italy and matched controls were selected from the general population. Exposure information was obtained by direct interview and also by use of an a priori job-exposure matrix to estimate pesticide exposures when a crop disease was reported.

For NHL and CLL combined, the study found an OR of 1.74 (0.93-3.27) based on recall of DDT exposure in 27 combined cases and 61 controls. They also found an OR of 1.70 (0.91-3.17), based on matrix-estimated DDT exposures in 28 cases and 65 controls. When the analysis was restricted to CLL and low grade NHLs (31 of the total of 162 NHL cases), they found ORs of 2.33 (0.93-5.85) for recalled exposure to DDT and 2.16 (0.86-5.43) for estimated DDT exposure. No data were presented for the other types of NHLs. Thus, the authors found weak, non-statistically significant associations between DDT exposure and NHL for all NHL cases.

When a subset analysis was done for a small portion of the NHL cases, the ORs went above 2.0, but again, the results were not statistically significant. Further, there are serious concerns about the analyses performed in this study.

The paper has several important limitations. Foremost, there was no attempt made to perform multivariate analyses to control for confounding effects of exposure to multiple chemicals despite the authors recognition that "[i]n farmer-animal breeders, the use of each pesticide was strongly correlated with the use of the others." Because there were eight main categories of pesticides and the numbers of individual exposures to each agent were relatively small, the authors state that "it was impossible to introduce in the same model more than one pesticide category to evaluate their separate effects." Given their observation of strong correlations between the other various pesticides and the weak associations observed for DDT, it is highly likely that the DDT association is confounded by other chemical exposures as other larger studies consistently have demonstrated.

An additional concern is with the artificial slicing of the data to produce a category of combined CLL and low grade lymphomas that result in non-significant ORs for DDT of 2.33 (0.93-5.85) by recall and 2.16 (0.86-5.43) by job matrix assessment of exposures. First, the combination of CLL and a subset of other lymphomas is unusual for epidemiologic studies. Second, no similar results are presented for other categories of NHL such as medium or high grade NHL. Are the ORs for these other categories less than 1.0 and demonstrative of a protective effect? Third, it is unclear as to how they selected the 31 cases with CLL or low grade lymphomas for analysis in Table 3. As described in the materials and methods section, there were 79 cases in this category – 56 with low grade NHL and 23 with CLL. Though there were 79 total cases in this category, the authors inexplicably analyzed data for only 31 cases. This

suggests they performed an analysis only for a subset of the subset. The analysis of results for this arbitrary subset is suspicious of "data dredging" to demonstrate stronger associations. Nevertheless, neither of the results for this subset analysis is statistically significant for DDT.

In conclusion, this study is fraught with methodologic problems that render interpretation of the results very difficult. Nevertheless, none of their findings for DDT are persuasive or statistically significant. The performance of multivariate analyses would have strengthened the paper and likely would have demonstrated confounding.

C. Detailed Analyses of Case-Control Studies of DDT Levels in Biologic Specimens and NHL

(1) De Roos AJ, Hartge P, Lubin JH, et al. Persistent organochlorine chemicals in plasma and risk of non-Hodgkin's lymphoma, 2005. This is a case-control study in which congener of PCBs, furans and pesticides or pesticide metabolites in plasma were measured and compared in 100 untreated NHL cases and 100 controls. Subjects were derived from a large NCI case-control study that also was used for the study by Colt, et al. 2005. The authors used the same multiple imputation procedures to fill in missing values as were used in the Colt, et al., study and conditional logistic regression methods for their analyses. For DDE and NHL, they found an OR = 0.85 (95% CI = 0.37-1.94) when comparing the highest versus the lowest quartiles of measured plasma DDE levels. Curiously, for the third quartile of DDE levels (>450.5-872.5), the OR demonstrated a highly statistically significant protective effect (OR = 0.33, 0.14-0.80), a finding not discussed by the authors. For DDT and NHL, the odds ratio for the highest versus lowest DDT categories was 1.2 (0.39-3.70). The text of the paper reports that for "extreme levels of exposure, [the authors] found elevated ORs for p,p'-DDT (OR, 3.3; 95% CI, 0.7-15.9)..." and other chemicals. Thus, they found no significant association at all between

NHL and DDT or DDE in subjects' serum, save for a protective effect of moderately high levels of DDE.

This study suffers from the concern typical to all sero-epidemiologic studies that study serum levels of fat-deposited substances after a cancer diagnosis – namely, that weight loss and cachexia associated with cancer might mobilize tissue stores of chemicals. The authors tried to minimize this effect by studying cases before initiation of treatment, but many cancer patients present with weight loss at diagnosis. Thus, any results from a study such as this must be interpreted cautiously. Additionally, this study represents another subset analysis of an NCI study which, like Lee, et al. (2004), Zahm, et al. (1993), raises concerns that multiple looks at the same data set can produce many chance findings.

An additional concern is with the authors failure to provide information on the specific levels that constitute "extreme levels" of the chemicals studied in Table 5. They also do not provide the numbers of cases and controls in this category, but the authors recognize that such numbers for DDT were small. Nevertheless, such "extreme level" subjects would be subsumed in the data in Table 5 for the top quartile of DDT levels (>9.9). The OR for this quartile (1.2) was only slightly increased over the null value of 1.0, was not statistically significant, and had a broad confidence interval as well.

Another concern is that the authors apparently were biased towards emphasizing an elevated finding for DDT (OR = 3.3) that was provided only in the text and was based on very small numbers (that are unspecified) and was not significant. This contrasts with their ignoring a weak protective effect overall for DDE, with a strong, statistically significant, protective effect for one of the levels of DDE (OR of 0.33, which is the inverse equivalent of an OR of 3.3). In

summary, this is a paper that provides little useful information regarding the association between DDT exposure and NHL.

(2) Quintana PJE, Delfino RJ, Korrick S, et al. Adipose tissue levels of organochlorine pesticides and polychlorinated biphenyls and risk of non-Hodgkin's lymphoma, 2004. This paper reports the results of a nested case-control study of pesticide levels in cadaver and surgical specimens and risk of NHL. Subjects were selected from a national repository of adipose tissue collected by the U.S. EPA. There were 175 cases (167 case specimens obtained at autopsy, 8 specimens were surgical samples) and 481 controls (173 controls from accident victims and 308 with myocardial infarction).

For DDT, there was a statistically significant trend with increasing concentrations, but there were no significant elevations of DDT residues in any of the exposure categories. For the highest level of DDT residue, the OR only reached the level of 1.39 (95% CI = 0.78-2.47). Based on these findings, the authors conclude: "Rothman, et al. (1997) also reported no significant association between total lipid-corrected serum concentrations of DDT and risk of NHL, and this finding is supported by the present study, in which we found no clear association between exposure to DDT and NHL." I agree with this conclusion and also conclude that the study found no clear association between DDT and NHL.

For DDE, they found an odds ratio of 1.99 (1.14-3.47) for the highest tissue concentration of DDE (>7.21 ppm). Oddly, for the DDE tissue residue level of 2.40-4.38 ppm, they found an OR of 0.53 (0.29-0.96), which is a statistically significant protective effect. As will be shown below, this slight elevation was lowered remarkably when statistical adjustment was made for other confounding chemical residues.

When correlations between the pesticides studied were assessed, numerous low or moderate correlations between the various chemicals were observed. As a result, they assessed "between-pesticide confounding" using conditional regression models. When both heptachlor and DDE were included in their statistical model, the odds ratio for the highest quartile of DDE residues (>7.21 ppm) was reduced by 41.2% to 1.32 and was no longer statistically significant (0.73-2.39). The ORs for the highest quartile of DDE residue levels were similarly reduced and became non-significant in models containing pairs of pesticides. Thus, the weak association observed between cadaver tissue levels of DDE and NHL in this study likely was confounded by other chemical residues. Once again, this study demonstrates that weak statistical associations between DDT and NHL risk usually prove to be the result of confounding by other chemicals when multivariate analyses are done.

However, this study also has certain problems similar to the De Roos, et al., study. The biologic materials collected for the study likely introduced a bias. Cases were decedents from NHL and death in this cancer as in most cancers is preceded by cachexia and other severe metabolic changes. Controls were more likely to have died a sudden death (from accidents or heart attacks) and thus would not have had any pre-mortem severe weight loss or metabolic changes. In fact, 308 of the 481 controls were decedents from myocardial infarction, a group that is likely to have suffered from greater overweight before death than the general population. Since it was adipose tissue that was the basis for the chemical assays, there is almost certainly a large difference in the amount, if not the quality, of adipose tissue in the case and control groups.

In summary, this study likely had significant design flaws that could introduce considerable bias. Nevertheless, the authors still did not find any significant association between NHL and DDT, nor did they find any significant association for DDE in tissues after controlling

for confounding by other chemicals. Although this study should be interpreted cautiously, it is a negative study that provides no evidence of an association between tissue levels of DDT or DDE in cadavers and risk of NHL.

(3) Hardell L, Van Bavel B, Lindstrom G, et al. Higher concentrations of specific polychlorinated biphenyl congeners in adipose tissue from non-Hodgkin's lymphoma patients compared with controls without a malignant disease, 1996. This is a very small case-control study of 28 NHL patients and 17 surgical controls that compared, among many comparisons of other chemicals, DDE levels in adipose tissues of subjects. The source of patients and controls is not stated. Samples of adipose tissue were obtained surgically from subjects' "abdominal wall." A mean DDE concentration of 1420 ng/g lipid was found in cases compared to 1068 in controls (P = 0.29), with considerable overlap in the range of levels between the two groups. Thus, cases did not differ significantly from controls in tissue levels of DDE, a major metabolite of DDT. As in the previous paper by Hardell, et al. (1994), the primary focus of this paper was on other chemicals and there is little discussion of the DDE results.

This study measures adipose tissue levels of a DDT metabolite after a diagnosis of NHL was made and is thus subject to the possible effects of weight loss or other cancer-related metabolic changes on tissue DDE levels. Nevertheless, the authors conclude: "In this investigation no association between NHL and DDE concentration in adipose tissue was found." In summary, I agree with the authors' conclusion, but believe this study is very small, is subject to bias from possible weight loss in cases, and is analyzed in a rudimentary way. As a result, this study provides little useful information.

(4) Hardell L, Eriksson M, Lindstrom G, et al. Case-control study on concentrations of organohalogen compounds and titers of antibodies to Epstein-Barr virus

antigens in the etiology of non-Hodgkin lymphoma and exposure to pesticides, 2001. This is a two-part case-control study in which adipose tissue samples were obtained from 50 NHL cases and 47 controls in the first part and blood samples from 32 NHL cases and 36 controls in the second part. Cases and controls were obtained at two Swedish hospitals. It appears that the 50 NHL cases in the first part included the 28 cases from the Hardell, et al., (1996) study of adipose tissues and pesticides. In this study, an odds ratio of 1.2 (0.60-2.5 95% CI) was found for NHL and DDE. An OR of 1.2 was found for multivariate analysis as well, but with a wider confidence interval. Interactions between DDE levels and EBV early antigen antibody titers were evaluated with no significant associations.

This study has several problems in addition to its small size. First, it must be remembered that this study is not independent from the Hardell, et al. (1996) paper on the same subject. Second, it uses both tissue and serum levels of chemicals and combines them for analyses. Tissue levels would reflect past exposure levels while serum levels would reflect recent exposure levels and/or mobilization of the chemicals from fat stores, as in a patient losing weight. Third, the EBV interactions only could be determined in the subset of subjects providing blood samples and analyses of interactions only considered EBV early antigen antibodies. Thus, the EBV results are limited and hard to evaluate. Nevertheless, no association between tissue and blood levels of DDE and NHL were found.

(5) Spinelli, J, Ng, C, Weber, J, et al. Organochlorines and risk of non-Hodgkin lymphoma, 2007. This is a population-based case-control study of NHL done in British Columbia, Canada. A subset of participants in a larger NHL case-control study, 422 cases and 460 frequency-matched, community controls, were studied. Exposure information was collected

by self-administered questionnaires and CATI. Blood samples were obtained from cases after diagnosis and from controls.

The study found for "p',p'-DDT" an OR for level > 3.24 ng/g versus no level of 0.91 (0.68-1.20). For p,p'-DDE, the OR for the highest quartile versus the lowest quartile was 1.42 (0.92-2.19). A trend test for the quartiles of DDE levels yielded a p-value of 0.027, yet there was no statistically significant finding for any of the quartiles. For follicular lymphoma, the lymphoma type of the plaintiff Ms. Garza, ORs were 0.7 (0.5-1.1) for p,p'-DDT and 1.8 (0.9-3.3) for p,p'-DDE. Multivariate analyses were not performed for DDE or DDT.

This study found no statistically significant associations between NHL and DDE or DDT. The authors performed a trend test on the results of analysis of p,p'-DDE by quartiles of blood levels and found a statistically significant trend. As a result, they state in the paper's abstract that there was a significant association with p,p'-DDE. This is an incorrect conclusion. The analysis of the associations of p,p'-DDE by quartiles found no significant associations for any of the levels. For the highest level, > 512.02 ng/g, the OR was 1.42 (0.92-2.19), and none of the other strata was significant either. The only conclusion they can reach is that there was a significant trend in non-significant data. My interpretation of these data is that there is no statistically significant association between p,p'-DDE and NHL in their study.

This study provides interesting insights into the issue of the effects of weight loss and disease in NHL patients and their effects on studies of DDT and DDE content in blood and adipose tissues. The authors attempted to deal with weight loss in NHL patients and its possible biasing effects on plasma levels of organochlorine compounds by excluding cases found to have over 10% weight loss prior to diagnosis. Nevertheless, the authors report that "organochlorine study cases had significantly lower measured plasma total lipids than controls (6.66 vs. 7.14.0

[sic] g/L,p<0.001)." They go on to state that "thirty-two cases were excluded from analyses due to weight loss or unavailable weight loss information. Organochlorine levels were generally higher in these cases compared to cases without weight loss." These findings support my concerns about the validity of results from studies of DDT and DDE levels in autopsy and other biologic specimens collected after NHL diagnosis. Both DDT and DDE are stored in body fat, and the data from the Spinelli, et al., study suggest that lipid levels differ between cases and controls and that in subjects with weight loss, results differ from those without weight loss. It must be remembered that weight loss is a relatively frequent presenting sign of NHL leading to diagnosis. Weight loss becomes more severe in terminal NHL patients. In summary, results of DDT and DDE assays of biologic specimens obtained at death or after diagnosis must be interpreted with extreme caution.

(6) Cocco P, Brennan P, Ibba S, et al. Plasma polychlorobiphenyl and organochlorine pesticide level and risk of major lymphoma subtypes, 2008. This is a case-control study of subjects from the "Epilymph study, a multicentre European case-control study of environmental exposures and lymphoid neoplasms." Cases and controls are from three countries: Spain, France, and Germany. The paper provides no further information on methods for case identification and selection or for the source of controls and what matching procedures were used. "Information on potentially confounding covariates was based on personal interviews using a structured questionnaire." Covariates used in the final regression model for analyses included age, gender, educational level, study center, and individual chemical exposure. NHL ORs were calculated using unconditional logistic regression. No further detail was provided. As a result, it is difficult to assess the methodology used in assembling subjects for this case-control study and for data collection. Additionally, analytic details are vaguely defined.

For p,p'-DDE, the OR for NHL in the highest level category ($\geq$1431.08 ppb) was 1.2 (0.7-2.4). The lowest level category ($\leq$394.99 ppb) was the reference category used. A test for trend across the categories was not statistically significant (p=0.48). The analyses also were performed separately for two subsets of NHL, diffuse large B-cell lymphoma (DLBCL) and for chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). The OR for the highest level category was 1.3 (0.5-3.6) for DLBCL and 1.0 (0.4-2.5) for CLL/SLL. Trend tests for ORs and serum levels for both subtypes were not statistically significant, p=0.48 and 0.92 for the two subcategories respectively.

The paper attempted to deal with the possible problem of assaying serum levels after chemotherapy was initiated by performing separate analyses for the subset of Spanish patients who had blood samples drawn before treatment was begun. The results were comparable for the pre- and post-treatment cases, but no specific data were provided. Attempts were made to assess whether or not the PCB findings were confounded by p,p'-DDE levels. Although no specific data were provided in the tables or text, the authors note that PCB results did not change when controlling for DDE and "no significant interaction whatsoever was identified." No comment was made as to whether controlling for PCB levels affected DDE results.

In summary, this paper is seriously lacking in essential details for proper evaluation. There are few details regarding the study's design and methodology. For example, there is no information on who the controls were and how they were selected and/or matched. Nevertheless, no statistically significant associations (ORs of 1.0-1.3) were found between risk of NHL and its major subtypes and serum levels of p,p'-DDE.

(7) Hardell K, Carlberg M, Hardell L, et al. Concentrations of organohalogen compounds and titres of antibodies to Epstein-Barr virus antigens and the risk for non-

Hodgkin lymphoma, 2009. This study has features of both a case-control study and a cross-sectional study. The case-control study portion is based on a subset of subjects from an earlier study by the same research group (Eriksson, et al. 2008). One hundred cases and 100 controls were selected from the subset of subjects in the earlier study who had provided blood samples. The blood samples were obtained after cases were diagnosed with NHL, and thus, it is not clear whether the values obtained for cases were indicative of pre-diagnostic status or whether they were the result of cases' NHL. Data on exposure to DDT and other pesticides were obtained in the earlier, Eriksson, et al., study. Blood specimens were assayed for organohalogen compounds and EBV antigens. Both viral capsid antibody (VCA) and early antibody (EA) titers were assayed, but only data for EA titers were presented in the tables.

Overall, there was no significant difference between cases and controls with regard to blood concentrations of p,p'-DDE ($p = 0.11$). For follicular lymphoma, an OR of 1.2 (95% CI = 0.4-3.5) was found for p,p'-DDE. The median VCA antibody titer level was 1,280 in cases and 2,560 in controls ($p = 0.86$). The median EA antibody titer level was 80 in cases and 40 in controls ($p = 0.007$). Although there is only a one dilution difference in EA levels between cases and controls, there is a very significant difference between the two groups. This is likely due to at least one outlier EA value in the cases: the upper bound of the range for cases was 10,240 and only 640 in controls.

In Table IV, data are presented for both p,p'-DDE in terms of EA titers ≤ 40 and >40. For the cell > the median p,p'-DDE level and EA >40, an OR of 3.3 (1.4-7.7) was found. In Table V, similar analyses are presented for follicular NHL only ($n = 20$). For the cell > the median p,p'-DDE level and EA >40, an OR of 1.2 (0.3-4.3) was found.

It is not clear what this paper means and what its relevance to this case might be. The paper has several significant problems that limit its usefulness. First, it is based on a subset of an earlier study that found no significant association between DDT exposure and NHL risk. Second, the measurement of EBV antibody titers was based on samples obtained after cases were diagnosed. EA antibody levels are likely to be affected by the cases' NHL. EA antibody titers are typically elevated in early stages of infection by the EBV or in reactivation responses triggered by immunosuppressive events. VCA antibody titers, in contrast, occur later during EBV infection and persist for life in most persons. VCA titers are typically not elevated as part of a reactivation response as might be seen in a patient undergoing organ transplantation. Analyses of VCA antibody titers would have been more relevant for making inferences regarding possible causal roles, since these titers are less likely to be affected by development of NHL. So it is difficult to interpret the meaning of the EA findings. Third, this paper reports numerous subset analyses raising the likelihood that at least several of the findings are due to chance. Fourth, this is a small study, for example, data are available for only 20 follicular NHL cases, and there is excessive "slicing and dicing" of the data. Lastly, the relevance of these findings to Ms. Garza is unclear since we do not have any data on her EBV antibody levels nor on any blood pesticide levels. In summary, this study is small in size, difficult to interpret, and of unknown relevance with respect to Ms. Garza. Nevertheless, this study does not demonstrate an association between p,p'-DDE levels and risk of follicular NHL.

III. DETAILED ANALYSES OF COHORT STUDIES OF DDT AND NHL IN HUMANS

(1) Laws EH Jr., Curley A, Biros FJ. Men with intensive occupational exposure to DDT, 1967. This early paper reports the results of an evaluation of a group of men who were occupationally heavily exposed to DDT for more than five years. This U.S. government study

used subjects from a California manufacturing facility (Montrose Chemical Corporation of California) that solely produced DDT and had been in operation continuously from 1947. Ditraglia, et al. (1981) and Brown (1992), which are discussed below, also studied workers at this same facility. A total of 35 men with a mean of 15 years of exposure at the plant were assessed. The men gave medical histories, underwent physical examinations, had chest x-rays, and provided blood, fat biopsies and urine specimens. The heavy exposure of this group to DDT was reflected in mean DDT levels in fat specimens that were 39 to 128 times higher than levels in the general population. Their evaluations "did not reveal any ill effects attributable to exposure to DDT." They also reported that "[n]o cancer or blood dyscrasia was found in the 35 men studied."

This was a very small study of workers occupationally heavily exposed to DDT, and solely to DDT. Levels of DDT exposure were high, and this was reflected in levels in biologic specimens from the men. Neither adverse health effects nor NHL or any other cancers were found. Only about 0.1 NHL case would have been found if general population rates were applied to the number of person-years of observation of this cohort. Nevertheless, what the study does tell us is that very high DDT exposure levels do not cause demonstrable adverse health effects, even after a mean of 15 years of exposure. It also suggests that there were no excesses of cancer occurrence within this highly exposed cohort.

In summary, this is a very limited study in terms of sample size. What it does show is that there are likely no adverse heath effects of very high levels of DDT exposures in the workplace on average 15 years after exposures began.

(2) Ditraglia D, Brown DP, Namekata T, Iverson N. Mortality study of workers employed at organochlorine pesticide manufacturing plants, 1981. This paper reports the

results of a NIOSH retrospective cohort study of mortality at four organochlorine pesticide-manufacturing facilities in the U.S. This U.S. government study relied on personnel records provided by the four facilities. The study group totaled about 2,100 individuals. One of the four plants studied (Plant 4) was in California and solely produced DDT dating back to 1947. None of the other three plants produced DDT. Among Plant 4 workers, there were 6 observed deaths from all malignant neoplasms for an SMR of 68 (25-247) based on 7,601 person-years of observation. There were no deaths from "lymphatic and hematopoietic system" cancers, a category that includes NHL. Deaths from all causes at Plant 4 totaled 42 for an overall SMR of 86 (62-116).

This was a relatively small cohort study of workers at organochlorine pesticide manufacturing facilities. Specific data were available for one plant that produced only DDT dating back to 1947. No increased cancer mortality was observed among the DDT plant workers, and there were no deaths in the cancer category that includes NHL. Based on the number of person-years of follow-up, about one NHL death would have been expected, yet none was observed in this group of workers heavily exposed to DDT. The small numbers of subjects and limited numbers of deaths preclude further conclusions.

(3) Brown DP. Mortality of workers employed at organochlorine pesticide manufacturing plants – an update, 1992. This paper reports the results of continued follow-up of workers at four plants that produced organochlorine pesticides. The first study was done by Ditraglia, et al. (1981), and this government study continues the initial follow-up. One plant, Plant 4, was in California and produced only DDT. Workers were white men who had worked at the four plants for at least 6 months prior to December 31, 1964. Mortality in these workers was assessed through December 31, 1987. For all malignant neoplasms, an SMR of 0.87 (95% CI =

0.52-1.39) was determined for workers in Plant 4. This was similar to the SMR for all four plant workers combined (SMR = 0.88). No deaths from lymphatic/hematopoietic neoplasms were found for Plant 4 workers. Thus, there were also no deaths from NHL which is a component of this category. For workers at all four plants combined, an SMR of 0.98 was observed for this category (95% CI = 0.55-1.62, based on 15 deaths).

This study followed 328 workers at Plant 4, which only produced DDT, for a total of 9,797 person-years of follow-up. There were 90 deaths in this cohort and none from NHL or other hematologic neoplasms. While this cohort was small, it represents a group of industrially exposed workers who produced DDT only. If DDT were truly a cause of NHL, we would have expected to see at least two or more NHL deaths in these highly exposed individuals with very specific exposure to DDT. This study, done by NIOSH, was limited by a lack of detailed exposure information. However, for a small subset (N = 35) of workers at Plant 4, DDT was assayed in fat samples and found to range from 38 ppm to 647 ppm, compared with an average of 8 ppm for the general population. The observed worker levels were **4.75 to 80.9 times greater** than general population levels. It was estimated that the average daily intake of DDT in the 35 workers ranged from **438 to 450 times** that of the general population. Thus, workers at Plant 4 were **very heavily and specifically** exposed to DDT.

In conclusion, this study, while relatively small, provides highly specific information on subjects with well-defined, high exposure levels to DDT. No deaths from any of the category of lymphatic/hematopoietic neoplasms were observed for 9,797 person-years of follow-up. At least two NHL deaths would have been expected based on general population rates, and none was found. If risks were elevated in DDT-exposed workers, even more deaths would have been

expected. While this government-conducted study is of relatively small size, it demonstrates that workers with **very high** levels of DDT exposure did not show any increased NHL risk.

(4) Cocco P, Blair A, Congia P, et al. Proportional mortality of dichloro-diphenyl-trichloroethane (DDT) workers: A preliminary report, 1997(a). This is one of a series of three papers based on a cohort of workers exposed to DDT in Sardinia as part of a post-World War II malaria eradication program initiated by the Rockefeller Foundation. The exposures occurred from 1946-1950.

This paper reports the results of a proportional mortality study of 1,043 deaths that occurred during 1956-1992 in men who used mostly DDT in the anti-malaria campaign in Sardinia, Italy. They found PMRs of 81 for NHL (95% CI = 9-294) in exposed subjects and 53 (1-295) in unexposed subjects. Unfortunately, these PMRs are based on 1 death from NHL in the unexposed group and 2 deaths in the exposed group, which makes the results very unstable and of limited value.

Although this was a study of mostly DDT exposure (chlordane and lead arsenate also were used for a short time), it was relatively small and there were very few deaths from NHL. The major study limitation was the use of proportional mortality analyses which can produce biased results if there are disproportionate deaths from other causes. Nevertheless, no excess of NHL was observed among deaths in this cohort of heavily exposed workers. This paper reports the exact same results as those in another 1997 publication by the same authors, discussed below.

(5) Cocco P, Blair A, Congia P, et al. Long-term health effects of the occupational exposure to DDT, 1997(b). This paper reports the exact same results as the prior paper by Cocco, et al (1997a). This paper was published in a monograph and probably was not peer-reviewed. As reported above, results in this paper also are based on 1,043 deaths that occurred in

the cohort between 1956 and 1992. Analyses provide only proportional mortality ratios. In exposed decedents, there was a PMR of 81 (95% CI = 9-294), and in unexposed subjects, the PMR was 53 (1-295). However, these results are based on 2 NHL diagnoses in the exposed and 1 NHL diagnosis in the unexposed subjects.

This study is severely limited by the sparse number of cancer endpoints and by its use of proportional mortality statistics. The combination of these two problems renders the study of limited value for explicating the relationship between DDT and NHL mortality.

(6) Cocco P, Fadda D, Billai B, et al. Cancer mortality among men occupationally exposed to dichlorodiphenyltrichloroethane, 2005. This paper deals with an expansion of Cocco, et al.'s, earlier study of cancer mortality in a Sardinian cohort of men occupationally exposed to DDT as part of a malaria eradication program. They conducted a mortality follow-up study of 4,552 male workers exposed to DDT from 1946-1950. In an analysis that compared observed, cause-specific mortality with expected regional mortality rates, they observed an SMR of 101 (95% CI = 65-157) for "lymphatic cancer" in applicators (who were directly exposed). This is based on 20 deaths from lymphatic cancer in the exposed group. The SMRs for lymphatic cancer were 83 (44-153) for bystanders (those indirectly exposed) and 174 (112-271) for unexposed men. Thus, there was a statistically significant increase in lymphatic cancer mortality for **unexposed men**, while no increased mortality was found for applicators.

In another analysis in which comparisons were made between the unexposed and exposed groups, the results were similar. For applicators the relative risk was 0.7 for lymphatic cancer and for bystanders 0.6. However, in this analysis, the referent group was the unexposed group that has a statistically significantly elevated SMR for lymphatic cancers. Nevertheless, in this

enlarged study, no excess risk (mortality) of lymphomas (not further specified) was found in this well documented DDT exposure cohort.

This study is useful since it deals with a large cohort of DDT exposed men with good exposure data available for them. There was also a long follow-up period (from 1956-1999) to allow ample time for any increased cancer risk to have become manifest, and no excess lymphoma mortality was found. Unfortunately, no breakdown of NHL and Hodgkin lymphoma deaths was provided. Most of the deaths from lymphomas would be expected to be NHL, based on the relative incidence and mortality of the two groups of diseases. It is clear from the paper that leukemias were not included in this category. The reporting of data for an undefined category of lymphomas ultimately limits the usefulness of this paper.

(7) Purdue MP, Hoppin JA, Blair A, Dosemici M, Alavanja MCR. Occupational exposure to organochlorine insecticides and cancer incidence in the Agricultural Health Study, 2006. This is the most recent cohort study evaluating the incidence of cancers following occupational exposures to DDT and other organochlorine insecticides. It provides results from a large prospective cohort study of licensed pesticide applicators in Iowa and North Carolina (N = 57,311). Workers were recruited between 1993 and 1997 and were followed through 2002. The mean follow-up time was 7.3 years. Exposure assessment was via self-administered questionnaires and incident cancer diagnoses were obtained from State tumor registries. A total of 12,035 applicators were exposed to DDT. A relative risk of 0.9 (95% CI = 0.6-1.5) was found for NHL and DDT exposure. This was based on 37 NHL cases in the exposed and 63 cases in the unexposed groups. This is a large study that had relatively large numbers of NHL cases in the study groups and this is reflected in the narrow confidence interval found.

The study has a potential problem that could have biased the results in that exposure data only were available for 44% of the enrolled study subjects (i.e., those subjects who completed the take-home questionnaire). However, this potential for bias might have been mitigated in several ways. First, in an earlier analysis, the authors found that subjects completing the take-home questionnaire were older on average than non-respondents, but were otherwise comparable. Since DDT use was stopped in 1972, older subjects would be more likely to have worked with DDT. This would add to the study's statistical power by increasing the number of exposed subjects. Second, it should be recognized that a total of 12,035 subjects reported exposure to DDT before the onset of any cancer. Such a large number of exposed workers are less likely to represent a very skewed or biased subset of the study subjects.

Thus, despite such potential limitations, the study also has considerable strengths such as the large number of exposed subjects, the use of incidence data, the collection of exposure data in advance of the outcomes and the large numbers of workers who developed NHL. On balance, this study provides persuasive evidence that DDT is not a cause of NHL.

IV. DETAILED ANALYSES OF ECOLOGIC STUDIES

(1) Cocco P, Kazerouni N, Zahm SH. Cancer mortality and environmental exposure to DDE in the United States, 2000. This is an ecologic study that examined the association between (1) 1968 adipose DDE levels of population samples from 22 U.S. states and (2) age-adjusted mortality rates for these states during 1975 and 1994 for (3) several cancers including NHL. Population samples are analyzed in relation to state mortality rates with no individual DDE levels in cases or controls available. They found a statistically significant **inverse correlation** between DDE levels and NHL mortality in three of the four study groups (white men, white women and African American women). Higher tissue DDE levels were protective against NHL for three of the four population groups studied. In a multivariate

analysis, NHL mortality significantly decreased with increasing DDE levels in whites, but not in African Americans. Thus, they found that for most subjects, higher tissue levels of DDE were associated with lower NHL mortality, suggesting a protective effect.

This study is of limited value since it is an ecologic study and merely correlated area-based DDE tissue levels with cancer mortality in the same areas. As in all such ecologic studies, exposure data are not available for the individual cancer decedents. Nevertheless, the study suggests that high adipose DDE levels **protect** against NHL.

(2) Pavuk M, Cerhan JR, Lynch CF, Schecter A, Petrik J, Chovancova J, Kocan A. Environmental exposure to PCBs and cancer incidence in Slovakia, 2004. This is an ecologic study conducted in two districts in eastern Slovakia. One of the two districts chosen had "extensive environmental contamination from a former PCB production site (Michalovce) and the other matched on geography but with low (background) levels (Svidnik)." The paper was focused primarily on PCB measurements but also measured population serum levels of DDE, DDT and HCB (hexachlorobenzene). A sample of 115 males and 110 females from Michalovce and 102 males and 105 females from Svidnik provided blood samples for the chemical analyses. A large number of PCB congeners were assayed as well as DDE, DDT and HCB in the blood specimens obtained. Statistically significant differences were found in the geometric mean levels of DDT and DDE, but not HCB, between the two sampled geographic areas. However, there was considerable overlap in the range of DDE and DDT levels between the two areas.

The authors also examined NHL standardized incidence ratios (SIRs) for NHL occurrence in the two areas. The NHL SIR for males for the high exposure area, Michalovce district, was 1.12 (0.80-1.52), and for the low exposure area, Svidnik, 1.11 (0.62-1.84). The

corresponding SIRs for females were 1.04 (0.70-1.49) and 0.56 (0.22-1.28) in the two areas respectively. Thus, there was no excess in NHL incidence in the high exposure zone with the SIRs ranging from 1.04 to 1.12. Results for the low exposure area ranged from 0.56 to 1.11. The SIR of 0.56 was based on only 6 observed cases and was not statistically significant. It should be pointed out that the proper comparisons to be made are the observed numbers of cases with the expected number of cases (based on population incidence statistics for eastern Slovakia as a whole) rather than the ratio of SIRs from the two areas. Thus, the data as presented show no excess of NHL incidence in the high exposure region and similar incidence ratios in the low exposure region.

Unfortunately, this study is of limited value due to its being an ecologic study. The investigators had no information on specific chemical levels in cases and non-cases; rather they determined mean chemical levels for a very small population sample in the two regions studied. These mean levels were then related to area incidence of NHL. With regard to DDT and DDE levels, no effort was made to tease apart the possibly confounding effects of other chemical exposures. Such a study can be used for hypothesis generation at best. In summary, this study is of very limited scientific value owing to its design. Nevertheless, no increase in NHL incidence was found in the high exposure area.

October, 2009

Curriculum Vitae

Seymour Grufferman, M.D., M.P.H., S.M., Dr.P.H.

Office Address:	14 Brahma Lane Santa Fe, NM 87506 505-820-2611 (phone) 505-820-2621 (fax) E-mail: sgrufferman@salud.unm.edu

Date and Place of Birth:	November 29, 1937; New York, NY
Citizenship:	United States
Marital Status:	Married- Sue Y.S. Kimm, M.D.

Education:

B.S. - City College of New York, 1960.
M.D. - State University of New York (Syracuse), 1964.
M.P.H. - Harvard School of Public Health, 1968.
S.M. - Harvard School of Public Health, 1974.
Dr.P.H. - Harvard School of Public Health, 1979.

Medical Training:

Rotating Internship: University of Illinois Research and Educational Hospitals, Chicago, IL, 1964-65.

Pediatric Residency: New York Hospital - Cornell Medical Center, New York, NY. 1965-67.

Professional Experience:

Lecturer, Department of Biology, City College of New York, New York, NY, 1960.

Lecturer (part-time), Division of Allied Health Sciences Program in Health Care Administration, Northeastern University, Boston, MA, 1967-68.

Major, Medical Corps, U.S. Air Force; Chief of Pediatrics and Public Health, and Fifth Air Force Consultant in Pediatrics, U.S. Air Force Hospital, Tachikawa, Japan, 1968-1971.

Assistant Professor and Chairman, Department of Public Health, Gondar Public Health College, Haile Selassie I University, Gondar, Ethiopia, 1971-73.

Full-time student, candidate for Dr. P.H. degree in epidemiology, Harvard School of Public Health, Boston, MA, 1973-76. Epidemiologist, Management Sciences for Health, Cambridge, MA, 1973-74.

Teaching Fellow, Department of Epidemiology, Harvard School of Public Health, Boston, MA, 1975-76.

Volunteer Physician, The Medical Van, Bridge Over Troubled Waters (Archdiocese of Boston & Massachusetts General Hospital), Boston, MA, 1975-76.

Assistant Professor, Department of Pediatrics, Duke University Medical Center, Durham, NC, 1976-81.

Director, Epidemiology and Biostatistics Unit, Duke University Comprehensive Cancer Center, Durham, NC, 1976-87.

Attending Pediatrician, Duke University Hospital, Durham, NC, 1976-87.

Director, Epidemiology Study Program, Duke University School of Medicine, Durham, NC, 1978-87.

Associate Professor (with tenure), Department of Pediatrics, Duke University Medical Center, Durham, NC, 1981-87.

Director, Cancer Prevention and Control Program, Duke University Comprehensive Cancer Center, Durham, NC, 1981-87.

Adjunct Associate Professor, Department of Epidemiology, School of Public Health, and Member, Graduate Faculty, University of North Carolina at Chapel Hill, Chapel Hill, NC, 1982-87.

Assistant Professor (Secondary Appointment), Department of Medicine, Duke University Medical Center, Durham, NC, 1984-87.

Chief, Clinical Epidemiology Division, Department of Pediatrics, Duke University Medical Center, Durham, NC, 1984-87.

Professor, Department of Epidemiology, Graduate School of Public Health, University of Pittsburgh, Pittsburgh, PA, 1987-88.

Associate Director for Epidemiology and Preventive Oncology, Pittsburgh Cancer Institute, Pittsburgh, PA, 1987-89.

Chairman, Department of Family Medicine and Clinical Epidemiology, University of Pittsburgh School of Medicine, Pittsburgh, PA, 1988-98.

Professor, Department of Family Medicine and Clinical Epidemiology, University of Pittsburgh School of Medicine, Pittsburgh, PA, 1998-2004.

Director, Family Medicine Division, Children's Hospital of Pittsburgh, Pittsburgh, PA, 1993-98.

President, University Family Practice Associates, Pittsburgh, PA, 1994-98.

Senior Research Associate in Epidemiology and Biostatistics, European Institute of Oncology, Milan, Italy, 1994-2000.

Active Staff, Family Medicine Division, Children's Hospital of Pittsburgh, Pittsburgh, PA, 1994-2003.

Chief of Family Medicine Service, University of Pittsburgh Medical Center, Pittsburgh, PA, 1995-98.

Active Staff, University of Pittsburgh Medical Center, Pittsburgh, PA, 1995-2003.

President, University Physicians Practice Association, University of Pittsburgh Medical Center, Pittsburgh, PA, 1995-97.

Research Professor, Department of Pathology, School of Medicine, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, 2004-2005.

Research Professor, Department of Internal Medicine, Division of Epidemiology and Biostatistics, School of Medicine, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, 2005-2007.

Full Member, Cancer Research and Treatment Center, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, 2004-.

Voluntary Adjunct Professor, Department of Internal Medicine, Division of Epidemiology and Biostatistics, School of Medicine, University of New Mexico Health Sciences Center, Albuquerque, New Mexico, 2007-.

Pittsburgh Cancer Institute, Executive Committee, 1987-89.

University of Pittsburgh School of Medicine, Executive Committee, 1988-98.

University of Pittsburgh School of Medicine, Council of Clinical Chairmen, 1988-98.

University of Pittsburgh Medical Center, Executive Planning Council, 1988-95.

University of Pittsburgh, Annual Family Practice Refresher Course, Planning Committee, 1988-98.

University Health Network Inc., Board of Directors, 1988-96; Member, Executive Committee, 1994-96.

University of Pittsburgh, Graduate School of Public Health, Occupational Medicine Residency Advisory Committee, 1989-98.

University of Pittsburgh School of Medicine, Chairman, Curriculum Revision Task Force on Ambulatory and Community Health, 1990-91.

Baby Your Baby Internship Program, Committee Member, 1990-95.

University of Pittsburgh School of Medicine, Applicant Interview Committee, 1992-93.

University of Pittsburgh School of Medicine, Chairman, Committee on Secondary Faculty Appointments, 1992-98.

University of Pittsburgh, Fibromyalgia Research Committee, 1994-95.

University of Pittsburgh Medical Center, Managed Care Committee, 1994-95.

University of Pittsburgh Medical Center, Primary Care Focus Group, 1994-96.

University of Pittsburgh Medical Center, Advisory Committee for the Center for Health Services Research, 1994-98.

Children's Health Network, Member, Manpower Committee, 1995-96.

University of Pittsburgh Medical Center, Member, Network Partnership Committee, 1995-96.

University of Pittsburgh Medical Center, Co-Chair, Committee on Satellite Clinics, 1995-96.

University of Pittsburgh Medical Center, Member, Physician Hospital Organization Planning Committee, 1995-96.

University of Pittsburgh and St. Margaret Memorial Hospital, Member, Affiliation Oversight Committee, 1995-96.

Tri-State Health System, Member, Board of Directors, 1995-97.

University of Pittsburgh Medical Center Keystone/Security Blue HMO Committee, 1995-96.

University of Pittsburgh Center for Biomedical Informatics, Advisory Committee, 1996-98.

University of Pittsburgh Medical Center Primary Care Task Force, 1996-97.

University of Pittsburgh School of Medicine, Planning and Budgeting Committee, 2000-2006.

Regional and National:

Intergroup Rhabdomyosarcoma Study Committee, 1978-95.

State of North Carolina Secretary of Human Resources' Commission on Cancer, 1979-81.

Pediatric Oncology Group, Co-chairman, Epidemiology Committee, 1983-91.

North Carolina Division, American Cancer Society, Public Education Committee, 1984-87.

National Council on Radiation Protection and Measurements, Scientific Committee 81 (Assessment of Exposures from Radiation Therapy), 1985-87.

Children's Oncology Group, Chairman, Hodgkin's Disease Epidemiology (CCG E13) and Rhabdomyosarcoma Epidemiology Committees, 1988-

SmithKline Beecham, Inc., Member, Urology Advisory Panel, 1995.

Institute of Medicine, National Academy of Sciences, Member, Committee to Review the Health Effects in Vietnam Veterans of Exposure to Herbicides, Washington, DC, 1995-96.

University of Helsinki, Faculty of Medicine, Member, Search Committee for the Professor of Public Health, 1999-2000.

Peer Review Experience:

Ad Hoc Member, Epidemiology and Disease Control Study Section, Bethesda, National Institutes of Health, 1978.

Member, Cancer Center Support Review Committee, Bethesda, National Cancer Institute, 1979-83.

Ad Hoc Grant Reviewer, American Cancer Society, 1981, March of Dimes Birth Defects Foundation, 1981, and Saudi Arabian National Center for Science and Technology, 1981.

Ad Hoc Conference Grant Reviewer, National Cancer Institute, 1981-88.

Member, Special Study Section on the Acquired Immunodeficiency Syndrome, Bethesda,

National Institutes of Health, 1982-83.

Chairman, Ad Hoc Contract Review Committee on "The Natural History of Acquired Immunodeficiency Syndrome in Homosexual Men," (The Multicenter AIDS Cohort Study) Bethesda, National Institute of Allergy and Infectious Diseases, 1983.

Ad Hoc Member, Cancer Center Support Review Committee, Bethesda, National Cancer Institute, 1985.

Member, Special Study Section to review a grant for "Screening for Neuroblastoma in Infants", Montreal, National Cancer Institute, 1987.

Chairman, Epidemiology and Technology Transfer Subcommittee, Acquired Immuno-Deficiency Syndrome Research Review Committee (AIDSRRC), Bethesda, National Institute of Allergy and Infectious Diseases, 1987-91.

Member, Scientific Advisory Committee on Clinical Investigations III - Prevention, Diagnosis and Therapy Review Committee, Atlanta, GA, American Cancer Society, 1987-91.

Member, Special Study Section-1, for review of a grant application for "Screening for Neuroblastoma in Infants". Bethesda, National Cancer Institute, 1988.

Ad Hoc Grant Reviewer, March of Dimes Birth Defects Foundation, 1989.

Chairman, Special Study Section on Biostatistics (SSS-1) (RI), Washington, National Institutes of Health, 1991.

Member, National Institutes of Health Reviewers Reserve, Bethesda, MD, 1991-95.

Member, Grant Review Committee, Aidan O'Neil Foundation for the Prevention of Childhood Cancer, Nebraska, 1993.

Member, Special Study Section to review a program project, "Cancer Prevention Research Program," Fred Hutchinson Cancer Center, National Cancer Institute, December, 1993.

Ad Hoc Member, Cancer Centers and Research Programs Grant Review Committee (Subcommittee D), National Cancer Institute, Bethesda, MD, 1994.

Ad Hoc Member, NCI Grant Review Subcommittee E, Cancer Epidemiology. Prevention and Control, Bethesda, MD, 1997.

Member, Cancer Center Support Grant Site Visit Team, Fred Hutchinson Cancer Research

Center, Seattle, WA, 1998, NCI.

Ad Hoc Member, NCI Grant Review Subcommittee E, Cancer Epidemiology, Prevention and Control, Bethesda, MD, 1998.

Member, Cancer Manpower and Training Grant Review Subcommittee (NCI-F), National Cancer Institute, Bethesda, MD, 1997-2001, 2001-2002.

Ad Hoc Member, NCI Grant Review Subcommittee E, Cancer Epidemiology, Prevention and Control, Bethesda, MD, 2001.

Member, Special Emphasis Panel and Scientific Grant Review Groups, NCI Loan Repayment Program, Washington, DC, 2003, 2004, 2005, 2006, 2007, 2008, 2009.

Ad Hoc Member, NCI Grant Review Subcommittee F, Cancer Education, Washington, DC, 2003.

Member, NCI Special Emphasis Panel, Long-Term Cancer Survivors: Research Initiative, Washington, DC, 2003.

Charter Member, NIH Centers for Scientific Review, Cancer Biomarkers Study Section, Washington, DC, 2003-4. Ad Hoc Member, 2004 –.

Mail Reviewer, Center for Scientific Review, Special Emphasis Panel on Chronic Fatigue Syndrome, Fibromyalgia Syndrome, and Temperomandibular Dysfunction. Washington, DC, 2006.

Member, Site Visit Team to review the Cancer Center Support Grant of the Fred Hutchison Cancer Research Center, Seattle, WA, 2008, NCI.

Member, Site Visit Team to review a Cancer Center Support Grant application at Emory University, Atlanta, Georgia, 2008, NCI.

Member, Site Visit Team to review a Cancer Center Support Grant application at the University of Texas, Southwestern Medical Center, Dallas, TX, 2009, NCI.

Membership on Special Review Committees (SRC):

SRC to review a program project on "Diet, Lifestyle and Cancer," Baltimore, NCI, 1982.

SRC on Acquired Immunodeficiency Syndrome, Bethesda, NIDA, 1983.

SRC to review the Center for Ulcer Research and Education, Los Angeles, NIADDKD, 1983.

SRC on Cancer Control Science Programs, Houston and Bethesda, NCI, 1984

SRC to review a program project on "Social Epidemiology of Cancer," Buffalo, NCI, 1984.

SRC to review a Cancer Center Support Grant, San Juan, NCI, 1984.

SRC to review master agreements for clinical research on the acquired immunodeficiency syndrome, Bethesda, MD, NIAID, 1985.

SRC to review the Immunodeficiency-Cancer Registry, Minneapolis, MN, NCI, 1985.

SRC for program review of studies on the natural history of HTLV- III infection, Bethesda, MD, NIAID and NCI, 1986.

SRC on Acquired Immunodeficiency Syndrome, NIDA, Rockville, MD, 1986.

SRC to review Outstanding Investigator Awards, NCI, Bethesda, MD, 1988.

SRC to review a Consortium Cancer Center Support Grant, Northern California Cancer Program, NCI, Belmont, CA, 1988.

Chair, SRC to review the Drew-Meharry-Morehouse Consortium Cancer Center Support Grant, NCI, Bethesda, MD, 1988.

SRC to review proposals for "Community Programs for Clinical Research on AIDS", NIAID, Rockville, MD, 1989.

SRC to review a Cancer Center Support Grant, University of Southern California Comprehensive Cancer Center, NCI, Los Angeles, CA, 1990.

Chair, SRC to review the Drew-Meharry-Morehouse Consortium Cancer Center Support Grant, NCI, Bethesda, MD, 1990.

SRC to review a program project on "Human Papilloma Virus: Biology Clinical Significance and Epidemiology", Fred Hutchinson Cancer Center, NCI, Seattle, WA, 1991.

Chair, SRC to review a program project on "Prevention of Primary Hepatocellular Carcinoma", Fox Chase Cancer Center, Philadelphia, PA, 1991, NCI.

Special Emphasis Panel to review a program project on "Human Papilloma Virus: Biology, Clinical Significance and Epidemiology", Fred Hutchinson Cancer Center, Reverse Site

Visit, NCI, Chevy Chase, MD, 1992.

Chair, SRC to review a program project on "Molecular Epidemiology of Primary Hepatocellular Carcinoma" Fox Chase Cancer Center, Reverse Site Visit, NCI, Bethesda, MD, 1992.

Grant Review Team to review a Program Project, "Molecular Biomarkers for Environmental Carcinogenesis", NIEHS, Research Triangle Park, NC, 1992.

SRC to review NIAID Institutional Training Awards for Clinical Research on the Acquired Immunodeficiency Syndrome, NIAID, Chevy Chase, MD, 1992.

Special Emphasis Panel to review a program project supplement on "HPV: Biology, Clinical Significance and Epidemiology", NIH telephone review, 1993.

SRC to review a program project on "Studies of Monoclonal Gammopathies", Mayo Clinic, Rochester, MN, 1993, NCI.

SRC to review a program project on "Studies of Monoclonal Gammopathies", Mayo Clinic, Rochester, MN; reverse site visit, NCI, Chevy Chase, MD, 1994.

Chair, SRC to review a Cancer Center grant application for the "Drew-Meharry-Morehouse Consortium Cancer Center", NCI, Bethesda, MD, 1994.

SRC to review a program project on "Evaluation of Carcinogenic Risks to Humans," NCI telephone review, 1995.

SRC to review grant applications for "Collaborative Cancer Prevention Research Units", NCI, Rockville, MD, 1995.

SRC to review the Small Grants Program for Cancer Epidemiology (PAR-95-077), tele-conference review, 1996, NCI.

Peer Review of Progress of the Drew-Meharry-Morehouse Consortium Cancer Center, teleconference review, 1997, NCI.

Special Emphasis Panel to review a program project on "Studies of Monoclonal Gammopathies", Mayo Clinic, Rochester, MN, 1997, NCI.

Chair, Special Emphasis Panel to review a program project on "Molecular Epidemiology of Hepatocellular Carcinoma", Fox Chase Cancer Center, Philadelphia, PA, 1997, NCI.

Special Emphasis Panel to review "Cohort and Nested Case-Control Study of AIDS-Related

Non-Hodgkin's Lymphoma, Kaposi's Sarcoma and Other Malignancies-Phase III", Rockville, MD, 1998, NCI.

Member, Special Emphasis Panel to review a program project on "Head and Neck Cancer Rehabilitation", Northwestern University, Evanston, IL, 2001, NCI.

Member, Special Emphasis Panel to review a program project on "Pre-Diagnosis Serologic Biomarkers of NHL Risk", Harvard University, Boston, MA, 2001, NCI.

Member, Special Emphasis Panel/Scientific Review Group, ZCA1-GRB-S (J1)R, Molecular Oncology – Basic, Translational and Clinical Studies, Rockville, MD, 20009, NCI.

Editorial Appointments:

Guest Editor, Reviews of Infectious Diseases, 1991.
Guest Editor, Blood, 1995.
Consulting Editor, Annals of Medical Science, 1993-2000.
Member, Editorial Board, Journal of Epidemiology and Biostatistics, 1995-2001.

Reviewer for Journals:

Cancer Epidemiology, Biomarkers and Prevention, JAMA, Clinical Cancer Research, International Journal of Cancer, Journal of Clinical Epidemiology (Journal of Chronic Diseases), American Journal of Epidemiology, Journal of the National Cancer Institute, Cancer, Lancet, New England Journal of Medicine, Cancer Causes and Control, Medical and Pediatric Oncology, Journal of Pediatric Hematology/Oncology, Epidemiology, Environmental Health Perspectives, Annals of Epidemiology, Journal of Occupational Medicine, Preventive Medicine, Cancer Research, Kidney International, American Journal of Obstetrics and Gynecology, Epidemiologic Reviews, British Journal of Cancer, Family Practice Recertification, European Journal of Cancer, Clinical Infectious Diseases and National Medical Journal of India.

Consultant Appointments:

Participant in Workshop/Conferences on Alzheimer's Disease, Senile Dementia and Related Disorders, Bethesda, MD (NINCDS, NIA, NIMH), 1977; Functional Gastrointestinal Disorders, Bethesda, MD (NIAMDD, NIMH), 1979; Epidemiology and Biostatistics in Clinical Cancer Education, Bethesda, MD (NCI), 1979; Inflammatory Bowel Disease, Princeton, NJ (NIADDKD), 1982; Neoplasia in Rheumatoid Arthritis, St. Simons Island, GA (Arthritis Foundation), 1984; Epidemiology of Multiple Myeloma, Bethesda, MD

(NCI), 1990; Cambridge Symposium on Myalgic Encephalomyelitis, Cambridge, U.K. (Nightingale Foundation), 1990; 1990 Research Conference, Chronic Fatigue Immune Dysfunction Syndrome Society, Charlotte, SC (CFIDS) NC, 1990; AIDS Epidemiology Investigators Meeting (NCI), Bethesda, MD, 1990; Workshop on Chronic Fatigue Syndrome (NIAID & NIMH), Bethesda, MD, 1990.

Research Triangle Institute, Research Triangle Park, NC, 1977-78.

International Agency for Research on Cancer (Organized and taught courses in cancer epidemiology in Zambia, Poland, Pakistan, Thailand, German Democratic Republic and U.S.S.R.), 1981-89.

World Health Organization Tropical Disease Research Programme, Geneva, 1981.

Rockefeller Foundation, New York, NY, 1982.

Panel Member, National Institutes of Health, Technology Assessment Meeting on the Feasibility and Effectiveness of a National Bone Marrow Donor Registry, Bethesda, MD, 1985.

Plough, Inc., Memphis, TN, 1985-93.

Member, National Bone Marrow Registry Evaluation Panel, National Institutes of Health, Bethesda, MD, 1988.

Member, Scientific Advisory Committee, Norris Cotton Cancer Center, Dartmouth University, Hanover, NH, 1988.

Chair, Working Group on Cancers of Childhood; The Use of Biomarkers in Field Studies of Environmentally Associated Cancers, Agency for Toxic Substances and Disease Registry, Atlanta, GA, 1994.

Member, Scientific Advisory Group on Benzene, European Institute of Oncology, Milan, Italy, 1995.

Agency for Toxic Substances and Disease Registry (ATSDR), Chair, Panel on General Methodological Challenges, Workshop on "Studying Environmental Exposures Among Children with Cancer: Current Technologies, Methodological Challenges, and Community Concerns", Atlanta, GA, 2000.

Agency for Toxic Substances and Disease Registry (ATSDR), Member, Tremolite Asbestos Registry Expert Working Group, Atlanta, GA, 2002.

Certification:

National Board of Medical Examiners (1965)
American Board of Pediatrics (1975)
American College of Epidemiology (1981)
Medical Licensure: New York (1965) (Inactive)
North Carolina (1976)
Pennsylvania (1989) (Active Retired)

Awards and Honors:

A.G. Levy Award (Chemistry) - C.C.N.Y.
J.L. Heffron Award (Medicine - Surgery) - S.U.N.Y.
N.I.H. Individual Research Fellowship - Harvard School of Public Health.
Student Prize Paper Award, Society for Epidemiologic Research, 1979.
Who's Who in the South and Southwest, 1989-90.
Who's Who in Science and Engineering, 2nd Ed., 1994-95.
Who's Who in the East, 22nd Ed., 1992; 24th Ed., 1994; 25th Ed., 1995.
Who's Who in the World, 12th Ed., 1995.
Elected Fellow, American Association for the Advancement of Science, 1995.
Who's Who in Medicine and Healthcare, 4th Ed., 2002.
Who's Who in American Education, 6th Ed., 2004-2005.
Who's Who in Science and Engineering, 9th Ed., 2006-2007, 10th Ed. 2008-2009.
Who's Who in American Education, 8th Ed., 2007-2008.
Who's Who in America, 2009.

Professional Memberships:

American Association for the Advancement of Science (Fellow)
American College of Epidemiology (Fellow)
Children's Oncology Group

Grufferman S, Principal Investigator: Case-Control Study of Hodgkin's Disease in Childhood (Competitive Renewal), RO1 CA47473, N.I.H., $1,025,078, 2/l/94-9/9/99.

Expert Report of
Marion J. Fedoruk M.D., CIH, DABT, FACMT

Case No. C-4885-99-F(10)

Guadalupe Garza v. Allied Chemical Corporation, et al.
332nd Judicial District, District Court of Hidalgo County, Texas

Table of Contents

1.0 Purpose

The purpose of this report is to provide my opinions with respect to the issue of whether or not Guadalupe Garza, a 66-year-old resident of Mission, Texas developed follicular B-cell non-Hodgkin lymphoma (NHL) as a result of her alleged exposure to DDT and/or its metabolites from the Hayes-Sammons mixing facility in Mission, Texas.

The report includes an assessment concerning the issue of whether or not DDT and/or its metabolites cause or contribute to the development of NHL. The report also examines the assumptions, methods and conclusions of plaintiff's expert, Dr. Sawyer, regarding Ms. Garza's alleged exposure to DDT and her NHL. Also examined is the basis for Dr. Sawyer's general causation opinion that DDT causes NHL, as well as his specific causation opinions concerning Ms. Garza's NHL.

This report also examines the assumptions, methods and conclusions of plaintiff's other expert, risk assessor Dr. Strauss. Dr. Strauss conducted a health risk assessment which purports to provide predictions of Ms. Garza's DDT intake and overall theoretical "cancer risk" allegedly associated with the Hayes-Sammons site.

2.0 Summary of Opinions

- It is my opinion, to a reasonable degree of medical probability, that the scientific literature does not demonstrate that DDT and/or its metabolites cause or contribute to the development of NHL, including follicular lymphoma.
- DDT is considered to be one of the most investigated pesticides with respect to the occurrence of NHL.
- Cohort studies of workers with DDT exposure have not demonstrated a statistically significant increased NHL incidence and/or mortality.

- Case-control studies involving DDT, including studies that utilize DDT biomarkers, show no or very limited associations between DDT and NHL that largely disappear following adjustment for other exposure.
- Ecological data on NHL rates and DDT use in the U.S. and other countries do not support the conclusion that DDT causes NHL.
- Texas Department of Health investigations that have been conducted to evaluate potential health impacts from Hayes-Sammons show no increased cancer rates in Mission, Texas and no increased serum DDT levels in persons living and/or working in close proximity to Hayes-Sammons.
- Dr. Sawyer's claim that DDT causes, or substantially contributes to NHL is not substantiated by the epidemiological literature.
- Dr. Sawyer's reliance on the risk assessment process and Dr. Strauss's theoretical "cancer risk" estimates for the purpose of determining the cause of Ms. Garza's NHL lacks scientific validity.
- Dr. Strauss's health risk assessment is based upon incomplete environmental data and consequently her predicted theoretical "cancer risk" estimates are unreliable.
- Dr. Strauss's 3-fold increase of Ms. Garza's theoretical "cancer risk" is inconsistent with EPA guidance.
- Dr. Strauss's estimates of Ms. Garza's theoretical "cancer risk," even when increased by 300% for "506 Nicholson," are insignificant when compared to her actual background cancer risk.
- Dr. Strauss's presumed DDT intake level for Ms. Garza while residing at "506 Nicholson" is similar to the background daily intake reported for the general public, whereas Dr. Strauss's presumed DDT intake for Ms. Garza while at 1015 Nicholson is less than the amount she would have received in her diet at that time.
- Ms. Garza has other risk factors for NHL. One risk factor, obesity, is increasingly being recognized through several studies as being important. Another potential risk factor is Ms. Garza's past employment in a cleaning occupation. Although these risk factors cannot be determined as casual for her follicular lymphoma, they serve to highlight the speculative nature of the plaintiff's experts' claims that

a known cause can be specified, such as DDT. Yet, her presumed DDT intake is similar or less than that of the general public, and her theoretical "cancer risk" is minute compared to her overall background risk of developing cancer.

3.0 Qualifications

I am a licensed medical doctor, practicing in the fields of occupational and environmental medicine, medical toxicology and industrial hygiene. I received my medical degree with Distinction from the University of Alberta, Edmonton, Canada, in 1978. I performed postgraduate medical training through McGill University, Montréal and my residency in Occupational Medicine at University of California Irvine from 1981 to 1983.

I hold a primary board certification by the American Board of Preventive Medicine in Occupational Medicine. I also hold a subspecialty certification in Medical Toxicology from the American Board of Preventive Medicine. The Medical Toxicology subspecialty board is sponsored by three primary medical boards: Emergency Medicine, Pediatrics and Preventive Medicine. There are fewer than fifty physicians in the United States that hold board certification in both occupational medicine and medical toxicology. Also, I am board certified as a toxicologist by the American Board of Toxicology, and hold a board certification in industrial hygiene from the American Board of Industrial Hygiene, with a specialty focus in toxicology. The discipline of industrial hygiene deals with the assessment of workplace and environmental hazards and measures to control such hazards. As an industrial hygienist, I have expertise in the use of environmental exposure data to assess human exposure and ascertain potential doses that an individual might receive from different environments.

Currently, I am employed by the University of California, Irvine ("UCI") at the Center for Occupational and Environmental Health (COEH). The COEH was established within the University of California to train occupational health scientists and professionals, conduct research on occupational and environmental health issues, and provide services

to the public, employers and workers. I hold the title of Clinical Professor of Medicine in the Department of Medicine. I was designated as the Senior Physician at the UCI COEH occupational and environmental medicine specialty clinic, a designation awarded to a physician with outstanding expertise in their field. I am also employed as a Principal Scientist for Exponent in the Health Sciences practice. I was also elected a Fellow of the American College of Medical Toxicology (FACMT). This recognition is awarded by the American College of Medical Toxicology, the specialty society that represents the nation's medical toxicologists, to medical toxicologists who meet the highest standing in their field.

I have extensive experience in the assessment of pesticide-related hazards as well as medical assessment of persons exposed to pesticides. This includes periodic testing of pesticide exposed workers as well as treatment of persons with accidental pesticide exposure. I served as an expert member of a joint panel convened by the U.S. Department of Labor, U.S. EPA and U.S. Department of Food and Agriculture for developing a national program for training the nation's health care providers on how to recognize pesticide-related health problems. I also served on a USC/NIOSH advisory panel to develop training programs for public health and Department of Agriculture officials concerning how to deal with pesticide-contaminated waste sites.

In addition, I have conducted studies and published articles in the areas of occupational and environmental medicine, and authored chapters in several books, including the World Health Organization's Encyclopedia of Occupational Safety and Health, and the Encyclopedia of Toxicology. I am the recipient of the Merit in Authorship Award from the American College of Occupational and Environmental Medicine and the Jean Spencer Felton Award for Excellence in Scientific Writing from the Western Occupational and Environmental Medical Association.

Attached is my current curriculum vitae.

4.0 Disease at issue – Non-Hodgkin Lymphoma

Non-Hodgkin Lymphoma (NHL) is a term used to describe a heterogeneous group of malignancies that arise from lymphoid tissue. NHL occurs when a particular lymphoid cell (B-cell, T-cell, or NK cell) undergoes malignant transformation. NHL can originate in any lymphoid tissue including lymph nodes, gut-associated lymphatic tissue, and the spleen. Criteria used to classify lymphoid tumors have varied, but currently the World Health Organization (WHO) system is principally used to classify different types of lymphoma. The most common NHL types in Western countries are diffuse large B-cell (DLBC) type and follicular lymphoma.

NHL represents approximately 4 percent of cancer incidence and approximately 3 percent of all cancer-related deaths in the U.S. In 2006, about 58,870 new cases were predicted and approximately 18,840 persons were expected to die of lymphoma in the United States (Jemal, et al., 2006). The disease incidence increases with age. In the 1970s and 1980s, age adjusted incidence increased by about 3-4 % annually. In the 1990s, the increasing rate diminished. The increased incidence is attributable in part to the HIV epidemic since persons with HIV infection are at substantially greater risk of developing NHL.

The cause for most types of NHL, including follicular lymphoma, has not been established (Hartge, et al., 2006). Several risk factors have been identified for particular NHL types. Immunosuppression is considered to be a significant risk factor and persons with congenital immunodeficiency disorders are at very high risk of developing NHL. Use of immunosuppressive medications following organ or stem cell transplantation results in a substantially increased risk. Autoimmune disorders including Sjögren's syndrome and celiac disease are associated with an increased risk. Some viral infections are strongly associated with NHL risk. Infection with HTLV-1, an endemic retrovirus found in the Caribbean, Southwestern Japan, and Southeastern U.S., results in adult T-cell leukemia/lymphoma. Epstein-Barr virus infection has been identified as playing a

significant role in Burkitt's lymphoma. Obesity is being increasingly recognized as being a risk factor for NHL (Maskarinec, et al., 2008; Chiu, et al., 2007; Willet, et al., 2005; Rapp, et al., 2005; Skibola, 2007).

Numerous occupations have been identified as potential risk factors including cleaners, meat workers, farmers, animal husbandry, heavy truck drivers, metal product manufacturing, teachers, wood workers, printing industry work and textile workers (Boffeta and deVocht 2007; t'Mannetje, et al., 2007; Svec, et al., 2005; Karunanayake, et al., 2008; Alexander, et al., 2007). Numerous dietary factors have also been studied, including total fat intake, meat intake, dairy intake, fruit and vegetable consumption, and micronutrients (Cross and Lim 2006; Alexander, et al., 2007). Agricultural and residential pesticide exposures including insecticides, herbicides and fumigants have been evaluated as potential risk factors. A causal association between a specific environmental factor and NHL has not been established (Müller, et al., 2005; Alexander, et al., 2007).

Genetic factors are increasingly being recognized as underlying risk factors for NHL. Historically, familial NHL clusters have been reported and having a family member with the disease represented an increased risk factor. Proposed genetic risk factors for NHL have included polymorphisms on nitric oxide synthetase genes, which modify interactions between fruit and vegetable intake and NHL risk (Han, et al., 2009) and oxidative stress genes (Wang, et al., 2006).

Many epidemiological studies have focused on NHL in aggregate and not on the individual NHL subtype. Since NHL represents a heterogeneous group of disorders, risk factors for each subtype may vary. Several epidemiological studies are beginning to evaluate risk factors for individual subtypes. Advances in testing for genetic markers enable epidemiological studies to now begin to evaluate the role of genetic susceptibility factors.

Several studies have assessed potential risk factors for follicular lymphoma, the NHL at issue in this case. Factors reported in certain studies to potentially increase follicular lymphoma risk include use of permanent hair dyes before 1980, polymorphism in the *MGMT* gene, and the *NAT2* acetylation phenotype (Morton, et al., 2008). Variations of the *BCL2L11* gene have also been reported as a potential susceptibility factor for follicular lymphoma (Morton, et al., 2009). Obesity has also been reported to be associated with an increase in follicular lymphoma risk (Skibola, et al., 2004). Future epidemiological investigations that measure and evaluate more specific disease risk factors or potential confounders, such as genetic susceptibility, offer the potential to better understand the true cause(s) of the different types of NHL, including follicular lymphoma.

5.0 Epidemiological concepts

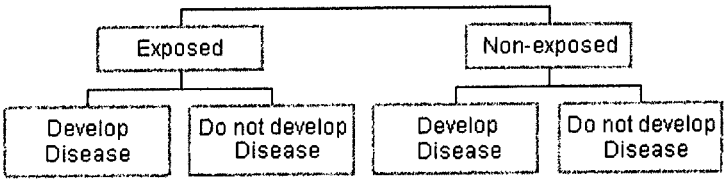
Epidemiology is the study of the cause of disease in human populations. Epidemiological studies examine the occurrence or distribution of disease in populations to help ascertain if a causal relationship exists between any exposure at issue in the population and a particular disease. Medical toxicologists routinely examine epidemiological literature as a main source of information about the effects of a chemical substance on humans. This information coupled with consideration of dose, exposure routes, and exposure duration is evaluated in aggregate to ascertain whether a substance is responsible for a specific health effect.

There are two main types of analytical epidemiological studies that are performed to evaluate whether a factor such as an environmental, occupational, or lifestyle exposure is responsible for causing a disease. The two types of epidemiological investigations are cohort and case-control studies. These are described below.

5.1 Cohort Studies

Cohort studies involve a study population that is followed over time for the occurrence of disease or death from the disease. Mortality data can be used to assess the occurrence of disease, especially when disease leads to death in the majority of cases, (e.g., lung cancer). The basis for defining the study population is the presence or absence of exposure to the factor of interest. For example, a cohort may include a population of workers exposed to coal dust. Following this population over time for development of new cases of disease (or death) provides data to define an incidence or mortality rate. A control or non-exposed population is also followed over time to serve as a comparison group for evaluating the effects of exposure in the exposed population. Cohort studies have the advantage that exposure information is collected prior to the onset of disease. A depiction of a cohort study is presented below.

Cohort Study Design



The term relative risk (RR) is used to describe the ratio of disease incidence or death in exposed individuals compared to the incidence of disease or death in unexposed individuals. Sometimes the rate of disease in a study group is compared to an external population such as a country, state, or county. The terms proportionate and standardized incidence (or mortality) ratios are used to describe such comparisons. These types of ratio measures are typically standardized by age and sex to provide a summary adjusted relative risk estimate that accounts for these factors.

If the relative risk or other risk estimate (PIR, SIR, SMR, etc.) equals 1, the incidence of disease in the exposed group equals the incidence of disease in the unexposed group and

the result is interpreted as "no association." If the RR is > 1, the incidence of disease in the exposed group exceeds the incidence of disease in the unexposed group and the result is interpreted as demonstrating an association, though not necessarily a causal association. If the RR is < 1, the incidence of disease in the exposed group is lower than the incidence of disease in the unexposed group and the result is interpreted as not demonstrating an association. If the ratio is significantly less than 1.0, it may indicate that exposure is protective in instances where the research interest concerns a vaccine, medical treatment, or some type of public health prevention program. Otherwise, without a strong biological rationale as to why exposure might be protective, it is usually interpreted simply as not associated.

5.2 Case-Control Studies

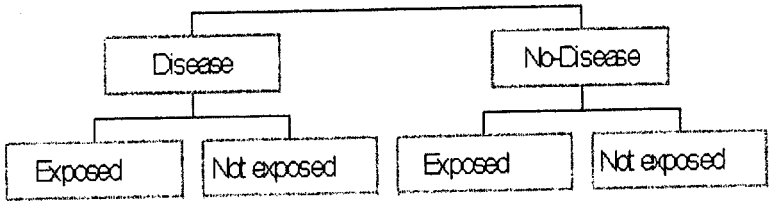
Case-control studies are used to assess factors that may cause or contribute to a disease by comparing the presence of the factor in persons with disease (cases) to persons without the disease but who are otherwise similar. Thus, the study population is defined by the presence or absence of disease. In contrast, cohort studies define study population on the basis of exposure potential. Data about exposure is obtained from persons with the disease and compared to data from control population in an attempt to ascertain whether the factor is associated with the disease.

Case-control studies are particularly useful for studying rare diseases, for which a cohort study may not be feasible because of the large population size and resources needed to conduct such a study. In a case-control study, cases are typically identified through disease registries, hospital, or medical claims data sources. Controls are then selected in a way to be representative of the population that generated the cases with respect to exposure history. In some studies the general population is selected (referred to as "population controls"), or they can also be selected from the same hospital where the cases were treated or identified. A nested case-control study is one that identifies cases and controls from within a cohort.

Case-control studies, because they involve much smaller numbers of participants, may permit more intensive collection of health, work history and other information from study participants than is typically obtained from subjects in a cohort study. Case-control studies however have several limitations including recall and selection bias. Recall bias can occur when persons with disease recollect past exposures more readily than controls. Selection bias can occur when the control population does not adequately represent cases. Because case-control studies often rely on self-reported exposure information from interviews and/or questionnaires rather than quantitative unbiased information that may be available in a cohort study (before disease has occurred), exposure misclassification can occur and bias the risk estimates.

A depiction of a case-control study is presented below.

Case-Control Study Design



To analyze an association between exposure and disease in a case-control study, the concept of odds ratio (OR) is used. An OR compares the probability that the event will occur to the probability that the event will not occur. In a case-control study, the OR represents a comparison of odds of exposure to a risk factor among cases to the odds of the same exposure among controls. Thus, the OR is a measure of relative risk in case-control studies.

Similar to the relative risk estimates, if the OR equals 1, the incidence of disease in the exposed group equals the incidence of disease in the unexposed group and the result is interpreted as "no association." If the OR is > 1, the incidence of disease in the exposed

group exceeds the incidence of disease in the unexposed group and the result is interpreted as demonstrating an association, though not necessarily a causal association. If the OR is < 1, the incidence of disease in the exposed group is lower than the incidence of disease in the unexposed group, and the result is interpreted as not demonstrating an association; although, when significantly less than one, it may indicate a protective effect.

5.3 Statistical Significance

Because the presence of an association may be due to chance, tests for statistical significance are used to evaluate the possibility of whether an observation or association occurred by chance. Two general statistical terms are used to assess the likelihood that findings occurred by chance: confidence intervals (CIs) and *p*-values. The concepts of CIs and/or *p*-values are recognized by the scientific community as valid methodologies for assessing whether observations occurred by chance.

5.3.1 Confidence intervals

Confidence intervals provide information about whether or not an association is statistically significant in addition to assessing the precision of the measure of a potential association. A confidence interval is a range of values for a parameter of interest (e.g., relative risk) constructed so that this range has a specified probability of including the true value. A 95% confidence interval indicates that the investigators are 95% confident that the true results lie within its upper and lower limit. Confidence intervals at the 95% range are routinely used in epidemiology to evaluate the possibility of whether a study finding is due to chance.

If a 95% confidence interval includes 1.0, the result is considered non-significant since the findings could be due to chance. If the 95% confidence interval does not include 1.0, the probability of an association being due to chance alone is 0.05 or lower. If the confidence interval is very wide, this indicates there is considerable uncertainty in the

value of the "true" relative risk estimate. A small number of observations can result in wide confidence intervals. Narrow confidence intervals are indicative of less uncertainty about where the "true" estimate lies.

5.3.2 *P*-Value

A *p*-value is used as a measure of the probability (likelihood) that the observed findings are due to chance alone. The lower the *p*-value, the less likely it is that the study results occurred by chance. When the probability is sufficiently low, the result is considered statistically significant. Most commonly, the cutoff for statistical significance is a *p*-value equal to, or less than, 0.05, which means that there is at most a 1 in 20 chance that the study results are due to chance.

5.4 Interpretation of Epidemiological Studies

The presence of an association, even if it is statistically significant, does not establish causation. Associations can occur as a result of chance or design factors in the study which can affect outcomes. These factors can include subject selection bias, differences in case ascertainment or definition, information bias, confounders, and misclassification of exposure. These factors should be considered in evaluating an epidemiological study.

In determining whether causation exists between specific factors and disease outcomes, the broad range of scientific literature should be examined. The Bradford Hill Criteria are guidelines commonly used to assess causation (Hill, 1965). This includes examining the scientific literature from several perspectives, including:

1) Strength of the association: Is the magnitude of change large enough to be statistically significant?

2) Consistency: Has it been repeatedly observed in different studies conducted by different researchers, in different places, circumstances and times?

3) Specificity: Is the available information sufficient to identify the specific cause and is the disease at issue specific enough to draw reasonable conclusions?

4) Time course: Is the onset of the specific health condition consistent with its natural history and the time of exposure to the chemical? i.e. have studies clearly established that exposure precedes disease and is not a consequence of the disease process?

5) Dose-response: Does the severity of incidence of the health condition increase as the magnitude or duration (or both) of exposure increase(s)?

6) Biological plausibility: Is there scientific information that offers a rational explanation for how the disease in question could be caused by the chemical?

7) Experimental association: Do changes that reduce or increase exposure also reduce or increase the occurrence or severity of the disease?

8) Analogy: Do similar exposure situations with toxicologically similar chemicals suggest an association with the disease?

9) Coherence of evidence: The cause and effect interpretation of the chemically induced disease should not seriously conflict with generally known facts of the natural history and biology of the disease. The evidence from various sources (histopathology, epidemiology, clinical studies, etc.) should be both convincing and consistent for reaching the conclusion of causation.

I understand that there is a legal standard in Texas, derived from a case called Merrell Dow Pharmaceuticals Inc. versus Havner (Havner), that is utilized by courts to interpret epidemiological studies. This standard indicates that for an epidemiological study to be considered relevant for supporting causation, the study has to demonstrate a statistically significant increased relative risk or odds ratio (OR) of more than 2.0. The approach used in Havner for evaluating epidemiological literature is consistent with the approach I used to analyze epidemiological studies dealing with DDT and NHL.

6.0 Studies of human populations do not demonstrate that DDT and/or its metabolites cause or contribute to the development of NHL

To determine whether DDT or its metabolites cause NHL, I conducted a review of the medical and scientific literature to identify studies that evaluated the potential association of DDT and/or its metabolites and NHL. I searched for peer-reviewed scientific literature using electronic data bases of the National Library of Medicine (Pub-Med and Toxline) with the search terms DDT, organochlorines, NHL, lymphoma, and follicular lymphoma. I also examined the bibliographies of published scientific review papers concerning DDT for other potential studies. I also examined textbooks dealing with occupational medicine, toxicology, and industrial hygiene for other studies that may not have been identified. Finally, I examined public health agency publications regarding DDT, including publications by the National Toxicology Program, Agency for Toxic Substances and Disease Registry, and International Agency for Research on Cancer. My objective was to identify all studies that provided information concerning both NHL and DDT–specific exposures.

I reviewed 38 published studies, including occupational cohort studies, population case-control and nested case-control studies where cases were selected from a larger cohort study. To assess the potential effects of DDT with respect to NHL, only studies that included DDT-specific exposure or biomarker data and NHL were included. Studies that

examined general risk factors such as farming or agricultural work that did not include DDT-specific exposure information were not utilized to determine the effect of DDT on NHL since they lacked the requisite specificity. Based upon a review of these 38 published studies (a very large literature set), I have concluded that studies of human populations do not demonstrate that DDT and/or its metabolites cause or contribute to the development of NHL.

The studies that I relied upon are described below.

6.1 Cohort Studies

6.1.1 Occupational cohort studies of DDT-exposed populations

Occupational or worker cohort studies provide unique insights into whether a substance is responsible for producing a particular disease since they frequently involve relatively high exposures making the occurrence of agent-specific adverse health effects more likely. Cohort studies obtain exposure information before the cohort member (person) develops the disease at issue. Consequently, differential reporting of exposures between cases and controls which can occur in case-control studies can be avoided.

Occupational cohort studies include:

- Purdue, et al., 2006: The National Cancer Institute's Agricultural Health Study is a large prospective cohort study of 57,311 private and commercial pesticide applicators in North Carolina and Iowa. The cohort was recruited between 1993-1997 and cancer incidence data were collected through December 31, 2002. Exposure was assessed by questionnaire and evaluated 28 pesticides. For organochlorine exposures, cumulative exposure was estimated for each organochlorine (including DDT) and for organochlorines that shared structural similarities (aldrin/dieldrin and chlordane/heptachlor). No association was found

between the subcohort of DDT-exposed applicators (n= 12,035) and NHL (RR = 0.9; 95% CI=0.6-1.5). Moreover, DDT use was not associated with any increased cancer risk. This study's strengths include large populations with pesticide exposure, detailed exposure information prior to diagnosis as well as controlling for a variety of potentially confounding factors, such as demographics and lifestyle.

- Cocco, et al., 1997a; Cocco, et al., 1997b: Cocco and colleagues conducted a mortality study of male Sardinian workers who had been exposed to DDT from working in an anti-malarial campaign from 1946-1950. DDT was used to eradicate malaria-carrying mosquitoes and flies. The cohort also had some exposure to chlordane and arsenic. The cohort included 2,908 workers who mainly applied DDT and inspected after DDT applications and 2,285 workers such as supervisors, administrative staff, laboratory staff, and directive staff who were considered unexposed. Applicators were reported as applying DDT both inside homes and outdoors. The DDT exposure concentrations were estimated to range from 170 – 600 mg/m^3 indoors and 24-86-mg/m^3 outdoors. Vital status was reported for 2,115 subjects and death certificates were available for 1,123 (53%) subjects. Deaths that occurred from 1956-1992 (1,043 subjects) were selected for a proportionate mortality study with the reference population consisting of Italian males. The PMR for NHL was 81 (95% CI=9-294). Thus, less than the number of expected NHL deaths was observed in this worker population.

- Cocco, et al., 2005: The Sardinian worker cohort was reexamined to include deaths through to December 31, 1999 for an additional seven years of mortality data. This cohort included 4,552 men who were subdivided into three sub cohorts: applicators (n=2,578), bystanders (n=683), and non-exposed workers (n=1,291). Among this group were 3,037 deaths, 2,726 of which had adequate death certificates. Estimates of DDT dose were assessed for this population using the European Predictive Operator Exposure Model (EUROPOEM). Daily DDT

doses were estimated to range from 54 µg to 140,400 µg and groups were divided into exposure quartiles. Mortality experience was compared to the Sardinian population to estimate a SMR. The non-exposed cohort served as an internal reference and Poisson regression was used to model specific cause of death as a function of both cumulative exposures, age of starting exposure, age at exit of exposure and ethnic origin.

The SMR for lymphatic cancer for applicators was 101 (95% CI=65-157); for bystanders 83 (95% CI=44-153); and for unexposed workers was 174 (95% CI=112-271). Cause-specific mortality risk (adjusted for age at exit for follow up, age at first exposure, ethnicity) for lymphatic cancer by DDT exposure category for applicators was 0.7 (95% CI=0.4-1.3); for bystanders 0.6 (95% CI= 0.3-1.2); and for all exposed 0.7 (95% CI= 0.4-1.1). No significant increased risk for any quartiles of daily exposure for any cancer was observed among applicators.

- Laws, et al., 1967: This study examined the health outcomes of workers at Montrose Chemical Corporation of California plant. The study included medical evaluations of 35 men who were considered to have high or medium exposure to DDT. These men had significantly elevated DDT levels compared to the general population and their total DDT adipose levels (38 to 647 ppm) were much higher than general population levels which were reported to be around 8 ppm. Medical records from 63 workers with DDT exposures over the prior five years revealed no cancers or blood dyscrasias.

- Ditraglia, et al., 1981: This study examined mortality of workers employed in the manufacture of organochlorine pesticides at four plants, including one California plant that only manufactured DDT since 1947. The study cohort included workers employed for at least six months prior to December 1964. Mortality was followed to December 31, 1976. The plant manufacturing DDT had 354

employees and included 7601 person-years of observation. Vital status was ascertained for 90% of the cohort, and death certificates were used to classify cause of death. Mortality was compared to age-adjusted mortality of U.S. white males. The SMR for all malignancies was 68 (95% CI=25-247). This decrease was attributed to healthy worker effect and possibly a lack of complete vital status ascertainment. No lymphatic or hematopoietic malignancy was reported for this DDT-exposed cohort.

- Brown 1992: This is a reassessment of the workers at the DDT plant previously evaluated by Ditraglia, et al. Mortality data was obtained through 1987. There were no deaths reported for any type of lymphatic cancer. Daily intake of DDT in heavily exposed workers at the plant formulating DDT was considered to range from 17,500-18,000 µg/day.[1]

6.2 Case-Control Studies with biomarkers

Case-control studies have been performed utilizing biomarkers which assess tissue levels of DDT and/or its metabolites as markers of exposure. The term "biomarker" is used to describe tests that can be used to measure a person's exposure to a chemical agent by measuring the substance and/or its metabolites in body tissues (e.g., blood, urine, adipose tissue, etc.). Case-control studies involving biomarkers offer a unique opportunity to evaluate the potential impact of DDT exposure on occurrence of NHL by being able to assess exposure potential through an objective measure and ascertain which subjects in the study populations were actually exposed, and depending upon the validity of the biomarker, the magnitude of such exposure.

As a medical toxicologist, I find that studies which use biomarker exposure measurements, such as blood and tissue levels of a compound, can be especially useful in examining the relationship, if any, between a chemical and a specific health outcome.

[1] Dr. Strauss estimates that Ms. Garza's daily intake during her residence at "506 Nicholson" was about 108 µg/day.

Such studies minimize ambiguity and bias that may occur when an exposure estimate is based on a person's recollection or memory, or when exposure is simply assumed to have occurred because of an individual's placement in a particular class of workers. In many case-control studies, exposure information from deceased subjects is obtained from spouses or next of kin who are even less familiar about exposure potential than persons who developed the condition.

Measurement of DDT and/or its metabolites has some limitations for determining exposure potential. One particular concern is the potential for NHL to affect tissue DDT levels. Biological changes from NHL might affect tissue DDT concentrations. Cachexia from cancer and chemotherapy can affect serum/plasma DDT levels (Baris, et al., 2000; Hoppin, et al., 2000). Weight loss in general can produce changes of DDT or its metabolites (Pelletier, et al., 2003; Backman and Kolmodin-Hedman, 1978; Chevrier, et al., 2000). Thus, when evaluating the results of case-control studies that utilized DDT biomarkers and NHL, it is essential to ascertain whether the DDT tissue samples were collected before disease onset to avoid bias that may occur from a selective effect on tissue levels in cases.

Case-control studies with biomarkers of exposure are described below:

- Cocco, et al., 2008: This case-control study examined the association between blood levels of *p,p'*-DDE and 25 other organochlorines and NHL risk. The study also evaluated association between plasma *p,p'*-DDE and two major NHL subtypes: diffuse large B-cell (DLBC) lymphoma and chronic lymphocytic leukemia/small lymphocytic lymphoma (CLL/SLL). The study population consisted of 174 NHL cases and 203 controls (French, German and Spanish subjects) drawn from the European multicenter case-control study concerning the etiology of lymphoma (Epilymph). Blood was collected after diagnosis but before chemotherapy had started. Plasma *p,p'*-DDE levels were adjusted and categorized into quartiles. Information about potential covariates was obtained by

interview and questionnaire. Factors included in the final analysis included age, gender, education level, center, and levels of other organochlorines. There was no overall increased risk of NHL.

- Engel, et al., 2007a: This nested case-control study examined the association between serum or plasma *p,p'*-DDE levels and other organochlorines and NHL. The study population included 294 cases and 415 controls drawn from three cohorts: Janus -190 cases and 190 controls drawn from 87,600 Norwegian men and women; CLUE I -74 cases and 147 controls drawn from 23,938 Washington County, Maryland residents; and Nurses' Health Study -30 cases and 78 controls drawn from 121,700 female nurses. The 174 cases from the CLUE I cohort were previously described (Rothman, et al., 1997). Blood collection was performed years prior to NHL diagnosis. *p,p'*-DDE levels were lipid adjusted (ng/gram lipid) and categorized into exposure quartiles. Separate statistical analyses were performed for each cohort because of differences in time when blood was collected and differences in blood analyses between cohorts. Organochlorine levels were adjusted for body mass index in the Janus and Nurses' Health Study cohorts but not for CLUE I.

  The ORs and 95% CIs for NHL in relation to *p,p'*-DDE concentrations were not significant. In the Janus cohort, when examined for early (2-16 year) follow-up, the OR for the highest *p,p'*-DDE quartile (7,513 ng/gm lipid median) was 4.3 (95% CI=1.2 -15.0). This *p,p'*-DDE effect was diminished and was no longer statistically significant when controlled for PCB exposure. The OR was not significant for the late follow-up period OR 0.8 (95% CI=0.3-2.0) in the Janus cohort. In the CLUE I cohort, the ORs were not statistically significant, and there was no difference in ORs between early and late follow-up period. Importantly, the *p,p'*-DDE effect in all instances decreased and ORs were not statistically significant when controlled for PCB exposure. In contrast, *p,p'*-DDE adjustment had only a minimal effect on PCB risk estimates. The authors concluded that

there was no apparent trend or exposure response between *p,p'*-DDE and NHL in most of the analyses.

- Hardell, et al., 2009: The 99 NHL cases in this study were drawn from four county regions in Sweden with cases of newly diagnosed NHL, presumably from 2000-2002. This included 20 cases of follicular lymphoma. Controls were drawn and apparently already enrolled in a NHL study examining effects of cell phones on NHL. Blood was collected after NHL diagnosis but before treatment. No information is provided whether cases had experienced weight loss or other disease complications that could affect *p,p'*-DDE levels. Blood was analyzed for several organochlorines including PCBs, *p,p'*-DDE and PBDE. Chemical analyses of blood included internal PCB standards but apparently no standard for *p,p'*-DDE. IgG antibodies to Epstein-Barr virus (EBV) capsid antigen and to early antigen (EA) were also examined. NHL cases were divided into low and high categories based upon median *p,p'*-DDE levels and low and high EA antibody titers.

  There was no significant difference in *p,p'*-DDE between all NHL cases and controls. The OR for follicular lymphoma was 1.2 (95% CI=0.4-3.5). Of note, the BMI of cases was significantly different from controls which could be an indication that NHL disease process could be affecting *p,p'*-DDE levels in cases and influencing study findings.

- Hardell, et al., 2001: This case-control study examined the association between lipid-adjusted blood or adipose tissue *p,p'*-DDE levels and NHL. The study population included 82 cases and 83 controls. 50 NHL cases diagnosed between 1994-1997 had adipose tissue samples while 32 cases diagnosed between 1997-1999 provided blood samples. EBV antibody titers were also measured for viral capsid antigen and early antigen.

The study showed no significant association between NHL and persons with *p,p'*-DDE levels above the median value (663 ng/gm-either blood and adipose tissue) – OR 1.2 (95% = 0.60-2.5); multivariate analyses showed similar results. There was no statistically significant increased NHL risk in persons who had values above the median *p,p*-DDE level.

- Hardell, et al., 1996: *p,p'*-DDE levels in adipose tissue (collected from abdominal wall) of a group of 28 newly diagnosed patients with NHL of B-cell type were not significantly different from 17 surgical controls.

- Rothman, et al., 1997: This nested case-control study examined the association between NHL risk and serum concentration of DDT and PCBs. The study population consisted of 74 NHL cases and 147 controls drawn from persons in the Campaign against Cancer and Stroke (CLUE I) cohort from Washington County, Maryland. Controls were members of the CLUE cohort who did not have cancer and were matched for several factors including race, sex, date of birth (within 1 year) and date of blood collection (within 15 days). NHL cases and controls had prediagnostic testing for serum DDT and its metabolites and questionnaires. Serum DDT (sum of *o,p'*-DDT, *p,p'*-DDT, *o,p'*-DDE, and *p,p'*-DDE) levels were lipid corrected.

  There was no significant difference in total lipid corrected serum DDT concentrations (sum of *o,p'*-DDT, *p,p'*-DDT, *o,p'*-DDE, and *p,p'*-DDE) between NHL cases and controls. Although NHL risk was reported to increase weakly with increasing DDT concentrations, this was not considered to be significant. A non significant association was observed between NHL risk and DDT with an OR 1.9 (95% CI=0.8-4.5) for highest quartile (DDT 4140-20,500 ng/gm lipid). This risk diminished after adjustment for PCB resulting in an OR 1.2 (95% CI=0.5-3.0) for highest serum DDT quartile and OR 1.1 (95% CI=0.4-2.7) for the 2nd quartile.

The authors concluded that "total lipid-corrected serum concentrations of DDT were not associated with risk of non-Hodgkin lymphoma."

- Spinelli, et al., 2007: This case-control study examined the potential associations of plasma levels of *p,p'*-DDE and *p,p'*-DDT, and 23 other organochlorines, including other pesticides and PCBs, with NHL risk. The study examined NHL subtypes including follicular, diffuse large cell, T-cell and other B-cell lymphoma. The study population included 422 NHL cases in males and females and 460 controls. Plasma *p,p'*-DDT and *p,p'*-DDE levels were lipid-corrected and categorized into quartiles. Plasma levels were measured before starting treatment and the cases were reported to not have sustained weight loss in excess of 10% prior to NHL diagnosis. Confounders which were reported to be examined in stepwise models used for data analysis included age, sex, region, education, BMI, ethnicity, farming, and family history of NHL.

  The authors reported that six of eight pesticide analytes were significantly associated with NHL. For *p,p'*-DDE, a significant trend was reported for NHL risk. The OR for all quartile lipid adjusted plasma *p,p'*-DDE levels showed no statistically significant association. The significant *p,p'*-DDE trend diminished after adjustment for oxychlordane. A significant trend was also reported for *p,p'*-DDE and follicular lymphoma. The ORs for follicular lymphoma for the largest compared to the smallest *p,p'*-DDE quartile was 1.8 (95% CI=0.9-3.3). *p,p'*-DDT levels were not associated with NHL.

  Data identified as lacking by the authors included current body mass index (BMI) (the authors collected weight data one year prior to interview), body fat index, and lactation history, all of which could have affected measured *p,p'*-DDE levels. The authors indicated that measurement error between analytes and/or random variation may also have contributed to observed results. Another explanation for findings was that unmeasured organochlorines related to NHL and correlated with

measured organochlorines were confounding the results. The authors recommended further research into possible interactions between organochlorines and other agents such as viruses and genetic markers.

- De Roos, et al., 2005: This population based case-control study examined the potential association between NHL risk and plasma levels of *p,p'*-DDE, *p,p'*-DDT and 66 other organochlorine compounds. The study population included 100 cases and 100 controls drawn from the National Cancer Institute NHL study from four SEER regions (Iowa, Los Angeles County, Detroit, and Seattle). The cases were randomly selected from 1321 newly diagnosed NHL cases (i.e., between July 1998 and June 2000). The population controls were selected by random digit dialing and from Medicare records. Response rate was 59% cases and 44% controls. Plasma levels were lipid adjusted and categorized in quartiles. Adjustments were made for age, sex, study site, and date of blood draw, but other potential confounders were also considered. Blood was only obtained from cases that had not received treatment.

  NHL risk was not associated with *p,p'*-DDE and *p,p'*-DDT levels for any quartile plasma levels. The authors, however, conducted an ad hoc analysis of an unspecified number of persons described as representing the "extremes of our exposure distributions" for *p,p'*-DDT. This analysis yielded an OR of 3.3 with a wide confidence interval (95% CI=0.7-15.9). The number of cases was not reported and overall significance of this finding is unclear. The authors found no clear association between NHL risk and *p,p'*-DDT and *p,p'*-DDE plasma levels.

- Quintana, et al., 2004: This study utilized tissue samples that were collected from 1969 to 1983 as part of the U.S. EPA National Human Adipose Tissue Survey (NHATS). The NHATS study measured adipose concentrations of organochlorines in about 20,000 persons. Cases represented persons with NHL diagnoses that were included in the NHATS data set. Of 175 NHL cases, 167

specimens were obtained at autopsy, and 8 were taken from pathology specimens obtained during surgical procedures. 481 controls were utilized and adipose tissue was obtained from subjects who had accidental death, injury, or myocardial infarction.

The mean levels of *p,p'*-DDT and *p,p'*-DDE were not significantly different between cases and controls. *p,p'*-DDT quartiles were not significantly associated with NHL but there was a significant trend when considered as a continuous variable for log transformed data. For *p,p'*-DDE, the highest exposure quartile had an increased OR of 1.99 (95% CI=1.14-3.47) with a significant trend. The increased risk for the highest *p,p'*-DDE quartile was no longer present when the risk was adjusted for other select other organochlorines. The authors reported that there was "no clear association" between exposure to DDT and NHL, and that the association with *p,p'*-DDE was confounded by other organochlorines.

6.3 Non-biomarker case-control studies

Most case-control studies have not utilized biomarkers (i.e., levels of DDT and/or its metabolites in tissues) to assess exposure to DDT. Typically, questionnaire and/or interviews are used to collect exposure information. In some case-control studies, the exposure information collected is very limited and consists of a simple yes-or-no question as to whether the person was ever exposed, without consideration for the duration or frequency of exposure. In other studies, exposures are simply assumed to have occurred based on whether a person held a specific job (e.g., cattle farmer), although there can be significant variability in exposure between workers who hold or held the same job title. Some studies attempt to obtain more detailed exposure information by asking questions concerning items such as names of products (chemicals) used, days applied, type of application, protective equipment used, size of area applied, etc. As described above, I examined case-control studies where specific information was provided about DDT exposure.

Case-control studies examining association of DDT with NHL are discussed below:

- Eriksson, et al., 2008: This case-control study examined the relationship between NHL cases, including NHL subtypes and exposure to pesticides, organic solvents, and several other chemicals. The study population included 910 cases and 1,016 controls including both males and females diagnosed between December 1999 and April 2002. Cases were selected from four of seven regions in Sweden and diagnosed between December 1, 1999-April 30, 2002. Controls were randomly selected from same health regions and were matched for age and sex. Exposure was assessed by questionnaire. Cases had been previously interviewed about lifestyle factors for another study being conducted of the same population. Logistic regression was conducted and adjustments were made for age, sex, and year of diagnosis. The participation rate was 91% of potential cases. No statistically significant increased OR was reported for DDT use—OR 1.46 (95% CI=0.94-2.28).

- De Roos, et al., 2003: This study of three pooled case-control studies from Nebraska, Iowa and Minnesota, and Kansas was conducted to assess the potential NHL risk from individual and combined pesticide exposures that farmers encounter. The study population consisted of 650 NHL cases and 1,933 controls for multiple pesticides analyses; the overall study population was 870 cases and 2,569 controls. ORs were provided for 47 individual pesticides and combinations of these pesticides using two statistical approaches that incorporated multivariate analysis. When adjusted for other used pesticides, the OR for DDT was 1.0 (95% CI=0.7-1.3), the same for both models. There were no super additive effects reported between DDT and chlordane. The authors concluded that determination of potential pesticide NHL risks should focus on individual chemicals and not groups of pesticides within classes. This study does not show a significant

association between NHL and DDT, even among subjects who had multiple pesticide exposure.

- Colt, et al., 2005: Colt and colleagues conducted a case-control study that examined the potential association between NHL and concentrations of organochlorine compounds in carpet dust. Analyses were also conducted for NHL subtypes. Carpet dust samples were collected from the homes of 603 cases with newly diagnosed NHL (Iowa, Los Angeles County, Detroit, and Seattle) and 443 controls. *p,p'*-DDT and *p,p'*-DDE concentrations in dust were divided into tertiles.

  The authors reported that the presence of *p,p'*-DDE in carpeting was associated with increased NHL risk (OR 1.3, 95% CI=1.0-1.7) when examined by tertile. The risk was statistically significant only at the highest tertile (OR 1.6, 95% CI=1.1-2.2). A significant positive trend was reported for *p,p'*-DDE and NHL risk. The association was only significant among men versus women (OR 1.6, 95% CI=1.1-2.3 and OR 1.1, 95% CI=0.7-1.5, respectively), and the response was not monotonic. There was no significant trend or association between NHL risk and *p,p'*-DDT. Factors associated with higher levels of *p,p'*-DDE and *p,p* -DDT included homes built before 1960, oriental rugs, and education level.

- Lee, et al., 2004: This case-control study is a pooled analysis of two NHL population-based case-control studies of farmers in Iowa, Minnesota, and Nebraska (Zahm, et al., 1990; Cantor, et al., 1992). The study evaluated the potential association between pesticide use, asthma, and NHL. The population included 872 cases and 2,381 controls. Specifically for DDT, there was no significant NHL risk for either asthmatic farmers (OR 1.2, 95% CI=0.6-2.4) or non-asthmatic farmers (OR 1.2, 95% CI=0.9-1.5) who reported ever using DDT.

- Hardell, et al., 2002: This study examined the potential association between exposure to a wide array of pesticides and NHL and hairy cell leukemia (HCL), which is a rare type of NHL. Two case-control studies were pooled: one NHL and one HCL. The total population included 515 cases and 1141 controls. Associations between NHL and HCL and exposure to herbicides, insecticides (mostly DDT), fungicides, impregnating agents, and organic solvents were evaluated. Exposure was assessed by questionnaire. The OR for DDT use was 1.27 (95% CI=0.92-1.73). Time span for last exposure and NHL diagnosis did not differ between early or latter follow-up periods.

- Hardell, et al., 1999: This case-control study examined the potential association between NHL and exposure to pesticides. The study population included 404 male cases and 741 controls, diagnosed between 1987-1990. Exposures were assessed by questionnaire supplemented with telephone interviews regarding use of herbicides, insecticides (mostly DDT), fungicides, and impregnating agents. There was no statistically significant increased NHL risk associated with 66 cases reporting DDT use (OR 1.1, 95% CI=0.7-1.7).

- Hardell, et al. 1994: This case-control study involving 105 male cases and 335 controls examined the relationship between specific pesticides, solvents, asbestos, smoking and oral snuff and NHL. Using univariate analysis, NHL risk was increased for DDT use (OR 2.4, 95% CI=1.2-4.9), but this relationship became insignificant with multivariate analysis (OR 1.5, 95% CI=0.6-3.6). The authors reported no significant relationship for DDT.

- McDuffie, et al., 2001: This case-control study examined the potential relationship between specific pesticides and NHL in 517 male cases and 1506 controls from six Canadian provinces. Exposures were assessed by questionnaire, and persons reporting more than 10 hours of pesticide use per year, as well as 15% of controls, received telephone interviews. Based on 32 cases and 59

controls, DDT exposure was associated with an increased adjusted OR of 1.73 (95% CI=1.08-2.76). After controlling for other pesticides and study covariates (e.g., medical history), DDT was found "not to contribute significantly to the risk of NHL." The authors identified several study concerns including poor study response rates (67% cases, 48% controls), differential reporting of exposures among cases, and possibility of chance for statistically significant associations in studies involving multiple comparisons.

- Miligi, et al., 2003: This case-control study examined the relationship between pesticide exposure and NHL as well as solvents and leukemia. The study population consisted of 1,145 NHL cases who were diagnosed during the period of 1990-1993. The study population came from 11 different geographic areas within Italy, which included nine high or mixed-use agricultural areas. 1,232 controls were randomly selected from the general population and matched by sex and 5-year age group. Data on exposure and lifestyle factors were obtained by interview. An agriculture-specific questionnaire was utilized and compared to a pesticide crop exposure matrix developed by agronomists. Aggregate data were presented for both NHL and chronic lymphocytic leukemia (CLL). Multivariate analyses considered adjustment for factors other than age and area, including certain professions. For DDT, the OR for NHL/CLL in males was 0.6 (95% CI=0.3-1.1) and 0.3 (95% CI=0.1-0.8) in females.

- Nanni, et al., 1996: This case-control study examined occurrence of NHL and chronic lymphocytic leukemia in association with farming or animal breeding workers from Forli in Northeastern Italy. CLL was included in the study population because the authors reported a high degree of misclassification between CLL and low grade NHL. The study population included 187 newly diagnosed cases between 1987-1990. Controls (n=977) were selected from the general population and were matched by sex and five-year age group. Exposure data were obtained by interview. A pesticide crop exposure matrix was

developed based on expert input, which linked pesticide use with different crops/plant diseases. Cases were asked about use of pesticides, but also about crops, which could be cross-referenced with questionnaire response (recall) for pesticide use. Adjustments to OR calculations were made for age and sex, as well as altitude of municipality, family history of hematopoietic malignancy, and prior Herpes zoster infection.

No significant association was found for any pesticide when either recall or a pesticide matrix was used to classify exposure. For DDT, the OR for NHL/CLL was 1.74 (95% CI=0.93-3.27) based on recall, and 1.7 (95% CI=0.91-3.17) based on job matrix.

- Schroeder, et al., 2001: This case-control study examined the association of agricultural risk factors in males with NHL who were positive or negative for t(14;18) translocation. The NHL cases were drawn from a cohort of 780 newly diagnosed NHL cases from the Factors Affecting Rural Men (FARM) study (Cantor, et al., 1992). 1245 controls were also drawn from the FARM study. Archived tumor blocks were obtained from 248 (40%) of NHL cases and 182 (19%) were successfully assayed for this translocation using PCR analysis. Exposure information was obtained by in-person interviews.

  The adjusted odds ratios for DDT and NHL t(14;18)-positive cases versus controls was 1.1 (95% CI=0.6-1.9) and for t(14;18) negative NHL cases the OR was 1.2 (95% CI= 0.8-1.7). This study did not find a significant association between NHL and DDT in either t(14;18) positive or negative cases.

- Baris, et al., 1998: This study pooled results from three prior published case-control studies involving four states: Nebraska, (Zahm, et al., 1990); Iowa and Minnesota (Cantor, et al., 1992); and Kansas (Hoar, et al., 1986). The pooled study population included 933 NHL cases and 2918 controls that were reported in

published studies. The investigators stated that a principal impetus for this study was to pool data from three prior smaller studies to enable a more detailed analysis of DDT than had been previously performed and to assess the impact of confounding from other pesticide exposures. Information regarding exposure was obtained in-person (Iowa and Minnesota) or telephone interviews (Kansas and Nebraska). Factors that were examined included use of particular pesticides, use of protective equipment, use before and after 1965.

The OR for NHL cases (n=161) who reported use of DDT on animals and crops had an overall non-significant OR for NHL of 1.2 (95% CI=1.0-1.6). For farmers not using DDT, the OR was 1.1 (95% CI=0.9-1.4). Farmers from Nebraska, Iowa and Minnesota who used DDT for greater than 15 years had a non-significant OR of 1.5 (95% CI= 0.9-2.3). The risk for farmers in Nebraska who used DDT for more than 5 days a year was reported to be OR 2.1 (95% CI=0.9-4.9). All ORs adjusted for other pesticide use, including organophosphates and phenoxyacetic acid herbicides, were non-significant. ORs for specific NHL subtypes, including follicular lymphoma, were also examined. For farmers who reported using DDT, the OR for follicular lymphoma was 1.3 (95% CI= 0.8-1.9) and for farmers not using DDT, it was 1.2 (95% CI= 0.9-1.7).

Baris and colleagues concluded that the data did not show any strong evidence that DDT is associated with NHL in male farmers. They concluded that their findings were consistent with two recent investigations which showed no association between either serum DDT or adipose DDT levels and NHL (Rothman, et. al., 1997; Hardell, et.al., 1996).

- Zahm, et al., 1993: This case-control study reported results for females, including 119 cases and 471 controls who had lived or worked on a farm. Cases and controls resided on eastern Nebraska farms. The investigators reported that most of the prior studies involving agricultural risk factors and NHL had focused on

men rather than women. Telephone interviews were utilized to obtain information regarding agricultural risk factors.

The authors reported for DDT use an OR of 1.7 (based on 16 cases and 36 controls), did not provide any CIs, but did state that the OR was not significant. No significant increased risk was observed for any individual insecticide. The authors concluded that this study suggests that NHL risk from pesticides among women who live or work on farms "if real," is smaller than for men.

- Cantor, et al., 1992: This case-control study included 622 newly diagnosed NHL cases in white males drawn from an Iowa state registry and from a surveillance program involving Minnesota hospital records and 1245 population controls. Interviews were used to collect information regarding farming occupations, farming activities including work with crops and livestock. ORs were adjusted for several known and suspected risk factors, including hair dye use. ORs were also calculated for specific NHL subtypes, including follicular lymphoma.

  The authors calculated ORs by pesticide class, individual pesticides, use prior to 1965, and "*ever*" handling, mixing, or applying pesticides, use on crops, animals, and use of protective equipment. Risk for handling DDT used as an animal insecticide was OR 1.2 (95% CI= 0.9-1.7), and use on animals prior to 1965 was OR 1.3 (95% CI=0.9-1.8). Risk for handling with protective equipment for animals was 1.2 (95% CI=0.9-1.7) and without protective equipment OR 1.3 (95% CI=0.9-1.8). Risk for DDT use on crops was OR 1.7 (95% CI=1.2-2.6) and use before 1965 was OR 1.8 (95% CI=1.1-2.7). Risk for handling with protective equipment for crops was OR 1.7 (95% CI=1.2-2.6) and without protective equipment OR 2.0 (95% CI=1.3-3.1). No significant association was found for follicular lymphoma.

The authors concluded that interpretation of these study results regarding any individual pesticide was problematic because multiple exposures occur in modern agriculture and the chance occurrence of positive findings, when multiple comparisons are performed. Further epidemiological investigation was recommended.

- Cantor, et al., 1993: Cantor and coauthors wrote a letter to the editor of the Journal of Cancer Research regarding the above-referenced 1992 study. The investigators stated that their 1992 publication did not include information concerning number of days of pesticide use among cases and controls since this information was not collected in subject interviews. However, the investigators collected additional data on pesticide use on a subset of this cohort (i.e., 110 cases and 211 controls) drawn from the Iowa population several years later.

  When days of exposure (1-4 days, 5-9 days, and 10+ days) were analyzed for this subgroup, the OR for DDT and NHL was not statistically significant for use on either animals or crops. Since interviews were collected several years after the interview and by telephone, the authors reported concerns about the validity of this more recent information and felt it only provided very weak evidence in assessing possibility of causal association.

- Woods, et al., 1987: This is a population-based case-control study of 576 NHL cases and 694 randomly selected controls. The study was largely focused on evaluating the potential association between NHL and soft tissue sarcoma with occupational exposure to phenoxyacetic acid herbicides and chlorinated phenols. Exposure information was obtained by personal interviews.

  The investigators reported an increased OR for occupational exposure to DDT (OR 1.82, 95% CI=1.04-3.2). However, only 4% of the study population reported DDT as an occupational risk factor, so the OR is based upon very small numbers.

Furthermore, although detailed questions were asked regarding phenoxyacetic acid herbicides and chlorinated phenols, data collected regarding DDT appears much more limited. This is a small study with a weak increased risk.

- Woods and Polissar, 1989: This study examines a subset of subjects who were farmers from the Woods, et al., 1987 study. The weak association previously observed was no longer statistically significant—OR 1.68 (95% CI=0.9-3.3).

- Persson, et al., 1999: This pooled case-control study population consists of 199 NHL cases and 479 controls drawn from two prior case-control studies that examined the potential association between occupation and pesticide use with NHL (Persson, et al., 1989; Persson, et al., 1993). Questionnaire data were used to obtain exposure information. For DDT, the OR was 1.4 (95% CI=0.3-5.9) based upon the presence of 4 cases and 6 controls that reported DDT use.

- Persson, et al., 1993: This case-control consisted of 93 NHL cases and 31 Hodgkin's Disease (HD) cases drawn from a regional Swedish cancer registry. 204 controls were identified as being randomly selected from a population registry used for other studies. The authors investigated the association between NHL and HD with various occupations and exposures. Exposure information was obtained by a mailed questionnaire. Crude odds ratios with a 90% CI were calculated for various occupational exposures, such as solvents, pesticides, welding, etc. For DDT exposure and NHL, the OR was not statistically significant (OR 2.0, 90% CI=0.3-13), but this was based only upon 4 cases.

- Persson, et al., 1989: This case-control study included 106 NHL cases, 54 Hodgkin's Disease cases, and 275 controls drawn from a regional Swedish cancer registry. Exposure data was obtained by questionnaire. Crude odds ratios with a 90% CI were calculated for various occupational exposures, such as solvents,

pesticides, metal fumes, etc. No increased risk of NHL was reported for DDT, and no cases reported DDT use.

6.4 Ecological studies

Ecological studies examine populations to assess hypotheses regarding associations between factors in the population and health outcomes. The analysis, however, is not assessed on an individual level but rather the aggregate population, i.e. group rather than individual information are evaluated for associations.

- Cocco, et al., 2000: This study correlated the presence of state-specific adipose tissue levels collected in 1968 with age-adjusted mortality rates for 1975-1994 for NHL and other cancers. The adipose tissue samples were tested as part of the EPA-sponsored human biomonitoring program. For this analysis, adipose tissue measurements represented samples collected in 22 states. Age adjusted NHL mortality during 1975 and 1994 was not associated with DDT. In fact, among whites, NHL mortality significantly decreased with increasing adipose DDE levels.

- Pavuk, et al., 2004: This study consisted of an initial population-based cross-sectional study that measured serum levels of PCBs and organochlorine pesticides, including *p,p'*-DDT and *p,p'*-DDE, in residents of two districts in eastern Slovakia. This was followed by an ecological study that compared cancer incidence in these two districts for the period 1985-1994. One of these districts (Michalovce) had extensive environmental contamination from a former PCB production site, and the other had low background levels (Svidnik) and was used for comparison. Cancer incidence rates were compared to age-specific cancer incidence rates of the Eastern Slovakia population and standardized incidence ratios (SIR) were calculated.

The age-adjusted geometric means for the sum of 15 PCB congeners and *p,p'*-DDT levels were significantly higher in males and females of Michalovce compared to Svidnik. Levels of *p,p'*-DDE were significantly higher in females of Michalovce compared to those of Svidnik. Although levels of *p,p'*-DDE were higher in males of Michalovce as well, this difference was not statistically significant (p=0.05). Cancer incidence rates for NHL were not significantly increased in males or females of Michalovce (males: SIR 1.12 [95% CI=0.80-1.52]; females: 1.04 [95% CI=0.70-1.49]).

6.5 Overall summary of epidemiological studies

Multiple epidemiological studies have examined the potential association between DDT and/or its metabolites and NHL. DDT is considered to be one of the most investigated pesticides with respect to NHL occurrence (Engel, et al., 2007b). Based upon my review and analysis of all the relevant epidemiological literature regarding DDT and NHL, it is my opinion, to a reasonable degree of medical certainty, that DDT is not a cause of, or contributing factor to, NHL. These studies do not demonstrate a significant or strong association between DDT exposure and NHL. Most studies do not reveal a significant association, or demonstrate substantially diminished associations when adjustments are made for other chemical exposures (Engel, et al., 2007b).

Occupational cohort studies have not demonstrated increased NHL mortality and/or incidence even in heavily exposed workers. A strength of these studies is that they involve intense DDT exposure hundreds of times greater than the general population including the alleged intake for Ms. Garza, the plaintiff at issue in this case.

Case-control studies that have utilized DDT biomarkers have not demonstrated overall significant associations with NHL. Two published studies which measured DDT biomarkers before NHL diagnosis showed no overall significant association with NHL risk (Rothman, et al., 1997; Engel, et al., 2007a). A particular strength of these studies is

that DDT biomarkers were measured well before NHL diagnosis and thus the biomarker results would not be biased by the disease itself. Seven other studies involved collection of blood and/or adipose tissue samples after NHL diagnosis and thus could have been biased since NHL could preferentially affect DDT levels in cases. Nonetheless these biomarker studies overall revealed no or weak associations that in most cases were substantially diminished when adjusted for other factors, including other pesticides (De Roos, et al., 2005; Quintana, et al., 2004; Hardell, et al., 2001; Hardell, et al., 1996; Hardell, et al., 2009; Spinelli, et al., 2007; Cocco, et al., 2008). Similarly, non-biomarker case-control studies reveal no or weak findings, and demonstrate the importance of adjusting for confounding factors, including potentially confounding exposures (e.g., Baris, et al., 1998; McDuffie, et al., 2001; Rothman, et al., 1997; Cantor, et al., 1992; De Roos, et al., 2003).

Based on a search for all pertinent studies and my assessment of all epidemiological studies that have examined the potential association between DDT and NHL, and specifically, follicular lymphoma where available, it is my opinion, to a reasonable degree of medical certainty, that DDT exposure is not an established cause or a contributing factor to the occurrence of NHL.

6.6 Experimental Studies

DDT was administered to human volunteers in two studies (Hayes, et al., 1956; Hayes, et al., 1971) to ascertain whether administration of DDT at levels hundreds of times greater than background, but still considered safe, would result in clinical effects. The studies provide direct information regarding health effects of DDT in humans at levels substantially greater than the "theoretical" intake that the plaintiff's experts have assumed Ms. Garza received while residing at "506 Nicholson." The two studies are described below:

- Hayes, et al., 1956: Fifty-one male volunteers from a correctional facility received daily doses of either recrystalized *p,p'*-DDT or technical grade DDT at doses of 0 (placebo), 3,500 ug/day, or 35,000 ug/day for periods of up to 18 months. Medical examinations were performed to determine whether any participants were experiencing DDT-related adverse effects, with emphasis on neurological and liver function tests. A total of 44 volunteers completed 1 month of dosage, among which 14 also completed 12 months of dosage, and 5 completed 18 months of dosage. A total of 35 volunteers completed the final medical examination. The investigators concluded that no volunteers had symptoms or test results that showed any sign of injury related to DDT exposure.

- Hayes, et al., 1971: Twenty-four volunteers received recrystalized *p,p'*-DDT or technical grade DDT at concentrations of either 3,500 ug/day or 35,000 ug/day for 21.5 months and were observed for an additional 25. 5 months. Sixteen of the 24 were followed for 5 years. Medical examinations were conducted with emphasis on neurological tests and liver function tests. The investigators reported no symptoms or test results that showed any sign of injury related to DDT intake.

6.7 Assessment by Public Health and Government Agencies

Several public health and governmental agencies have evaluated scientific evidence concerning whether DDT has been recognized to cause cancer in humans. These agencies have determined that DDT is not a recognized cause of human cancer. These assessments include the following:

- The Agency for Toxic Substances and Disease Registry (ATSDR) of the U.S. Department of Health and Human Services. ATSDR concluded that there was insufficient evidence that DDT was a human carcinogen (ATSDR, 2002).

- The U.S. EPA determined that there was insufficient evidence that DDT was a human carcinogen (U.S. EPA, 1991). In 2002, EPA conducted a screening-level literature review of recent toxicology literature relating to its cancer assessment for DDT (U.S. EPA, 2002). EPA did not change its classification for DDT based on this most recent review.

- The National Toxicology Program of the National Cancer Institute reviewed the literature pertaining to DDT and also concluded that there was inadequate evidence of human carcinogenicity (NTP, 2005).

- The International Agency for Research on Cancer of the World Health Organization concluded that there was insufficient evidence that DDT caused cancer in humans (IARC, 1991).

The relevant public health agencies have not concluded that DDT and/or its metabolites cause human cancer.

7.0 Ecological data on NHL rates and DDT use in the U.S. and other countries do not support the conclusion that DDT causes NHL

Ecologic studies are a type of epidemiological investigation that examines the prevalence of disease in a group rather than in an individual for the purpose of exploring potential relationships between risk factors and disease outcome. Data regarding disease occurrence in a general population with a specific risk factor can be compared to other populations without the risk factor. Thus, ecological studies can provide insight into determining potential causal factors for diseases among populations. For example, it is well known that chronic infection with hepatitis B virus (HBV) is causally associated with primary liver cancer. Therefore, it is not surprising that geographic areas with a high prevalence of this virus, such as Southeast Asia, also tend to have high prevalence of liver cancer in these populations (Cancer Research UK, 2006). Ecological data must be

viewed cautiously since individual data on whether a particular person in the at-risk population who developed the disease was exposed to the risk factor are missing. However, aggregate population data can be used to assess causal hypotheses.

In a similar vein, I compared rates of NHL in countries that no longer use DDT with those of countries that permit its use to see if there is any apparent relationship between DDT use and NHL. A number of factors may affect NHL rates, but countries in which DDT was used continuously appear to have lower NHL rates than countries in which it has not been used for many years. One interesting example—Mexico, where DDT was used until 2000, has an age-standardized incidence rate (ASIR) for males of 5.7 per 100,000, while the United States, which stopped using DDT in late 1972, has an ASIR for males of 17.1 per 100,000. In Mozambique, where DDT was not used, the ASIR for males is 8.6 per 100,000, while in South Africa and Swaziland that are next to Mozambique and which still use DDT, the ASIRs for males are 5.1 per 100,000 and 3.0 per 100,000, respectively[2]. Moreover, in general, the rates of NHL have been increasing in developed societies even though use of DDT has been decreasing. The ASIR for NHL in males in more developed regions is 10.4 per 100,000 and for less developed regions is 4.3 per 100,000 (Ferlay, et al., 2004). In addition, developed countries have a higher rate of NHL than developing countries even though some developing countries still use DDT (Figure 1). Thus, this data suggests the absence of a relationship between DDT exposure and NHL.

While there are limitations to this approach, and one cannot use these data to prove or disprove whether a causal association may exist, one would expect that if there were a strong association between DDT and NHL, it would be apparent in this type of comparison, similar to the example of HBV and liver cancer. Nevertheless, alternative explanations cannot be ruled out, such as incomplete reporting of NHL by the registries. For this reason, epidemiologists and other scientists rely on "analytical" epidemiological

[2] The ASIRs for Mexico, United States, Mozambique, South Africa, and Swaziland are estimates for the year 2002, based on the most recent incidence, survival, and mortality data collected about 2-5 years earlier (Ferlay, et al., 2004).

studies such as case-control and cohort studies to evaluate causal hypotheses. However, in proper context, ecological studies can be viewed together with data from other types of studies to determine whether a coherent and consistent pattern of study results is evident. In this case, ecological, cohort and case-control study data together do not support a causal association between DDT exposure and NHL.

8.0 Texas Department of Health investigations show no increased cancer rates in Mission, Texas and no increased serum DDT levels in persons living and/or working in close proximity to Hayes-Sammons

Coupled with the epidemiological data in the scientific literature, we also have data concerning the cancer rates in this specific Mission, Texas community and data on their potential exposures analyzed from blood samples. This unique data represent specific health information about the community and therefore are useful in addressing health concerns or speculations that exist regarding the claimed impact of operations at the former Hayes-Sammons facilities.

As discussed below in further detail, the Texas Department of Health (TDH) examined whether excess cancer was present in the Mission, Texas community and evaluated serum levels of persons residing or working in close proximity to Hayes-Sammons. The TDH blood data is especially relevant because future health risks, if any, are dependent upon past exposure, and blood levels serve as a marker of exposure. Conclusions of these two analyses show both no excess cancer and no increased serum DDT levels in Mission, Texas. This is further evidence of a lack of an association between DDT exposure and health effects in this community from the Hayes-Sammons site.

8.1 TDH investigations of persons living in the Mission, Texas zip codes do not reveal excess cancer incidence or mortality

TDH conducted a series of investigations to ascertain whether or not persons residing in Mission, Texas zip codes have an increased rate of, or death from non-Hodgkin lymphoma or any other cancers. TDH examined incidence rates for the period 1995 to 2001 and mortality rates from 1993 to 2002 and concluded there was no increased incidence or mortality from non-Hodgkin lymphoma (Texas Department of Health, Cancer Registry Division 2005). Given their findings, TDH did not recommend further study.

8.2 Persons residing around the Hayes-Sammons mixing facility did not have excessive serum DDT levels

In addition to the TDH investigations of cancer experience, TDH also conducted a study to ascertain levels of certain pesticides, including DDT, in persons residing around the Hayes-Sammons mixing facility (Texas Department of Health, 1981). Blood samples were collected from both adults and children in 1980. The population categorized as "exposed" consisted of neighborhood residents, shop teachers, bus drivers, and mechanics working at the Mission Independent School District (MISD) facility adjacent to the Hayes-Sammons mixing facility. This "exposed" group included persons living across the street from the Hayes-Sammons mixing facility on the same block where Ms. Garza indicates she resided. A control population removed from the facility was selected for comparison purposes. After analyzing serum DDT and other pesticide levels from both groups, TDH concluded that "the analysis failed to show any consistent pattern of elevation of serum pesticide levels in Exposed individuals above those seen in Controls."

Therefore, although the "exposed" population had potential contact with pesticides from the Hayes-Sammons mixing facility, they did not have any demonstrable significant elevations of DDT in serum.

The finding that persons residing around the site do not have a consistent pattern of elevated DDT is not unexpected. Investigations also have not shown a correlation between soil DDT and serum DDT levels. A study in Mexico demonstrated that, in a population residing in houses with dirt floors and wooden walls, there was a poor correlation between DDT levels in outdoor soil, indoor soil, or house dust and measured blood DDT levels (Herrera-Portugal, et al., 2005). In this 2005 study, total DDT levels in outdoor soils ranged from 0.35 to 11.74 ppm, with an average level of 4.76 ppm. The indoor soil concentrations ranged from 2.08 to 68.3 ppm with an average level of 21.92 ppm. Indoor dust levels ranged from 2.66 to 108.48 ppm with average concentrations of 30.84 ppm.[3] Despite these DDT concentrations, there was no correlation between soil or house dust measurements and blood DDT concentrations in children ranging from ages 6 to 12.

In sum, based on the TDH data, the Mission, Texas community, which includes Ms. Garza, has not experienced an excess rate of any type of cancer, including non-Hodgkin lymphoma. Moreover, persons residing and/or working near the Hayes-Sammons mixing facility, where Ms. Garza reportedly lived, did not have serum DDT levels that differed substantially from a control population, suggesting that living and/or working near the facility did not result in DDT exposure sufficient to affect serum levels.

9.0 Overview of Dr. Sawyer's main opinions regarding Ms. Garza

The following represent Dr. Sawyer's main opinions concerning the cause of Ms. Garza's NHL:

- DDT is recognized to cause NHL;
- Epidemiological studies serve as a surrogate measure of Ms. Garza's DDT dose;

[3] The average soil concentration of 4.76 ppm total DDT in this 2005 study is similar to outdoor total soil DDT concentrations utilized by Dr. Strauss.

- Risk assessment is an appropriate methodology for determining causation of Ms. Garza's NHL;
- Dr. Strauss's generic cancer risk estimates for DDT can be compared with background NHL rates for the purpose of determining the cause of Ms. Garza's NHL.

10.0 Assessment of Dr. Sawyer's main opinions and methodology utilized to conclude that Ms. Garza's NHL was caused by exposure to DDT

10.1 Dr. Sawyer's claim that DDT causes NHL is not substantiated by the epidemiological literature

Dr. Sawyer has made broad, sweeping, unsubstantiated claims with respect to the findings of epidemiological studies that have examined DDT and NHL. He claimed in his initial (2005) report that DDT causes NHL and that NHL is a "common toxicological end point" for DDT and other organochlorines. At that time, he did not provide any scientific citations to support this claim. In his December 9, 2008 report, Dr. Sawyer listed fifteen epidemiological studies that he claimed were relevant to the issue of organochlorines and NHL causation. Finally, in his January 15 and February 4, 2009 deposition, he identified five epidemiological studies that he claims are sufficient to support his opinion that DDT causes NHL.

The five studies that Dr. Sawyer indicates are sufficient for demonstrating that DDT exposure causes NHL are overviewed in Section 6 of this report and are discussed in more detail below.

- Quintana, et al., 2004: Dr. Sawyer's analysis of the Quintana study is flawed and he misunderstands and/or misinterprets several critical aspects of this study, including: (1) study design, (2) potential effects of NHL and NHL treatment on

study findings, and (3) study findings, including the authors' conclusions regarding the study significance.

Dr. Sawyer appears to be confused about the study design. He provides contradictory testimony regarding a key study design parameter: the type and timing of collection of tissue samples. Dr. Sawyer testifies the study involved analysis of blood samples for organochlorines from persons who had blood historically archived (deposition p. 104). Dr. Sawyer is incorrect since this study did not involve blood testing. However, at other times, Dr. Sawyer acknowledges that adipose or fat samples were analyzed.

Dr. Sawyer also provides contradictory testimony regarding the sample collection protocol. The timing of adipose tissue collection is a critical study parameter since NHL itself may affect tissue DDT levels (Quintana, et al., 2004). If DDT levels are affected by NHL, then spurious associations could occur in a case-control study that compares adipose DDT levels in NHL cases to controls. At one point, Dr. Sawyer acknowledges that adipose tissue samples were obtained at autopsy, but then contradicts this testimony and indicates that the samples were "historically collected; that is, if a person had subsequently lost or gained weight, or breast fed, the samples were already in the freezer" (deposition pp. 241-242). Thus, in his mind, the NHL cases had tissue samples collected before their cancer had a significant impact on their body weight. In actuality, most of the NHL cases were dead at the time of sample collection since they represent autopsy specimens.

Dr. Sawyer also misunderstands the influence that NHL and NHL treatment could have on DDT adipose tissue levels and consequently fails to recognize a significant study limitation which even the authors acknowledge. Dr. Sawyer testifies that organochlorine levels would be lower rather than higher in NHL cases and thus the study results could only be more significant since the NHL

cases would have been expected to have higher organochlorine levels before the study samples were taken. (deposition p. 106) Dr. Sawyer testifies that some persons with NHL would have undergone chemotherapy which could only decrease organochlorine levels. Dr. Sawyer further testifies that no other effect would be expected and indeed "there is no pharmacologic or toxicologic mechanism plausible" for persons to have increased blood level of organochlorines from chemotherapy (deposition p. 109).

The basis for Dr. Sawyer's conclusion that organochlorine levels could only diminish as a consequence of NHL appears to be based upon a single study that measured blood organochlorine levels, including DDT, in NHL patients undergoing chemotherapy (Baris, et al., 2000). NHL cases who had undergone chemotherapy had decreased organochlorine levels. However, in the Baris, et al. study, patients had gained weight and had higher lipid content following chemotherapy, i.e., cancer patients can gain weight as their disease improves following chemotherapy. The assumption that the patients in Baris, et al., who gained weight, are comparable to the subjects in Quintana, et al., who died from the disease, is false.

In actuality, persons dying from NHL following unsuccessful chemotherapy would be expected to have weight loss or substantial wasting associated with terminal cancer. The term cachexia is used to describe wasting that occurs in persons with terminal cancer. Bioconcentration of DDT and other organochlorines occurs in cachexic patients (Hoppin, et al., 2000). Weight loss even in persons with no cancer is known to increase adipose tissue concentrations of organochlorines (Pelletier, et al., 2003; Backman, et al., 1978; Chevrier, et al., 2000). Thus, Quintana and colleagues indicate that NHL-associated cachexia could affect adipose organochlorine levels and even though they tried to exclude such cases, they could not ascertain whether such efforts were effective. The authors also acknowledge that clinical information from the NHL cases was

lacking, including data on weight loss or the presence of cachexia. Thus, Dr. Sawyer fails to understand the generally recognized limitations of the study.

Dr. Sawyer was unaware that the adipose tissues used for the Quintana, et al. study were collected as part of the U.S. EPA National Human Adipose Tissue Survey (NHATS) program, which was severely criticized by the National Research Council (NRC), one of the nation's most respected scientific organizations (NRC, 1991). The NRC raised many concerns about the program, including whether the collected samples were representative of the U.S. population. Significant concerns were raised about the integrity of data concerning donors, i.e., persons from whom samples were collected, and whether they actually had the conditions reported, i.e., some samples may not have come from persons with accidental deaths. The integrity of stored tissue samples also was severely questioned, including the possibility of contamination during storage and inadequate storage temperatures. The NRC concluded that the stored adipose tissue samples would have little or no value.

Dr. Sawyer also reaches conclusions regarding the study's findings, especially with respect to establishing causation, that are not supported by the investigators. Although Dr. Sawyer testified that Quintana, et al. was one of five studies that were sufficient to establish general causation between DDT and NHL, Quintana and colleagues concluded as follows: "We found no clear association between exposure to DDT and NHL. We report associations with *p,p'*-DDE that were confounded by heptachlor epoxide." Based on this conclusion, this study does not provide evidence of a causal association between DDT or its metabolites and NHL.

Dr. Sawyer's failure to understand (1) the potential impact of NHL on adipose organochlorine levels, (2) the many weaknesses of the Quintana, et al. study, and (3) the findings of the study generally undermines his adoption of this study as

one of the support pillars for his general causation conclusion that DDT causes NHL.

- Colt, et al., 2005: Dr. Sawyer indicates that the Colt, et al. study is important for proving causation since it demonstrates a significant dose-response trend (deposition p. 77). Dr. Sawyer also testifies that this study can be used to assess dose. Although Dr. Sawyer considers this study as being very significant to proving causation, the authors did not reach such a sweeping conclusion. The authors only conclude that the data provide "some" evidence that carpet dust *p,p'*-DDE can contribute to NHL risk, but that further research is needed to evaluate the significance of carpet dust DDE levels. In contrast to Dr. Sawyer's assertion that the study is useful to determine the dose, the authors indicate that carpet dust levels are only a "crude" indicator of historic organochlorine exposure (i.e., not dose) and cannot be used to determine the DDT source or when such compounds entered the carpet. It also is unknown if DDT was added to the carpet when it was manufactured. The limitations of using carpet contaminant levels to determine exposure potential and health risk are well recognized (Lioy, et al., 2002). The authors further acknowledge that the main source of DDT in NHL cases of this study would have originated from the diet rather than carpet dust. Thus, the Colt, et al. study does not determine a DDT dose nor any level of DDT intake for the NHL cases and thus cannot serve to provide a meaningful comparison to any DDT studies where dose is measured (e.g., feeding studies) or to theoretical dose estimates predicted by Dr. Strauss.

  The limitations of using *p,p'*-DDE carpet dust for assessing NHL risk is highlighted by the finding from De Roos, et al., 2005. This study measured blood *p,p'*-DDE levels in NHL cases also included in the Colt, et al. study and found no correlation between *p,p'*-DDE or *p,p'*-DDT and NHL.

- Baris, et al., 1998: Dr. Sawyer indicates that this is a key study for demonstrating causation between DDT and NHL. However, based on their findings, the authors concluded that there was no strong evidence that DDT was associated with NHL. Moreover, the authors reported that their study findings were consistent with two recent studies which found no association between DDT exposure and NHL risk (Rothman, et al., 1997 and Hardell, et al., 1996). Dr. Sawyer did not cite these two studies in any of his reports as being relevant for his analysis.

- Cantor, et al., 1992: Dr. Sawyer indicates that this study was also key in demonstrating causation between DDT and NHL. This study involved making multiple comparisons between numerous pesticides and NHL, which led the authors to caution readers that drawing conclusions about any single pesticide was "fraught with difficulties" because of the likelihood of a chance occurrence of a positive finding as a result of conducting multiple comparisons. Thus, the authors concluded that this study lacks specificity with respect to making causal determinations between individual pesticides such as DDT and NHL. In contrast, Dr. Sawyer utilizes this data to make a causation conclusion about a specific agent, DDT.

  Dr. Sawyer also identified the Cantor, et al. study as being useful for demonstrating a significant dose response between DDT and NHL (deposition p. 77). This study, however, did not determine a dose or demonstrate a dose response relationship. The study did not present any dose data or even data concerning the years or days of pesticide use which might theoretically be used to formulate a theoretical dose estimate. With respect to duration of exposure, a crucial element of any dose response determination, the authors only reported pesticide use into two groups: before and after 1965. Thus, the study does not evaluate any dose response relationships. Moreover, Dr. Sawyer was not aware that subsequently Cantor and colleagues published data on a subset of these NHL cases where they reported data concerning days of pesticide use and that a non-

significant relationship was found between days of DDT use and NHL (Cantor, et al., 1993).

- Spinelli, et al., 2007: Dr. Sawyer identifies this as a key study for demonstrating a causal association between DDT and NHL. This study evaluated the potential association between plasma levels of *p,p'*-DDE or *p,p'*-DDT and NHL. Dr. Sawyer failed to note that although the study demonstrated a significant trend between plasma *p,p'*-DDE and NHL risk, but the trend diminished substantially after adjustment for oxychlordane, and the authors found no statistically significant association between quartiles of DDT/DDE exposure and NHL or follicular lymphoma. Thus, the findings do not support Dr. Sawyer's conclusions.

Dr. Sawyer's claim that the epidemiological literature shows that DDT causes NHL is not substantiated. Dr. Sawyer misinterprets and/or utilizes isolated study segments to support the claim of a causal association, even when the scientists conducting the study recognize their findings have limitations with respect to determining causation or provide no evidence of an association. Dr. Sawyer did not conduct a comprehensive analysis of the scientific literature between DDT exposure and NHL and mainly cited a few studies that he claims support his position. Dr. Sawyer was not even aware that the Cantor, et al., 1992 authors published additional data that was not consistent with such a relationship (Cantor, et al., 1993). Although Dr. Sawyer indicated that he conducted a weight of the evidence analysis of the scientific literature and used the Bradford-Hill criteria, his report and testimony do not show this type of analysis or assessment.

10.2 Dr. Sawyer's use of the human health risk assessment process for making individual disease determinations lacks scientific validity

Dr. Sawyer utilizes the human health risk assessment process to opine that Ms. Garza's potential exposure to DDT was sufficient to produce or significantly contribute to the

production of her non-Hodgkin lymphoma. He utilizes theoretical "cancer risk" data derived by Dr. Strauss for this assessment.

Human health risk assessment was defined by the National Academy of Sciences/National Research Council (NAS/NRC) in the milestone document entitled "Risk Assessment in the Federal Government: Managing the Process," commonly referred to as the "Red Book" (National Research Council, 1983). The risk assessment process is aimed at the protection of public health before the occurrence of a disease. It is an analytical tool used by health and regulatory agencies to establish standards or guidelines to protect public health and establish cleanup levels. The risk assessment process incorporates many conservative assumptions and errs on the side of health protection. It includes the calculation of theoretical cancer risks that are used to prioritize and allocate public health resources. Given the purpose of the risk assessment process and specifically the reasons outlined below, risk assessment is not a tool that is used for making individual disease determinations.

10.2.1 Dr. Sawyer's use of risk assessment is inconsistent with U.S. EPA guidance

As indicated above, Dr. Sawyer relies upon Dr. Strauss's theoretical cancer risk estimates derived from the risk assessment process. In turn, this process utilizes a U.S. EPA cancer slope factor for DDT developed by the Integrated Risk Information System (IRIS), to calculate this theoretical "cancer risk" for Ms. Garza. However, the EPA cautions against using the slope factor for making specific disease determinations such as those made by Dr. Sawyer for Ms. Garza.

Specifically, U.S. EPA states as follows:

> "In general IRIS values (e.g., cancer slope factors) cannot be validly used to accurately predict the incidence of disease or the types of effects that chemical

> exposures have on humans. This is due to the numerous uncertainties involved in risk assessment, including those associated with extrapolation from animal data to humans, and from high experimental doses to lower environmental exposure. The organs affected and type of adverse effect resulting from chemical exposure may differ between the study animals and humans. In addition, many factors besides exposures to a chemical influence the occurrence and extent of human disease." (U.S. EPA IRIS, 2009)

Despite this U.S. EPA guidance, Dr. Sawyer uses "cancer risk" estimates developed by Dr. Strauss to determine that Ms. Garza developed NHL. His methodology violates the accepted use of cancer "slope factor," and as a result, his use of the risk assessment process, which is based upon the "slope factor," is not scientifically valid.

10.2.2 Theoretical "cancer risks" are extrapolated from animal data, and therefore do not predict the cause of NHL in an individual

Dr. Sawyer uses Dr. Strauss's DDT "cancer risk" as being equivalent to Ms. Garza's NHL risk for purposes of determining the cause of her NHL. However, Dr. Strauss's theoretical "cancer risk" is not based on human data but on data derived from rodent feeding studies. Extrapolating the effects from such studies to lower exposure levels in humans is a process that involves considerable uncertainty (U.S. EPA, 2005a). Differences in uptake rate, species metabolic variability, biologic half-life and potential metabolites, target tissue susceptibility, and species differences in ability to repair DNA can contribute to differences in severity or type of effects across species.

Because many regulated chemicals lack sufficient study in human populations, in the regulatory context, the use of high dose animal cancer studies is assumed to predict upper bound human cancer risks at much lower environmental doses. However, the common use of these assumptions and calculations in regulatory risk assessments does not correlate to cause and effect in populations or individuals. Thus, although EPA may

predict theoretical cancer risks for populations based upon carcinogenic responses in animals, this does not establish that cancer in humans would be expected to occur from such exposures.

10.2.3 The U.S. EPA DDT cancer slope factor is based on mouse liver tumors and thus lacks specificity for NHL

The cancer risk estimates used by Dr. Sawyer for Ms. Garza from her alleged DDT exposure are not based upon NHL, but are based upon the occurrence of liver tumors in mice fed high doses of DDT (U.S. EPA IRIS, 2009). There is no scientific evidence that demonstrates that occurrence of liver tumors in mice is related to the risk of NHL in humans. Dr. Sawyer's transference of a risk based on rodent liver tumors to human NHL risk lacks scientific validity since there is no data to support that rodent liver tumors are related to human NHL. To reach a conclusion about NHL risk and/or cause, a person should examine data concerning the specific cancer at issue rather than the most sensitive tumor endpoint identified in rodents.

10.2.4 Human health risk assessments do not focus on a specific disease

The risk assessment process is aimed at the protection of public health before the occurrence of a disease. It predicts a theoretical lifetime cancer risk typically based on cancer occurrence in animals. In reality there is no "generic cancer disease," but rather separate types of cancer, each with individual risk factors and susceptibilities. For example, basal cell skin cancer is related to excessive sunlight exposure and persons with fair skin are at increased risk, while others, such as cancer involving female reproductive organs have other separate risk factors. Therefore, it is inappropriate to apply a theoretical generic cancer risk estimate to a specific cancer like NHL.

10.2.5 The risk assessment process involves a conservative approach employed by regulatory agencies to protect public health and as a result, are expected to overestimate health risk

Risk assessment is an analytical tool that is used by regulatory agencies to establish standards or guidelines to protect public health and often to establish site cleanup levels. The process incorporates many highly conservative assumptions to err on the side of health protection and provide a margin of safety. For example, the process incorporates a default linear extrapolation model that is used for predicting responses from low level exposures when the mode of action of an agent has not been ascertained (U.S. EPA, 2005a). This hypothesizes that there is a "no threshold" assumption for cancer risk, i.e., that some positive cancer risk occurs at any dose above zero, even though there may be no scientific proof for such a premise and the human body has defense mechanisms for protection of carcinogenicity. In addition, the cancer slope factor likely overestimates the risk of a substance in producing cancer, in part because it is based upon the occurrence of cancer in the most sensitive animal species tested for the most sensitive tumor end point. The cancer slope factor also is based upon a 95% upper confidence limit. The use of this 95% upper confidence interval for cancer potency makes it very unlikely that the risk could be higher, and is much more likely to be lower than predicted.

The U.S. EPA recognizes the inherent conservatism incorporated in risk assessment and the slope factor and has indicated the following:

> "Because the slope factor is often an upper 95th percentile confidence limit of the probability of a response based on experimental animal data used in the multistage model, the carcinogenic risk estimate will generally be an upper-bound estimate. This means that EPA is reasonably confident that the "true risk" will not exceed the risk estimate derived through use of this model and is likely to be less than that predicted." (U.S. EPA, 1989, p. 8-6)

Furthermore, the U.S. EPA concludes as follows:

> "It should be emphasized that the linearized multistage procedure leads to a plausible upper limit to the risk that is consistent with some proposed mechanisms of carcinogenesis. Such an estimate, however, does not necessarily give a realistic prediction of risk. The true value of risk is unknown, and may be as low as zero." (U.S. EPA, 1986)

Consequently, Dr. Sawyer's use of generic cancer risk data from risk assessment to determine the cause of Ms. Garza's NHL is inappropriate and lacks scientific validity.

10.3 Dr. Sawyer misunderstands the Department of Energy's (DOE) risk assessment guidelines and misapplies the guidelines

Dr. Sawyer takes the position that risk assessment is a valid methodology for determining disease causation and relies upon the DOE guidelines as an example of how risk assessment can be used for making disease determinations (deposition p. 198). The DOE risk assessment methodology for determining individual cancer risk, however, is a fundamentally different process than Dr. Strauss's risk assessment, which Dr. Sawyer relies upon to reach a medical causation determination.

The DOE approach does not validate Dr. Sawyer's use of Dr. Strauss's theoretical "cancer risk" estimates to make a causation determination for Ms. Garza's NHL. Instead, the DOE guidelines describe a risk assessment process for determining if a cancer is related to radiation in workers who manufactured nuclear weapons. The DOE cancer risks are not based upon animal data, but on actual human health cancer data, e.g., Japanese atomic bomb blast survivors. The DOE guidelines also incorporate the use of real exposure data in estimating a worker's cancer risk. As a result, the DOE calculates cancer risks for different organs based upon actual experience of populations exposed to different types of radiation, and thus provides a real world measure of cancer risk. In

contrast, Dr. Strauss's risk estimates are based upon mice liver tumor data, incorporate no actual human cancer risk data and are based on a hypothetical dose or intake, not actual exposure measurements. Moreover, because the DOE guidelines incorporate person, agent (radiation), and organ specific information to determine a specific person's risk, Dr. Sawyer's testimony that the DOE methodology does not calculate risk for individual tumors is false (deposition p. 129).

10.4 Dr. Sawyer's comparison of Dr. Strauss's theoretical "cancer risk" with Ms. Garza's background risk of NHL for causation determination is scientifically inappropriate

To assess whether Ms. Garza's NHL is attributable to DDT, Dr. Sawyer compares Dr. Strauss's generic, theoretical "cancer risk" to Ms. Garza's background NHL risk from SEER data. He testifies that once Dr. Strauss's theoretical cancer risk exceeds the background NHL risk for a woman like Ms. Garza, i.e., 2.3 in 10,000 (deposition p. 86), it is established that these agents caused Ms. Garza's NHL. This premise is false. First, Dr. Sawyer does not have any data on Ms. Garza's actual risk, if any, of developing NHL from DDT. Thus, he cannot conduct a "person to person comparison" (i.e., compare risk of NHL from DDT to background risk). Second, he is comparing theoretical risk of mice developing liver tumors to background risk of NHL in human populations without even demonstrating that the two species (mice and humans) or conditions (mouse liver tumor and human NHL) are similar. Even Dr. Strauss admits that her generic theoretical "cancer risk" estimate does not predict the risk of developing NHL (deposition pp.105-106). For these reasons, there is no scientific basis for Dr. Sawyer's use of this comparison to reach a causation determination of Ms. Garza's NHL.

11.0 Increased "cancer risks" estimated for DDT by Dr. Strauss and used by Dr. Sawyer are insignificant when compared to background cancer risk levels

Assuming Dr. Strauss's theoretical "cancer risk" estimates are valid and relevant to Ms. Garza, which they are not for the reasons discussed previously, they are insignificant when compared to her actual background cancer risk.

To provide a benchmark for interpreting the quantitative significance of Ms. Garza's theoretical DDT-related "cancer risks," they can be compared to the actual cancer risks of a woman of similar age and race in Texas. The actual cancer risk (based on historical occurrence in human populations) of a 55-year-old Hispanic woman (Ms. Garza was age 55 at time of diagnosis) can be obtained from cancer incidence data reported for the State of Texas. Table 1 provides a listing of age-specific probability of cancer risk for Hispanic females derived from the State of Texas cancer registry. At the time of her diagnosis, Ms. Garza's accumulated risk of developing any cancer was 6.5% or 0.065. This background risk is about 650 times greater than Dr. Strauss's theoretical "cancer risk" for DDT based upon mouse liver tumor data (i.e., 0.15% of her background cancer risk). Even with the application of a 3-fold increase in cancer potency for early life exposures, Ms. Garza's actual accumulated background cancer risk was about 216 times greater than Dr. Strauss's theoretical cancer risk (i.e., 0.5% of background cancer risk). Thus, the hypothetical contribution that DDT had with respect to causing Ms. Garza's NHL is insignificant given the magnitude of difference between her actual background and Dr. Strauss's theoretical "cancer risk," i.e., hundreds of times less.

12.0 Predicted DDT intake is less than WHO Acceptable Daily intake (ADI)

Several organizations have developed acceptable daily intake levels of DDT. The World Health Organization has also suggested an Acceptable Daily Intake (ADI) for DDT and its metabolites of 0.01 mg/kg/day. The ADI represents daily intake that is considered to

be safe for a lifetime. Dr. Strauss's predicted daily intakes of DDT/DDE are all less than the WHO acceptable intake, i.e., 0.003 mg/kg during Ms. Garza's period of occupancy in the initial Nicholson residence (assumes 108 µg day intake for her combined DDT, DDE and DDD). Ms. Garza's combined DDT, DDE, and DDD intake during her residence at 423 Canal would be substantially less. The Permissible Exposure Level (PEL) established by the Occupational Safety and Health Administration (OSHA) for DDT is 1 mg/m^3 for an eight-hour work day (29 CFR, 1910.120). Based on the assumption that 10 cubic meters of air is inhaled over an eight-hour work day (EPA 1997), a worker would receive about 1,000 micrograms a day for a lifetime of work. Ms. Garza's combined DDT intakes, assuming they are accurate, are well below these levels. In sum, Dr. Strauss's predicted DDT intakes for Ms. Garza are below WHO and OSHA thresholds.

13.0 Overview of Dr. Strauss's risk assessment and opinions regarding Ms. Garza

- Dr. Strauss's health risk assessment is based upon incomplete environmental data and consequently the predicted theoretical cancer risk estimates are unreliable.
- Dr. Strauss has no objective evidence that chickens would have fed at the MISD location across the lateral irrigation canal.
- The presumed DDT intake, calculated by Dr. Strauss, is similar to daily background intake.
- Dr. Strauss's 3-fold increase of Ms. Garza's "cancer risk" is inconsistent with EPA guidance.

Assuming Dr. Strauss's theoretical "cancer risk" estimates have any relevance for Ms. Garza, which they do not, as previously discussed, Dr. Strauss's risk assessment suffers from several shortcomings.

14.0 Dr. Strauss's health risk assessment is based upon incomplete environmental data and consequently the predicted theoretical cancer risk estimates are unreliable

As discussed in detail in the report of Austin Cooley, P.E., in Guadalupe Garza vs. Allied Chemical Corp., et al., Dr. Strauss, in her initial report, used only five soil samples to estimate Ms. Garza's theoretical "cancer risk." In Dr. Strauss's supplemental report, she expands the number of soil samples she relies upon to only 13, ignoring thousands of soil data points available in or around the Hayes-Sammons mixing facility. See above-referenced Cooley report. Furthermore, based upon Mr. Cooley's report, I understand that the DDT soil concentrations used by Dr. Strauss to determine Ms. Garza's theoretical DDT intake ignore data on or adjoining Ms. Garza's former residence and represent a limited subset of available data relating to Ms. Garza's residence. Consequently, Dr. Strauss's theoretical cancer risk estimates for Ms. Garza are unreliable for the reasons noted below.

One of the key requirements in performing a health risk assessment is to determine the actual concentrations that were present at the site for the relevant time period (U.S. EPA). To that end, a risk assessor must analyze all available environmental data to develop accurate exposure estimates, which are necessary to calculate reliable cancer risk estimates. Reliance on environmental measurements that are not representative of actual historical concentrations can lead to misleading risk estimates. Dr. Strauss's risk assessment relies on a very limited data set that was obtained decades after Ms. Garza's alleged exposure on the 500 block of Nicholson and therefore is based upon non-validated extrapolated data. Consequently, Dr. Strauss's risk assessment does not reliably predict Ms. Garza's DDT intake. Indeed, the majority of all of Ms. Garza's theoretical DDT intake and theoretical DDT "cancer risk" is based upon a single soil sample. As a toxicologist, I find it highly suspect that the majority of Dr. Strauss's calculated chemical intake for Ms. Garza is based on a single soil sample when a multitude of other samples are available yet not included in her analysis. See Mr. Cooley's report. Thus, Dr. Strauss's risk assessment cannot be considered to be valid

since it is based upon limited environmental data and does not incorporate many environmental measurements which characterize actual DDT levels near or around Ms. Garza's prior Nicholson residence.

14.1 Dr. Strauss has no objective evidence that chickens would have fed at the MISD location across the lateral irrigation canal

According to Dr. Strauss, Ms. Garza ate eggs on a daily basis for seven years during her childhood. The eggs were reported to be produced by free-range chickens living near her "506 Nicholson" residence. Dr. Strauss assumes that (1) these chickens ingested soil containing DDT, (2) the chickens ingested soil from around the home and the area across the irrigation canal, and (3) the DDT was transferred from the soil to the chicken and then transferred to the eggs consumed by Ms. Garza. Based on Dr. Strauss's predicted DDT intakes, Ms. Garza's egg consumption represented about 98% of her daily DDT intake for about seven years. Critically, the majority of the DDT received by the chickens and entering the eggs originates from soil the chickens supposedly ingested from the area across the irrigation canal.

Dr. Strauss provides no reliable evidence concerning the anticipated range of chickens or whether these chickens were able to or even likely to cross an irrigation canal. For example, chickens are considered to be animals that would not be expected to swim across an irrigation canal. Chickens lack natural adaptations associated with swimming, including having non-water proof feathers and absence of webbed feet. Lack of webbed feet would be expected to make paddling difficult in a chicken compared to ducks, or other species of birds with webbed feet. In addition, some birds have a fat layer beneath the skin to keep them buoyant in the water, such as ducks and geese, but chickens lack this feature (USDA, 2006). Dr. Strauss lacks objective data that these free-range chickens crossed the irrigation canal near Ms. Garza's residence, and as a result, Dr. Strauss's assumption that chickens would regularly cross the irrigation canal is unsubstantiated.

14.2 The presumed DDT intake, calculated by Dr. Strauss, is similar to daily background intake

Ms. Garza's presumed intake of DDT, DDE, and DDD according to Dr. Strauss, from multiple exposure pathways is similar to background DDT intake levels. Table 2 summarizes Dr. Strauss's initial predicted daily DDT intake (DDT and metabolites) for Ms. Garza while she resided at "506 Nicholson" for several childhood years. Her presumed intake at this location was 108 µg. For her residence at 1015 Nicholson, from 1975 to 1999, Ms. Garza's presumed DDT intake was less than 1 microgram a day.

The predicted total DDT intake that Ms. Garza presumably received is within the range of reported DDT intakes for the general population during the same general time period.[4] An assessment of DDT intake published in 1959 reported that an average man consuming about 2,974 calories daily would have an intake of about 184 µg of total DDT (Hayes, 1959). The Food and Drug Administration began to collect data on DDT and other pesticides beginning in the mid-1960s. The estimated daily total DDT intake from 1964-1967 for a 34 kg person was about 31 µg/day (Duggan 1968). For the time period from 1968 to 1970, a 34 kg person would be expected to consume about 18 µg/day (Duggan and Corneliussen, 1972). Thus, the range of Ms. Garza's presumed DDT intake was similar to or less than intake from background consumption of food during the 1950s, 1960s and 1970s.

14.3 Dr. Strauss's 3-fold increase of Ms. Garza's "cancer risk" is inconsistent with EPA guidance

Dr. Strauss increased the theoretical "cancer risk" for Ms. Garza by 300% for her purported exposure at "506 Nicholson." She claims this 3-fold increase is consistent with EPA guidance for evaluating risks for early life exposures (deposition p. 82; Original

[4] Throughout this time period, the key source of DDT intake for the general population was diet, including dairy products, meat, vegetables, fruits, and grains.

Report, page 18). Dr. Strauss's application of a 3-fold increase is erroneous for the following reasons:

- EPA has established guidance for conducting risk assessments that involve childhood exposures because of the concern that children may be more susceptible to select agents (U.S. EPA, 2005b). Based on this guidance, EPA recommends for risk assessment purposes that a default 3-fold increase be applied to cancer risks only for carcinogens that act through a mutagenic mode of action (U.S. EPA, 2005b). In this same guidance, EPA uses DDT as an example of a non-mutagenic compound. Because DDT does not have a mutagenic mode of action, according to this guidance, the application of a 3-fold default factor by Dr. Strauss to DDT contradicts EPA guidance.

- Despite clear guidance by EPA, Dr. Strauss attempts to justify her application of a 3-fold increase by relying on juvenile-adult ratios derived from a single study of male mice. Specifically, Dr. Strauss testified that a study in the EPA guidance demonstrated a 2.5 increased ratio, supporting the 3-fold increase of risk for Ms. Garza's "506 Nicholson" exposures (deposition pp. 99-100). Regardless of what this single study may or may not show, the guidance is clear that the 3-fold increased risk should only apply to carcinogens that act through a mutagenic mode of action.

In summary, Dr. Strauss's risk assessment and resulting theoretical "cancer risk" estimates for Ms. Garza are unreliable. The estimates are based on incomplete soil data, and unsupported assumptions, including the notion that free-range chickens regularly crossed an irrigation canal, consumed certain soil with DDT, and Ms. Garza daily consumed DDT through those eggs. Dr. Strauss also misapplies EPA guidance in estimating Ms. Garza's theoretical "cancer risks." Moreover, as Dr. Strauss admits, the theoretical "cancer risks" are unrelated to human NHL risks and have no significance for determining the cause of Ms. Garza's NHL.

15.0 Summary of opinions

- It is my opinion, to a reasonable degree of medical probability that the scientific literature does not demonstrate that DDT or its metabolites cause or contribute to the development of NHL, including follicular lymphoma.
- DDT is considered to be one of the most investigated pesticides with respect to the occurrence of NHL.
- Cohort studies of workers with DDT exposure have not demonstrated a statistically significant increased NHL incidence and/or mortality.
- Case-control studies involving DDT including studies that utilize DDT biomarkers show no or very limited associations between DDT and NHL that largely disappear following adjustment for other exposure factors.
- Ecological data on NHL rates and DDT use in the U.S. and other countries do not support the conclusion that DDT causes NHL.
- Texas Department of Health investigations that have been conducted to evaluate potential health impacts from Hayes-Sammons show no increased cancer rates in Mission, Texas and no increased serum DDT levels in persons living and/or working in close proximity to Hayes-Sammons.
- Dr. Sawyer's claim that DDT causes, or substantially contributes to NHL is not substantiated by the epidemiological literature.
- Dr. Sawyer's reliance on the risk assessment process and Dr. Strauss's theoretical "cancer risk" estimates for the purpose of determining the cause of Ms. Garza's NHL lacks scientific validity.
- Dr. Strauss's health risk assessment is based upon incomplete and extrapolated environmental data; consequently, her predicted theoretical "cancer risk" estimates are unreliable and misapplied to show causation of NHL.
- Dr. Strauss's 3-fold increase of Ms. Garza's theoretical "cancer risk" is inconsistent with EPA guidance.
- Dr. Strauss's estimated Ms. Garza's theoretical "cancer risk," even when increased by 300% for "506 Nicholson," are insignificant when compared to her

actual background cancer risk based upon Texas and national data for a woman her age.

- Dr. Strauss's presumed DDT intake levels for Ms. Garza while residing at "506 Nicholson" is similar to background daily intake reported for the general public at that time, whereas Dr. Strauss's presumed DDT intake for Ms. Garza while at 1015 Nicholson is less than the amount she would have received in her diet.
- Ms. Garza has other risk factors for NHL. One risk factor, obesity, is increasingly being recognized through several studies as being important. Another risk factor is Ms. Garza's past employment in a cleaning occupation. Although these risk factors cannot be determined as causal for her follicular lymphoma, they serve to highlight the speculative nature of the plaintiff's expert claims that a known cause can be specified, such as DDT. Yet, her presumed DDT intake is similar or less than that of the general public, and her theoretical increased "cancer risk" is minute compared to her overall background risk of developing cancer.

I reserve the right to modify and/or supplement this report and my opinions if and when additional information becomes available.

Respectfully submitted September 30, 2009,

Appendix

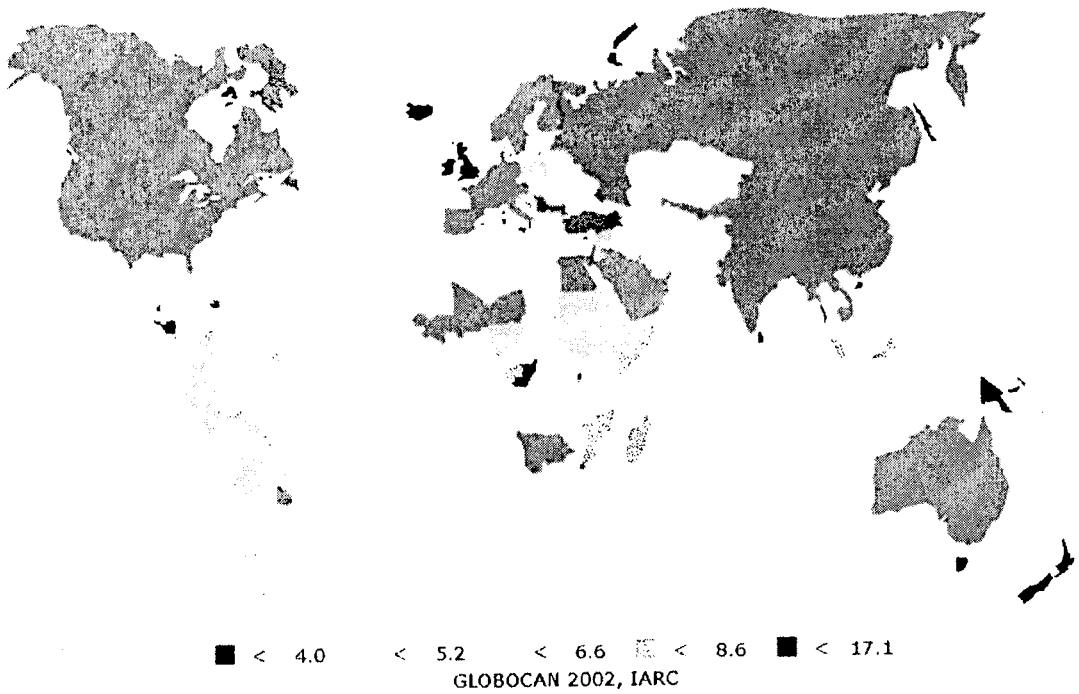

Figure 1. Non-Hodgkin Lymphoma, Males. Age-standardized incidence rate per 100,000 from GLOBOCAN 2002 (Ferlay, et al., 2004).

Table 1. All cancer cumulative risk rates by age (5-year increments), among Hispanic females (Texas Cancer Registry (1998-2002), Department of State Health Services).

Age	Age Group	All Cancer Rate (per 100,000)	Cumulative Risk by age
25	15-34	39.900	0.00655741
30	15-34	39.900	0.00853735
35	35-44	165.200	0.01175239
40	35-44	165.200	0.01988170
45	45-54	344.100	0.02968159
50	45-54	344.100	0.04623312
55[1]	55-64	625.600	0.06513767
60	55-64	625.600	0.09392754
65	65-74	1004.200	0.12514927
70	65-74	1004.200	0.16799098
75	75-84	1330.000	0.21130847
80	75-84	1330.000	0.26205058
85	85+	1459.800	0.31042375
90	85+	1459.800	0.35896293
95	85+	1459.800	0.40408545

1. Age of Ms. Garza at diagnosis.

Table 2. Dr. Strauss's theoretical DDT, DDE, and DDD intakes for Ms. Garza at "506 Nicholson" (Assumes average body weight of 34 kilograms and original Exposure Point Concentration).

	DDT (mg/day)	DDE (mg/day)	DDD (mg/day)	Total (mg/day)	Total (µg/day)
Soil Ingestion[1]	51.68 E-5	160.48 E-5	11.76 E-5	224.0 E-5	2.2
Dermal Contact[1]	11.83 E-5	36.72 E-5	2.69 E-5	51.2 E-5	0.51
Inhalation[2]				9.0 E-5	0.09
Ingestion of Eggs[3]	3,130 E-5	7,290 E-5	0.882 E-5	10,500 E-5	105.0
			Total	**0.108 mg/day**	**108.0 µg/day**

1. Soil EPCs assumed for soil ingestion and dermal contact from "506 Nicholson."
   DDT (o,p' & p,p') 1.292 mg/kg
   DDE (o,p' & p,p') 4.013 mg/kg
   DDD 0.294 mg/kg
2. Inhalation based upon assumption of 0.009 µg/m^3 DDT (total) and inhalation rate of 10 m^3/day.
3. Soil EPCs for ingestion of eggs assuming average soil concentration for "506 Nicholson" and MISD side of canal.

	"506 Nicholson"	MISD Side	EPC for Hens
DDT (o,p' & p,p')	1.292 mg/kg	9.14 mg/kg	5.22 mg/kg
DDE (o,p' & p,p')	4.013 mg/kg	20.30 mg/kg	12.16 mg/kg
DDD	0.294 mg/kg	(assumed 0)	0.15 mg/kg

Marion Joseph Fedoruk, M.D., CIH, DABT, FACMT
Principal Scientist

Professional Profile

Dr. Marion Joseph Fedoruk is a Principal Scientist in Exponent's Health Sciences and is an advisor to all the Health Sciences Centers. Dr. Fedoruk holds subspecialty board certification in Medical Toxicology and primary board certification in Occupational Medicine from the American Board of Preventive Medicine. There are fewer than 40 physicians in the U.S. who hold both these certifications. He is also a Diplomate of the American Board of Toxicology (DABT) and is also certified by the American Board of Industrial Hygiene as a Certified Industrial Hygienist (CIH).

Dr. Fedoruk maintains an active clinical practice and is engaged in teaching and research at the University of California, Irvine, where he is Clinical Professor of Health Sciences, and Senior Physician at the UCI Center for Occupational and Environmental Health Clinic.

Dr. Fedoruk has extensive experience in the assessment of exposure and related health effects for a broad range of chemical and biological hazards. His 25-year experience involves evaluating health significance from environmental, occupational, and product related exposures. His assessments have involved mercury, lead, arsenic, cadmium, nickel, polychlorinated biphenyl (PCBs), benzene, volatile organic hydrocarbons, isocyanates, pesticides, combustion products, talc, silica, and other dusts. He has designed, developed, and implemented medical monitoring programs for workers in several industries including hazardous waste, energy, asbestos, and electronics, and directed a course on medical surveillance. He performed an assessment of health needs for military and civilian personal involved in chemical weapons destruction in Johnson Atoll, in Micronesia. His work has involved assessment of air quality problems in homes, offices, schools, and work environments including assessments for microbial hazards.

Dr. Fedoruk has served as advisor occupational and environmental health matters to both government and industry. He served as a member of an expert panel convened by EPA and the U.S. Department of Labor to develop national priorities for educating health care providers about the adverse health effects of pesticides. Dr. Fedoruk has served as advisor to NFPA for developing medical guidelines for the Nation's firefighters. He has assisted health and fire departments in evaluating public health impacts associated with accidental chemical releases. He has also been involved in developing occupational medical programs and guidelines for several jurisdictions, including the City of New York.

Dr. Fedoruk has conducted studies and published articles in the areas of occupational and environmental medicine. He authored chapters in several books, including the World Health Organization's Encyclopedia of Occupational Safety and Health, the Encyclopedia of Toxicology, and textbooks in occupational lung diseases and thoracic oncology. He most

recently designated as a Fellow of the American College of Medical Toxicology, the society for board certified medical subspecialists.

Academic Credentials and Professional Honors

M.D., University of Alberta, Edmonton, Canada (with distinction), 1978
Biology Studies, University of Alberta, Edmonton, Canada, 1974
Premed, Selkirk College, British Columbia, Canada (honors standing), 1971

Medical Toxicology, Subspecialty, Certification in 1998 (certified by the American Board of Preventive Medicine)
Occupational Medicine, Specialty, Certification in 1984 (certified by the American Board of Preventive Medicine)
Certified Industrial Hygienist, Toxicology Aspects Certification December 1985 (certified by the American Board of Industrial Hygiene
Diplomate, American Board of Toxicology (DABT), Certification in 1987

Residency: Occupational Medicine, Department of Community and Environmental Medicine, University of California, Irvine, California, 1981–1983; Internship: Montreal General Hospital, Montreal, Canada (McGill University), mixed internship, 1978–1979

1995 Recipient of Merit in Authorship Award from the American College of Occupational and Environmental Medicine for publication, "Personal Risk Assessment Under the Americans with Disability Act: A Decision Analysis Approach," Journal of Occupational Medicine 1993, 35:1000–10

2001 Recipient of The Jean Spencer Felton Award for Excellence in Scientific Writing awarded by The Western Occupational and Environmental Medical Association

Fellow American College of Medical Toxicology, 2007

Adolph G. Kammer Merit in Authorship Award, American College of Occupational and Environmental Medicine, 1995

Congressional Testimony

Hearing on San Bernardino, California Pipeline Rupture, Subcommittee on Investigations and Oversight Committee on Public Works and Transportation, U.S. House of Representatives, July 7, 1989.

Academic Appointments

- Clinical Professor of Medicine, Department of Medicine, University of California, Irvine, School of Medicine, 2002–current
- Associate Clinical Professor of Medicine, Department of Medicine, University of California, Irvine, School of Medicine, 1998–2002
- Assistant Clinical Professor of Medicine, Department of Community and Environmental Medicine, University of California, Irvine, School of Medicine, 1985–1991; Department of Medicine 1991–1997
- Assistant Clinical Professor of Medicine, Pulmonary Division, Department of Medicine, University of California, San Diego, School of Medicine, July 1991–January 2000
- Lecturer, Graduate School of Public Health, Division of Public Health, Division of Occupational and Environmental Health, San Diego State University, 1983–1988
- Clinical Instructor of Medicine, Department of Medicine, University of California, San Diego, School of Medicine, 1985–1986

Teaching Experience

Graduate of Public Health, Division of Occupational and Environmental Health, San Diego State University. Primary instructor for two courses:

- "Occupational Medicine"—Core 3-unit course for MPH students specializing in occupational health, 1984–1987
- "Occupational Health Management"—3-unit course for MPH students specializing in occupational health, 1985

University of Southern California, Institute of Safety Systems and Management, Los Angeles, California:

- Instructor for several USC-sponsored extension programs and lecturer on several subjects including industrial hygiene, toxicology, occupational disease and carcinogens.
- Developed and presented a one and one half day course regarding the development and management of medical surveillance programs. This course was given in September 1985, and has been presented biannually through 1990.

EX

Department of Health Services Division of Toxics, State of California, 1987–1988:

- Instructed portions of a course entitled "Introduction to Toxicology" for State of California, D.H.S. employees engaged in Hazardous Waste Operations. (Los Angeles, Berkeley) Sacramento.

University of California, Irvine. Instructor for courses entitled:

- "Air Pollutants and Toxic Chemicals," Social Ecology; 498.3; 1988–1991
- "Managing Indoor Air Quality Episodes," Social Ecology; February 12, 1991

University of California, Berkeley/Northern Occupational Health Center:

- Instructor for a course entitled "Pesticide Contaminated Hazardous Waste Sites" and taught section on pesticide toxicology and medical surveillance, 1989

Committees

American Lung Association, Committee on Environmental and Occupational Health, San Diego, California, 1983–1987.

County of San Diego, Subcommittee Advisory Panel, Hazardous Materials Management Team. Designated representative of County of San Diego Medical Society. The subcommittee advises County Government about the applicability, enforcement, and technical aspects of County Ordinances dealing with hazardous materials management, 1984–1987.

Agricultural/Urban Pesticide Issues Task Force. Task force member of a committee appointed by the County Board of Supervisors to review pesticide usage and determine how it impacts on both urban and agricultural concerns, January 1986–November 1986.

NIOSH/Northern and Southern California Educational Resource Centers. Served on the Advisory Committee on pesticide related hazardous waste training for health and safety professionals, 1989–1990.

National Fire Protection Association. Subcommittee member on the 1001 and 1500 committees concerning medical and physical fitness criteria for structural firefighters, 1989–present.

American College of Occupational and Environmental Medicine. Planning committee member for 1990 State of the Art Conference on Fitness for Work. Pittsburgh, Pennsylvania, October 8–12, 1990.

American College of Occupational and Environmental Medicine. Member of Occupational and Clinical Toxicology committee, 1991–2000, appointed chairman, May 1992.

American College of Occupational and Environmental Medicine. Member of Committee on Scientific Affairs, May, 1992–2000.

EX

American College of Occupational and Environmental Medicine. Member of Committee on Medical Surveillance May, 1993–2000.

Toxicology Excellence for Risk Assessments, Cincinnati, Ohio. Member of Peer Review Committee sponsored by EPA, Health Canada and Metal Finishing Association of Southern California, concerning a risk assessment on the carcinogenicity and toxicity of soluble nickel salts.

U.S. Environmental Protection Agency. Member of expert panel concerning the development of a strategy for educating the nation's health care providers on pesticide-related health matters. Proceedings published in Pesticides and National Strategy for Health Care Providers, July 1998 (EPA 735-R-98-001).

Special Projects

American College of Occupational Medicine, Chicago, IL. Developed questions for the national Medical Self-Assessment Program 2 for physicians to test their knowledge base in occupational medicine.

American Lung Association. Prepared "Solvents in the Workplace" fact sheet for ALA publication Lung Hazards at Work, a program developed to inform employers and employees on the control of harmful occupational exposures that can lead to lung disease.

City of San Diego Fire Department. Developed and presented a risk communication program concerning the fetal health risks from physical and chemical exposures to female firefighters. The program covered the areas of health effects of heat stress, carbon monoxide and other agents on the fetus. The program was presented to all female firefighters with the City of San Diego in 1988 and 1990.

EX

DIGEST OF DEPOSITION OF MR. CHRISTOPHER BEEGAN, STATE WATER WATER BOARD STAFF, PROJECT MANAGER FOR DEVELOPMENT OF THE SEDIMENT QUALITY OBJECTIVES

All page and line references to: Transcript of Beegan Dep. October 11, 2010, In Re Tentative Cleanup and Abatement Order No. R9-2011-0001, Cal. Reg. Water Quality Control Bd., San Diego Region

Participants:
Deponent – Mr. Christopher Beegan – State Water Board Staff, Project Manager for development of the Sediment Quality Objectives
Deposing counsel – Mr. Paul Singarella, Latham & Watkins, LLP
Defending counsel – Mr. Dan Fuchs, Deputy Attorney General, California Attorney General's Office

Other deposing counsel – Mr. Bill Brown, Brown & Winters

Pages(s) : Line(s)	Topic	Text of Deposition
11:9-13	Scope of deposition	By Mr. Fuchs: "Mr. Beegan's testimony will be limited to the following subject: How Mr. Beegan would expect the Phase I Sediment Quality Objectives, DSQOs [sic], to be applied in the abstract without reference to any particular location."
38:20-21, 24-25 39:6-12	Use of stressor identification	By Mr. Singarella: "Q. Turning back to page 13 of Part 1 VI, Human Health . . . Did I understand you to testify that VI contains Lines of Evidence?" By Mr. Beegan: "A. . . . Sections V and VI still describe how you would determine whether sediments – umm – meet or exceed both the human health and the benthic community sediment quality objectives. If you've determined that you've had an exceedance under certain conditions, you move on to stressor identification."
40:16-25 41:1-10	Steps in stressor identification	By Mr. Singarella: "Q. Turning back to stressor identification on page 17, please, there are certain components of stressor identification identified in Section F; correct?" By Mr. Beegan: "A. Yes." "Q. And one step is a confirmation and characterization process; correct?"

		* Edited by Mr. Beegan after the deposition. Original said, "total logical."
47:11-21	Confounding factors	By Mr. Singarella: "Q. . . . I was asking about confounding factors and how are physical disturbance and nonpollutant constituents – how are they confounding factors." By Mr. Beegan: "A. They can – confounding factors – um [affect*] – the response of the indicator in a way that – um – masks the signal you're looking for, and that is the primary reason why we are using multiple Lines of Evidence to assess sediment quality." "Q. And what signal are you looking for?" "A. We're looking for a toxic pollutant-related signal." *Edited by Mr. Beegan after the deposition. Original said, "a fact."
48:21-25 49:1-25	Confounding factors	By Mr. Singarella: "Q. There's a confirmation step under stressor identification; correct?" By Mr. Beegan: "A. Correct." "Q. And one of the things being confirmed is the absence of confounding factors; right?" "A. Correct." "Q. And confounding factors are those nontoxic constituent factors that could result in the signal; right?" "A. Correct." "Q. And the signal that you're looking for is impacts to sediment from toxic constituents; correct?" "A. Correct." "Q. Because you've got a sequential process here; is that right?"

		"Q. In other words, the confounding factors can produce a condition that does not appear protective; correct?" "A. Correct." "Q. Even though that condition is not caused by toxic pollutants; correct?" "A. Correct."
67:10-25 68:1-18	Pollutant identification	By Mr. Singarella: "Q. Turning to page 18 of Part 1, pollutant identification, what is the purpose of pollutant identification?" "A. When you follow Part 1, you apply the three Lines of Evidence, you end up with simply a station categoric – categorization for each station. I've described those in the past. Shall I describe them again?" "Q. No, that's fine." "A. Okay. Umm – in order to proceed further, you need to determine what is causing the problem – umm – so likely impacted, clearly impacted, possibly impacted, it doesn't – the – it only is used in the assessment. After that to determine what the stressor is you need to determine – you need to go down this stressor identification process. As we've gone over in the past, you rule out other nonpollutant-related factors like dredging, prop wash. The next step would be, okay, what pollutant is causing the problem? Once you've identified what pollutant is causing the problem, you can – umm – manage it, or restore, or cleanup, or control. Does that help?" "Q. Yes. Thank you." "A. Okay." "Q. And so is pollutant identification a mandatory component of stressor identification?"

		We clearly stayed [sic, probably stated] up front, don't use these chemistry values to identify which chemical is causing the problem, because that's not a fruitful or accurate approach. Those sediment quality guidelines basically – I believe they have similar limitations. The empirical ones have similar limitations. In some cases where your – umm – you have one pollutant that's screaming, maybe multiples of the sediment quality guideline it – they perform better. But in general their use was intended for assessment, not stressor identification." "Q. Uh-huh. When you say 'screaming' you mean exceedingly high concentrations?" "A. Yeah, like two, three, five times the – um – the guideline." "Q. And probably where there aren't other pollutants around?" "A. Correct. There's – we could spend a day talking about the limitations of empirical and mechanistic guidelines."
76:12-17	Steps in stressor identification	By Mr. Singarella: "Q. So with regard to the structure of stressor identification, it has three principal components; correct?" By Mr. Beegan: "A. Yes." "Q. Are they all mandatory?" "A. Yes."
76:24-25 77:1-22	Management actions	By Mr. Singarella: "Q. Do you see the reference to 'management actions?'" By Mr. Beegan: "A. Yes."

		By Mr. Beegan: "A. No."
87:19-25 88:1-25 89:1-13	Pollutant-specific concentration-based approaches	By Mr. Singarella: "Q. Now turning back to page 19 of Part 1, Sub-H refers to the Site-Specific Sediment Management Guidelines; correct?" By. Mr. Beegan: "A. Yes." "Q. Would that be a pollutant-specific concentration-based approach?" "A. Oh, yes. Yes." "Q. So there was a shifting away from pollutant-specific concentration-based approaches; right?" "A. Yes." "Q. Help me understand why it came back in in the last section of Part 1, Section H." "A. Okay. The – umm – there – umm – I'm trying to figure out how to state this in a way that makes sense, but – The assessment approach was the portion that I was referring to. Many people want to chemic – sediment chemistry based numeric values that could be applied broadly to all bays and all estuaries. The level of science isn't there to create reliable numeric sediment chemistry values. So that – umm – so we use the multiple Line of Evidence approach, the three LOE. The chemistry is – has confounding factors, toxicity, benthic community. They all have confounding factors. So what I was referring to in the shifting away was – umm – to state up front that we can't develop numeric sediment chemistry-based objectives, however, once you identify the stressor and it's a pollutant-related stressor, the – I guess the practical way in which you manage that is to develop some sort of concentration-based approach.

		"A. Yes." "Q. There's no indication that a pollutant-specific guideline may be designated prior to the establishment of that relationship; right?" "A. Right."
94:8-25 95:1-18	Site-specific cleanup levels	By Mr. Singarella: "Q. You mean the numbers on page 8 are used to set site-specific cleanup levels?" By Mr. Beegan: "A. Oh, absolutely not." "Q. I'm sorry. Then I may have misunderstood." "A. Oh, okay. Okay. So these are not – these- these values are not intended to drive cleanup, or a site-specific cleanup, or even be water body or –umm – segment-specific sediment targets. These are only for use as a – one of the LOE, Line of Evidence, and the assessment framework. Once you've moved through – once you've applied the assessment framework –." "Q. Sir, may I hold you up there? When you said 'These values are not used as cleanup levels,' were you referring to the values in Table 6 and 7 on page 8 of Part 1?" "A. Yes. Yes." "Q. Thank you for that clarification. Please proceed with your answer." "A. So, again, those values that we discussed in those tables are only for the assessment purpose. The next step is stressor identification, and then once you define a – that it's a pollutant-related stressor you look at – um – relationships between the stressor identified at your site

		"Q. And ERL is empirical based?" "A. Yes." "Q. You did not use either of these in the sediment chemistry prong of the SQO; right?" "A. Right."
107:23-25 108:1-8	Purpose of SQOs	By Mr. Singarella: "Q. And is it – is it your understanding that the SQOs are a means to differentiate sediment?" By Mr. Beegan: "A. Yes." "Q. Basically between the impacted and those that are not impacted; right?" "A. Correct." "Q. By bioavailable toxic pollutants; correct?" "A. Correct." "Q. So it's a tool to distinguish the good sediment from the bad sediment; right?" "A. Essentially, yes."
119:5-22 120:1-19	Use of chemistry LOE	By Mr. Singarella: "Q. And it absolutely says that the chemistry LOE shall not be used for setting cleanup levels; correct?" By Mr. Beegan: "A. Correct." "Q. What does that mean? "A. It means that those values in – umm – in those tables – umm – are – are inappropriate for use as establishing cleanup levels. I – I - ."

	evidence and causality	correct?" By Mr. Beegan: "A. Absolutely correct."
122:1-16	Use of Lines of Evidence	By Mr. Singarella: "Q. And, in fact, the Lines of Evidence are not sufficiently reliable to be used independent in isolation of the other Lines of Evidence; right?" By Mr. Beegan: "A. Correct." "Q. Because they can underestimate the risk in some circumstances; right?" "A. Correct." "Q. Or overestimate risks in other circumstances; correct?" "A. Correct." "Q. And this imprecision can be significant; correct?" "A. Correct."
126:1-11	SQO process	By Mr. Singarella: "Q. And so the way this works is you go through the MLOE; right?" By Mr. Beegan: "A. Yes." "Q. You do stressor identification; correct?" "A. Yes." "Q. And then, if you identify a particular constituent associated with an unacceptable impact from a particular source, at that point the Regional Board requires the discharger to take management actions; correct?" "A. Correct."
191:7-25	Rejection of	By Mr. Singarella: Referencing a page of the SQO staff report: "Q. Turning to page 5-

		"A. Umm – correct." "Q. And McDonald et al, 2000; right?" "A. Uh-huh." "Q. Yes?" "A. Yes."
206:8-25 207:1-25 208:1	Relationship between SQOs and TMDLs	By Mr. Brown: "Q. Okay. And then just one last generalization question. I'm going to be off very quickly. I'm still trying to separate in my mind, Mr. Beegan, the difference between the TMDL track and the SQO track. Did they run parallel or do they intersect at some point? By Mr. Fuchs: "Objection. Vague and ambiguous. Also calls for a legal conclusion. If you understand the question, you can take a stab at answering it." By Mr. Beegan: "A. Well – I'm sorry. I must not have – umm – answered the question – umm – clearly before, because -." By Mr. Brown: "I wouldn't presume that, but I'm trying to take in a lot of information all at once. You may have answered it very clearly." By Mr. Beegan: "No. No. So – umm – the Sediment Quality Objectives are used to assess sediment. Once you've assessed sediment – umm – and you have a sediment quality related listing – umm – your – In order to restore it you would go down the TMDL path. You've demonstrated that your sediment quality isn't meeting the narrative. From there stressor identification, target – umm – some sort of sediment target or load, waste load allocation would be – umm – appropriate. I – A TMDL is developed based on a degradation or an impairment of a water body. A

		"Q. And that paragraph – I'm sorry. Did I cut you off?" "A. No. The – the regulatory decisions that are referred to are referring to the exceedance of a sediment quality guideline and biological effects, and it's attempting to explain that these are not good – indicators of cause, they merely establish occurrence or co-occurrences, or, you know, an association." "Q. So they would build more or less a circumstantial case against a particular compound?" "A. Right." "Q. When there might be a host of other potential causative agents at play; right?" "A. Correct."
255:10-23	TMDLs and SQOs	By Mr. Singarella: "Q. . . . And then third sentence refers to enormous resources applied instead of focusing on the causes; correct?" By Mr. Beegan: "A. Right." "Q. What does that mean?" "A. It means that – umm – that TMDLs – to develop – TMDLs develop for stressors – and I use – I shouldn't use the term 'stressors.' TMDLs develop for pollutants based on a – an exceedance of a sediment quality guideline, with associated biological effects – may not result in an improvement of sediment quality."
260:11-25 261:1-	Limitations of the SQOs	By Mr. Singarella: "Q So the multiple Line of Evidence approach just doesn't go to the issue of cause; correct?" By Mr. Beegan: "A. It does not identify pollutants that are causing impacts."

		By Mr. Beegan: "Okay." By Mr. Singarella: "Q. If I wanted to find the level of constituent that's protective of the critters in the – in here, can you point me to it?" By Mr. Beegan: "A. No." "Q. If it were in here, you'd be able to point me to it; right?" "A. Correct."

Dear Mr. Waterman:

Re: TRANSCRIPT OF VIDEOTAPED DEPOSITION OF DAVID CHRISTOPHER BEEGAN, OCTOBER 11, 2010; CORRECTIONS AND SIGNATURE PAGE

Enclosed please find a copy of the edits and signature of Mr. Beegan following his review of the above-referenced deposition transcript. I am informed that I am to retain the original copy of the transcript. Please contact me if you need anything further in reference to this matter.

I can be reached at (916) 341-5169.

Sincerely,

Marleigh Wood,
Senior Staff Counsel

CALIFORNIA REGIONAL WATER QUALITY CONTROL BOARD

SAN DIEGO REGION

IN THE MATTER OF:

TENTATIVE CLEANUP AND ABATEMENT ORDER NO. R9-2011-0001

BE IT REMEMBERED, that on Monday, October 11, 2010, commencing at the hour of 8:09 a.m. thereof, at the offices of Carol Nygard & Associates, 2295 Gateway Oaks Drive, Suite 170, Sacramento, California, before me, Carol Nygard Drobny, a Certified Shorthand Reporter of the State of California, there personally appeared

DAVID CHRISTOPHER BEEGAN,

called as a witness by the Designated Party, who, being by me first duly sworn, was thereupon examined and interrogated as hereinafter set forth.

VIDEOGRAPHER: My name is Sean McAleer. 08:06:36

I will be videotaping this proceeding on behalf of Peterson Reporting & Video Services at 530 B Street, Suite 350 in San Diego, California. 08:06:40 08:06:44 08:06:51

The date is October 11th, 2010. The time on 08:06:56

the video monitor is 8:06 a.m. 08:06:59

Our location is 2295 Gateway Oaks Drive, Suite 170 in Sacramento, California. 08:07:03 08:07:10

We are here in the matter of Tentative Cleanup and Abatement Order Number R9-2011-0001. 08:07:13

This is the deposition of Chris Beegan. 08:07:25

The noticing attorney is Paul Singarella. 08:07:29

The Court Reporter is Carol Nygard of Peterson Reporting. 08:07:32 08:07:36

This is a single-track recording. Overlapping voices cannot be separated. Private discussions while on the record will also be recorded. 08:07:37 08:07:41 08:07:44

Will counsel please identify yourselves, your firms, and those you represent. 08:07:46 08:07:48

MR. SINGARELLA: Good morning. 08:07:50

Paul Singarella from Latham & Watkins representing National State and Shipbuilding Company, also referred to as NASSCO, N-A-S-S-C-O. 08:07:52 08:08:01

MR. RICHARDSON: Kelly Richardson with Latham & Watkins also for NASSCO. 08:08:04 08:08:08

MR. FUCHS: Dan Fuchs, California Attorney General's Office, Deputy Attorney General, representing the State Water Resources Control Board and here for Mr. Beegan today. 08:08:09 08:08:13 08:08:15 08:08:18

(Thereupon the oath was administered to the

Witness by the Court Reporter.)

MR. SINGARELLA: Good morning, Mr. Beegan. 08:08:32

THE WITNESS: Good morning.

MR. SINGARELLA: Could you state your full 08:08:33
name and -- and place of residence. 08:08:34

MR. FUCHS: Before you do that I just have a 08:08:39
preliminary statement I wanted to read in to the record. 08:08:42

MR. SINGARELLA: I was going to turn it right 08:08:42
over to you after. 08:08:44

MR. FUCHS: Okay. I figured now that he's 08:08:45
been sworn before any responses are given. 08:08:46

MR. SINGARELLA: Sure. 08:08:48

MR. FUCHS: This deposition is being taken 08:08:48
under protest. 08:08:49

The State Water Resources Control Board does 08:08:51
not concede that the deponent, Chris Beegan, has any 08:08:53
nonprivileged information relative to Tentative Cleanup 08:08:57
and Abatement Order R9-2011-0001 or the Draft Technical 08:09:05
Report accompanying the same. 08:09:07

Mr. Beegan specifically has no information 08:09:09
regarding the Regional Board's rationale for selecting 08:09:11
its methodology and application thereof. 08:09:16

The State Water Resources Control Board 08:09:17
continues to view this deposition as an impermissible 08:09:19
inquiry in to the mental processes of its 08:09:22

decision-makers and an impermissible and unethical attempt to engage in discovery regarding the Superior Court action entitled Cal Chamber versus State Water Resources Control Board, Sacramento County Superior Court Case Number 34-2008-00006509, which case has been stayed by stipulation. 08:09:26 08:09:28 08:09:30 08:09:35 08:09:38 08:09:48

As described in the conference call overseen by Discovery Referee Tim Gallagher on September 27th, 2010, Mr. Beegan's testimony will be limited to the following subject: How Mr. Beegan would expect the Phase I Sediment Quality Objectives, DSQOs, to be applied in the abstract without reference to any particular location. 08:09:49 08:09:52 08:09:56 08:09:59 08:10:02 08:10:07 08:10:10

Accordingly, the following subjects, for example, are beyond the scope of this deposition and Mr. Beegan will be instructed not to respond to any questions regarding them: Any questions regarding how and by whom the Phase 1 SQOs were developed and the bases of the Phase 1 SQOs and any questions regarding use or application of the Phase 1 SQOs, if any, by the San Diego Regional Board or its Cleanup Team or by anyone else. 08:10:11 08:10:14 08:10:17 08:10:20 08:10:23 08:10:28 08:10:33 08:10:38 08:10:41

This is a nonexclusive list of subjects outside the scope of this deposition, and I will instruct Mr. Beegan not to respond to any questions 08:10:41 08:10:44 08:10:47

outside the very limited scope described above, even if not included in the foregoing examples. 08:10:50 08:10:53

Mr. Beegan is appearing as a percipient and not an expert witness. He has not been retained, noticed or paid as an expert. 08:10:55 08:11:00

Further, pursuant to numbered paragraph 3 of the September 27, 2010 correspondence from Kelly Richardson to Tim Gallagher by taking Mr. Beegan's deposition today NASSCO and its counsel are stipulating that Mr. Beegan's provision of deposition testimony today will not affect his ability to advise the State Water Board in any future proceeding regarding the Phase 1 SQOs; that insofar as Mr. Beegan is a member of State Water Board staff, his deposition testimony will not prevent the State Water Board from independently evaluating the CAO/DTR or the validity of the Phase 1 SQO themselves if it is ultimately called upon to do so, and that Mr. Beegan's deposition testimony will in no way constitute a predetermination of issues by the State Water Board. 08:11:02 08:11:05 08:11:08 08:11:12 08:11:14 08:11:17 08:11:21 08:11:25 08:11:29 08:11:32 08:11:36 08:11:42 08:11:46 08:11:51 08:11:52

By proceeding NASSCO and its counsel further stipulate that they will not use nor will they permit or suggest that anyone else use the testimony given today or the documents received pursuant to the subpoena duces tecum served in this matter in the aforementioned 08:11:53 08:11:57 08:11:59 08:12:02 08:12:08

Superior Court case in any form or manner. 08:12:09

MR. SINGARELLA: Mr. Fuchs, if you had wanted a stipulation, you could have approached this over the last week, so let's table that for right now. 08:12:15 08:12:17 08:12:19

I will take your objection as including a request for a stipulation. We will be glad to discuss said stipulation with you when you properly join the subject with us. 08:12:23 08:12:27 08:12:31 08:12:34

You have not properly joined the subject by coming in here and starting off with a unilateral statement about what we're stipulating to or not. 08:12:36 08:12:38 08:12:42

That's not the way lawyers enter in to stipulations, and you know it. So we'll discuss that later. 08:12:45 08:12:48 08:12:52

In terms of the substance of your statement, the suggestion that this is unethical is taken personally and is just way out of line. 08:12:53 08:12:58 08:13:02

I really don't think I have any other burden at this point to respond. 08:13:06 08:13:09

I thought that your characterization of where you're going to instruct Mr. Beegan to not answer is incredibly crad and unlimited in light of where we were in front of the Special Master last week, but I think we ought to proceed and -- and see where we get, and if we reach an impasse, as you know, Mr. Gallagher is 08:13:10 08:13:14 08:13:22 08:13:25 08:13:29 08:13:32

available and we can take it up with -- with him. 08:13:35

EXAMINATION 08:13:40

BY MR. SINGARELLA: 08:13:40

Q. Good morning, Mr. Beegan. 08:13:41

Could you state your full name for the record 08:13:42

and your place of residence. 08:13:44

A. My name is David Christopher Beegan. 08:13:45

I reside at 3828 Arden Way, Sacramento, 08:13:49

California. 08:13:55

Q. And we understand that you are employed by the 08:13:55

State Water Resources Control Board? 08:13:57

A. Yes, that is true. 08:13:59

Q. And what is your title at the State Water 08:14:01

Board? 08:14:03

A. Engineering Geologist. 08:14:03

Q. And this morning I'll refer to your employer 08:14:06

as "The State Board" or "The State Water Board." 08:14:11

Is that acceptable to you? 08:14:13

A. Yes. 08:14:14

Q. And how long have you held that position at 08:14:14

The State Water Board? 08:14:17

A. Umm -- going on 11 years -- umm -- in 08:14:18

November. 08:14:31

Q. Did you start work at The State Water Board in 08:14:31

about 1999? 08:14:36

A. Yes. 08:14:37

Q. And so you've held that position since -- since you started working there? 08:14:37 08:14:40

A. Yes. 08:14:41

Q. And do you have a particular relationship or responsibility with respect to the Sediment Quality Objectives Initiative of the State Board? 08:14:41 08:14:48 08:14:53

A. Yes. 08:14:55

Q. And what is your relation to the Sediment Quality Objectives Initiative? 08:14:56 08:14:59

A. I guess the business description would be as a Project or Program Manager. 08:15:01 08:15:07

Q. And when I refer to "Sediment Quality Objectives," you'll understand that I'm referring to the statutory program being implemented by The State Board to develop Sediment Quality Objectives for bays and estuaries in the State of California? 08:15:08 08:15:15 08:15:20 08:15:23 08:15:28

A. Yes. 08:15:29

Q. And I may refer to "Sediment Quality Objectives," or just "The Objectives," or "SQOs." 08:15:29 08:15:35

Is that agreeable to you? 08:15:39

A. Yes. 08:15:40

Q. And you'll understand what I mean when I refer to "SQOs" or "The Objectives"? 08:15:40 08:15:43

A. Yes. 08:15:46

Q. Thank you. 08:15:46

What was your prior employment before coming 08:15:47
to the State Water Board? 08:15:49

A. I worked for a -- engineering environmental 08:15:50
consulting firm here in Sacramento. I worked as a 08:16:02
geologist. 08:16:03

Q. And the name of that firm was? 08:16:04

A. Art & Lawson Associates, which -- I guess 08:16:07
became MacTech, either right before I left or right 08:16:10
after. 08:16:18

I'm not sure. 08:16:19

Q. Did you work on issues of sediment quality 08:16:20
while at Art & Lawson? 08:16:23

A. Not that I recall. 08:16:25

Q. And when did you first start working on issues 08:16:27
of sediment quality? 08:16:30

A. Probably some time around 2002. 08:16:32

Q. As part of your work for the State Water 08:16:40
Board? 08:16:43

A. Yes. 08:16:43

Q. And could you give me your educational 08:16:43
background, just college and any grad studies. 08:16:48

A. Umm -- Bachelors Degree in -- Bachelors of 08:16:51
Science in geology from Cal State Long Beach. 08:16:56

Q. And while at Cal State Long Beach did you have 08:17:03

occasion to learn about or study sediment quality? 08:17:05

A. Umm -- sediment quality -- no. 08:17:10

Q. And you understand that you're under oath here today, Mr. Beegan? 08:17:25 08:17:30

A. Right. Yes. 08:17:31

Q. And you understand that it's as if you were testifying in a Court of Law with reference to potential penalties of perjury? 08:17:32 08:17:35 08:17:39

A. Correct. 08:17:40

Q. Have you had your deposition taken before, Mr. Beegan? 08:17:40 08:17:44

A. No. 08:17:44

Q. Well, the way a deposition works is I'll be asking you a series of questions. 08:17:45 08:17:52

You understand that? 08:17:54

A. (Nodding head) 08:17:55

Q. And it's -- it's important that you answer each question orally, not with -- nodding of the head -- 08:17:56 08:17:59

A. Yes. 08:18:05

Q. -- and so forth; correct? 08:18:05

And the best way for this to work is -- is for you to give me the opportunity to get my question fully out and -- and on the record, and the technical nature of -- of this subject matter is such that I may struggle in doing so, so please be patient with me. 08:18:09 08:18:12 08:18:15 08:18:19 08:18:22

Once I get my question out you'll be given a full and fair opportunity to respond. 08:18:26 08:18:28

Is that agreeable to you? 08:18:30

A. Yes, it is. 08:18:31

Q. And, if you don't understand my question or any part of it, you have no burden to respond, but I would ask you to please tell me, "Counselor, I can't answer that question. I don't understand it. Could you please rephrase it." 08:18:32 08:18:36 08:18:39 08:18:45 08:18:48

Is that acceptable to you? 08:18:49

A. Yes. 08:18:49

Q. And if you do go ahead and answer the question, I'll assume that you did understand the question. 08:18:50 08:18:53 08:18:56

Is that agreeable to you? 08:18:57

A. Yes. 08:18:59

Q. The Court Reporter is creating a transcript of the proceedings. 08:18:59 08:19:06

You will be given an opportunity to review that transcript a month or so after the deposition ends, and you'll also be given the opportunity to make any changes or edits to the transcript that you wish to make. 08:19:07 08:19:09 08:19:14 08:19:17 08:19:20

Do you understand that? 08:19:20

A. Yes. 08:19:21

Q. If you do make changes, however, at any hearing on the matter or in any trial I will have the opportunity to comment on those changes including issues of -- of credibility and things of that nature. 08:19:21 08:19:25 08:19:30 08:19:35

Is that -- is that understood? 08:19:38

A. Yes. 08:19:40

Q. Now, you're represented by Mr. Fuchs here today, who's already made an objection on the record. 08:19:40 08:19:50

He actually may make additional objections on the record today. 08:19:53 08:19:55

If he does make an objection on the record, it does not mean that -- that you should not answer the question. In fact, let him make his objection, and then please answer my question. 08:19:56 08:19:59 08:20:01 08:20:05

Is that agreeable to you? 08:20:06

A. Umm -- I guess I'll -- I'll -- umm -- I'll answer -- umm -- if -- umm -- Mr. Fuchs says that that is okay. 08:20:07 08:20:16 08:20:26

Q. Well, Mr. Fuchs in addition to making an objection may actually instruct you to not answer. 08:20:27 08:20:33

A. Oh, right. 08:20:36

Q. That's an instruction. 08:20:36

A. Right. Okay. 08:20:38

Q. That's not an objection. 08:20:38

A. Yes. Okay. 08:20:40

Q. As a matter of fact, he has suggested that he may be making such instructions today, but that would be different than an objection. 08:20:41 08:20:43 08:20:46

If he's just saying "Objection to the form of the question" or "Objection. Asked and answered," something like that, let him make his objection and -- and -- and please go ahead and answer the question. 08:20:47 08:20:49 08:20:51 08:20:54

I think that's acceptable to your attorney. I want to make sure it's acceptable to you. 08:20:57 08:21:01

A. Yes. Yes. 08:21:02

Q. Thank you. 08:21:03

And is there any reason today that you can't answer my questions once they're understood -- at least fully and truthfully? 08:21:04 08:21:08 08:21:12

A. No. There's -- no reason. 08:21:13

Q. Is there any reason that the deposition should not proceed today? 08:21:19 08:21:22

A. No. 08:21:23

Q. Are you of clear mind today and ready to proceed? 08:21:24 08:21:27

A. For a Monday, yes. 08:21:28

Q. As clear as any Monday? 08:21:29

A. Yes. 08:21:31

Q. Excellent. Excellent. 08:21:31

Okay. As we proceed, people are drinking 08:21:33

coffee and -- and such, and we'll probably break at some point. 08:21:36 08:21:41

It's at your -- at your convenience, please. 08:21:42

Let me know if you'd like to take a break. 08:21:45

If you do want to take a break, I would most likely ask you to answer any question pending at the time before we break. 08:21:48 08:21:50 08:21:54

Is that acceptable to you? 08:21:55

A. Yes. 08:21:57

Q. Okay. Let me just say a little bit about the exhibits that will be placed in front of you, and I -- I simply want to refer to the numbering scheme so that you have an understanding of it before we proceed. 08:21:57 08:22:03 08:22:06 08:22:09

In this matter there have been a number of depositions, and I think there will be some -- some further depositions of different people, and so we have created a master set of common exhibits, and we've numbered those 1 through whatever. 08:22:12 08:22:14 08:22:17 08:22:20 08:22:25

I'm going to be presenting you, for example, with the SQOs themselves, and that's Master Exhibit Number 6. 08:22:28 08:22:31 08:22:37

I don't want you to get thrown off by not having Exhibits 1 through 5. 08:22:37 08:22:40

A. Okay. 08:22:42

Q. And -- and then when I put in front of you an 08:22:42

exhibit that's unique to your deposition, I'll start that with a new hundred series. 08:22:46 08:22:49

I'm not sure what hundred series we're using today, it might be 200 or 300, but when we get to Beegan exhibits that are unique to this depo it will start with a 200 series. 08:22:51 08:22:54 08:22:58 08:23:02

Do you understand that? 08:23:04

A. Yes. 08:23:04

Q. I just don't want you to get thrown off -- 08:23:05

A. Okay. 08:23:08

Q. -- by -- by the numbering system. 08:23:09

A. Okay.

Q. Thank you. 08:23:12

Do we have in front of the witness Master Exhibit Number 6? 08:23:12 08:23:18

Yes? 08:23:25

A. Yes. 08:23:25

Q. We've caused to be placed in front of you Master Exhibit Number 6. 08:23:25 08:23:28

Do you see that, Mr. Beegan? 08:23:30

A. Yes. 08:23:31

MR. SINGARELLA: Let me just hand out our copies of this around the room. 08:23:39 08:23:41

MR. FUCHS: Thank you. 08:23:44

BY MR. SINGARELLA: 08:23:45

Q. Okay. Turning to Master Exhibit Number 6, do you recognize this document, Mr. Beegan? 08:23:55 08:23:59

A. Yes. 08:24:00

Q. And do you understand it to be the Part 1 SQOs? 08:24:01 08:24:05

A. Yes. 08:24:06

Q. And could you just take a quick look at it for me and verify that it is, in fact, the Part 1 SQOs? 08:24:07 08:24:10

A. Yes, it appears to be Part 1 SQOs. 08:24:39

Q. Thank you. 08:24:43

Could you turn to the Resolution and Acting Part 1. 08:24:43 08:24:46

And you see Resolution Whereas Number 6 referring to the Narrative SQOs? 08:24:49 08:24:53

A. Yes. 08:24:57

Q. And by -- by "Narrative Objectives" is that to be differentiated from "Numeric Objectives"? 08:24:59 08:25:05

A. Yes. 08:25:09

Q. And so the Part 1 SQOs are Narrative Objectives; is that right? 08:25:15 08:25:19

A. Correct. 08:25:20

Q. And they consist of words; is that right? 08:25:20

A. Yes. 08:25:25

Q. And -- and formula; is that right? 08:25:26

A. I don't understand what you mean by "formula." 08:25:29

Q. Do you sometimes use the word "formula" with regard to the work that you do? 08:25:35 08:25:38

A. No. 08:25:40

Q. The -- help me out then. 08:25:41

In the Lines of Evidence there are certain calculations that are made? 08:25:46 08:25:49

A. Oh. Correct. Correct. 08:25:50

Q. So would you be more comfortable referring to those parts of the SQO as "calculations"? 08:25:52 08:25:55

A. Sure. 08:25:58

Q. And there are also numbers in the Narrative SQOs; is that right? 08:26:04 08:26:09

A. Yes. 08:26:11

Q. So you've got words, and calculations, and numbers, and that is a Narrative to be distinguished from a Numeric Objective; correct? 08:26:12 08:26:17 08:26:21

A. I think of it as -- I think of it a little differently. 08:26:23 08:26:36

I think of the Narrative Objective -- umm -- as a statement of what sediment -- the quality the sediment needs to be at to be healthy or -- unimpacted, and then I think of the -- what you call "the calculations," the three Lines of Evidence, as being used to interpret the Narrative Sediment Quality Objective. 08:26:38 08:26:44 08:26:52 08:27:00 08:27:05 08:27:11 08:27:22

Q. Okay. Thank you. 08:27:24

Thank you. 08:27:25

And did you write Part 1? 08:27:26

A. Yes. Umm -- I was not alone in the preparation or the -- 08:27:31 08:27:39

Q. And by "Part 1" you'll understand that I'm referring to Master Exhibit Number 6? 08:27:43 08:27:46

A. Umm -- yes. 08:27:50

Q. And why is it called "Part 1" versus any other Part? 08:27:51 08:27:55

A. That's -- the -- Water Quality Control Plan for Enclosed Bays and Estuaries -- there are potentially other issues that could be included in that Water Quality Control Plan. 08:27:55 08:28:04 08:28:15 08:28:19

Umm -- I think -- umm -- the Division of Water Quality State Water Board is working on various other -- umm -- Water Quality Objectives for -- umm -- Enclosed Bays and Estuaries, and so those would become potentially Part 2, Part 3, Part 4. 08:28:21 08:28:28 08:28:34 08:28:39 08:28:43

It was a means to -- umm -- if those additions were made, to keep things -- umm -- kind of clean in terms of separating out different portions. 08:28:48 08:28:52 08:28:58

That's the only reason. 08:29:02

Does that make sense? 08:29:04

Q. Yes, it does. 08:29:05

Thank you. 08:29:06

Well, let's turn to one of the Lines of 08:29:07
Evidence, and when I refer to "Lines of Evidence" or 08:29:13
"LOE," you'll understand that I'm referring to the three 08:29:16
Lines of Evidence in Part 1? 08:29:19

A. Yes. Yes. 08:29:22

I apologize. 08:29:28

Q. I wanted to give you time to remind yourself 08:29:29
of -- 08:29:32

A. Yes. 08:29:33

Q. -- actually giving the -- the verbal answer. 08:29:33

Thank you very much. 08:29:36

So, turning to Master Exhibit Number 6 at page 08:29:36
6, I want to ask you some questions to help us 08:29:40
understand how this methodology is intended to work; is 08:29:46
that okay? 08:29:52

A. Yes. 08:29:52

Q. Okay. And specifically with reference to 08:29:53
sediment toxicity I'm actually looking at the last 08:29:58
paragraph on the top of page 6 dealing with the 08:30:01
averaging process. 08:30:06

Are you with me? 08:30:21

A. Yes. 08:30:22

Q. And you see there's a statement about taking 08:30:22
an average of all test categories. 08:30:26

Do you see that? 08:30:29

A. Yes. 08:30:30

Q. And by "test categories" could you describe to me perhaps with reference from the prior page what is meant by that? 08:30:32 08:30:36 08:30:39

A. Yes. 08:30:40

So in Part 1 you generally -- you're -- you're required -- umm -- to perform both the survival and sublethal toxicity test and the -- umm -- your response. 08:30:44 08:30:51 08:31:00

The -- the test response will fit in to one of these categories on Table 4. 08:31:12 08:31:15

Do you see that? 08:31:18

Q. I do. 08:31:20

A. Okay. Umm -- so -- umm -- if -- if you get a response, it will fit in to either nontoxic, low toxicity, moderate toxicity, or high toxicity. 08:31:21 08:31:29 08:31:33

If you have two -- if you have -- what that -- umm -- what number 4 is trying to explain is -- if you -- when you're trying to -- categorize your overall toxicity, you would -- umm -- you would take the average of the two. 08:31:39 08:31:40 08:31:45 08:31:52 08:31:58

Umm -- so you're -- 08:32:01

I'm sorry. I'm not explaining this very well. 08:32:02

But if your survival is nontoxic and your Mytilus is low toxicity -- 08:32:06 08:32:13

Do you see those? 08:32:16

Q. So let's -- let's walk through this. 08:32:18

So let's say survival is nontoxic and it's for the first critter. 08:32:20 08:32:26

A. Yes. 08:32:27

Q. How do you pronounce that? 08:32:28

A. Eohaustorius. 08:32:29

Q. Eohaustorius? 08:32:30

I'll spell it. It's E-o-h-a-u-s-t-o-r-i-u-s. 08:32:32

So if Eohaustorius is nontoxic, let's assume there's a hundred percent survival. 08:32:39 08:32:43

A. Yes. 08:32:46

Q. Okay. 08:32:46

A. And then Mytilus, M-y-t-i-l-u-s. 08:32:47

Q. And the example you gave for Mytilus would be low toxicity? 08:32:54 08:32:57

A. Yes. 08:32:58

Q. Let's assume it's 79 percent. 08:32:58

A. Umm -- right. 08:33:06

And so -- 08:33:06

Wait. No. 08:33:07

Mytilus, let's assume it's -- umm -- 08:33:08

Oh, yeah. 08:33:12

Umm -- let's assume -- 08:33:14

Umm -- 08:33:29

Umm -- yeah, okay. 08:33:30

So it's significantly, getting in to more 08:33:31
details -- umm -- Mytilus if you're significantly 08:33:34
different from controls, and you're at 79 percent, you 08:33:39
would become -- umm -- you would be -- you would fall in 08:33:42
to the category of low toxicity. 08:33:46

For the Eohaustorius we're at -- we're in the 08:33:48
nontoxic category. 08:33:52

So in this case what number 4 says is that you 08:33:53
would -- you would take the result -- umm -- you would 08:33:58
round up -- umm -- so -- umm -- you would use -- umm -- 08:34:01
low toxicity. 08:34:08

Q. Then how do you actually take the average? 08:34:12

What numbers would you use to come up with the 08:34:16
average for those two tests that we just ran through? 08:34:20

Would it just be a function of taking 100 08:34:35
percent survival for the Eohaustorius and 79 percent for 08:34:38
Mytilus, adding those two and dividing by two? 08:34:43

A. No. 08:34:47

Q. Okay. Then please explain. 08:34:47

A. Umm -- I think the term "average" was used in 08:34:54
there -- umm -- because there is an option to run more 08:35:01
than two tests, and -- umm -- 08:35:07

Q. More than two tests? 08:35:21

A. Toxicity tests. 08:35:24

Q. So let's assume then that you've got more than two tests for sediment toxicity with lethality being the end point; okay? 08:35:26 08:35:30 08:35:38

A. (Nodding head) 08:35:40

Q. Yes? 08:35:40

A. Oh. Yes. 08:35:41

Q. This is a very particularized kind of proceeding, Mr. Beegan, so I know you haven't been deposed before, so we'll -- we'll get you there in terms of avoiding the -- the nods of the head. 08:35:42 08:35:48 08:35:53 08:35:56

Can -- can you -- 08:35:58

Let's assume for purposes of -- of this example then that there's an Eohaustorius test and a Rhepoxynius test. 08:36:02 08:36:06 08:36:14

Those are both for the lethality end point; correct? 08:36:14 08:36:18

A. Yes. 08:36:19

Q. And Rhepoxynius is spelled R-h-e-p-o-x-y-n-i-u-s. 08:36:20

So if you had two results or two tests for lethality -- 08:36:29

Lethality is l-e-t-h-a-l-i-t-y. 08:36:39

How would you apply paragraph 4 on page 6 to determine the appropriate result? 08:36:42 08:36:47

A. Umm -- you would take the average -- well -- 08:36:48

umm -- you would take the average of the -- the three results -- umm -- so in the case of -- well -- umm -- nontoxic -- if you had two nontoxic and you had a low toxicity -- umm -- let's assume that Rhepoxynius was nontoxic. 08:37:02 08:37:12 08:37:27 08:37:32 08:37:38

Your overall response for that LOE would be nontoxic. 08:37:39 08:37:43

Q. So the "averaging" refers to the categories then? 08:37:44 08:37:49

A. Yes. 08:37:49

Q. As opposed to the specific numeric values? 08:37:50

A. Yes. But -- 08:37:54

Umm -- yes. Yes. 08:37:58

Q. And so that's what's meant by the "average of all test response categories" on the top of page 6? 08:38:01 08:38:09

A. Yes. 08:38:12

Q. The average of the categories? 08:38:13

A. Yes. Yes. 08:38:17

Q. The average of the categories determines the final category; correct? 08:38:18 08:38:21

A. Yes. 08:38:23

Q. What happens if you have more than one test for any particular test species -- if you know? 08:38:23 08:38:33

A. I don't know. 08:38:45

We -- I don't think -- 08:39:05

Umm -- in terms of a recent -- umm -- I guess you could look at it in terms of the most recent data would be applied. 08:39:08 08:39:19 08:39:26

I guess when you have multiple tests for a single station of the same organism -- umm -- I guess there are a variety of ways you could apply it. 08:39:29 08:39:34 08:39:42

If you're looking at temporal changes over time, you would use them separately -- umm -- but I don't think we -- thought of taking a -- a single grab for a particular -- from a particular sampling event and running multiple -- umm -- independent tests on that sample -- or that sediment. 08:39:45 08:39:47 08:39:51 08:40:05 08:40:11 08:40:21

Q. When you say you did not contemplate, you mean you did not comment on it in Part 1? 08:40:26 08:40:29

A. Umm -- yes. 08:40:31

Q. Part 1 requires a minimum of one test for lethality; correct? 08:40:34 08:40:46

A. Uh-huh, yes. 08:40:46

Q. And a minimum of one test for sublethal; correct? 08:40:47 08:40:56

A. Yes. 08:40:56

Q. And, in fact, on pages 4 and 5 you see that under Section F "sediment toxicity" refers to those minimums. 08:40:57 08:40:59 08:41:04

Both in F paragraph 1 and F paragraph 2, it 08:41:05

says "a minimum of 1"? 08:41:09

Do you see that, sir? 08:41:11

A. Umm -- yes. 08:41:11

Q. And that's -- when you indicated that there's an option to run more than two tests, you're referencing the fact that it's allowable to exceed the minimum of one; correct? 08:41:18 08:41:23 08:41:29 08:41:33

A. Yes -- umm -- one each. 08:41:34

Q. Right. 08:41:43

"One each" meaning? 08:41:43

A. One sublethal test and one acute test. 08:41:44

So that's the minimum. You can go beyond the minimum. 08:41:47 08:41:50

Q. Is there any maximum that's specified in the Part 1? 08:41:51 08:41:56

A. No. 08:41:56

Q. Is there some data cutoff where you've got too much data? 08:42:02 08:42:08

A. No. 08:42:10

Q. And on page 4 of Part 1 under paragraph E, "Laboratory Testing" -- are you with me? 08:42:15 08:42:26

A. Yes. 08:42:27

Q. It says "All samples will be tested in accordance with -- with certain methods." 08:42:28 08:42:32

Do you see that? 08:42:34

A. Yes. 08:42:35

Q. And so the SQO requires the -- the actual analysis of all samples; is that right, sir? 08:42:35 08:42:42

A. Could -- could you rephrase that last part. 08:42:46

Q. Sure. 08:42:56

A. It requires the analysis of all samples? 08:42:56

Umm -- I guess I don't understand what you mean by "all samples." 08:42:59 08:43:02

Q. What -- what is meant by the reference to "all samples" in paragraph -- 08:43:04 08:43:07

A. Oh, okay. Okay. 08:43:10

So basically what Paragraph E is saying is that -- umm -- for -- umm -- for the -- for the samples that you are applying or collecting for the purposes of assessing sediment quality in relationship to this direct effects SQO, the community protection SQO, all samples will be tested in accordance with these particular methods where they exist. 08:43:13 08:43:18 08:43:27 08:43:32 08:43:37 08:43:42 08:43:45

Q. Okay. Thank you. 08:43:50

Now, going back to Table 4 on page 5, you need a minimum of two samples to apply Table 4; correct? 08:43:57 08:44:09

A. Umm -- two samples? 08:44:15

Q. Two tests? 08:44:20

A. Two tests, -- 08:44:22

Q. Thank you. 08:44:23

A. -- two samples. 08:44:24

Q. How would you distinguish those two? 08:44:25

A. Umm -- you can take a -- 08:44:28

MR. SINGARELLA: Bless you. 08:44:37

MR. BROWN: Thank you.

THE WITNESS: -- a benthic grab. 08:44:40

There's -- you -- a single grab could 08:44:43
potentially use -- be used for multiple tests or 08:44:50
multiple analyses. 08:44:54

So -- usually a single grab sample, regardless 08:44:58
of how you split up the -- apportion the sediment in 08:45:09
that grab for different tests, it's considered same 08:45:15
sample, or the same station -- yeah, same station -- umm 08:45:20
-- sample -- or you may need to take multiple grabs at 08:45:27
the same time. 08:45:35

Those would all be considered the same -- the 08:45:37
same sample or the same -- 08:45:44

Yeah, the same sample. 08:45:46

BY MR. SINGARELLA: 08:45:48

Q. So if you had a grab sample with multiple test 08:45:49
results, would you use those test results to apply Table 08:45:58
4? 08:46:02

A. Yes. 08:46:03

Q. And, referring to page 4 of Part 1 under C, 08:46:04
"Water Bodies," C(2) -- 08:46:30

Are you with me, Mr. Beegan? 08:46:33

A. Yes, I am. 08:46:38

Q. Do you see the reference to situations where LOE, referring to Lines of Evidence, measurement tools are unavailable? 08:46:43 08:46:47 08:46:53

Do you see that, sir? 08:46:54

A. Yes. 08:46:55

Q. So in those situations there's an alternative procedure described in Part 1; correct? 08:46:55 08:47:00

A. Yes. 08:47:04

Q. And that's described in Section V.J; right? 08:47:04

A. Yes. 08:47:12

Q. I don't want to go to section V.J yet. 08:47:13

I simply want to distinguish situations where the tools are unavailable from situations where they are available. 08:47:20 08:47:23 08:47:25

Are you with me? 08:47:26

A. Yes. 08:47:27

Q. So in situations where the tools are available, you use them; right? 08:47:27 08:47:30

A. Yes. 08:47:31

Q. And in situations where the measurement tools are unavailable there's an alternative approach provided in Part 1; correct? 08:47:32 08:47:35 08:47:40

A. Yes. 08:47:42

Q. Okay. Let's turn to page 17, please, of Part 1. 08:47:42 08:47:51

Now, help me understand what Part 1 consists of. This section, F, "Stressor Identification," is it -- is it correct that this is part of a program of implementation? 08:47:52 08:48:08 08:48:14 08:48:21

A. Yes. 08:48:22

Q. Is it to be -- is stressor identification to be distinguished from the SQOs themselves? 08:48:22 08:48:27

MR. FUCHS: Objection. Calls for a legal conclusion. 08:48:29 08:48:32

You can answer. 08:48:32

THE WITNESS: Yes. 08:48:34

BY MR. SINGARELLA: 08:48:35

Q. And in the first sentence of Section F it refers to sediments that failed to meet the narrative SQOs in accordance with Sections V and VI. 08:48:39 08:48:44 08:48:49

Do you see that? 08:48:54

A. Yes. 08:48:55

Q. Is that meant to indicate that the narrative SQOs are contained in Sections V and VI? 08:48:55 08:49:01

MR. FUCHS: Objection. Vague and ambiguous. 08:49:07

You can answer if you can answer. 08:49:19

THE WITNESS: Umm -- can you repeat that, Mr. Singarella? 08:49:21 08:49:50

MR. SINGARELLA: Absolutely. 08:49:50

Could you read it back for Mr. Beegan. 08:49:51

MR. SINGARELLA: She can repeat it. 08:49:55

THE WITNESS: Okay. 08:49:57

(Record Read) 08:49:57

THE WITNESS: No. What -- what it -- umm -- 08:50:13

what that sentence was intended to mean was if you've 08:50:21

failed the narrative sediment quality objective that 08:50:34

protects benthic communities as determined within 08:50:41

Sections V and VII, so you're -- your interpretation 08:50:49

tools are in Section V; right? 08:50:52

Am I -- the LO -- the LOE MLOE are in V and 08:50:54

VII. 08:51:00

If -- if through those analyses you've 08:51:02

demonstrated a failure to meet that narrative SQO, then 08:51:08

you move on to stressor identification under certain 08:51:14

conditions, which come in in the next couple of 08:51:23

sentences in Section F. 08:51:28

BY MR. SINGARELLA: 08:51:30

Q. Okay. Turning back to page 13 of Part 1 VI, 08:51:31

Human Health -- 08:51:37

Are you with me? 08:51:54

A. Yes. 08:51:55

Q. Did I understand you to testify that VI 08:51:55

contains Lines of Evidence? 08:51:59

A. That was my mistake. 08:52:02

I thought -- umm -- 08:52:19

It's more generalized than what -- after 08:52:35

reading it, it's more general than how I had stated my 08:52:39

previous response. 08:52:46

So -- umm -- those Sections V and VI still 08:52:47

describe how you would determine whether sediments -- 08:52:53

umm -- meet or exceed both the human health and the 08:53:01

benthic community sediment quality objective. 08:53:09

If you've determined that you've had an 08:53:14

exceedance under certain conditions, you move on to 08:53:20

stressor identification. 08:53:23

That's -- 08:53:24

Q. Well, I notice that -- that Part 1 is called a 08:53:30

"Water Quality Control Plan;" correct? 08:53:35

A. Yes. 08:53:36

Q. And the title actually of Part 1 does not 08:53:36

refer to Sediment Quality Objectives. 08:53:40

Do you see that? 08:53:43

A. Yes. 08:53:44

Q. So my questioning here is really to try to get 08:53:45

at the structure of this to understand where the 08:53:49

Sediment Quality Objectives are versus a program of 08:53:51

implementation. 08:53:55

Do you -- do you understand? 08:53:56

A. Yes. Yes. 08:53:57

Q. Do you have something that can help us on that? 08:53:59 08:54:02

A. Umm -- 08:54:03

MR. FUCHS: Objection. Vague and ambiguous. 08:54:04

THE WITNESS: The -- umm -- the narrative objectives that -- the Sediment Quality Objectives are solely contained in -- Section IV. 08:54:08 08:54:16 08:54:23

BY MR. SINGARELLA: 08:54:41

Q. IV? 08:54:42

A. Yes. 08:54:42

Q. And -- 08:54:43

A. Everything else would be Program of Implementation. 08:54:48 08:54:56

Q. Thank you. 08:54:56

Turning back to stressor identification on page 17, please, there are certain components of stressor identification identified in Section F; correct? 08:55:04 08:55:10 08:55:26 08:55:30

A. Yes. 08:55:31

Q. And one is a confirmation and characterization process; correct? 08:55:32 08:55:36

A. Yes. 08:55:38

Q. And the second is a pollutant identification process or step; correct? 08:55:38 08:55:42

A. Yes. 08:55:44

Q. And then the third is a source identification step; correct? 08:55:49 08:55:53

A. Yes. 08:55:53

Q. And to do a complete stressor identification would it be important to complete those three steps? 08:55:58 08:56:07

A. Not necessarily all three. 08:56:10

Umm -- I believe the third one is -- umm -- not absolutely necessary to determine which pollutant is causing a problem. 08:56:36 08:56:45 08:56:57

Q. Okay. And in the first paragraph of -- of this section it indicates that "The Water Boards shall direct the regional monitoring coalitions or Permittees to conduct stressor identification." 08:56:58 08:57:13 08:57:22 08:57:26

Do you see that? 08:57:28

A. Yes. 08:57:28

Q. So with reference to that first paragraph stressor identification is mandatory? 08:57:29 08:57:32

A. No. 08:57:41

Q. Well, it says "shall direct." 08:57:42

In what way is that nonmandatory? 08:57:43

A. Well, there's -- umm -- there's certain criteria, and that's what I was getting at. 08:57:46 08:57:52

If -- umm -- if your sediments are characterized as possibly impacted, but there are no 08:57:57 08:58:05

clearly likely impacted sites, shall -- umm -- conduct confirmation monitoring. 08:58:13 08:58:21

Q. But not necessarily stressor identification? 08:58:23

A. Correct. 08:58:27

Q. And with respect to the confirmation and characterization step -- 08:58:27 08:58:37

Are you with me? 08:58:40

A. Yes. 08:58:42

Q. That is to confirm pollutant-related impacts; correct? 08:58:42 08:59:01

MR. FUCHS: Objection. Vague and ambiguous. 08:59:01

THE WITNESS: It's to confirm -- 08:59:13

In general, yes, I would -- I would say yes. 08:59:18

BY MR. SINGARELLA: 08:59:22

Q. Well, I really don't want this to be either vague or ambiguous. So -- 08:59:22 08:59:24

A. Okay. Well, there's -- 08:59:27

MR. FUCHS: Wait for a question. 08:59:29

BY MR. SINGARELLA: 08:59:30

Q. So in the fourth paragraph there's an indication that step 1 "consists of confirmation and characterization of pollutant related impacts;" correct? 08:59:32 08:59:37 08:59:41

A. Yes. 08:59:46

Q. You wouldn't need a step to confirm pollutant-related impacts unless they required 08:59:46 08:59:51

confirmation; correct? 08:59:56

A. Say that once more, please. 08:59:59

Restate. 09:00:04

Q. You wouldn't need a -- a step to confirm pollutant-related impacts unless the impacts needed to be confirmed? 09:00:05 09:00:08 09:00:13

MR. FUCHS: Objection. Total logical. 09:00:15

MR. SINGARELLA: But important. 09:00:22

And we're only here because of prior objections. 09:00:27 09:00:29

THE WITNESS: The -- the -- the direct effects assessment described in -- umm -- Section V, it was designed to develop -- developed and intended to categorize sediment quality in a -- a robust manner using multiple Lines of Evidence. 09:00:33 09:00:46 09:00:58 09:01:09 09:01:24

By using those three Lines of Evidence, by applying them, the framework -- 09:01:32 09:01:38

By using three Lines of Evidence the -- the -- the station classification is stronger than relying on one or two Lines of Evidence. 09:01:47 09:01:52 09:01:57

The end result is that you have an integrated scheme that provides a series of categories for each station. Those stations are, you know -- categories are unimpacted, likely unimpacted, possibly impacted, likely impacted, clearly impacted. 09:02:01 09:02:09 09:02:16 09:02:23 09:02:28

That's it. They don't identify what the problem is. They don't identify what the specific pollutant is. 09:02:31 09:02:35 09:02:38

And, as a result, if there is some degradation to proceed further you would need to perform stressor identification to get at the cause. 09:02:43 09:02:52 09:03:00

So -- I'm trying to -- assess whether I'm getting at your question or not. 09:03:07 09:03:15

BY MR. SINGARELLA: 09:03:18

Q. Thank you. 09:03:19

Yes. That's really helpful. 09:03:19

Okay. Let's approach it a slightly different way. There's a reference to confounding factors -- 09:03:25 09:03:28

A. Yes. 09:03:30

Q. -- under stressor identification. 09:03:30

Correct? 09:03:32

A. Yes. 09:03:32

Q. For example. Physical disturbance; right? 09:03:33

A. Correct. 09:03:36

Q. Or nontoxic constituents? 09:03:36

It says "nonpollutant constituents." 09:03:41

Do you see that? 09:03:45

A. What page? 09:03:46

Q. I'm sorry. 09:03:47

That sentence was compound. 09:03:47

I'm on page 17. I'm referring to confounding factors on F(1). 09:03:49 09:03:53

Are you with me? 09:03:54

A. Yes. 09:03:55

Q. And there's a reference "nonpollutant constituents." 09:03:56 09:03:58

Do you see that? 09:04:00

A. Yes. 09:04:00

Q. As opposed to "toxic constituents;" correct? 09:04:01

A. Yes. 09:04:05

Q. What are "nonpollutant constituents"? 09:04:05

MR. FUCHS: Do you mean examples or a definition? 09:04:14 09:04:15

MR. SINGARELLA: I'm going to ask for both, but let's start, how would you define "nonpollutant constituents"? 09:04:19 09:04:20 09:04:25

THE WITNESS: I guess temperature, turbidity -- umm -- debris -- umm -- 09:04:27 09:04:50

BY MR. SINGARELLA: 09:05:12

Q. Anything else, Mr. Beegan? 09:05:12

A. I'm -- I'm sure there are others, -- 09:05:13

Q. Okay. 09:05:15

A. -- but I can't think of any at the moment. 09:05:16

Q. And then the reference to "physical disturbance," to what does that refer? 09:05:18 09:05:20

A. That could refer to anything that would disturb the surficial sediments, prop wash, dredging, scour from currents or tidal action. 09:05:24 09:05:30 09:05:46

In shallow waters can be wave action. 09:05:50

I'm sure there's others. 09:06:02

I -- that's it off the top of my head. 09:06:04

Q. Thank you. 09:06:07

And how are these confounding factors? 09:06:07

VOICE ON TELEPHONE: Hello? 09:06:24

MR. SINGARELLA: Good morning. 09:06:26

We're in the middle of a deposition here. 09:06:27

Are you intending to sit in on the deposition of Mr. Beegan? 09:06:29 09:06:32

VOICE ON TELEPHONE: Yes, I am. 09:06:33

MR. SINGARELLA: Well, then welcome. 09:06:35

VOICE ON TELEPHONE: Thank you.

MR. SINGARELLA: And who are you? 09:06:36

VOICE ON TELEPHONE: This is Kristin Reyna for the City of San Diego. 09:06:37 09:06:40

MR. SINGARELLA: Welcome, Kristin. 09:06:40

This is Paul Singarella. 09:06:41

And while we're at it, just so Mr. Beegan knows who's in the room and who's on the phone, a couple of gentlemen have come in since we started, so let's have them introduce themselves on the record. 09:06:43 09:06:46 09:06:48 09:06:51

MR. BROWN: Hi. I'm Bill Brown. I'm appearing for the Port of San Diego. 09:06:53 09:06:55

MR. TRACY: I'm Mike Tracy. I represent BAE Shipyards. 09:06:57 09:07:01

MR. SINGARELLA: Thank you. 09:07:01

Always nice to know who's in the room -- as a courtesy to you. 09:07:05 09:07:08

BY MR. SINGARELLA: 09:07:09

Q. Okay. So we were in the middle of a question, but let me -- let me tee it back up for you. 09:07:12 09:07:15

I was asking about confounding factors and how are physical disturbance and nonpollutant constituents -- how are they confounding factors. 09:07:18 09:07:21 09:07:25

A. They can -- confounding factors -- umm -- a fact -- the response of the indicator in a way that -- umm -- masks the signal you're looking for, and that is the primary reason why we are using multiple Lines of Evidence, to assess sediment quality. 09:07:28 09:07:39 09:07:49 09:08:03 09:08:11

Q. And what signal are you looking for? 09:08:18

A. We're looking for a toxic pollutant-related signal. 09:08:20 09:08:25

Q. And by "toxic pollutant" to what are you referring? 09:08:25 09:08:29

A. Priority pollutants, anything -- umm -- current use pesticides, priority pollutants, that sort 09:08:29 09:08:40

of thing, as opposed to -- umm -- nutrients, which will have a -- could have an effect, but -- for the purpose of this plan we didn't consider nutrients as toxic pollutants. 09:08:45 09:08:52 09:08:59 09:09:06

Q. So nutrients also could be a confounding factor? 09:09:08 09:09:12

A. Umm -- yes, there are many things that could be -- that could -- umm -- be considered potentially confounding. 09:09:13 09:09:22 09:09:28

Q. And the idea under step one of stressor identification, at least in part, is to confirm the absence of such confounding factors? 09:09:29 09:09:33 09:09:36

A. Yes. 09:09:39

Q. And that is because the SQOs themselves do not rule out confounding factors? 09:09:45 09:09:55

MR. FUCHS: Vague and ambiguous. 09:09:59

Calls for a legal conclusion. 09:10:01

MR. SINGARELLA: I'm asking for the technical here, Mr. Beegan. 09:10:03 09:10:05

BY MR. SINGARELLA: 09:10:07

Q. There's a confirmation step under stressor identification; correct? 09:10:07 09:10:10

A. Correct. 09:10:11

Q. And one of the things being confirmed is the absence of confounding factors; right? 09:10:12 09:10:14

A. Correct. 09:10:17

Q. And confounding factors are those nontoxic constituent factors that could result in the signal; right? 09:10:18 09:10:24 09:10:27

A. Correct. 09:10:28

Q. And the signal that you're looking for is impacts to sediment from toxic constituents; correct? 09:10:28 09:10:33

A. Yes. 09:10:38

Q. And so step 1 of stressor identification is to rule out those confounding factors as the cause of the signal; right? 09:10:38 09:10:47 09:10:52

A. Correct. 09:10:54

Q. Because you've got a sequential process here; is that right? 09:10:54 09:10:59

A. Yes. 09:11:00

Q. And at this step in the sequence it's important to take that confirmation step; right? 09:11:00 09:11:04

A. Yes. 09:11:08

Q. And it's also important to do characterization of the impact; correct? 09:11:09 09:11:14

A. Correct. 09:11:16

Q. And so step 1 of stressor I.D. is not only to confirm the absence of confounding factors, but also to characterize the pollutant-related impacts; correct? 09:11:20 09:11:25 09:11:28

A. Correct. 09:11:32

Q. And under the last paragraph of page 17 under "Physical Alteration" do you see the reference to "prop wash from passing ships"? 09:11:33 09:11:40 09:11:44

A. Yes. 09:11:47

Q. And how can that mask the signal? 09:11:54

A. It can -- umm -- disturb or -- umm -- it could disturb the benthic community, but that's just one of the Lines of Evidence. 09:11:58 09:12:13 09:12:25

Q. And prop wash from passing ships is another form of a stressor; correct? 09:12:26 09:12:31

A. I don't know if I would define that as a "stressor." 09:12:33 09:12:49

Only -- umm -- that's -- I'm having a hard time with that label associated with prop wash. 09:12:53 09:13:06

Let's proceed. 09:13:15

Q. Well, can -- can prop wash from passing ships produce a nonreference condition? 09:13:18 09:13:22

A. Absolutely. 09:13:29

Q. And on page 17, last paragraph, does that paragraph basically tie the concept of prop wash to the concept of stressors? 09:13:29 09:13:37 09:13:45

A. Oh, okay. 09:13:47

Yes. Yes. Yes. 09:13:53

Q. There's -- the first sentence refers to prop wash from passing ships; correct? 09:13:54 09:13:57

A. Yes. 09:13:59

No, I agree with you now. 09:13:59

Q. Yeah. 09:14:01

Thank you. 09:14:01

And then just to -- just to be clear here, though, then the second sentence refers to "these types of stressors"? 09:14:02 09:14:04 09:14:07

A. Right. Right. 09:14:08

Q. Referring back to, among other things, prop wash from passing ships; right? 09:14:09 09:14:12

A. Yes. 09:14:14

Q. And stressors for purpose of the deposition is spelled s-t-r-e-s-s-o-r-s. 09:14:14 09:14:21

And the second sentence refers back to very fine or coarse grain size as well; correct? 09:14:21 09:14:25

A. Correct. 09:14:28

Q. Which is another stressor; right? 09:14:28

A. Yes. 09:14:31

Q. That can also produce a nonreference condition; right? 09:14:32 09:14:35

A. Yes. 09:14:36

Q. And what is that a reference to, grain size? 09:14:36

Help me understand that. 09:14:43

A. Umm -- grain size can affect the communities. 09:14:47

It's a habitat factor. 09:14:58

Umm -- some organisms, many organisms, prefer fine grain sediments. If you get to the point where the sediments are too coarse, you'll see a change in the community, you'll also see potential effects with your toxicity test response over -- umm -- a range of grain sizes. 09:15:03 09:15:10 09:15:15 09:15:22 09:15:35 09:15:44

But most toxicity tests have been evaluated as well as the -- umm -- the benthic community have been evaluated with regard to how they respond to those grain sizes. 09:15:46 09:15:56 09:16:01 09:16:08

Q. So, turning back to page 3, V, "Benthic community protection," the Lines of Evidence -- are you with me? 09:16:10 09:16:17 09:16:20

A. Page 3. 09:16:21

Q. You know that this section, V, does not refer explicitly to confounding factors; correct? 09:16:31 09:16:36

A. I guess I would have to read it all the way through. 09:16:41 09:16:55

Umm -- should I? 09:16:55

Q. Well, -- 09:17:02

A. Umm -- 09:17:09

Q. -- not right now. I really -- 09:17:12

Sorry. I thought you'd know offhand. 09:17:15

A. Okay. Well, I mean -- 09:17:17

Q. Is there anything in V that deals explicitly 09:17:19

with confounding factors? 09:17:27

MR. FUCHS: If you can answer without reading it, -- 09:17:38 09:17:40

THE WITNESS: Oh. 09:17:40

MR. FUCHS: -- because he just told you not to read it. 09:17:41 09:17:43

THE WITNESS: Oh, right. Okay. 09:17:44

I think "Limitations" states that there are certain -- umm -- factors -- 09:17:45 09:17:49

I don't know if it describes them as confounding factors. 09:17:56 09:17:58

BY MR. SINGARELLA: 09:18:13

Q. Yes. 09:18:14

And on the top of page 4, referring to the Lines of Evidence applied to assess biological effects, it says that the lines "can respond to stresses associated with natural or physical factors;" right? 09:18:14 09:18:21 09:18:27 09:18:32

A. Correct. 09:18:35

Q. "Such as sediment grain size;" right? 09:18:37

A. Correct. 09:18:40

Q. Which we just identified as a confounding factor; correct? 09:18:41 09:18:44

A. Correct. 09:18:45

Q. And physical disturbance, another confounding factor; right? 09:18:46 09:18:49

A. Correct. 09:18:50

Q. How about organic enrichment? 09:18:51

Is that also a potential confounding factor? 09:18:54

A. Yes. 09:18:56

Q. And to what does that refer? 09:18:56

A. Umm -- organic matter that settles on the bottom, could be plant matter, could be -- 09:18:58 09:19:20

Q. So plant matter could -- 09:19:36

A. Animal matter -- umm -- that's it. 09:19:38

Q. So plant -- plant matter -- 09:19:59

A. Umm -- I guess organic matter from a discharge. 09:20:07 09:20:11

Umm -- I can't think of anything else. 09:20:15

Q. I'm sorry I interrupted you. I didn't realize you were in mid-thought there. 09:20:21 09:20:26

So plant matter is a confounding factor; is that right? 09:20:29 09:20:34

A. An enrichment of organic matter composed the -- umm -- dead and decaying aquatic plant matter -- umm -- anything -- any enrichment in organic detritus that settles on the bottom could alter the community, and it could -- umm -- affect your toxicity test, but there are measurements that you would take, total organic carbon and ammonia, that could allow you to factor in -- umm -- those issues. 09:20:35 09:20:51 09:21:03 09:21:12 09:21:27 09:21:40 09:21:50 09:22:00

Q. And with specific reference to this first full sentence on page 4 -- 09:22:02 09:22:09

Are you with me? 09:22:11

A. Umm -- 09:22:12

Q. I do want you to read that sentence, the one that begins "The LOEs apply." 09:22:16 09:22:20

A. "The LOEs applied to assess biological effects can respond to stresses associated with natural or physical factors, such as sediment grain size, physical disturbances, or organic enrichment." 09:22:25 09:22:29 09:22:33 09:22:36

Q. Yes. 09:22:39

Is that -- is that sentence intended to inform the reader that the LOEs in this section may mistake an impact caused by these other stressors for an impact caused by toxic pollutants? 09:22:41 09:22:47 09:22:58 09:23:02

A. Yes. 09:23:04

Q. It -- that sentence is not meant to inform the reader that these confounding factors are actually taken in to account in this section, V? 09:23:11 09:23:16 09:23:20

MR. FUCHS: Vague and ambiguous as to what "taken in to account" means. 09:23:25 09:23:27

THE WITNESS: Well, let me think about that for a minute; okay? 09:23:37 09:23:46

MR. SINGARELLA: Sure. 09:23:47

THE WITNESS: The -- the -- 09:23:48

As I said before, the multiple Lines of Evidence are used to minimize the potential for confounding factors to -- to drive the -- overall assessment. 09:24:09 09:24:13 09:24:22 09:24:37

Umm -- the -- the way the categories were set up, the station categories, the -- at the high end we are very confident or most confident that issues are pollutant driven. 09:24:42 09:24:49 09:24:59 09:25:07

That's what I mean by the categories of likely or clearly impacted, where you have responses from at least two indicators that are relatively strong. 09:25:10 09:25:13 09:25:22

We have a category of possibly impacted where the potential for confounding factors to -- umm -- affect the station category are greater, and that is why -- umm -- we include it, a lot of this -- a lot of these -- umm -- these -- umm -- texts about, you know, things to be concerned about. 09:25:32 09:25:41 09:25:50 09:25:58 09:26:10 09:26:17

The whole idea with this framework is to use multiple Lines of Evidence so you're confident in your assessment, acknowledging that the tools are imperfect. 09:26:20 09:26:25 09:26:30

Once you've completed your assessment there's still a chance that things are driven by nonpollutant-related stressors. 09:26:39 09:26:42 09:26:51

At the high end likely clearly that's unlikely the way the indicators were developed, but there's a 09:26:54 09:27:04

chance, so you want to rule those out first. 09:27:08

The other thing to do is to make sure that -- 09:27:19

umm -- the endusers have a thorough understanding of 09:27:25

their data, they've reviewed it, they've looked at 09:27:32

controls, they've looked at ammonia measurements, 09:27:37

compared with, you know, what the guidance or the EPA 09:27:42

manual says is within range, because those things are 09:27:50

important even if confounding factors -- umm -- aren't a 09:27:54

problem. 09:28:02

Q. Referring to data and controls, would 09:28:05

replicate help rule out the potential for confounding 09:28:18

factors causing the signal? 09:28:20

A. Potentially. 09:28:25

Q. And, Mr. Beegan, at one point with respect to 09:28:29

the possible impacting category did you recommend that 09:28:34

possibly impacted be a category that actually satisfied 09:28:42

the SQO protective measure? 09:28:47

MR. FUCHS: That -- that would, I think, fall 09:28:53

outside the scope of the inquiry permitted here insofar 09:28:59

as it invades the mental processes of the 09:29:03

decision-makers and involves extra record evidence 09:29:06

unless you're asking whether the SQOs themselves contain 09:29:12

that question. 09:29:20

If you're saying in the development of the 09:29:21

SQOs did he consider that, then that's outside the 09:29:23

scope. 09:29:28

BY MR. SINGARELLA: 09:29:30

Q. During the -- during the development of the methodology there was considerable discussion about where the cut-off between protective and nonprotective is; right, Mr. Beegan? 09:29:33 09:29:35 09:29:38 09:29:41

MR. FUCHS: That -- 09:29:45

I'm sorry. That's outside the scope. 09:29:46

Are we talking about -- 09:29:48

MR. SINGARELLA: Are you telling him not to answer? 09:29:48 09:29:50

These are question about the methodology and where the line should be drawn. 09:29:51 09:29:53

This is completely relevant to how the line should be drawn in this case. 09:29:54 09:29:57

I'm not talking about San Diego Bay. I'm purposefully trying to stay away from San Diego Bay, but that cut-off is essential to our ability to defend ourselves against the use of this method in San Diego Bay. 09:29:58 09:30:01 09:30:05 09:30:11 09:30:17

I don't understand. 09:30:17

I can't believe you're going to tell him not to answer this, Dan. 09:30:18 09:30:20

MR. FUCHS: I understand where -- what you're saying, but the SQOs as they are are taken as given, and 09:30:21 09:30:24

the decisions that went in to development of them are outside the scope. 09:30:31 09:30:36

So you can ask him where the line is, but not how that line was drawn. 09:30:38 09:30:43

BY MR. SINGARELLA: 09:30:48

Q. Do you recall the discussion of where the cut-off should -- should be drawn, Mr. Beegan, during the SQO proceedings? 09:30:48 09:30:51 09:30:55

MR. FUCHS: You can answer that question. 09:30:58

THE WITNESS: Vaguely. 09:31:00

BY MR. SINGARELLA: 09:31:00

Q. And -- and do you recall that there was some debate as to whether possibly impacted should be in or outside of the protective condition? 09:31:03 09:31:07 09:31:11

MR. FUCHS: I think when we get to that question that goes with beyond the scope, and I'm going to instruct you not to answer. 09:31:14 09:31:16 09:31:19

MR. SINGARELLA: Okay. Well, we'll have to go in front of Mr. Gallagher at some point, but maybe we'll just add this up and meet with Mr. Gallagher later today, but I definitely want an answer to that question, and I think it's fundamental to the use and application of the methodology. 09:31:20 09:31:21 09:31:30 09:31:32 09:31:35

THE WITNESS: Can I take a break? 09:31:39

MR. SINGARELLA: Absolutely. 09:31:41

THE WITNESS: Okay. 09:31:43
MR. SINGARELLA: Good place to take a break. 09:31:43
THE WITNESS: Okay. 09:31:45
MR. SINGARELLA: Thank you, Mr. Beegan. 09:31:46
VIDEOGRAPHER: We're going off the record at 09:31:47
9:31 a.m. 09:31:49
(Thereupon a recess was taken at 9:31 a.m. 09:31:50
and the deposition resumed at 9:39 a.m.) 09:39:35
(Exhibit 700 was marked for Identification.) 09:39:35
VIDEOGRAPHER: We are back on the record at 09:40:35
9:40 am. 09:40:42
This is the beginning of disk number two. 09:40:43
BY MR. SINGARELLA: 09:40:45
Q. Mr. Beegan, welcome back. 09:40:46
A. Thank you. 09:40:48
Q. Mr. Beegan, I'm placing in front of you a 09:40:48
device that you brought in this morning. 09:40:52
Do you see that? 09:40:54
A. Yes. 09:40:55
Q. Is that a flash drive? 09:40:55
A. Yes, it is. 09:40:57
Q. Okay. And is it -- 09:40:58
Can you tell me what's on this flash drive? 09:41:00
A. Umm -- what's on that flash drive is -- umm -- 09:41:03
I think there's three or four folders in there. 09:41:08

Last week I had provided the State Board attorney with a list of links to State Board SQO-related documents and technical reports. 09:41:16 09:41:18 09:41:27

Umm -- this flash drive, I tried to assemble all those technical documents, Water Board documents, in to a couple of folders, and I also included -- umm -- a few peer reviewed journal articles which are not readily available on the web without a subscription or something. 09:41:37 09:41:41 09:41:44 09:41:48 09:41:56 09:42:01

And so I put all those files on that USB flash drive, so that you would be able to -- grab them for your own purposes. 09:42:03 09:42:10 09:42:16

I'm sure you have a bulk of the material, but -- just trying to make sure you had it all. 09:42:18 09:42:23

Q. We'll do our level best to try to download the information today. If we can't accomplish it today, could we get this flash drive back to you later in the week? 09:42:25 09:42:30 09:42:34 09:42:37

A. Oh, sure. 09:42:37

No problem. 09:42:38

Q. Okay. Thank you. 09:42:39

If you don't mind handing it back to me. 09:42:40

A. Oh. 09:42:43

Q. Thank you. 09:42:44

And the documents on this flash drive, how far 09:42:44

back in time do they go approximately? 09:42:49

A. Umm -- maybe 2004. 09:42:51

I'm guessing -- or -- yeah. 09:43:05

Q. And the development of the Part 1 SQOs, does that process go back to 2004? 09:43:08 09:43:15

A. Yes. 09:43:17

Q. Was it a long-term proceeding with interim work product, so-to-speak, technical reports, and the like? 09:43:18 09:43:30 09:43:35

A. Yes. 09:43:36

Q. And these were, in essence, building blocks to eventually the production of the Part 1 SQO? 09:43:36 09:43:39

A. Yes. 09:43:43

Q. I'm placing in front of you what has been marked as Exhibit 700 to your deposition, which doesn't mean that we've been here for weeks. 09:43:43 09:43:55 09:44:00

It simply means that we've taken some other depos, and we're starting each one with a unique hundred series, and you're the lucky recipient of the 700 series. 09:44:02 09:44:06 09:44:11 09:44:17

Do you see that, sir? 09:44:17

A. Yes. 09:44:18

Q. And Exhibit 700 consists of the first page of Appendix E, the comments and responses related to the adoption of the Part 1 SQOs. 09:44:19 09:44:30 09:44:34

Do you see that, Mr. Beegan? 09:44:38

A. Yes. 09:44:39

Q. And then three pages providing comments and responses to particular comments. 09:44:39 09:44:46

Do you see that, sir? 09:44:48

A. Yes. 09:44:49

Actually, four pages. 09:44:57

Q. Three pages after the first page? 09:44:59

A. Oh. Yes. Sorry. 09:45:01

Q. And did you write the responses to comments? 09:45:02

MR. FUCHS: Objection. Vague and ambiguous as to whether he wrote them alone, or with others, or how. 09:45:12 09:45:16

MR. SINGARELLA: He's objecting to the form of the question. So -- 09:45:23 09:45:25

MR. FUCHS: Oh, you can go ahead and answer if you can answer. 09:45:26 09:45:29

THE WITNESS: Oh. I -- 09:45:29

Yes, with help from others. 09:45:38

BY MR. SINGARELLA: 09:45:42

Q. And so on the second page of Exhibit 700 you see the response to comment number 60? 09:45:43 09:45:49

Do you see that? 09:45:53

A. Uh-huh. 09:45:55

MR. FUCHS: Is that a "yes"? 09:45:59

THE WITNESS: Yes. Sorry. 09:46:00

MR. SINGARELLA: Thank you, Mr. Fuchs. 09:46:02

BY MR. SINGARELLA: 09:46:04

Q. And at the end of that response there's a description of reference conditions. 09:46:04 09:46:07

Do you see that? 09:46:09

A. Yes. 09:46:10

Q. And it refers to a condition as defined by benthic indices; correct? 09:46:17 09:46:25

A. Yes. 09:46:28

Q. And to what does the phrase "benthic indices" refer? 09:46:48 09:46:54

A. Well, in reference to -- umm -- the Water Quality Control Plan Part 1 SQOs it would refer to the BRI, IBI, RBI, and the RIVPACs. 09:46:55 09:47:06 09:47:11

THE REPORTER: I'm sorry. "And the --"

THE WITNESS: RIVPACs, R-I-V-P-A-C-s. 09:47:23

BY MR. SINGARELLA: 09:47:27

Q. And those are acronyms all capitalized? 09:47:27

A. Yes. Good point. 09:47:30

Which are benthic community metrics. 09:47:33

Q. And the "reference condition" is defined by benthic indices as one in which stressors have not detectably altered the assemblage of species expected for the habitat. 09:47:40 09:47:43 09:47:48 09:47:53

Do you see that, sir? 09:47:54

A. Yes. 09:47:56

Q. And do you agree with that? 09:47:56

MR. FUCHS: That is outside the scope -- so please don't answer that question. 09:48:01 09:48:05

BY MR. SINGARELLA: 09:48:05

Q. To your knowledge is that a correct statement of the reference condition? 09:48:06 09:48:08

MR. FUCHS: That's vague and ambiguous as to what is meant by "correct." 09:48:17 09:48:19

THE WITNESS: Can I -- 09:48:23

MR. FUCHS: If you understand the question, you can -- you can answer it. 09:48:25 09:48:26

THE WITNESS: Yes. 09:48:28

BY MR. SINGARELLA: 09:48:28

Q. And the last sentence indicates that "This provides a standard to assure that sensitive species within the assemblage are protected;" correct? 09:48:30 09:48:35 09:48:42

A. Correct. 09:48:45

Q. And, tying those two sentences together, does that mean that the reference condition is considered protective? 09:48:45 09:48:50 09:48:55

A. Correct. 09:48:57

Q. Okay. And turning back to page 17 of Part 1, bottom paragraph, middle of the paragraph, there's a reference to how the confounding factors may produce a 09:48:58 09:49:32 09:49:37

nonreference condition; correct? 09:49:41

A. Yes. 09:49:43

Q. In other words, the confounding factors can produce a condition that does not appear protective; correct? 09:49:45 09:49:49 09:49:53

A. Correct. 09:49:53

Q. Even though that condition is not caused by toxic pollutants; correct? 09:49:59 09:50:04

A. Correct. 09:50:06

Q. And it is the impacts of toxic pollutants that is the subject of the SQO Part 1; correct? 09:50:06 09:50:12

A. Correct. 09:50:17

Q. And so then, turning back to page 5 of Part 1, Table 4, the categories -- are you with me? 09:50:18 09:50:29

A. Table 4, page 5? 09:50:35

Yes. 09:50:38

Q. With regard to low toxicity, can confounding factors produce low toxicity? 09:50:38 09:50:41

A. Yes. 09:50:48

Q. And with respect to moderate toxicity, can confounding factors produce moderate toxicity? 09:50:55 09:51:04

A. Potentially. 09:51:13

Q. And also high toxicity? 09:51:28

A. Potentially. 09:51:30

Q. So one of the goals of stressor identification 09:51:40

is to confirm that low, moderate, or high toxicity is not caused by confounding factors; correct? 09:51:48 09:51:57

A. I disagree with that. 09:52:01

Q. In -- in what respect do you disagree? 09:52:18

A. Stressor identification is intended to -- identify the cause of the overall integrated response of the three Lines of Evidence, which -- umm -- again, is intended to minimize the influence of confounding factors on the conclusion or the overall assessment. 09:52:22 09:52:39 09:52:52 09:53:01 09:53:05

Q. Turning to page 18 of Part 1, pollutant identification, what is the purpose of pollutant identification? 09:53:19 09:53:26 09:53:41

A. When you follow Part 1, you apply the three Lines of Evidence, you end up with simply a station categoric -- categorization for each station. 09:53:42 09:54:02 09:54:14

I've described those in the past. 09:54:17

Shall I describe them again? 09:54:20

Q. No, that's fine. 09:54:21

A. Okay. Umm -- in order to proceed further, you need to determine what is causing the problem -- umm -- so likely impacted, clearly impacted, possibly impacted, it doesn't -- the -- it only is used in the assessment. 09:54:24 09:54:31 09:54:41 09:54:46

After that to determine what the stressor is you need to determine -- you need to go down this stressor identification process. 09:54:53 09:54:55 09:54:59

As we've gone over in the past, you rule out other nonpollutant-related factors like dredging, prop wash. 09:55:02 09:55:08 09:55:15

The next step would be, okay, what pollutant is causing the problem? 09:55:15 09:55:19

Once you've identified what pollutant is causing the problem, you can -- umm -- manage it, or restore, or cleanup, or control. 09:55:21 09:55:26 09:55:33

Does that help? 09:55:52

Q. Yes. Thank you. 09:55:54

A. Okay. 09:55:55

Q. And so is pollutant identification a mandatory component of stressor identification? 09:55:56 09:56:02

A. Yes. 09:56:04

Q. And up to the point where the pollutant is identified under stressor identification has it been previously identified? 09:56:04 09:56:06 09:56:10

A. No. No. No. No. 09:56:11

Q. Now, with regard to pollutant identification, one of the recommended approaches is this TIE approach, TIE, do you see that? 09:56:19 09:56:28 09:56:32

A. Yes. 09:56:33

Q. And what is a "TIE" method? 09:56:34

A. It's -- umm -- nobody calls it "TIE." 09:56:39

Everybody refers to it as "T-I-E." 09:56:45

Just -- 09:56:47

Q. Thank you. I'm not -- 09:56:48

Shows that I'm out of the loop. I'm just not 09:56:50
in the know. 09:56:52

A. Umm -- but -- basically it's -- umm -- it's -- 09:56:53
umm -- using sediment toxicity tests to -- umm -- to 09:56:59
isolate the fraction of -- pollutants that are causing 09:57:12
the toxicity. 09:57:26

It's analogous with EPA's TIE protocols used 09:57:32
on waste water effluence, if you're familiar with that 09:57:44
process. 09:57:50

Q. Are there other methods identified in Part 09:57:51
1 -- 09:57:57

A. Yes. 09:57:58

Q. -- that will identify the fraction of 09:57:58
pollutants? 09:58:01

A. Umm -- there are other tools that you can use. 09:58:01

It's an iterative approach. 09:58:19

It -- like the assessment process itself, 09:58:23
typically requires multiple Lines of Evidence or -- umm 09:58:26
-- a series of tests, or a series of tools. 09:58:39

It's -- there's no one test that will -- umm 09:58:48
-- give you a result. It's -- those tools are not 09:59:01
available to us right now. 09:59:05

Q. When you refer to the use of multiple Lines of 09:59:07

Evidence under pollutant identification, were you referring to the MLOE approach in V? 09:59:14 09:59:16

A. No. No. 09:59:20

That's -- I was referring to the -- a multiple Line of Evidence approach in general, so that in V is a multiple Line of Evidence approach applied to the assessment process because the indicators are not as reliable when used alone. 09:59:21 09:59:30 09:59:35 09:59:38 09:59:47

So that's an example. 09:59:49

In this case it's another situation where you would use -- you would perform different analyses or tests. 09:59:51 09:59:57 10:00:03

Q. Does the TIE itself identify the specific pollutant causing the impact to the sediment? 10:00:05 10:00:08

A. Yes, but you would want to look at your data set or confirm that -- you would look for secondary confirmation -- umm -- some other way. 10:00:12 10:00:30 10:00:37

Q. So the identification would be as part of the fraction to which you referred? 10:00:41 10:00:46

A. Yes. 10:00:49

Q. So you'd narrow it down to this fraction of pollutants under the TIE; right? 10:00:50 10:00:55

A. Yes. 10:01:00

Q. Then you'd use other Lines of Evidence as part of stressor identification to identify the actual 10:01:00 10:01:04

stressor? 10:01:07

A. Yes. 10:01:08

Q. And at that point, if all goes well, you know what particular toxic agent is causing the particular impact? 10:01:08 10:01:11 10:01:16

A. Correct. 10:01:18

Q. But you wouldn't know that before that point in time? 10:01:18 10:01:21

A. No. 10:01:22

Q. With regard to page 18 under "Confirmation and Characterization" there's a reference to "mechanistic benchmarks." 10:01:32 10:01:39 10:01:42

Do you see that? 10:01:43

A. Umm -- 10:01:45

Q. Under C, little C? 10:01:45

A. Oh, yes. 10:01:49

Q. These are benchmarks that are used as part of the confirmation and characterization; correct? 10:01:49 10:01:54

A. Yes. 10:01:56

Q. And they're a specific kind of benchmark; right? 10:01:56 10:02:02

A. Yes. 10:02:02

Q. Mechanistic benchmarks; right? 10:02:03

A. Correct. 10:02:06

Q. There's no recommendation here to use 10:02:06

empirical benchmarks; correct? 10:02:09

A. Correct. 10:02:11

Q. Or consensus benchmarks; correct? 10:02:13

A. Correct. 10:02:15

Q. What are "mechanistic benchmarks"? 10:02:16

A. They are -- umm -- equilibrium-partitioning coefficients. 10:02:18 10:02:32

They're based on a relationship between -- umm -- pore water chemistry -- umm -- and -- 10:02:33 10:02:39

Well, they are -- they establish a relationship between water quality criteria and the -- the concentrations of specific chemicals in pore water. 10:02:48 10:02:50 10:02:59

MR. FUCHS: For the Reporter "pore" here is p-o-r-e as opposed to p-o-o-r. 10:03:08 10:03:13

THE WITNESS: Oh. Thank you for the -- yes.

MR. SINGARELLA: "TIE" is without periods, just all caps, T-I-E. 10:03:17 10:03:19

I told Carol this would be a challenge. 10:03:23

THE WITNESS: Do we need to -- 10:03:26

I think -- toxicity identification evaluation for -- 10:03:27 10:03:30

BY MR. SINGARELLA: 10:03:34

Q. You wouldn't use empirical benchmarks for this confirmation step? 10:03:37 10:03:41

A. No. 10:03:43

Q. Why not? 10:03:43

A. They are -- 10:03:44

MR. FUCHS: Let me interrupt during this 10:04:03

pause. 10:04:05

Why were they not adopted in the Phase 1 SQOs? 10:04:06

If that's the question, then that's outside 10:04:10

the scope. 10:04:13

MR. SINGARELLA: I don't think that was the 10:04:13

pending question. 10:04:15

MR. FUCHS: Then I'll let this one go. 10:04:16

MR. SINGARELLA: I'm trying to understand the 10:04:18

boundaries of the methodology here, what's in, what's 10:04:20

out. 10:04:23

THE WITNESS: The -- umm -- the empirical 10:04:23

guidelines don't -- umm -- they -- they -- they can 10:04:28

classify a sediment as to the potential for toxicity or 10:04:46

biological effects, but they don't perform well when 10:04:54

used to identify which particular chemical is causing 10:05:01

the problem, and -- umm -- you'll actually see that in 10:05:08

-- umm -- some of the papers written by the empirical 10:05:16

guideline developers. 10:05:20

They are -- in general the intent of those 10:05:25

empirical approaches was just to help assess, as in the 10:05:30

use of our -- umm -- chemistry Line of Evidence in the 10:05:36

MLOE framework. 10:05:41

We clearly stayed up front, don't use these chemistry values to identify which chemical is causing the problem, because that's not a fruitful or accurate approach. 10:05:43 10:05:48 10:05:53 10:06:01

Those sediment quality guidelines basically -- I believe they have similar limitations. The empirical ones have similar limitations. 10:06:02 10:06:08 10:06:15

In some cases where your -- umm -- you have one pollutant that's screaming, maybe multiples of the sediment quality guideline it -- they perform better. 10:06:19 10:06:23 10:06:34

But in general their use was intended for assessment, not for stressor identification. 10:06:44 10:06:49

Q. Uh-huh. 10:06:54

When you say "screaming," you mean exceedingly high concentrations? 10:06:55 10:06:59

A. Yeah, like two, three, five times the -- umm -- the guideline. 10:07:00 10:07:06

Q. And probably where there aren't other pollutants around? 10:07:09 10:07:12

A. Correct. There's -- we could spend a day talking about the limitations of empirical and mechanistic guidelines. 10:07:14 10:07:16 10:07:21

Q. And you probably know that I would enjoy that. It says something about me. 10:07:23 10:07:26

And I don't think Mr. Fuchs is going to allow 10:07:29

us to go down that road. 10:07:32

Okay. Okay. I won't -- not the whole day. 10:07:36

And -- nor are consensus benchmarks referred to in stressor identification; correct? 10:07:40 10:07:46

A. Correct. 10:07:48

Q. Because they wouldn't be useful for stressor identification? 10:07:48 10:07:52

A. Correct. 10:07:54

Q. And why is that? 10:07:54

A. Umm -- the consensus benchmarks are all based on these empirical guidelines, and -- umm -- so they have -- umm -- since they're based on those empirical guidelines they're still -- they still suffer from the same limitations. 10:07:55 10:08:04 10:08:16 10:08:23 10:08:26

Q. Okay. Turning to page 19 of Part 1, the third step of stressor identification which is "Sources Identification and Management Actions," do you see that? 10:08:27 10:08:38 10:08:41

A. Yes. 10:08:43

Q. And you -- you mentioned that this is a nonmandatory step in stressor identification; correct? 10:08:45 10:08:52

A. Is that -- 10:08:56

I think you're miscategorizing what I had said previously. 10:09:12 10:09:15

You -- you asked if 3 was a necessary step to determine what pollutant was causing the problem -- or 10:09:16 10:09:25

at least that's how I interpreted it. 10:09:31

Q. I see. 10:09:34

And thank you, -- 10:09:35

A. And so -- 10:09:36

Q. -- because I actually did not mean that. 10:09:37

A. Okay. 10:09:39

Q. I was referring to the -- let me -- let me explain. 10:09:39 10:09:43

I was referring to the structure of Section F, Stressor Identification. 10:09:43 10:09:47

A. Yes. Yes. 10:09:47

Q. So with regard to the structure of stressor identification, it has three principal components; correct? 10:09:48 10:09:50 10:09:53

A. Yes. 10:09:53

Q. Are they all mandatory? 10:09:54

A. Yes. 10:09:55

Q. Thank you. 10:09:56

Is it with regard to this last step of stressor identification that you reached the issue of management actions? 10:09:56 10:10:06 10:10:10

MR. FUCHS: Objection. Vague. Ambiguous. 10:10:20

BY MR. SINGARELLA: 10:10:22

Q. Do you see the reference to "management actions"? 10:10:22 10:10:25

A. Yes. 10:10:25

Q. To what does that refer? 10:10:26

A. That would refer to -- umm -- some sort of final action, -- umm -- or a cleanup would be a management action. 10:10:28 10:10:42 10:10:53

A -- reopening a permit would be a management action. 10:10:55 10:10:59

Umm -- 10:11:02

BY MR. SINGARELLA: 10:11:13

Q. Could monitoring be a management action? 10:11:14

A. Yes. 10:11:20

Q. Could monitoring natural attenuation be a management action? 10:11:21 10:11:25

A. Yes. 10:11:26

Q. Might there be no management action if it was previously determined that confounding factors masked the signal? 10:11:26 10:11:33 10:11:37

A. Yes. 10:11:37

Q. And by "previously determined" I'm referring to in steps 1 and 2 of stressor identification. 10:11:41 10:11:45

Do you understand that? 10:11:49

A. Yes. 10:11:50

Q. Did you have occasion to read the SQOs Part 1 before you came to the deposition today? 10:11:52 10:12:02

A. Oh. Oh. I've -- I've read it. 10:12:04

But did I review it for purposes of today's deposition? 10:12:08 10:12:13

No, I did not. 10:12:14

Q. Okay. Do you understand that -- that this step 3 of stressor identification is where Part 1 addresses management actions? 10:12:15 10:12:19 10:12:25

A. No. I mean, I don't understand -- or I -- I'm not -- umm -- 10:12:29 10:12:41

There are -- umm -- other sections that influence management actions. 10:12:53 10:12:59

So to say that -- umm -- that that number 3 is it is -- umm -- is -- it's kind of misleading. 10:13:03 10:13:10

Q. Okay. Thank you. 10:13:15

I certainly don't mean to mislead. 10:13:16

A. Well, I -- 10:13:18

MR. FUCHS: It's okay. 10:13:20

MR. SINGARELLA: Just no intent. 10:13:22

THE WITNESS: Yeah. 10:13:23

MR. SINGARELLA: Just getting the questions phrased properly. 10:13:24 10:13:26

THE WITNESS: No. I didn't mean to imply. 10:13:27

MR. SINGARELLA: No. We're good, Mr. Beegan. 10:13:30

BY MR. SINGARELLA: 10:13:32

Q. So -- going back to V, are management actions addressed in V? 10:13:33 10:13:44

MR. FUCHS: Objection. Vague. Ambiguous. Calls for a legal conclusion. 10:13:52 10:13:55

THE WITNESS: Umm -- I don't think so. 10:13:57

Umm -- actually -- umm -- I think I was wrong. 10:14:24

Umm -- 10:14:31

BY MR. SINGARELLA: 10:14:56

Q. In what regard? 10:14:56

A. Well, "Program Section --" VII, "Program of Implementation," -- 10:14:58 10:15:07

Q. Yes? 10:15:07

A. -- there's -- umm -- I think, various references to what I would consider management actions, even if they're not specifically called out as management actions. 10:15:08 10:15:16 10:15:25 10:15:28

Much of it or some of it is -- umm -- related to M13 permitting. 10:15:33 10:15:38

Q. You're referring to number VII, Program of Implementation? 10:15:46 10:15:50

A. Yes. 10:15:50

Q. My question was whether management actions are -- are a subject of V, the MLOE approach. 10:15:51 10:15:54

A. Oh. Umm -- 10:15:59

MR. FUCHS: Same objection. 10:16:03

THE WITNESS: I'm looking. 10:16:04

MR. SINGARELLA: Sure. Take your time. 10:16:18

THE WITNESS: Based on my quick read -- umm -- no. 10:16:21 10:17:17

BY MR. SINGARELLA: 10:17:18

Q. And so is it safe to say that after application of the V, MLOE, there are additional steps before management action? 10:17:23 10:17:30 10:17:35

A. Correct. 10:17:38

Q. Including those identified under stressor identification on page 17 through 19; correct? 10:17:41 10:17:45

A. Correct. 10:17:49

Q. Thank you. 10:17:50

Now, on page 19 of Part 1, paragraph after E refers to a situation where stressor identification or stressor I.D. yields inconclusive results. 10:17:57 10:18:06 10:18:10

Do you see that? 10:18:19

A. Yes. 10:18:20

Q. What happens in that situation? 10:18:20

A. Umm -- in that situation "The Water Board shall require --" and I'm reading -- "-- the Permitee, or regional monitoring coalition to perform a one-time augmentation to that study, or, alternatively, the Water Board may suspend further stressor identification studies pending the results of future routine sediment quality objectives on it." 10:18:21 10:18:45 10:18:50 10:18:56 10:18:58 10:19:01 10:19:03

Q. Thank you. 10:19:07

So let's try to unpackage that a little bit -- 10:19:08
A. Sure. 10:19:10
Q. -- because it's not totally apparent to me. 10:19:11
This is with respect to stations classified as 10:19:14
possibly impacted; correct? 10:19:18
A. Yes. 10:19:19
Q. Stations or sites; right? 10:19:20
A. Yes. 10:19:22
Q. And do I -- do I read this right, you -- 10:19:22
Do you -- 10:19:27
I'm sorry. 10:19:27
Strike that. 10:19:28
Where you have a possibly impacted station and 10:19:29
inconclusive results do you -- proceed to Step 3 of 10:19:34
stressor identification or do you do something else? 10:19:41
A. That depends. 10:19:44
Q. Okay. Okay. 10:19:46
A. So earlier in Part 1, I don't know the 10:19:52
specific reference, but it describes situations where 10:19:56
you only have stations that are possibly impacted. You 10:20:01
do not have stations on your site, or segment, or area 10:20:09
of concern that are likely or clearly impacted. 10:20:13
In those sites -- in those segments where you 10:20:18
just have possibly impacted, you -- can -- rather than 10:20:23
jumping on to stressor identification you reconfirm your 10:20:32

results. 10:20:36

If you still come up with possibly impacted, 10:20:38
remember what "possibly impacted" means, you have low -- 10:20:41
or the -- the level of responses are not huge, they're 10:20:46
in the area where they're -- umm -- it looks like it's 10:20:51
-- could be impacted or caused by pollutants, or 10:20:56
concentrations could be high enough, but there's a lack 10:21:02
of confidence at that -- at that level of response, 10:21:09
which is why it's called "possibly impacted." 10:21:16

But you would reconfirm it by going back, 10:21:19
resampling. 10:21:23

If you get the same results, you would do 10:21:24
stressor identification in those cases. 10:21:31

If you have indicators that are responding at 10:21:39
a low level, it may be difficult to identify what the 10:21:46
particular cause is, and this Part 1 takes that in to 10:21:50
account. 10:21:57

Q. Thank you. 10:21:57

As part of the reconfirmation step that you 10:22:01
just mentioned, if you had replicate data that hadn't 10:22:09
been yet even run through the SQO, could you use it as 10:22:16
part of reconfirmation? 10:22:21

A. Yes, assuming it -- umm -- meets, you know -- 10:22:23
it's the tests -- or the -- the -- contains the data 10:22:40
that you need to apply the multiple Line of Evidence 10:22:46

approach. 10:22:51

Q. The data to apply V of Part 1? 10:22:51

A. Yes. Yes. 10:23:00

Q. If you had such replicate date, you wouldn't have to actually resample; right? 10:23:00 10:23:04

A. Assuming it's recent, I guess, there would be a temporal concern, yeah. 10:23:06 10:23:12

Q. In other words, the results -- 10:23:25

A. Recent. Recent. 10:23:26

Q. The results would only be good for the point of time where the replicates were collected? 10:23:28 10:23:31

A. Yes. 10:23:35

Q. Is that perhaps too limiting? 10:23:37

A. It may be. 10:23:43

Umm -- having no frame of reference in terms of 10 years -- 10-year-old data, 20-year-old data, 5-year-old data, the -- the -- the way Part 1 was written -- umm -- you were -- we were trying to address recent data, data from, you know, the time that Part 1 became effective forward. 10:23:45 10:23:53 10:23:57 10:24:04 10:24:12 10:24:20

So were we necessarily thinking of grabbing 10-year-old data? No. 10:24:22 10:24:27

And -- so we're moving -- this moves forward from, you know, August 25th, I guess, of 2009. 10:24:32 10:24:36

Q. Does stressor identification produce a 10:24:41

specific pollutant concentration to be achieved? 10:25:05

A. No. 10:25:11

Q. Would Section H, Development Of Site Specific 10:25:13

Sediment Management Guidelines on page 19 of Part 1, 10:25:19

produce that specific concentration value? 10:25:23

A. That is the intent of that section. 10:25:28

MR. SINGARELLA: 701. 10:25:47

(Exhibit 701 was marked for Identification.) 10:25:50

BY MR. SINGARELLA: 10:26:01

Q. I'm placing in front of you what has been 10:26:03

marked as Exhibit 701 to your deposition. 10:26:05

Do you see that, Mr. Beegan? 10:26:08

A. Uh-huh. 10:26:09

Q. And do you recognize this document? 10:26:12

A. Umm -- yes. 10:26:14

Q. Does this look like a PowerPoint that you 10:26:22

prepared for presentation to the Regional Board in San 10:26:25

Diego? 10:26:30

A. Yes. 10:26:30

Q. At a workshop on the SQOs back in August of 10:26:30

2005? 10:26:37

A. Yes. 10:26:37

Q. Could you turn to page 2 of the exhibit, 10:26:39

please. 10:26:45

You identified three challenges associated 10:26:48

with the development of SQOs; is that right? 10:26:56

A. Yes. 10:26:59

Q. And the first bullet refers to a "shifting away from a pollutant-specific concentration-based approach." 10:27:00 10:27:07 10:27:11

Do you see that? 10:27:11

A. Yes. 10:27:12

Q. And does Part 1 do that? 10:27:12

Does it shift away from a pollutant-specific concentration-based approach? 10:27:15 10:27:19

MR. FUCHS: Let me just object to this line of questioning regarding this PowerPoint. 10:27:22 10:27:25

I'm concerned that we may be beyond the scope. 10:27:33

It's not as clear as in the previous instances where I've made this objection. 10:27:37 10:27:40

Maybe you can explain why you think this is relevant to -- umm -- application in the abstract. 10:27:42 10:27:44

MR. SINGARELLA: Sure. 10:27:50

I'll tie it together with the actual methodology. That's my intent, is to understand the boundaries of the methodology and what the methodology is. 10:27:52 10:27:54 10:27:57 10:28:00

MR. FUCHS: I'll let it go for a couple more questions, but if it doesn't look like we're in the scope, I'm going to -- 10:28:02 10:28:04 10:28:07

MR. SINGARELLA: Sure. 10:28:08

I don't understand that objection, but -- 10:28:09

BY MR. SINGARELLA: 10:28:11

Q. So the first bullet refers to a shifting away 10:28:11

from a pollutant-specific concentration-based approach; 10:28:15

right? 10:28:20

Is part one a pollutant-specific 10:28:20

concentration-based approach? 10:28:23

A. No. 10:28:25

Q. What is a "pollutant-specific 10:28:25

concentration-based approach"? 10:28:32

A. Umm -- a -- I guess what I would consider that 10:28:33

would be a -- umm -- pollutant-specific -- 10:28:46

Or I'm sorry. 10:28:49

A con -- a pollutant -- 10:28:51

Yeah, pollutant-specific concentration-based 10:28:55

value. Classic example would be a numeric water quality 10:28:59

criteria, California Toxic Rule, those types of numeric 10:29:05

values that are -- umm -- single stand-alone criteria, 10:29:12

single Line of Evidence numeric-based 10:29:20

concentration-based. 10:29:24

Q. And the third bullet refers to the "need to 10:29:24

minimize BPJ;" correct? 10:29:37

A. Yes. 10:29:39

Q. And what is "BPJ"? 10:29:40

A. Best professional judgment. 10:29:42

Q. And what does "BPJ" mean? 10:29:44

A. Umm -- it's -- umm -- the use of judgment in assessing a site or assessing -- umm -- results from various tests, making a decision as to whether a particular result is -- umm -- great enough to be of concern or not. 10:29:47 10:30:01 10:30:08 10:30:18 10:30:27

There's -- best professional judgment is -- could be applied to -- umm -- just about any aspect of sediment quality assessment. 10:30:29 10:30:39 10:30:49

I -- I don't know if I'm explaining things very well, but it's a nonprescriptive approach, where you use experience, professional experience, knowledge, understanding, to make some sort of determination. 10:30:53 10:30:56 10:31:02 10:31:08

It's not prescribed in a guidance document, or a plan, or a policy. 10:31:12 10:31:18

Q. And does the Part 1 SQO minimize BPJ? 10:31:19

A. Yes. 10:31:26

Q. Now, turning back to page 19 of Part 1, Sub-H refers to the Site-Specific Sediment Management Guidelines; correct? 10:31:34 10:31:42 10:31:45

A. Yes. 10:31:46

Q. Would that be a pollutant-specific concentration-based approach? 10:31:47 10:31:53

A. Oh, yes. Yes. 10:31:56

Q. So there was a shifting away from pollutant-specific concentration-based approaches; right? 10:32:04 10:32:14 10:32:17

A. Yes. 10:32:17

Q. Help me understand why it came back in in the last section of Part 1, Section H. 10:32:17 10:32:27

A. Okay. The -- umm -- there -- 10:32:32

Umm -- I'm trying to figure out how to state this in a way that makes sense, but -- 10:32:49 10:32:56

The assessment approach was the portion that I was referring to. 10:33:01 10:33:11

Many people want to chemic -- sediment chemistry based numeric values that could be applied broadly to all bays and all estuaries. 10:33:14 10:33:20 10:33:27

The level of science isn't there to create reliable numeric sediment chemistry values. 10:33:38 10:33:50

So that -- umm -- so we use the multiple Line of Evidence approach, the three LOE. 10:33:59 10:34:08

The chemistry is -- has confounding factors, toxicity, benthic community. They all have confounding factors. 10:34:11 10:34:16 10:34:21

So what I was referring to in the shifting away was -- umm -- to state up front that we can't develop numeric sediment chemistry-based objectives, however, once you identify the stressor and it's a 10:34:21 10:34:24 10:34:31 10:34:41

pollutant-related stressor, the -- I guess the practical way in which you manage that is to develop some sort of concentration-based approach. 10:34:51 10:34:56 10:35:01

And on a site-specific level that is the -- umm -- standard practice. 10:35:05 10:35:11

But what concentration is protective at one site may be different at another site, because of various properties of the sediment. 10:35:13 10:35:18 10:35:25

So the assessment process is based on a multiple Line of Evidence approach. 10:35:33 10:35:36

Once you've assessed, you come back to or you -- you progress to a pollutant-specific concentration-based approach that's site specific. 10:35:39 10:35:46 10:35:51

Does that make sense? 10:35:58

Q. Yes. 10:35:59

When you indicated that the level of a constituent that can cause stress at different sites can be different, can it be substantially different? 10:36:01 10:36:03 10:36:09

MR. FUCHS: Vague and ambiguous. 10:36:14

THE WITNESS: Yes. 10:36:16

BY MR. SINGARELLA: 10:36:22

Q. Can it be different by a factor of two to your knowledge? 10:36:23 10:36:26

A. Yes. 10:36:26

Q. Factor of five? 10:36:26

A. Umm -- don't know. 10:36:28

Q. Is Section H on pages 19 and 20 -- is -- is that the step needed to tie a sediment impact to a specific concentration of a toxic pollutant? 10:36:34 10:36:47 10:36:52

A. Yes. 10:36:57

Q. And, as you indicated, that can be done -- you believe that can be done on a site-specific basis; right? 10:37:03 10:37:07 10:37:10

A. Yes. 10:37:10

Q. And then the product of that work in Subsection H, pages 19 and 20, would be to define a concentration that is protective; correct? 10:37:10 10:37:18 10:37:22

A. Correct. 10:37:28

Q. And for purposes of Part 1 it would be protective of the benthic community; correct? 10:37:29 10:37:32

A. Yes. 10:37:35

Q. Meaning the animals that live in the sediment? 10:37:35

A. Yes. 10:37:38

Q. And it would specify concentration if exceeded the animals would be at risk; correct? 10:37:38 10:37:42

A. Yes. 10:37:44

Q. And, if not exceeded, you would conclude that there is a protected -- or protective state; right? 10:37:45 10:37:50

A. Correct. 10:37:55

Q. So it creates more of a bright line rule; 10:37:55

right? 10:37:59

A. Correct. 10:37:59

Q. And on page 20, Mr. Beegan, first full paragraph refers to the goal of Section H as to establish a relationship; correct? 10:38:33 10:38:37 10:38:44

A. Umm -- page 20? 10:38:47

I'm sorry. 10:38:50

Section what? 10:38:51

Q. First full paragraph, second sentence, the goal of this Section H site-specific guidelines is to establish this relationship; correct? 10:38:52 10:39:00 10:39:04

A. Oh. Yes. Yes. Yes. Yes. Yes. Yes. 10:39:06

Q. Between the exposure of the animals in the sediment and the biological effect; correct? 10:39:10 10:39:13

A. Yes. 10:39:16

Q. The "exposure" is referring to a chemical concentration; correct? 10:39:16 10:39:19

A. Yes. 10:39:20

Q. And then it says, next sentence, "Once this relationship is established;" correct? 10:39:20 10:39:23

A. Yes. 10:39:24

Q. It says once that is established then the guideline may be designated; correct? 10:39:26 10:39:30

A. Yes. 10:39:33

Q. And by "designated" do you mean specified what 10:39:33

the concentration is? 10:39:37

A. Yes. 10:39:37

Q. There's no indication that a 10:39:38

pollutant-specific guideline may be designated prior to 10:39:45

the establishment of that relationship; right? 10:39:48

A. Right. 10:39:50

Q. Turning back to page 8 of Part 1, Table 6 -- 10:39:53

Are you with me? 10:40:13

Page 8, Table 6? 10:40:17

A. Yes, I'm with you. 10:40:20

Q. Does Table 6 identify the chemicals that are 10:40:21

part of the Part 1 SQOs? 10:40:25

A. It identifies which chemicals are used in the 10:40:28

chemistry Line of Evidence for assessing sediment 10:40:51

quality. 10:40:59

That's all. It doesn't do any more. 10:41:01

Q. And is the chemistry Line of Evidence in Part 10:41:06

5 -- is it based on knowledge of the relationship 10:41:10

between these chemicals listed in Table 6 and the 10:41:14

organism's exposure to those chemicals and the 10:41:19

subsequent biological effect? 10:41:24

A. Yes. 10:41:25

Q. Is it based on a numeric relationship between 10:41:28

the organism's exposure and the biological effect? 10:41:34

A. Yes. 10:41:38

Q. Is it based on site-specific sediment management guidelines defining those relationships? 10:41:38 10:41:43

A. No. 10:41:46

Q. What is the difference between what's in Section 5 and what is -- Section 5 -- Section 5(h), Sediment Chemistry, and what is described in Section H on site-specific guidelines? 10:41:46 10:41:50 10:42:07 10:42:10

A. Umm -- Section 5 was -- those values were developed through -- through empirical relationships with -- umm -- between biological effects and chemical concentrations in -- in all bays for which we had data in California. 10:42:13 10:42:27 10:42:38 10:42:44 10:42:55

So those represent -- umm -- a broader set of conditions and types of sediment and are intended to solely assess potential -- the potential for effects. 10:42:57 10:43:07 10:43:23

There is no -- there is no intended use of those chemical values for anything else other than assessing sediment quality with the other two Lines of Evidence. 10:43:33 10:43:38 10:43:43 10:43:50

The site specific -- umm -- section -- site development and site specific targets, is a very site-specific -- umm -- study that would provide more representative, more accurate, more -- a more precise concentration-based value. 10:43:51 10:43:57 10:44:01 10:44:09 10:44:17

And I think -- umm -- those empirical 10:44:21

relationships are strongest on a site specific basis, because of all the different -- umm -- you know, variations in organic carbon, grain size, percent fine grain sediment clays, silts. 10:44:27 10:44:36 10:44:42 10:44:47

On a site-specific basis those empirical relationships are typically used to establish cleanup levels, and I believe that's the standard practice 10:44:51 10:44:55 10:45:04

Q. You mean the numbers on page 8 are used to set site-specific cleanup levels? 10:45:06 10:45:10

A. Oh, absolutely not. 10:45:11

Q. I'm sorry. 10:45:13

Then I may have misunderstood. 10:45:14

A. Oh, okay. Okay. 10:45:16

So these are not -- these -- these values are not intended to drive cleanup, or a site-specific cleanup, or even be water body or -- umm -- segment-specific sediment targets. 10:45:17 10:45:24 10:45:30 10:45:36

These are only for use as a -- one of the LOE, Line of Evidence, and the assessment framework. 10:45:41 10:45:47

Once you've moved through -- once you've applied the assessment framework -- 10:45:53 10:45:54

Q. Sir, may I hold you up there? 10:45:56

When you said "These values are not used as cleanup levels," were you referring to the values in Table 6 and 7 on page 8 of Part 1? 10:45:59 10:46:01 10:46:05

A. Yes. Yes. 10:46:08

Q. Thank you for that clarification. 10:46:09

Please proceed with your answer. 10:46:11

A. So, again, those values that we discussed in those tables are only for the assessment purpose. 10:46:16 10:46:20

The next step is stressor identification, and then once you define a -- that it's a pollutant-related stressor you look at -- umm -- relationships between the stressor identified at your site and the biological responses at your site and use that data to develop whatever -- umm -- targets are appropriate. 10:46:25 10:46:30 10:46:37 10:46:43 10:46:50 10:46:57

It's all site specific. 10:47:05

Q. And with regard to the target development that you just mentioned, do you mean pursuant to a process similar to that spelled out on pages 19 and 20 -- 10:47:09 10:47:12 10:47:16

A. Correct. 10:47:19

Q. -- of Part 1? 10:47:20

A. Yes, correct. 10:47:22

Q. Thank you. 10:47:23

So, to be clear, on page 8 of Part 1, Tables 6 and 7, do those values reflect knowledge of the dose response relationship between any of these chemicals and sediment qualify effects? 10:47:24 10:47:30 10:47:33 10:47:38

A. Yes. 10:47:42

Q. How so? 10:47:48

A. They -- umm -- they represent the relationship between chemistry and biological effects for -- umm -- all bays. 10:47:49 10:47:56 10:48:07

So there's -- 10:48:14

Do you see the difference? 10:48:14

Developing empirical relationships for -- umm -- that are based on a data set from all bays versus doing the same thing for a very small specific site. 10:48:18 10:48:23 10:48:32

Q. Let's try to get there. 10:48:35

A. Okay. 10:48:38

MR. SINGARELLA: Would you mark that as 702. 10:48:40

(Exhibit 702 was marked for Identification.) 10:48:42

BY MR. SINGARELLA: 10:49:05

Q. I'm causing to be placed in front of you what has been marked as Exhibit 702 to your deposition. 10:49:10 10:49:14

Do you see that? 10:49:17

A. Yes. 10:49:18

Q. And is this a presentation that you made as part of the SQO Program to the Regional Board in San Diego? 10:49:19 10:49:23 10:49:28

A. Yes. 10:49:28

Q. On November 14th, 2007; is that right? 10:49:29

A. Uh-huh. 10:49:32

Q. And it's -- the pages aren't numbered, Mr. Beegan, but six or seven pages in there's a -- 10:49:34 10:49:38

A. Mine are numbered. 10:49:44

MR. SINGARELLA: Yours are numbered? 10:49:45

MR. FUCHS: I think you're looking at a different exhibit. 10:49:46 10:49:48

MR. SINGARELLA: Oh, great. Thank you. 10:49:49

Yes, slide 8. 10:49:52

BY MR. SINGARELLA: 10:49:53

Q. Dose response relationship in water. 10:49:55

Now, this is a relationship between copper and a biological endpoint in the water column; correct? 10:50:07 10:50:12

A. Yes. 10:50:17

Q. To be distinguished from a relationship between copper and some biological effect in the underlying bottom sediments; right? 10:50:17 10:50:21 10:50:25

A. Correct. 10:50:29

Q. And what was -- what was your intent, if you recall, in -- in showing this kind of dose response relationship? 10:50:29 10:50:33 10:50:37

MR. FUCHS: I'm going to object. 10:50:37

I just don't see how that is within the scope of this deposition. 10:50:39 10:50:41

MR. SINGARELLA: I'll tie it -- tie it in closely. 10:50:42 10:50:45

MR. FUCHS: Maybe you can explain how you're going to tie it in now. 10:50:46 10:50:47

MR. SINGARELLA: Well, Mr. Fuchs, I -- you know, you're really asking me a lot of questions about my deposition strategy, and it's wholly outside of Mr. Gallagher's limiting instruction to deal with the methodology of the SQO. 10:50:49 10:50:52 10:50:54 10:50:58

So, if you'll allow me, I'm sure I can tie it up to your satisfaction. 10:51:02 10:51:06

MR. FUCHS: I'll give you a little rope. 10:51:08

MR. SINGARELLA: Okay. 10:51:10

MR. FUCHS: Once he asks the question. 10:51:12

MR. SINGARELLA: Yeah. 10:51:15

BY MR. SINGARELLA: 10:51:15

Q. You show a series of slides showing dose response between copper and biology in water and then in sediment; right? 10:51:15 10:51:18 10:51:24

A. Right. 10:51:25

Q. Did you intend to draw a contrast? 10:51:25

A. Yes. 10:51:28

Q. To help -- to help inform people as to what the SQO methodology is and isn't; right? 10:51:29 10:51:33

A. Absolutely. 10:51:37

Q. Yes. 10:51:38

Okay. So on slide 8 you're showing a characteristic dose response relationship for copper in the water column; correct? 10:51:39 10:51:42 10:51:46

A. Yes. 10:51:47

Q. And then you have some notes. 10:51:48

Are these your notes underneath the slide? 10:51:49

Do you recall these being your notes? 10:51:51

A. Yeah. I -- yeah. 10:51:53

I mean, I don't -- I don't recall these notes, 10:51:59

but they're on my PowerPoint, so I'll assume for all 10:52:02

intents and purposes they are my notes. 10:52:05

Q. And there's an indication that there are two 10:52:07

reasons this works, referring to the dose relationship 10:52:10

in the water column; right? 10:52:14

A. Uh-huh. 10:52:15

Q. And the first is the linkage to the pipe or 10:52:16

plant; correct? 10:52:19

A. Yes. 10:52:20

Q. And the second is that the dose response in 10:52:20

water is known; correct? 10:52:22

A. Yes. 10:52:24

Q. And you know what will happen to organisms 10:52:24

exposed to at or above the specific levels; right? 10:52:29

A. Uh-huh. 10:52:32

Q. Is that a "yes"? 10:52:33

A. Yes. 10:52:33

I'm sorry. 10:52:34

Q. And then there's a statement "with sediments 10:52:35

we have neither;" correct? 10:52:38

A. Yes. 10:52:42

Q. And then there's a -- additional statement at the bottom that says "The dose response relationships are not predictable in the sediment;" correct? 10:52:43 10:52:49 10:52:54

A. Correct. 10:52:57

Q. And it says "does," but -- you understand that to be mean "dose;" correct? 10:52:57 10:53:00

A. Yes. 10:53:03

Q. Okay. So when it says here "With sediments we have neither," one of the implications is -- is with respect to the characteristic clean dose response in the water column; right? 10:53:04 10:53:09 10:53:15 10:53:18

A. Correct. 10:53:20

Q. And so then, turning to slide 9, we see an attempt to find a dose response relationship in the sediment; right? 10:53:20 10:53:29 10:53:33

A. Correct. 10:53:34

Q. And to do that you plot copper versus some biological endpoint; right? 10:53:34 10:53:38

A. Correct. 10:53:40

Q. And, in fact, were these data used, if you know, to develop the SQOs? 10:53:40 10:53:43

MR. FUCHS: That's -- that is beyond the scope. 10:53:45 10:53:49

How the SQOs were developed is beyond the scope of this deposition. How they are applied in the abstract is not. How they were developed is. 10:53:51 10:53:54 10:53:56

So please don't answer that question. 10:53:59

MR. SINGARELLA: Let's keep track of this because, obviously, to understand how the methodology works I think we're entitled to know what -- what data were used to build it. 10:54:02 10:54:04 10:54:07 10:54:10

BY MR. SINGARELLA: 10:54:12

Q. So do you recall where you obtained these data in Slide 9? 10:54:15 10:54:18

A. I don't recall. 10:54:20

I probably got it from -- umm -- Steve Bay. 10:54:27

Q. The keeper of the SQO database; right? 10:54:35

A. Umm -- yeah, and SCCWRP -- 10:54:41

Well, Steve Bay was, as you know, the principal scientist responsible for developing the various Lines of Evidence, and I would assume I got that particular slide from him. 10:54:44 10:54:46 10:54:54 10:55:02

Q. Does Slide 9 reflect a clean dose response relationship between copper in the sediment and a biological endpoint? 10:55:03 10:55:08 10:55:11

A. No. 10:55:12

Q. That's a little messy; isn't it? 10:55:13

A. Yes. 10:55:20

Q. And so, for example, just taking a -- 10:55:21
concentration of a hundred milligrams per kilograms or 10:55:28
there about -- 10:55:34
Are you with me? 10:55:35
A. Yep. Yes. 10:55:36
Q. You can have close to a hundred percent 10:55:37
survival of the test critters; right? 10:55:40
A. Yes. 10:55:48
Q. Or a hundred percent die off of the test 10:55:49
critters; right? 10:55:55
A. Yes. 10:55:57
Q. And that -- those two statements could be true 10:55:57
for a range of these copper concentrations; right? 10:56:01
A. Yes. 10:56:03
Q. And you can't develop a clean dose response 10:56:04
relationship when the critters might die or survive for 10:56:09
the same concentration; right? 10:56:13
A. Right. 10:56:14
Q. And is this -- to your knowledge is this 10:56:17
characteristic of the kinds of -- of data for different 10:56:22
chemical constituents? 10:56:27
A. It's characteristic of the kinds of data that 10:56:29
you observe in mixtures. So this is probably from -- 10:56:35
umm -- a variety of samples that contain a variety of 10:56:48
pollutants. 10:56:53

There could be other pollutants that are causing the biological effects in that plot. 10:56:58 10:57:02

Does that make sense? 10:57:10

Q. Yes, it does. 10:57:12

A. The relationship between these two slides is not absolutely -- umm -- the same. 10:57:14 10:57:20

The slide before was a -- probably -- probably, I'm surmising -- was probably a -- a laboratory test with spiked copper concentrations where copper was the only contaminant introduced. 10:57:26 10:57:31 10:57:37 10:57:42

This slide is probably a slide applied -- ambient sediment samples. 10:57:46 10:57:56

So there could be other pollutants in there causing that biological response. 10:58:00 10:58:04

Q. Or there could be confounding factors? 10:58:07

A. Absolutely. 10:58:09

Q. Or physical disturbance? 10:58:10

A. Well -- yes. Yes. Yes. 10:58:13

Q. And -- 10:58:15

A. It's probably the sum of those. 10:58:18

Q. With respect to "ERL," to what does that refer? 10:58:20 10:58:23

A. Umm -- it's a sediment quality guideline developed by -- I believe it was Ed Long. 10:58:23 10:58:34

It -- I think it stands for Effects Range Low. 10:58:39

I don't remember the exact -- umm -- mathematical relationship to the effects, but they're at the low end where you expect not to see biological effects in sediment. 10:58:45 10:58:54 10:59:01 10:59:08

Q. And this -- this figure shows that even above the ERL there's a tremendous amount of data showing no effects as well; correct? 10:59:10 10:59:15 10:59:23

A. Correct. 10:59:24

Q. And the ERM, is that another sediment-quality guideline? 10:59:25 10:59:31

A. Yes. 10:59:31

Q. Is it empirical based? 10:59:32

A. Yes. 10:59:34

Q. And ERL is empirical based? 10:59:34

A. Yes. 10:59:37

Q. You did not use either of these in the sediment chemistry prong of the SQO; right? 10:59:38 10:59:40

A. Right. 10:59:44

Q. Are CSI and CALRM -- are those empirical based? 10:59:46 10:59:52

A. Correct. 10:59:52

Q. If you know, is there a statistically significant relationship between copper and the biological endpoint shown in Slide 9? 10:59:53 11:00:04 11:00:08

A. I don't know. 11:00:10

Q. You wouldn't expect that, though, looking at the data; would you? 11:00:18 11:00:21

A. Umm -- a significant -- a statistically significant between concentrations and -- are talking about -- 11:00:22 11:00:32 11:00:34

Q. Survival. 11:00:35

MR. FUCHS: I'll object that lacks foundation and calls for speculation, but you can go ahead and answer if you can answer. 11:00:38 11:00:40 11:00:42

THE WITNESS: There may be. 11:00:44

Yeah, it would be -- umm -- 11:00:45

BY MR. SINGARELLA: 11:00:54

Q. So, going back to Slide 8, you understand when -- when people speak to statistically significant relationships, they're talking about fitting a curve; right? 11:00:54 11:01:01 11:01:05 11:01:08

A. Right. 11:01:08

Q. Drawing a line through data; right? 11:01:08

A. Right. 11:01:10

Q. You would agree that in Slide 8 you could draw a line through those data that would pretty much capture the data; right? 11:01:11 11:01:14 11:01:18

MR. FUCHS: That lacks foundation and calls for speculation, but you can go ahead and answer if you can answer. 11:01:21 11:01:23 11:01:28

THE WITNESS: The -- umm -- the -- umm -- 11:01:29

You could draw a curve to that, but I don't 11:01:42

know whether those top three points are significantly 11:01:45

different. 11:01:51

BY MR. SINGARELLA: 11:01:52

Q. Could you draw a line through it for me? 11:01:53

A. You would like me to? 11:01:56

Q. Please. 11:01:58

Let the record show that Mr. Beegan has drawn 11:02:22

a slight curve through the data on Slide 8 of Exhibit 11:02:25

702. 11:02:33

Is that correct, Mr. Beegan? 11:02:36

A. Yeah. 11:02:38

Q. Turning to Slide 9 -- could you draw a line 11:02:39

through those data. 11:02:48

A. Umm -- no. 11:02:50

MR. FUCHS: Let the record reflect that the -- 11:02:54

there are one, two, three, four, five, six dots on the 11:02:57

chart on page 8, and I wouldn't dare count how many 11:03:02

dozens on the chart on page 9. 11:03:07

BY MR. SINGARELLA: 11:03:14

Q. And, turning to Slide 10 -- I have trouble 11:03:19

with this line understanding the difference between the 11:03:33

black circles and the open circles. 11:03:36

Do you know what the distinction is? 11:03:39

A. Umm -- I don't recall. 11:03:43
Q. Would you be able to draw a fit to these data? 11:03:45
A. Umm -- 11:04:01
MR. FUCHS: Lacks foundation. Calls for 11:04:04
speculation. 11:04:05
THE WITNESS: The relationship looks better, 11:04:06
but I don't think I could -- umm -- draw a line to it. 11:04:16
MR. FUCHS: Again, let the record reflect that 11:04:23
the image on page 10 contains dozens of points. 11:04:26
Are we done with this exhibit? 11:04:37
MR. SINGARELLA: No. 11:04:40
What made you think that? 11:04:41
BY MR. SINGARELLA: 11:04:45
Q. Could we turn to Slide 5, -- 11:04:45
A. Sure. 11:04:48
Q. -- please, of Exhibit 702. 11:04:49
So this description of -- of SQOs in -- in the 11:04:53
first bullet, do you see that, sir? 11:05:07
A. Yes. 11:05:09
Q. And did you -- did you prepare this -- this 11:05:10
slide? 11:05:15
A. Yes. 11:05:16
Q. And is it -- is it your understanding that the 11:05:18
SQOs are a means to differentiate sediment? 11:05:22
A. Yes. 11:05:27

Q. Basically between the impacted and those that are not impacted; right? 11:05:29 11:05:34

A. Correct. 11:05:35

Q. By bioavailable toxic pollutants; correct? 11:05:35

A. Correct. 11:05:40

Q. So it's a tool to distinguish the good sediment from the bad sediment; right? 11:05:41 11:05:47

A. Essentially, yes. 11:05:49

Q. And when you say that the SQOs are a standard for sediment quality, what does that mean to you? 11:05:51 11:06:03

A. Umm -- 11:06:07

MR. FUCHS: You know, I'm going to put an end to this line of questioning. 11:06:19 11:06:22

I'm sorry. 11:06:23

This -- I just fail to see how any of the questions have been asked in the last 10 minutes regarding Exhibit 702 relate to the scope of this deposition as set forth by Mr. Gallagher in the conversation of September 27th, which is how in the abstract the Statewide Sediment Quality Objectives should be or could be applied. 11:06:24 11:06:26 11:06:28 11:06:34 11:06:37 11:06:40 11:06:44

MR. SINGARELLA: Well, Mr. Fuchs, I have to tell you I'm stunned by your failure to see that. 11:06:49 11:06:51

Are you telling him to stop here? 11:06:53

MR. FUCHS: Yeah. 11:06:56

MR. SINGARELLA: And so you don't think that we're entitled to find out whether the Sediment Quality Objectives are a tool to distinguish the good from the bad sediment versus a tool that would actually mandate cleanup? 11:06:57 11:06:58 11:07:01 11:07:05 11:07:09

This is what this is all about, Mr. Fuchs. That's what I've been talking about all morning. 11:07:10 11:07:12

We need to understand the boundaries of this policy. It doesn't speak for itself. 11:07:14 11:07:17

There's a lot of -- of detail and unpackaging that has to go in to this. 11:07:19 11:07:23

And I'm sorry. 11:07:25

And, you know, Mr. Beegan put a lot in to these materials, and they don't just come in and speak to us, and this is our opportunity to understand the boundaries of this policy. 11:07:26 11:07:30 11:07:32 11:07:35

This is extremely relevant to the use of the SQOs in San Diego Bay. 11:07:38 11:07:41

We don't want Donald McDonald or the board members to misunderstand what these are and what they aren't. 11:07:44 11:07:47 11:07:50

I'm very comfortable with what they are, but no one is going to listen to me. They need to hear from Mr. Beegan. 11:07:51 11:07:54 11:07:57

That's why we're taking this deposition. 11:07:58

That's why we're here. 11:08:00

I'm not on some wild goose chase here. I'm 11:08:01

trying to defend my client. 11:08:06

So take it under advisement, please, because 11:08:07

you're constantly interrupting me, and I don't think 11:08:11

it's fair. 11:08:14

This is about methodology. 11:08:15

MR. FUCHS: You asked him, and he answered as 11:08:18

to the -- this interesting question as to whether it's 11:08:21

to distinguish good from bad sediment, which I think is 11:08:24

kind of legally and scientifically a meaningless 11:08:31

statement, but I let it go. 11:08:34

Your argument can be made to Mr. Gallagher. 11:08:36

Please don't answer any more questions 11:08:40

regarding this exhibit. 11:08:42

I've let it go on quite a while. 11:08:43

MR. SINGARELLA: Well, fortunately, I'm 11:08:54

finished with this exhibit. 11:08:59

MR. FUCHS: A happy coincidence. 11:09:01

MR. SINGARELLA: Yes, I would agree. 11:09:04

BY MR. SINGARELLA: 11:09:05

Q. So, turning back to page 8 of Part 1, are -- 11:09:15

Strike that. 11:09:36

With regard to Tables 6 and 7, can you show me 11:09:37

where the dose response threshold is for copper? 11:09:43

A. The -- umm -- the -- there's two indicators that we use. 11:09:49 11:10:13

One is logistic direction. That would be the one identified in Table 7. 11:10:14 11:10:19

And the other one is the -- umm -- the CSI. 11:10:21

The CSI was derived from looking at relationships between chemistry and benthic community, and then the -- umm -- the LRM was developed looking at relationships between chemistry -- sediment chemistry and, you know, broad water bodies and toxicity. 11:10:29 11:10:35 11:10:42 11:10:49 11:10:57

To -- we developed the thresholds based first on a definition of categories, and so we had categories defined as, you know, reference, and we have the narrative -- umm -- we have the narrative description of those four categories, and I think they're defined in one of those technical documents, perhaps even the Staff Report. 11:11:05 11:11:12 11:11:19 11:11:25 11:11:30 11:11:33 11:11:37

I did not develop those or perform the statistics myself. 11:11:38 11:11:44

There is an empirical relationship -- umm -- and I -- I guess -- I don't know how to answer that question other than to say that both tables were developed based on a relationship between chemistry and biological effects, and the specific thresholds fall along a similar -- umm -- philosophy of what is 11:11:47 11:11:56 11:12:03 11:12:08 11:12:15 11:12:24

reference, what is considered low, what is considered moderate, and what is considered high. 11:12:33 11:12:37

And those categories and -- and the description of those categories was similar for each of the Lines of Evidence, and that's kind of what -- umm -- kind of the -- the overall framework for establishing the -- the thresholds based on a dose response relationship. 11:12:40 11:12:44 11:12:49 11:12:54 11:12:57 11:13:06

But those thresholds are only developed based on mixtures, so -- umm -- it's messy data, very messy data. 11:13:08 11:13:16 11:13:23

When you -- when you're looking at data from even one water body or multiple water bodies, it's very messy. 11:13:24 11:13:29 11:13:34

That probably didn't do a very good job, but -- umm -- it's difficult trying to be accurate yet -- umm -- describe the -- describe things in a way that's concrete. 11:13:36 11:13:39 11:13:45 11:13:55

There's a methodology. There are documents that describe that methodology that I've provided. 11:13:57 11:14:02

So I -- I guess I don't know how to better answer that question. 11:14:10 11:14:15

Q. Well, if we were dealing with a water quality objective for copper in the water column, we could go find the dose response relationship; correct? 11:14:16 11:14:21 11:14:25

A. Oh, yes. Yes. 11:14:28

Q. How would we do that here? 11:14:29

A. Umm -- you could -- 11:14:31

MR. FUCHS: Let me object just for a second. 11:14:38
That's vague and ambiguous. 11:14:40

You mean where in these tables does the dose 11:14:42
relationship appear? 11:14:45

Is that the question? 11:14:47

MR. SINGARELLA: If they're not here, where 11:14:48
are they, so we can go and look at it and confirm it and 11:14:49
understand it. 11:14:55

MR. FUCHS: If you understand the question, 11:14:57
you can answer. 11:14:58

THE WITNESS: Umm -- I think the background 11:15:00
for these indicators would be in one of those technical 11:15:16
documents by the Technical Team. 11:15:23

There may be some description of that in the 11:15:28
staff report. 11:15:32

BY MR. SINGARELLA: 11:15:35

Q. Is the dose response relationship actually in 11:15:41
Part 1? 11:15:43

A. It serves as the foundation for these values. 11:15:44

I -- I don't -- 11:15:53

The dose response relationship. 11:15:54

The empirical relationship between 11:15:57

concentration and biological effects was the basis for developing these values. 11:16:01 11:16:05

Q. And do you know if those empirical relationships are statistically significant? 11:16:16 11:16:18

A. I would assume they are. 11:16:22

I'm not -- umm -- I'm -- 11:16:24

I don't recall, but I would assume they are. 11:16:35

This goes back -- umm -- this is -- you know, five years ago. 11:16:38 11:16:46

To me it seems like 20 years ago. 11:16:47

I -- 11:16:51

Q. Where would we find these statistics demonstrating statistical significance between dose and response? 11:16:54 11:16:56 11:17:00

A. Umm -- one of the technical reports? 11:17:01

MR. SINGARELLA: Would you mark that, please. 11:17:35

(Exhibit 703 was marked for Identification.) 11:17:36

THE REPORTER: 703. 11:17:38

BY MR. SINGARELLA: 11:17:51

Q. I've placed in front of you what has been marked as Exhibit 703 to your deposition. 11:17:51 11:17:54

Do you see that, Mr. Beegan? 11:17:56

A. Uh-huh. 11:17:58

Q. Yes? 11:17:59

A. Yes, I do. 11:18:00

Q. Is this a document that you prepared for this deposition? 11:18:00 11:18:03

A. Yes. 11:18:03

Q. On October 5, 2010? 11:18:07

A. Yes. 11:18:09

Q. And is it an index to some of the technical documents that you were just referring to? 11:18:09 11:18:15

A. Yes. 11:18:17

Q. Do you have -- 11:18:17

Strike that. 11:18:28

Can you tell us where we would find the dose response relationship supporting this sediment chemistry Line of Evidence -- if you know? 11:18:28 11:18:30 11:18:35

MR. FUCHS: I'm going to object that the -- 11:18:48

Well, it's my standard objection. 11:18:50

We're beyond the scope. 11:18:52

How the -- Table 6 and Table 7 were developed is not relevant to how they are applied. 11:18:53 11:18:58

It's a different question. 11:19:01

I understand that they're related, but it's a different question. 11:19:03 11:19:06

MR. SINGARELLA: It's a fine read, indeed. 11:19:07

You can go ahead and answer, please. 11:19:10

THE WITNESS: Under the heading "Sediment Chemistry" there are a couple of SCCWRP reports. 11:19:13 11:19:19

They may also be -- umm -- included in similar articles provided on the -- that USB flash drive. 11:19:27 11:19:38

BY MR. SINGARELLA: 11:19:46

Q. And are these sediment chemistry references on the second page of Exhibit 703 -- are they helpful to make sure that the SQO is properly applied? 11:19:48 11:19:51 11:19:56

A. Yes. 11:20:04

Q. They relate to the SQO methodology; correct? 11:20:08

A. The methodology -- umm -- to assess sediment quality in relationship to direct effects, yes. 11:20:15 11:20:23

Q. And this is an extremely complicated subject area; right? 11:20:25 11:20:28

A. Yes. 11:20:30

Q. With a series of technical reports related to the Part 1 SQOs; correct? 11:20:30 11:20:37

A. Correct. 11:20:40

Q. Most of which aren't just raw data reports; right? 11:20:40 11:20:44

A. Correct. 11:20:44

Q. They are reports that inform the user of Part 1 how to you use it; correct? 11:20:44 11:20:50

A. Umm -- yes, and -- 11:20:51

Yes. 11:21:03

Q. Now, turning back to the sediment chemistry Line of Evidence, there are two empirical relationships 11:21:03 11:21:20

used in that Line of Evidence; right? 11:21:26

A. Yes. 11:21:28

Q. One is the CSI; right? 11:21:29

A. Yes. 11:21:31

Q. And the other is the California LRM; correct? 11:21:31

A. Yes. 11:21:34

Q. What does "CSI" stand for? 11:21:35

A. Umm -- I don't recall. 11:21:37

Q. What does "California LRM" stand for? 11:21:42

A. It's Logistic Regression -- umm -- 11:21:47

I don't remember what the "M" is. 11:21:51

Q. Can you turn to page 7, please, of Part 1. 11:21:53

Does this refresh your recollection that "CSI" 11:22:07

refers to Chemical Score Index? 11:22:11

A. Yeah. 11:22:13

Q. And that "California LRM" refers to California 11:22:13

Logistic Regression Model? 11:22:17

A. Yes. 11:22:20

Q. And to use the Part 1 SQO you need to use both 11:22:21

of those guidelines; right? 11:22:28

A. Correct. 11:22:30

Q. You can't just decide to use one or the other; 11:22:31

right? 11:22:36

A. Right. Correct. 11:22:37

Q. And, if you just used one, you might be using 11:22:37

a Line of Evidence, but you would not be using the multiple Lines of Evidence in Part 1; correct? 11:22:49 11:22:52

A. Correct. 11:22:54

Q. And with regard to the benthic indices, on pages 6 and 7 of Part 1 -- 11:22:58 11:23:11

Are you with me? 11:23:15

A. Yes. 11:23:18

Q. There are four of those; correct? 11:23:23

A. Yes. 11:23:26

Q. Written in to Part 1; right? 11:23:26

A. Correct. 11:23:28

Q. All four of them are required to be used; right? 11:23:29 11:23:33

A. Correct. 11:23:33

Q. To have an accurate and proper application of Part 1; right? 11:23:34 11:23:36

A. Correct. 11:23:37

Q. And, if you were to use fewer than four of these benthic indices, you might have a Line of Evidence, but you wouldn't have Part 1? 11:23:38 11:23:43 11:23:47

A. Correct. 11:23:50

Q. And, turning back to page 20 of Part 1, just before the glossary there's a reference to the chemistry LOE, Line of Evidence. 11:23:52 11:24:14 11:24:18

Do you see that? 11:24:20

A. Yes. 11:24:21

Number 5? 11:24:24

Q. Yes. 11:24:26

A. Absolutely. 11:24:26

Q. Yeah. 11:24:27

And it absolutely says that the chemistry LOE 11:24:28
shall not be used for setting cleanup levels; correct? 11:24:31

A. Correct. 11:24:34

Q. What does that mean? 11:24:35

A. It means that those values in -- umm -- in 11:24:36
those tables -- umm -- are -- are inappropriate for use 11:24:48
as establishing cleanup levels. 11:25:00

I -- I -- 11:25:03

Q. To you it's pretty plain? 11:25:07

A. It is. 11:25:09

Q. It's black-and-white, you just don't use the 11:25:09
chemistry Line of Evidence to set a cleanup level? 11:25:13

A. Right. 11:25:17

Q. Nor would you use the chemistry Line of 11:25:17
Evidence to set a numeric value for a technical TMDL; 11:25:24
correct? 11:25:28

A. Well, correct, yes. 11:25:29

But there is -- umm -- there's a note in this 11:25:35
Water Quality Control Plan that says something like -- 11:25:45
umm -- nothing in this Water Quality Control Plan or 11:25:52

nothing in this section shall limit a Regional Board's authority to develop TMDLs. 11:25:57 11:26:02

Are you familiar with that language? 11:26:06

I -- 11:26:07

Q. Yes. 11:26:08

I don't know where it is precisely. 11:26:09

A. Neither do I. I'm just trying to respond to your question accurately. 11:26:11 11:26:15

The intent was to -- for all sites, whether it's a TMDL cleanup, or whatever, other sediment-related problem, is to assess if problems go through stressor identification, and then develop some biologically-relevant target based on the site conditions, or the segment conditions, or the water body conditions. 11:26:16 11:26:25 11:26:30 11:26:39 11:26:47 11:26:51 11:26:54

Q. The sediment chemistry Line of Evidence does not provide the biologically-relevant target; correct? 11:26:56 11:27:05

A. For target for a site? 11:27:08

Correct. 11:27:23

Q. And then, turning back to page 19 of Part 1 -- I think I've covered this, Mr. Beegan. 11:27:24 11:27:55

Is -- is stressor identification relevant to defining appropriate remediation activity? 11:27:59 11:28:23

A. Yes. 11:28:26

Q. And -- and so, too, is the development of the 11:28:36

site specific guidelines in Section H? 11:28:44

A. Yes. 11:28:49

Q. Those are the parts of -- of this plan where you tie knowledge of sediment quality through the multiple Lines of Evidence with management action and cleanup; correct? 11:28:50 11:29:01 11:29:05 11:29:09

A. Correct. 11:29:10

Q. And the chemistry Line of Evidence does not establish causality; correct? 11:29:11 11:29:24

A. Absolutely correct. 11:29:27

Q. And what does that mean? 11:29:28

A. It means that -- umm -- the empirical guidelines, the CSI -- the empirical chemistry indicators, the CSI and the LRM, are -- empirical relationships based solely on association. 11:29:29 11:29:39 11:29:44 11:29:51

There is no -- umm -- 11:29:57

There's no -- 11:30:01

They don't assume cause. 11:30:05

They don't assume that -- that particular chemical at that concentration is causing the biological effects. 11:30:07 11:30:11 11:30:16

That is why we included stressor identification. Stressor identification is -- 11:30:18 11:30:23

The intent of stressor identification is to determine the cause. 11:30:27 11:30:30

Q. And, in fact, the Lines of Evidence are not sufficiently reliable to be used independent in isolation from the other Lines of Evidence; right? 11:30:31 11:30:42 11:30:46

A. Correct. 11:30:49

Q. Because they can underestimate risk in some circumstances; right? 11:30:52 11:31:06

A. Correct. 11:31:07

Q. Or overestimate risks in other circumstances; correct? 11:31:08 11:31:11

A. Correct. 11:31:11

Q. And this is a risk to the benthic community; correct? 11:31:11 11:31:15

A. Correct. 11:31:15

Q. And this imprecision can be significant; correct? 11:31:15 11:31:19

A. Correct. 11:31:19

Q. So let me just give you an example so I'm sure I understand this. 11:31:19 11:31:39

You're applying -- or you're attempting to apply the MLOE, but you used three of the benthic indices and not the fourth, and you used only lethal test results and not sublethal. 11:31:40 11:31:47 11:31:52 11:31:56

Are you with me? 11:31:59

A. Uh-huh. 11:32:00

Q. Yes? 11:32:00

A. Yes. Yes. 11:32:02

Q. You -- you would not actually be applying this MLOE, referring to Section 5 of Part 1; right? 11:32:03 11:32:07

A. Correct. 11:32:11

Q. To apply Section 5 of Part 1 you need sublethal test results; correct? 11:32:11 11:32:21

A. Correct. 11:32:23

Q. In addition to lethal test results; right? 11:32:23

A. Correct. 11:32:26

Q. You need to have information on the benthic community; correct? 11:32:26 11:32:31

A. Correct. 11:32:32

Q. Numbers of critters, fila, things of that nature; correct? 11:32:32 11:32:37

A. Correct. 11:32:37

Q. Sufficient to support the calculation of all four benthic entities; correct? 11:32:37 11:32:43

A. Correct. 11:32:44

Q. And then you need to use the results from all four of those calculations as part of the benthic community Line of Evidence; correct? 11:32:45 11:32:47 11:32:50

A. Correct. 11:32:50

Q. Turning to page 14, "Receiving Water Limitations," for a minute. 11:32:51 11:33:01

On page 14 Section C "Exceedance of receiving 11:33:05

water limit" describes two conditions that must be satisfied for there to be an exceedance of a Receiving Water Limit. 11:33:17 11:33:21 11:33:24

Do you see that? 11:33:26

A. Yes. 11:33:27

Well, -- yeah. Yeah. 11:33:29

Q. And what is a "receiving water limit" as used in this context? 11:33:30 11:33:33

A. Umm -- it's a -- umm -- it's a permanent limit. It's -- 11:33:34 11:33:41

Or it's a -- 11:33:43

Yeah, it's a permit limit. It's located in the receiving water rather than what most people think of as permit limits, which are effluent-based associated with the direct measure of effluent. 11:33:44 11:33:51 11:33:58 11:34:04

Q. And before there is an exceedance of such a limit you have to do -- you have to know two things; right? 11:34:07 11:34:13 11:34:18

A. Yes. 11:34:20

Q. And what is the first one? 11:34:20

A. Umm -- you have to have -- umm -- the total number of stations designated as not meeting the protective condition. 11:34:22 11:34:29 11:34:33

I think that's -- umm -- would characterize that as possibly likely or clearly impacted. 11:34:36 11:34:41

Supports the rejection of the null hypothesis as presented in Table 15. 11:34:44 11:34:48

Basically you need multiple stations to -- in order to be -- umm -- considered a potential exceedance, and the number of exceedance is relative to the total number of stations is identified in Table 15. 11:34:50 11:34:56 11:35:02 11:35:09

Q. And then there's a second element of determining the presence of an exceedance; correct? 11:35:12 11:35:17

A. Yes. 11:35:21

Q. And what is that, Mr. Beegan? 11:35:21

A. Umm -- it is demonstrated that the discharge is causing or contributing to SQO exceedance following the completion of the stressor identified studies. 11:35:23 11:35:27 11:35:31

Q. And that's a reference to the three-step process described in stressor identification in Part 1; correct? 11:35:35 11:35:39 11:35:41

A. Correct. 11:35:41

Q. And, in fact, when you get to Step 3, management actions, on page 19, there's a reference to requirements for dischargers; correct? 11:35:42 11:35:45 11:35:50

A. Yes. 11:35:52

Hold on. 11:35:56

19? 11:35:56

Q. Page 19, yeah. 11:35:57

A. Yes. 11:36:03

Q. And so the way this works is you go through the MLOE; right? 11:36:03 11:36:09

A. Yes. 11:36:15

Q. You do stressor identification; correct? 11:36:15

A. Yes. 11:36:18

Q. And then, if you identify a particular constituent associated with an unacceptable impact from a particular source, at that point the Regional Board requires the discharger to take management actions; correct? 11:36:18 11:36:26 11:36:32 11:36:37 11:36:41

A. Correct. 11:36:41

MR. SINGARELLA: Could we get Master Exhibit Number 7 out? 11:36:51 11:36:54

And we're almost out of tape according to Sean. 11:36:54 11:36:59

So why don't we take a five-minute break. 11:36:59

MR. FUCHS: All right. 11:37:03

VIDEOGRAPHER: We are going off the record at 11:36 a.m. 11:37:04 11:37:05

This is the end of disk number two. 11:37:07

(Thereupon a recess was taken at 11:36 a.m. and the deposition resumed at 11:54 a.m.) 11:37:10 11:54:08

(Exhibit No. 704 was marked for Identification.) 11:54:08 11:54:37

VIDEOGRAPHER: We are back on the record at 11:54:37

11:54 a.m. 11:54:46

This is the beginning of disk number three. 11:54:48

BY MR. SINGARELLA: 11:54:50

Q. Welcome back, Mr. Beegan. 11:54:51

A. Thank you. 11:54:52

Q. I've placed in front of you what has been marked as Exhibit 704 to your deposition. 11:54:53 11:54:56

Do you see that? 11:54:59

A. Yes. 11:55:00

MR. SINGARELLA: And this is just housekeeping, Mr. Beegan, but for the record and for Mr. Fuchs, this is actually -- I believe it's -- it's also Master Exhibit Number 7, but the original Master Exhibit does not seem to have made its way up here, so just out of an abundance of caution I'll reenter it as Beegan's 704. 11:55:01 11:55:03 11:55:07 11:55:10 11:55:13 11:55:16 11:55:21

BY MR. SINGARELLA: 11:55:22

Q. Mr. Beegan, do you recognize this document? 11:55:22

A. Yes. 11:55:25

Q. And what is it? 11:55:26

A. It's the Staff Report for the Water Quality Control Plan For Enclosed Bays and Estuaries, Part 1, Sediment Quality. 11:55:27 11:55:31 11:55:37

Q. And could you turn to page 2-1, please, sir. 11:55:37

Now, just by way of background, what is a 11:55:51

"Staff Report"? 11:55:54

A. Umm -- a "Staff Report" is our document that 11:55:55

acts as a functionally equivalent CEQUA document. 11:56:06

It also is -- provides the supporting or the 11:56:11

background information for the Water Quality Control 11:56:16

Plan. 11:56:19

It describes -- umm -- many factors that the 11:56:20

Water Board must consider when developing a Water 11:56:26

Quality Control Plan and/or objectives. 11:56:30

It's been called -- in the past we used to 11:56:38

call it a Functional Equivalent Document or FED. 11:56:42

Sometimes it's been referred to as an SED. 11:56:46

I think at this point we're calling them just 11:56:50

"staff reports." 11:56:54

Q. So this is staff's report used during the 11:56:56

proceedings to adopt the Part 1 SQO? 11:57:00

A. Yes. 11:57:04

Q. And it contains information relevant to the 11:57:05

SQO methodology; correct? 11:57:09

A. Yes. 11:57:11

Q. And, in fact, explains the agency's rationale 11:57:11

basis for Part 1? 11:57:18

A. Yes. 11:57:19

Q. And so on page 2-1 of the Staff Report, just 11:57:19

above the figure there's a reference to "diversity of 11:57:29

sources." 11:57:35

The last sentence, do you see that? 11:57:35

A. Yes. 11:57:37

Q. What -- what do you mean? 11:57:38

What sources are being referred to there? 11:57:42

A. Umm -- I assume -- 11:57:45

Well, it's referring to the sentences earlier 11:57:54
in that paragraph. 11:57:58

Umm -- so there's -- umm -- sources of 11:58:02
contaminants within the water body, and there's sources 11:58:15
from rivers, creeks, drainage channels, storm water, dry 11:58:22
weather run-off, industrial activities, municipal 11:58:27
activities, atmospheric deposition, contaminated 11:58:34
groundwater. 11:58:40

I think it's referring to all these sources 11:58:41
that are described. 11:58:43

Q. Are rivers, creeks, and channels a known 11:58:43
source of toxic pollutants to California bays? 11:58:47

A. They can be. 11:58:51

Q. Have they been identified as such? 11:58:52

A. Umm -- yes. 11:58:55

Q. Then there's a reference to "various physical 11:59:00
mixing processes." 11:59:04

Do you see that? 11:59:05

A. Yes. 11:59:06

Q. And in this context why are the physical mixing processes important? 11:59:10 11:59:15

A. The mixing processes are important because physical mixing can -- umm -- mix pollutants -- umm -- they -- this is kind of a generic sentence that talks about the combination of pollutants or pollutants mixing, settling out, being pushed around by various processes, so that it may not be obvious what the source is or what the problem actually is. 11:59:16 11:59:42 11:59:51 11:59:59 12:00:04 12:00:08 12:00:17

Q. So currents can obscure the source and nature of the problem? 12:00:20 12:00:26

A. Potentially, yes. 12:00:27

Q. Referring to impacted bottom sediments; right? 12:00:29

A. Yes. 12:00:34

Q. And how do currents potentially obscure the source and nature of the problem? 12:00:34 12:00:39

A. Well, I guess -- umm -- suspended sediments could be -- deposited in different areas, not necessarily located right at the source. 12:00:40 12:00:47 12:00:55

A pollutant from one discharge could be mixed with a pollutant from another discharge through the same currents. They all would eventually settle out in to fine grain areas. 12:01:01 12:01:05 12:01:08 12:01:13

In some places -- I think we talked about scour before, the physical processes that could 12:01:15 12:01:21

resuspend and move contaminants or contaminant bound sediments from one area and redeposit in another area. 12:01:26 12:01:31

Q. And can rivers and creeks produce such currents? 12:01:36 12:01:45

A. Yes. 12:01:46

Q. Can ships? 12:01:46

A. Umm -- produce currents? 12:01:48

Q. Vessel traffic? 12:01:50

A. Umm -- yes, I guess so on a very -- very small -- umm -- over a very small area, yeah, sure. 12:01:52 12:02:07

Q. How does ship traffic produce physical mixing processes? 12:02:10 12:02:13

A. Well, I guess the -- the prop wash, which we talked about before, the wave action generated by the bow wake. 12:02:14 12:02:17 12:02:24

Q. What is "prop wash"? 12:02:30

Is that a reference to a propeller? 12:02:32

A. Yes. 12:02:36

Q. And what is "wash from a propeller"? 12:02:36

A. "Wash" is the -- it's the pressure generated by the propeller that would be great enough to potentially stir up the -- surface layer sediments. 12:02:41 12:02:47 12:02:52

Q. And what is "bow wake" that you just referred to? 12:02:57 12:03:02

A. Umm -- when a surface vessel moves, it 12:03:03

generates a bow wake. Those waves can -- if they're large enough, they could stir up -- umm -- shallow sediments. 12:03:12 12:03:20 12:03:26

Q. Sorry to be asking you about concepts that may be obvious to you. 12:03:27 12:03:33

A. No. I just -- umm -- 12:03:34

Q. We're lawyers. Assume no pre-existing knowledge. 12:03:37 12:03:42

Well, thank you. 12:03:43

Can -- can anchors also produce physical disturbance? 12:03:47 12:03:49

A. Sure. Yes. 12:03:52

Q. And as part of -- of staff's preparation for adoption, did staff review the different bays around the state? 12:03:52 12:04:04 12:04:09

A. Yes. 12:04:12

Q. You wanted to look at the actual conditions where these SQOs would be implemented; correct? 12:04:13 12:04:18

A. Yes. 12:04:22

Q. And would apply; correct? 12:04:23

A. Yes. 12:04:24

Q. Could you turn to -- Chapter 3 of the Staff Report at page 21, 3-21? 12:04:25 12:04:33

First paragraph refers to San Diego Bay. 12:04:55

Do you see that -- on page 3-21? 12:04:59

A. Yes. 12:05:04

Q. And it's merely descriptive, it refers to the vessels moored in San Diego Bay; correct? 12:05:04 12:05:08

A. Yes. 12:05:12

Q. Up to 9,000; right? 12:05:16

A. Uh-huh. 12:05:20

Q. Yes? 12:05:21

A. Yes. 12:05:21

Q. And it refers to four major U.S. Navy bases; correct? 12:05:21 12:05:26

A. Yes. 12:05:26

Q. With approximately 80 surface ships and submarines; right? 12:05:26 12:05:30

A. Correct. 12:05:31

Q. And this was included in the Staff Report because of the potential for -- for, I imagine, contamination from these potential sources; right? 12:05:32 12:05:34 12:05:42

A. Umm -- I think it was broader. 12:05:45

Q. In what sense? 12:06:00

A. Umm -- to describe the overall use of the bay or what kind of -- bay, but -- 12:06:02 12:06:08

Yeah, I mean, the purpose of this is to get at -- umm -- potential problems. 12:06:13 12:06:19

Q. Would potential problems include potential confounding factors? 12:06:25 12:06:30

A. Sure. 12:06:31

Q. And vessel traffic can produce these phenomena 12:06:32
that you've described; right? 12:06:39

A. Under specific conditions, right. 12:06:41

Q. Prop wash; right? 12:06:45

A. Right. 12:06:47

Q. Bow wake; right? 12:06:47

A. Right.

Q. Physical disturbance of the bottom sediment; 12:06:49
right? 12:06:53

A. Right. 12:06:53

Q. Relative to other bays does San Diego have a 12:06:54
high level of vessel traffic? 12:07:01

MR. FUCHS: Lacks foundation, calls for 12:07:03
speculation and outside the scope. 12:07:05

I guess it's not particularly material, so you 12:07:14
might as well answer -- if you know. 12:07:18

THE WITNESS: Relative to what? 12:07:20

BY MR. SINGARELLA: 12:07:24

Q. Well, to the other bays that are discussed in 12:07:25
the Staff Report. 12:07:29

A. Umm -- I guess it's in the top three of 12:07:31
California. 12:07:53

Q. Okay. 12:07:53

A. I mean, -- 12:07:54

Q. Sure. 12:07:54

A. -- I think that's true to the best of my knowledge. 12:07:55 12:07:57

Q. Uh-huh. 12:07:57

I just didn't see any other description that had quite an impressive number of boats that were referred to. 12:08:03 12:08:06 12:08:10

A. To -- 12:08:11

Well -- okay. 12:08:12

Q. Seemed that that was relevant to staff, they included this information; correct? 12:08:19 12:08:26

A. I don't remember why I included that information, to be honest with you, or where -- what the source was. 12:08:31 12:08:33 12:08:36

Q. Fair enough. 12:08:38

Let's turn to Staff Report 5-6. 12:08:45

Now, the bottom of that page in the Staff Report just before the bullets refers to the "optimal sediment receptor." 12:08:57 12:09:06 12:09:10

Do you see that? 12:09:12

A. Can you repeat that once more, 5-6? 12:09:13

Q. Sure, 5-6 just above the bullets. 12:09:17

A. Oh, okay. 12:09:21

Q. "Benthic communities are recognized;" correct? 12:09:22

A. Yes. 12:09:29

Q. "As the optimal sediment receptor;" right? 12:09:30
A. Yes. 12:09:33
Q. What does that mean? 12:09:33
A. They exhibit characteristics that make them -- 12:09:37
umm -- an ideal indicator. 12:09:56
Umm -- they are ecologically important. 12:10:02
They are relatively sessile or exhibit for the 12:10:11
most part little movement. 12:10:21
Umm -- they live for long periods of time. 12:10:28
Umm -- they've been demonstrated to be 12:10:36
sensitive. 12:10:45
Umm -- and they are -- umm -- measurable in 12:10:45
terms of community composition and community health. 12:10:57
Q. And what does it mean that they're optimal? 12:11:02
A. Well, I guess what it means -- umm -- is that 12:11:07
there are -- umm -- there are a whole slough of 12:11:12
receptors out there that one could choose, but for 12:11:21
various reasons -- umm -- they're not considered as 12:11:25
reliable. 12:11:34
I guess the -- umm -- the example given is 12:11:37
aquatic plants. 12:11:46
Q. Aquatic plants? 12:11:47
A. Yeah. 12:11:51
If you read the -- the paragraph above, that's 12:11:53
an example of -- another receptor that you could apply, 12:11:58

but for various factors it wouldn't be optimal. 12:12:05

Q. And by "receptor," what does that term refer to? 12:12:13 12:12:16

A. "Receptor" is -- umm -- an organism that you've identified that's potentially at risk of exposure for the problem or the release that you're trying to address. 12:12:16 12:12:26 12:12:35 12:12:42

So I guess for sediment quality an improbable receptor would be a bear or a beaver. 12:12:44 12:12:52

Other receptors could be fish, could be humans that consume fish, could be wetland birds, marine -- or marine mammals. 12:13:00 12:13:04 12:13:12

Those are all receptors that are potentially exposed. 12:13:15 12:13:18

Q. And in which line of evidence is information about the benthic community explicitly used? 12:13:19 12:13:23

A. The -- the benthic community Line of Evidence. 12:13:27

Q. With the four indices? 12:13:40

A. Yes. 12:13:42

Q. So those -- those four indices relate to the optimal sediment receptor; correct? 12:13:43 12:13:54

A. Yes. 12:13:57

Q. Let me ask you a question on page 5-4 related to the "biologically active layer." 12:13:58 12:14:06

Are you familiar with that term? 12:14:09

A. Yes. 12:14:11

But you referred to a page? 12:14:12

Q. Yes, page 5-4, two pages prior. 12:14:14

A. Okay. 12:14:18

Q. Under Alternative 2, which was the staff recommendation, it refers to the "biologically active layer." 12:14:18 12:14:23 12:14:26

Do you see that? 12:14:27

A. Oh. 12:14:28

MR. FUCHS: Alternative 2 up at the top, not at the bottom. 12:14:32 12:14:35

THE WITNESS: Oh, oh, oh. 12:14:36

MR. SINGARELLA: Thank you, Dan. 12:14:38

THE WITNESS: I've got to get rid of this. 12:14:44

Yes, I see that. 12:14:49

BY MR. SINGARELLA: 12:14:50

Q. And it's referring to the tools; right? 12:14:51

A. Correct. 12:15:00

Q. That have been developed; right? 12:15:01

A. Correct. 12:15:03

Q. And is that a reference to Part 1? 12:15:03

A. Umm -- I'd have to read the previous page. 12:15:08

Q. Okay. Please -- please do. 12:15:15

A. Yes, you're correct. 12:15:54

Q. Thank you. 12:15:57

And I appreciate your patience working with me, Mr. Beegan, to get clarity on -- on these questions. 12:15:58 12:16:01

So Alternative 2 says, in essence, that -- that Part 1 has been developed solely to assess this biologically active layer; correct? 12:16:05 12:16:11 12:16:17

A. Correct. 12:16:19

Q. None other than that particular layer; correct? 12:16:20 12:16:23

A. Correct. 12:16:23

Q. And please tell me how the biologically active layer is defined spatially. 12:16:23 12:16:28

A. The biologically active layer is the active layer where most of the -- the benthic community resides in. 12:16:36 12:16:39 12:16:51

Q. Is there a depth of it that's relevant to Part 1? 12:16:51 12:16:57

A. Well, I think we've defined sufficient sediments -- in Part 1. 12:16:57 12:17:02

Q. As being what? 12:17:06

A. Oh. It may have even been in the Staff Report, but I think -- 12:17:07 12:17:15

Q. Page 22 -- of Exhibit 6? 12:17:25

A. Yes. Umm -- page 22 of Part 1, those sediments represent the most recent depositional materials and contain the majority of benthic 12:17:34 12:17:45 12:17:50

invertebrate community. 12:17:53

Q. Is there an understanding as to the 12:17:53

characteristic depth of that layer? 12:17:55

A. Umm -- for the purposes of applying the 12:17:59

multiple Lines of Evidence, there are criteria for -- 12:18:01

umm -- collecting samples, and I believe that is 12:18:07

contained in another section within Part 1. 12:18:11

Q. Let's see if we can -- if you can find it, 12:18:18

Mr. Beegan. 12:18:25

A. Field procedures? 12:18:26

Umm -- Part 5(d) -- umm -- Part 5(d) -- umm -- 12:18:29

4 -- or 3. 12:18:44

Yeah, upper five centimeters of sediment. 12:18:49

Q. About two inches; is that right? 12:18:55

A. Yes. 12:18:58

Q. And the -- the Part 1 doesn't assess the need 12:18:58

to do any cleanup below the top two inches; right? 12:19:13

A. Part 1 doesn't -- doesn't -- umm -- doesn't 12:19:20

require the assessment of deeper samples off the bat. 12:19:39

Q. After application of the MLOE in Section 5, do 12:19:49

you have information relevant to the quality of the 12:20:04

sediment below that top five centimeters? 12:20:09

A. No. 12:20:12

Q. When it comes to management actions, are you 12:20:13

aware of -- of management actions that can actually 12:20:25

address just the top two inches of sediment? 12:20:30

A. You're -- it's hard to understand. 12:20:33

Where the -- 12:21:03

Are you saying where contamination only or the -- the stressor only extends two-and-a-half inches? 12:21:04 12:21:07

Is that what you're asking, would that happen? 12:21:12

I -- 12:21:17

Q. No, no. 12:21:17

A. Does it limit? 12:21:18

Q. Are their techniques to just get at the two inches from a cleanup perspective -- if you know? 12:21:20 12:21:24

A. I don't know. I don't know. 12:21:34

Q. Okay. All right. 12:21:36

Can you turn to page 5-7, please. 12:21:37

A. 5-7. 12:21:42

Q. Second bullet back to benthic communities, there's a reference to benthic communities being an in-situ measure of actual conditions and biological effects that are or have occurred." 12:21:45 12:21:49 12:21:54 12:21:57

Do you see that? 12:22:00

A. Yeah. 12:22:00

Q. What does that mean, "in-situ measure," i-n hyphen s-i-t-u? 12:22:01 12:22:09

A. It's a -- umm -- in place -- umm -- measure of sediment quality, unlike other measures. 12:22:09 12:22:19

A laboratory method, that would not be in-situ. In-situ is in place -- umm -- undisturbed -- umm -- 12:22:26 12:22:34 12:22:41

Is that the part that you were having a question on? 12:22:46 12:22:49

Q. Yes. 12:22:49

A. Okay. 12:22:50

Q. And these other measures are, at best, surrogate measures; is that right? 12:22:50 12:22:58

A. Umm -- yes. 12:23:00

Q. What is meant by the word "surrogate" in that context? 12:23:02 12:23:06

A. Umm -- a -- umm -- an indicator that is applied to assess a particular in this case exposure where a more representative tool -- umm -- can't be developed or -- umm -- it was -- umm -- 12:23:07 12:23:26 12:23:36 12:23:49

A "surrogate tool" is a tool that you can interpret, but it only provides a secondary -- umm -- information -- or it's not considered as precise or accurate. 12:23:56 12:23:59 12:24:07 12:24:11

Q. Can you give me an example of a surrogate measure? 12:24:13 12:24:16

A. Umm -- off the top of my head, no. 12:24:17

There's plenty -- 12:24:28

Oh, how about temperature? 12:24:30

Q. How about it? 12:24:35
A. Okay. 12:24:36
Q. Why is that a surrogate? 12:24:36
A. Well, I mean -- umm -- if you have a -- if you're running -- if the human body is running hot, it means you're sick, but that's about all it tells you, yet there is probably -- there's probably -- it -- it helps, but the doctor would need more information -- umm -- to -- umm -- to determine what the true problem is, or to decide whether you're really sick or -- 12:24:39 12:24:46 12:24:51 12:24:54 12:24:58 12:25:04 12:25:07
I think that's a surrogate. 12:25:11
Q. But the benthic communities are a measure of the actual condition of what's actually happening in the sediment; right? 12:25:12 12:25:22 12:25:25
A. Yes. Yes. Yes. 12:25:26
Q. And it's desirable because of that? 12:25:30
A. It's desirable for several reasons. 12:25:33
That's one of them. 12:25:36
Q. And its an in place measure of the actual biological effects that are happening; right? 12:25:37 12:25:44
A. Yes. 12:25:46
Q. And in the next bullet there's a reference to "sublethal toxic effects." 12:25:46 12:25:53
Do you see that? 12:25:56
A. Uh-huh. 12:25:56

Q. And there's a reference to how those types of effects can cause subtle changes in community structure. 12:25:57 12:26:03

Do you see that? 12:26:07

A. Uh-huh. 12:26:09

Q. Is that one of the reasons that Part 1 includes a sublethal toxicity test? 12:26:10 12:26:15

A. Umm -- no. 12:26:19

I mean -- umm -- that's not the -- umm -- main reason. 12:26:32 12:26:39

The sublethal toxicity tests were included with the acute to -- because they represent different organisms, different exposures, and were thought to potentially respond to -- umm -- exposures that may not be picked up with the benthic community indices. 12:26:47 12:26:53 12:26:57 12:27:03 12:27:12

Q. So is the converse true, that a good community structure would suggest the absence of sublethal toxic effects? 12:27:16 12:27:21 12:27:25

A. Not necessarily. 12:27:25

I guess the -- umm -- the individual Lines of Evidence may -- umm -- have various strengths and weaknesses, which is going back to the reason why we're using multiple Lines of Evidence. 12:27:33 12:27:40 12:27:52 12:27:57

If one of these indicators was clearly better than the others, we would have gone with that one -- or we would have gone with one. 12:28:01 12:28:07 12:28:15

Q. You agree that the benthic index is -- 12:28:18

Strike that. 12:28:26

You agree that -- that the Line of Evidence 12:28:27

based on benthic community structure is the ultimate 12:28:30

endpoint; right? 12:28:34

A. It's the ultimate endpoint in relationship to 12:28:35

the Narrative Objective that protects the communities, 12:28:40

but that doesn't necessarily mean it's -- can't be 12:28:47

confounded or -- is necessarily the most precise. 12:28:51

Q. It's -- 12:29:00

Because it's the ultimate endpoint it's given 12:29:04

greater weight in the assessment; right? 12:29:08

A. It is given -- umm -- yes. 12:29:10

Yes. 12:29:15

MR. SINGARELLA: Turn -- 12:29:26

Well -- I'm sorry. 12:29:27

Did the food show up already? 12:29:29

MR. RICHARDSON: Yes.

MR. SINGARELLA: Well, know what? 12:29:32

12:30, you know, say you break at 12:00 or 12:29:33

12:30, shall we go off the record now, Mr. Beegan, or -- 12:29:38

THE WITNESS: I mean, that's up to you guys. 12:29:41

I can keep going if you want. 12:29:42

MR. SINGARELLA: Okay. You want to go until 12:29:44

-- we'll try another 15 -- 12:29:46

THE WITNESS: Sure. 12:29:47

MR. SINGARELLA: -- to 30 minutes? 12:29:48

THE WITNESS: Sure. 12:29:50

MR. SINGARELLA: I don't think the food is going to rot. 12:29:51 12:29:53

BY MR. SINGARELLA: 12:29:54

Q. Okay. Turning to 5-9, please -- third full paragraph refers to the "limited utility of sediment -- as a result of the factors described above"? 12:30:00 12:30:12 12:30:18

A. Okay. 12:30:21

Q. And it refers to "the limited utility of sediment quality indicators based on concentrations in sediment." 12:30:21 12:30:26 12:30:31

Do you see that? 12:30:31

A. Yes. 12:30:32

Q. And that's referring to constituent concentrations of chemicals in sediment; right? 12:30:32 12:30:34

A. Correct. 12:30:37

Q. And to what extent do those chemical concentrations have limited utility? 12:30:38 12:30:43

A. Umm -- I think we went over a lot of that earlier this morning. 12:30:46 12:30:54

We talked about the different factors affecting the empirical -- empirical guidelines. 12:30:55 12:30:57

Umm -- they're -- they're unreliable as 12:31:03

stand-alone indicators. 12:31:15

Q. And to what extent should their use be limited? 12:31:18 12:31:23

A. Umm -- the empirical guidelines uses should be limited to the -- umm -- assessment of chemical mixtures, to evaluate the potential for -- umm -- pollutant-associated effects. 12:31:23 12:31:30 12:31:39 12:31:48

I wouldn't go much further than that. 12:31:55

Q. Uh-huh. 12:31:57

And then in the next paragraph there's a reference to "the potential flaws of the other Lines of Evidence." 12:31:59 12:32:03 12:32:08

Do you see that? 12:32:08

A. Uh-huh. 12:32:09

Q. And you agree that the other Lines of Evidence have potential flaws? 12:32:12 12:32:16

A. Yes. 12:32:19

Q. And then further down in that paragraph there's a reference to "the hierarchal response scheme." 12:32:21 12:32:26

Do you see that? 12:32:35

A. Is that still on 5-9? 12:32:36

Q. 5-9, yeah. 12:32:38

A. Yes. Okay. 12:32:41

Q. What is the "hierarchal response scheme" referred to in that paragraph? 12:32:42 12:32:45

A. Umm -- it -- umm -- it's a scheme that basically breaks down this concept where effects will occur first at the cellular level within an organism and then they'll affect the whole organism, and then they'll affect the community. 12:32:47 12:32:54 12:33:04 12:33:11 12:33:18

So -- okay. 12:33:25

Basically it describes it in there. 12:33:37

Q. And this paragraph refers to that scheme as a "paradigm;" correct? 12:33:39 12:33:46

A. Umm -- right. 12:33:47

I guess that paragraph was included because some had made an argument that valued the toxicity test more so than benthic community indicator, and I guess ideally following that paradigm you would think it would be true, but it's not, and -- umm -- this sediment quality assessment -- because there's just too much -- umm -- uncertainty within our -- our variability than these individual lines. 12:33:53 12:33:57 12:34:07 12:34:16 12:34:19 12:34:26 12:34:31 12:34:38

Q. And is this the paradigm that was the understanding that led to development of water quality standards for the water column? 12:34:39 12:34:49 12:34:54

A. Umm -- 12:35:01

MR. FUCHS: Lacks foundation. Calls for speculation. 12:35:03 12:35:04

BY MR. SINGARELLA: 12:35:05

Q. Well, let's look at the paragraph. 12:35:06

It indicates that that paradigm formed the 12:35:08

basis for water quality control. 12:35:12

Do you see that, Mr. Beegan? 12:35:14

A. Should I go ahead? 12:35:16

MR. FUCHS: He's referring to a particular 12:35:18

sentence. 12:35:19

MR. SINGARELLA: Yeah. I'll just try it right 12:35:20

in to this sentence here to address Mr. Fuchs' 12:35:22

objection. 12:35:25

I'm only trying to understand this paragraph. 12:35:25

THE WITNESS: Okay. 12:35:28

BY MR. SINGARELLA: 12:35:28

Q. So this paragraph refers to water quality 12:35:29

control. 12:35:32

I was trying to get to the bottom of it, and I 12:35:33

thought that what you were referring to here is the use 12:35:36

of this paradigm to form, you know, water quality 12:35:39

standards. 12:35:44

A. Yes. 12:35:47

Q. And was your copper example from the other 12:35:48

exhibit -- was that the type of analysis you do in this 12:35:55

paradigm, compare concentrations versus some biological 12:36:00

endpoint -- 12:36:04

A. Yes. 12:36:05

Q. -- and relationship? 12:36:06

A. Yes. 12:36:08

Q. Here it says that that particular paradigm has never been proved in sediments. 12:36:08 12:36:14

Do you see that? 12:36:16

A. Right. 12:36:17

Q. And that's a reference to Griffith, et al., 2008; right? 12:36:17 12:36:22

A. Yes. 12:36:23

Q. An obscuring of the differences between methods. 12:36:24 12:36:33

Do you see that? 12:36:34

A. Yes. 12:36:34

Q. What does that refer to? 12:36:34

A. I -- umm -- I think what it means is that with the -- these many confounding factors, or variability between tests, or -- umm -- variability within results we can't tease out the -- or we -- we -- we can't come to a conclusion that the -- umm -- the toxicity test, the organism test, is more sensitive than the community tests. 12:36:36 12:36:42 12:36:48 12:36:55 12:37:03 12:37:09 12:37:14

Q. Yet in the water quality control situation the application of this paradigm leads to knowledge of dose versus response; correct? 12:37:15 12:37:23 12:37:26

A. Yes, the toxicity-spiked water column 12:37:28

bioassays have been used -- have been relied on for the development of water quality criteria. 12:37:38 12:37:44

Q. In the specification of the dose response relationship; correct? 12:37:47 12:37:49

A. Yes. 12:37:50

Q. And here at the end of this paragraph it refers to a number of factors weaken this relationship. 12:37:51 12:37:55

Do you see that? 12:37:59

A. Yes. 12:38:00

Q. And that's a reference to the sediment context; correct? 12:38:01 12:38:08

A. I believe so, yes. 12:38:08

Q. And so the first bullet under "Weaknesses" refers to different sensitivities to different contaminants. 12:38:10 12:38:18 12:38:23

Do you see that? 12:38:24

A. Yes. 12:38:26

Q. And what is -- what does that mean? 12:38:27

Relevant to test species. 12:38:31

A. Umm -- different organisms will respond differently to -- umm -- contaminants. 12:38:44 12:38:48

Q. And how is that -- how is that a weakness? 12:38:54

A. Well, I guess -- umm -- it's a weakness because you -- there's no such thing as an all-encompassing sensitive organism, that is, most 12:39:04 12:39:33 12:39:37

sensitive that you could apply to be kind of your -- your primary sentinel organism for -- establishing a level that would necessarily be protective of all other benthic communities. 12:39:50 12:39:53 12:40:04 12:40:11

Q. None of the animals used in the sediment toxicity Line of Evidence are -- are such all-encompassing organisms? 12:40:19 12:40:22 12:40:25

A. No. 12:40:27

Q. Those are traditional test species; right? 12:40:30

A. They're traditional test species that were selected because of various criteria, one of which was sensitivity, but, as I said before -- umm -- none of those species is going to represent all potential -- umm -- contaminant-type exposures in the sediment. 12:40:36 12:40:40 12:40:46 12:40:51 12:41:01

Umm -- feeding strategies -- umm -- metabolism -- umm -- all those factors which affect an organism's specific response. 12:41:07 12:41:14 12:41:19

So -- 12:41:20

Q. Do they come from the site? 12:41:22

A. No. 12:41:24

Q. Where do they come from? 12:41:25

A. Umm -- suppliers. 12:41:26

Are you talking about the laboratory test organisms? 12:41:34 12:41:38

Q. Yes. 12:41:39

A. Yeah. 12:41:40

Some -- I believe most of them come from 12:41:40

suppliers. Some may be -- 12:41:43

Yeah, they all -- I think all of them come 12:41:46

from suppliers. 12:41:49

Q. What do you mean by a "supplier"? 12:41:52

A. I think there are -- there are -- umm -- 12:41:54

companies out there that grow, collect test organisms 12:42:02

for the purposes of -- umm -- performing bioassays, 12:42:10

sediment bioassays. 12:42:19

Q. So the test species are not taken from the 12:42:22

in-situ benthic community? 12:42:27

A. Right. 12:42:28

Q. In that sense are they a surrogate? 12:42:29

A. Yes. 12:42:34

Q. Is sediment toxicity a surrogate measure for 12:42:35

the benthic community? 12:42:43

A. Umm -- at one time I believe it was thought to 12:42:44

be. 12:42:54

Now it's thought to be a -- umm -- a test that 12:42:54

-- umm -- isn't -- it's not intended to be a surrogate. 12:43:08

It's intended to measure -- umm -- 12:43:15

invertebrate response under a specific set of controlled 12:43:20

conditions, and that information is -- umm -- different 12:43:26

than what you get when you collect a benthic community 12:43:35

grab. 12:43:40

Q. If the test species is harmed in the lab test, does that mean that the benthic community at the site is harmed? 12:43:41 12:43:44 12:43:48

A. Not necessarily. 12:43:48

Q. Those test species may not even be present at the site; right? 12:43:49 12:43:55

A. May not be. 12:43:55

Q. On page 5-10, next page, Mr. Beegan, there's three more bullets. 12:43:56 12:44:01

I'd like to turn your attention to the last bullet, the "presence of natural factors." 12:44:02 12:44:05

Do you see that? 12:44:07

A. I'm sorry? 12:44:09

What -- "presence of --" 12:44:11

Yeah, sure. 12:44:13

Q. And that refers to "spurious results." 12:44:13

Do you see that? 12:44:19

A. Yes. 12:44:19

Q. How can the presence of natural factors produce spurious results? 12:44:20 12:44:25

A. I think we discussed that earlier under -- when we were talking about the water quality control plan. 12:44:27 12:44:34 12:44:36

We discussed confounding factors at length. 12:44:37

It's basically discussing -- it's the same thing, same concept. 12:44:43 12:44:46

Q. I think you had mentioned nutrients as a potential confounding factor; right? 12:44:47 12:44:51

A. Yes. 12:44:54

Q. Is ammonia one of the nutrients you had in mind? 12:44:54 12:44:58

A. Yes. 12:44:58

Q. Is hydrogen sulfide a confounding factor? 12:44:58

A. Potentially. 12:45:05

Q. What does "physical abrasion" mean? 12:45:06

A. Ooh. That's a good question. 12:45:09

Q. I'm glad I asked. 12:45:11

A. Yeah. 12:45:15

Scour? 12:45:18

I -- that's -- that's -- seems -- I -- would assume that that is referring to scour. 12:45:18 12:45:25

Q. And in what sense would the results be spurious? 12:45:30 12:45:36

A. Umm -- they would be -- umm -- the results would -- umm -- could potentially mislead you. 12:45:37 12:45:44

The results could be misinterpreted. 12:45:53

Q. And this is a weakness of the sediment toxicity line? 12:45:55 12:46:00

A. Umm -- yes. 12:46:00

Q. And why the hierarchal response scheme and a paradigm don't -- don't fit well in the sediment toxicity context? 12:46:09 12:46:16 12:46:22

A. Umm -- it doesn't fit well when you're trying to rank -- umm -- indicators and their importance in an assessment framework -- so subtle difference there. 12:46:23 12:46:30 12:46:39

Q. The bullet just above that "Toxicity tests do not mimic the sediment structure" and other things, do you see that? 12:46:46 12:46:52 12:46:56

A. Yes. 12:46:56

Q. What does that mean? 12:46:56

A. The -- umm -- toxicity tests are performed on disturbed samples. 12:46:58 12:47:04

By "disturbance" I mean when you take your benthic grab, structure the -- the way the sediments are layered, all that is disturbed when you take the grab. 12:47:08 12:47:11 12:47:20

Umm -- all the conditions that the benthic community are exposed to are based on that naturally occurring structure. 12:47:35 12:47:38 12:47:43

So the point in this bullet is that it's a disturbed sample, therefore, conditions in your toxicity test do not mimic those found in the -- umm -- natural surficial sediments. 12:47:43 12:47:46 12:47:52 12:48:01

Q. How can one ensure that the lab test is representative of the field condition? 12:48:02 12:48:05

A. Umm -- that's pretty difficult to accomplish in the lab. 12:48:07 12:48:19

Q. So is this weakness that disturbed sediment tested in the lab may not be representative of the field condition? 12:48:20 12:48:26 12:48:29

A. Yes. 12:48:30

Q. And, in fact, that's proven to be the case; right? 12:48:30 12:48:39

A. Yes. 12:48:39

MR. SINGARELLA: What I would like to do, Mr. Beegan, is when we get back from our sandwich break I've prepared a grossly over-simplified example of the MLOE, and I don't think we need to spend a lot of time on it, but I just want to make sure through this simple example that we understand how it works. 12:48:52 12:48:54 12:49:01 12:49:05 12:49:09 12:49:12

So I'm going to have it marked, and I'll put it in now, and we can -- we can discuss it after our break. 12:49:15 12:49:17 12:49:21

(Exhibit 705 was marked for Identification.) 12:49:22

MR. SINGARELLA: 705? 12:49:29

THE REPORTER: Correct. 12:49:30

MR. SINGARELLA: This is an attempt to honor the time honored principle, keep it simple. 12:49:53 12:49:55

THE WITNESS: Okay. 12:50:00

BY MR. SINGARELLA: 12:50:00

Q. I've placed in front of you what has been marked as Exhibit Number 705 to your deposition. 12:50:01 12:50:03

Do you see that? 12:50:07

A. Yes. 12:50:08

Q. This is a document that we prepared, Mr. Beegan. 12:50:08 12:50:11

Do you understand that? 12:50:13

A. Yes. 12:50:14

Q. And I simply want to ask you a few questions about it after our lunch break; is that okay? 12:50:15 12:50:17

A. Okay. 12:50:20

MR. SINGARELLA: Okay. I suggest we go off the record now, if that's okay with everyone. 12:50:24 12:50:26

VIDEOGRAPHER: We're going off the record at 12:50 p.m. 12:50:29 12:50:32

(Thereupon a recess was taken at 12:50 p.m. and the deposition resumed at 1:31 p.m.) 12:50:33 13:31:19

VIDEOGRAPHER: We are back on the record at 1:31 p.m. 13:31:19 13:31:22

BY MR. SINGARELLA: 13:31:23

Q. Mr. Beegan, good afternoon. 13:31:24

Before lunch I placed in front of you what has been marked as Exhibit Number 75 -- excuse me -- Exhibit Number 705 to your deposition. 13:31:26 13:31:29 13:31:34

Do you see that? 13:31:36

A. Yes. 13:31:36

Q. And I'm wondering if you can indulge me just 13:31:37
for a few minutes to make sure we understand how to work 13:31:41
through the MLOE. 13:31:44

Is that okay? 13:31:46

A. Okay. 13:31:46

Q. And you'll see that by coincidence we ended up 13:31:46
with a sediment toxicity example that is very similar to 13:31:50
the one we discussed this morning, using the 13:31:54
Eohaustorius and Mytilus. 13:32:01

Do you see that? 13:32:01

A. Uh-huh. 13:32:02

Q. Could you confirm that if you use values of 92 13:32:03
percent for survival and 80 percent for the sublethal 13:32:08
effect you end up with a result of nontoxic for the 13:32:14
sediment LOE? 13:32:18

A. Okay. Yes. I confirm. 13:32:19

Q. Thank you. 13:33:00

And how did you get to your conclusion? 13:33:01

A. Well, I made -- I looked at -- umm -- Table 4. 13:33:03

I looked at the -- Eohaustorius survival. 13:33:11

I made an assumption that there was 13:33:20
statistical difference -- statistical significance. 13:33:29

I went to the -- the row that was 90 to a 13:33:34
hundred, and I did the same for -- umm -- Mytilus 13:33:40

Normal. 13:33:53

Q. Okay. Thank you. 13:33:53

Now, moving to the benthic line, and with 13:33:54

reference to Exhibit 705, and Table 5 and Part 1, which 13:34:02

is on page 7, do you agree that the four values in 13:34:11

Exhibit 705 for BIR, IBI, RBI, and RIVPACs produce a 13:34:20

result using Table 5 of low disturbance? 13:34:29

A. Correct. 13:34:33

Q. And how did you reach that conclusion, sir? 13:34:33

A. I prepared an index value to the numbers 13:34:36

listed in the rows, and all four of the values were -- 13:34:40

values for each index fall in to the range -- umm -- 13:34:50

characterized as low disturbance in the Table 5 benthic 13:34:56

index categorization values. 13:35:00

Q. As you can see from Exhibit 705, the next step 13:35:03

in the illustration which we furnished you is to turn to 13:35:07

Table 9. 13:35:11

Do you see that? 13:35:12

Do you see that on Exhibit 705? 13:35:21

A. Yes. Yes. 13:35:23

Q. Is that an appropriate next step? 13:35:24

A. Let's see. 13:35:26

Yes. 13:35:30

Q. And did we use Table 9 correctly, taking the 13:35:44

value of sediment toxicity or the category of nontoxic 13:35:50

and the benthic category of low disturbance to determine 13:35:55
based on Table 9 that the severity of biological effects 13:35:59
is unaffected? 13:36:04
A. Yes. 13:36:05
Q. And how did you reach that conclusion? 13:36:06
A. Umm -- the Table 9 has -- umm -- toxicity 13:36:11
categories horizontally, going across the top, and the 13:36:23
benthic community condition categories vertically on the 13:36:32
right. 13:36:39
So you align your nontoxic -- or you identify 13:36:40
the nontoxic category for toxicity where it meets the 13:36:48
low disturbance category for Benthos. 13:36:54
There's an easier way in the back, but -- this 13:37:01
is -- follows the conceptual approach. 13:37:04
Q. Just for purposes of being complete, what is 13:37:09
the easier way in the back, sir? 13:37:12
A. It -- it -- it uses Attachment B where you 13:37:14
basically start with bullet -- 13:37:19
Umm -- it has each -- 13:37:25
It's not necessarily simpler. It results in 13:37:34
the same thing. Some people find Attachment B simpler 13:37:38
to use. 13:37:42
In this case there -- one LOE is held constant 13:37:44
while you run through all the other potential categories 13:37:52
for the other Lines of Evidence. 13:37:56

It's just a different way of resulting -- coming up with the same result. 13:38:00 13:38:05

Again, it was provided because some people thought that that would be easier. 13:38:07 13:38:10

Q. Thank you. 13:38:12

In our example, Exhibit 705, we next proceeded to Table 10. 13:38:12 13:38:18

Is that an appropriate next step? 13:38:20

A. I'm sorry. 13:38:23

Table 10? 13:38:26

Proceeding to Table 10? 13:38:27

Q. Yes. 13:38:29

A. Let me get there. 13:38:30

Yes. 13:38:31

Table 10 is the next one. 13:38:38

Q. And there we combined our assumption of high exposure for sediment chemistry with our conclusion of low disturbance for the benthic, which we -- we think results in a moderate potential. 13:38:40 13:38:45 13:38:48 13:38:56

Do you agree with that? 13:38:58

A. Let's see. 13:39:03

Exposure on the chemistry side? 13:39:04

And low disturbance on the -- 13:39:09

Yes, I agree. 13:39:43

You're -- you're -- I think used the term 13:39:46

"benthos" in there, and that was confusing. 13:39:50

Q. Is there a better term? 13:39:52

A. Well, I think we're at -- we're on Table 10, which is chemistry and toxicity, so I think you were confused with the previous table that was toxin benthos. 13:39:54 13:39:57 13:40:01

Q. Yes, Table 10. 13:40:07

A. Sediment toxicity plus chemistry. 13:40:12

Q. Yes. Thank you. 13:40:19

So is our formula -- 13:40:21

A. Yeah, so far it seems fine. 13:40:28

Q. But under "chemically mediated" we're combining -- 13:40:30 13:40:33

A. Sediment toxicity and chemistry. 13:40:34

Q. And the chemistry is high exposure but the sediment toxicity is nontoxic; right? 13:40:37 13:40:44

A. It's low disturbance; right? 13:40:47

How did we -- 13:40:50

I think there's an error in there. 13:40:51

Q. There may be. I want to explore that with you. 13:40:52 13:40:55

A. Okay. Unless -- 13:40:55

Q. This is why I wanted to go through an example. 13:40:56

This is a surprise to me if there is? 13:40:59

A. Wait. 13:41:01

Chemistry -- nontoxic -- 13:41:03

So that would be nontoxic and -- high exposure -- 13:41:06

Oh, oh okay. So maybe they -- umm -- used the wrong -- umm -- that could be a typo. 13:41:09 13:41:13 13:41:17

Q. Referring to? 13:41:21

A. "Low disturbance." 13:41:23

Q. Yes. That should say "nontoxic." 13:41:25

Do you agree? 13:41:28

A. Yes. 13:41:29

Q. Could you -- could you make that correction? 13:41:29

A. Oh, yeah. I am. I am. 13:41:31

Q. Thank you. 13:41:32

A. I am. 13:41:33

Q. Thank you. 13:41:34

I think you were doing that in your head for us, but if -- 13:41:40 13:41:43

Do you agree that with -- with your correction -- 13:41:44 13:41:46

A. High exposure and nontoxic is -- umm -- 13:41:49

High exposure, nontoxic is moderate potential. 13:41:59

MR. SINGARELLA: Yes. 13:42:05

Thank you. 13:42:06

Let the record show that Mr. Beegan corrected our Exhibit 705 by changing the phrase "nondisturbance" to "nontoxic." 13:42:07 13:42:10 13:42:15

MR. FUCHS: "Low disturbance." 13:42:18

MR. SINGARELLA: By changing the phrase "low disturbance" to "nontoxic." 13:42:20 13:42:22

Thank you. 13:42:24

BY MR. SINGARELLA:

Q. And do you agree that the next appropriate step is to move on to Table 11? 13:42:25 13:42:29

A. Yes. 13:42:31

Q. And did we appropriately use Table 11 in light of the unaffected bioeffects and the moderate potential for chemically mediating effects? 13:42:32 13:42:40 13:42:44

A. Umm -- yes. 13:42:48

And you got -- umm -- likely unimpacted, which is what I get. 13:42:53 13:42:57

Q. Okay. Thank you. 13:42:59

Turning back to the benthic community condition on page 6 of Exhibit 6, Part 1 -- 13:43:01 13:43:10

So we're on page 6 of Part 1. 13:43:15

You were looking at Exhibit 705. 13:43:26

Is there any follow-up on it? 13:43:30

A. A -- no. 13:43:32

I was just -- umm -- no. 13:43:33

Q. Okay. But you agree that with your one correction, and thank you, that applying -- 13:43:35 13:43:40

A. Well, -- 13:43:45

Q. -- the MLOE properly? 13:43:46

A. I would probably -- umm -- 13:43:48

We -- umm -- 13:43:54

Yeah. Yeah, you are. 13:43:59

Yeah. Yeah. Yeah. Yeah. 13:44:00

Q. Thank you. 13:44:01

Okay. Under "Benthic Community Condition" on page 6 -- 13:44:02 13:44:08

A. Umm -- "Benthic Community Condition." Page 6. 13:44:08

Q. -- I didn't see anything in here that was similar to the averaging approach taken for sediment toxicity. 13:44:13 13:44:17 13:44:20

Am I missing something? 13:44:23

A. Oh. 13:44:25

Q. Is it -- is it this median approach in the bottom paragraph on page 6, "The median of all benthic index response categories shall determine"? 13:44:38 13:44:44 13:44:49

A. Yes. 13:44:51

Q. So in your own words how do you combine -- 13:44:52

A. Umm -- 13:44:58

Q. Sorry. 13:45:00

A. Oh, no. 13:45:01

I guess if there was more, please finish -- the question. 13:45:01 13:45:05

Q. In your own words how would you combine 13:45:06

multiple benthic condition results from the same station? 13:45:08 13:45:13

A. In -- umm -- in this case what -- umm -- you would assign a category to each -- each indicator, and you would take the median category and use that in the -- umm -- in the assessment. 13:45:14 13:45:30 13:45:41 13:45:49

Does that make sense? 13:45:54

Q. It does. 13:45:55

So let's take an example. 13:45:56

For -- let's just say RIVPACs. 13:45:59

If you had four replicates for a station, one turned out to be reference, one turned out to be low disturbance, one turned out to be moderate disturbance, and one turned out to be high disturbance. 13:46:02 13:46:06 13:46:09 13:46:14

Are you with me? 13:46:16

A. Yeah, that -- I'm with you. 13:46:17

But we were thinking of -- umm -- a sample where RIVPACs gives you low disturbance, RBI gives you low disturbance, IBI gives you the next highest one, and maybe -- umm -- BRI gives you low disturbance. 13:46:22 13:46:33 13:46:45 13:46:51

And the -- 13:46:57

Q. But before -- give me your example again, please. 13:47:00 13:47:03

A. Okay. 13:47:04

Q. So you would give me a situation where you 13:47:04

have four tests from one station? 13:47:10

A. You -- so at each -- 13:47:13

For each station you apply all four metrics; 13:47:17

right? 13:47:20

Q. Right. 13:47:21

A. Not all four -- 13:47:22

Unlike your example, the -- one -- 13:47:24

The indexes may provide you with a slightly 13:47:33

different -- or a different category. 13:47:37

So you could have a BRI saying its reference, 13:47:39

an IBI saying it's -- what's the next one up? Low 13:47:43

disturbance, the RBI saying it's reference, and RIVPAC 13:47:48

saying it's reference. 13:47:53

You would apply the median to those 13:47:54

categories. 13:47:59

Does that make sense? 13:47:59

Q. Yes. 13:48:01

And what would you get in that scenario? 13:48:01

A. In that scenario you would get a reference. 13:48:04

Q. Because you have three reference and one low 13:48:06

disturbance? 13:48:09

A. Yes. 13:48:10

That was why -- umm -- that was the intent of 13:48:13

G benthic community condition 4, to do -- umm -- to 13:48:22

integrate when you have -- or to -- to come up with your 13:48:30

final benthic community category when you have individual indexes that don't all match or don't all give you the same categorical response 13:48:37 13:48:42 13:48:47

Q. Can we return to my example? 13:48:49

A. Yeah. 13:48:55

Q. If you actually had the same result, three reference and one low disturbance, but it was for one of the benthic indices because you were doing replicates at a site, would you apply the same logic? 13:48:56 13:49:01 13:49:06 13:49:10

A. Umm -- not necessarily. 13:49:12

I'd have to think about that. 13:49:21

Again, -- 13:49:23

Q. Okay. 13:49:24

A. -- that was not the -- the -- the basis for that integration of benthic categories. 13:49:24 13:49:29

Integration of benthic categories, again, was -- was to be applied to a given sediment that you had collected benthic community information on, and then you applied these four -- umm -- tools, and in the case where you didn't just get low disturbance all the way down the line, you say, okay, take the median value. 13:49:33 13:49:36 13:49:42 13:49:46 13:49:54 13:49:57

Q. Thank you. 13:50:01

Question on page 7 regarding the California LRM: Is that limited to amphipods toxicity results and the correlation of those results to sediment chemistry? 13:50:02 13:50:07 13:50:20

A. I don't recall specifically which test organisms it relates to, but it does relate to toxicity test organism response to -- umm -- sediment chemistry. 13:50:26 13:50:37 13:50:43

Q. Do you recall what "test organisms CSI" relates to? 13:50:49 13:50:54

A. It doesn't relate to test organisms necessarily. It relates to benthic community health. 13:50:55 13:50:59

Q. Do you recall that the LRM approach does relate to sediment toxicity results? 13:51:04 13:51:10

A. Oh, yes. 13:51:14

I think -- umm -- yeah. 13:51:15

Q. But the CSI is actually linked to benthic community directly? 13:51:17 13:51:23

A. Yes. 13:51:24

Q. And so the CSI involves the available information on benthic community structure at a site; right? 13:51:24 13:51:33 13:51:37

A. The CSI related statewide sediment chemistry to -- benthic community response on -- umm -- on a regional or a statewide basis. 13:51:37 13:51:50 13:52:00

So -- relating it to a given site, that's not entirely accurate. 13:52:02 13:52:09

Q. I'm just trying to get behind the biological nexus on the CSI versus the LRM. 13:52:10 13:52:22

One seems to tie to benthic community 13:52:27

structure, the actual critters in-situ at CSI; right? 13:52:29

A. Right. 13:52:34

Q. And the LRM is not tied directly to the in-situ information; right? 13:52:35 13:52:39

A. Correct. 13:52:40

Q. It's tied to those laboratory tests that we talked about this -- earlier today? 13:52:41 13:52:46

A. Correct. 13:52:48

Q. And so it's tied to the response of test species to disturbed sediment in a laboratory condition? 13:52:48 13:52:54

A. Correct. 13:52:59

Q. What you're not sure of is which test species are used to build the LRM? 13:53:00 13:53:05

A. Right. I mean -- 13:53:08

Q. We can find it? 13:53:09

A. -- I'm sure it's in there -- somewhere. 13:53:11

Q. Yeah. 13:53:13

Let's turn back to this Staff Report, Mr. Beegan. 13:53:17 13:53:24

We were on page 5-10. 13:53:25

This is Exhibit 704. 13:53:31

We were at the top there after those bullets. 13:53:38

And first full paragraph, the "however" sentence -- 13:53:49 13:53:55

A. I'm sorry. 13:53:57

5-10? 13:53:59

Q. 5-10, the first full paragraph there after the bullets? 13:54:00 13:54:05

A. Oh. 13:54:05

Q. I want to talk about that paragraph. 13:54:06

A. Okay. 13:54:08

Q. And there's a "however" sentence refers to "their use alone is problematic"? 13:54:08 13:54:12

A. Right. 13:54:14

Q. What does "their use" refer to? 13:54:15

A. Oh, benthic community, -- 13:54:17

Q. Okay: 13:54:18

A. -- "their use," 13:54:19

Q. Okay. And it indicates that the benthic community can be potentially affected by a large number of factors other than chemical contamination; correct? 13:54:27 13:54:30 13:54:33

A. Uh-huh. 13:54:37

Q. And then the next sentence -- 13:54:37

A. Excuse me. 13:54:42

Q. Sure. 13:54:43

The next sentence indicates that "Without the other lines it's difficult to distinguish --" 13:54:44 13:54:47

Right? 13:54:50

A. Correct. 13:54:52

Q. "Whether degraded benthic communities resulted 13:54:53

from chemicals or something else;" right? 13:54:57

A. Uh-huh. Yes. 13:55:00

Q. So this seems to be a rational basis for using chemistry and toxicity data when the benthic community is degraded; correct? 13:55:01 13:55:10 13:55:16

A. Umm -- 13:55:17

Sure. 13:55:39

Q. I mean, there's a reference to "degraded benthic communities" right in this sentence; right? 13:55:40 13:55:43

A. Yes. 13:55:46

Q. And the notion is be careful not to assume that the degradation resulted from chemical exposure; right? 13:55:46 13:55:50 13:55:55

A. Correct. 13:55:55

Q. Because it might also result from all these other confounding factors; right? 13:55:55 13:55:58

A. Right. 13:56:00

Q. So that suggests not to use benthic community structure in isolation when the community structure suggests a problem; right? 13:56:01 13:56:07 13:56:11

A. Umm -- yes. 13:56:13

It's an example of a -- umm -- a weakness within the Line of Evidence. 13:56:18 13:56:24

Q. That weakness does not pertain to the situation where the benthic community is actually 13:56:25 13:56:31

healthy; right? 13:56:34

A. Umm -- that is not -- one hundred percent 13:56:35
accurate, and I guess what I'm going on is -- umm -- my 13:56:47
memory from various discussions we had in developing the 13:56:54
Lines of Evidence. 13:57:07

Umm -- we don't know with one hundred percent 13:57:10
certainty that -- umm -- our benthic community measures 13:57:18
are sensitive or measuring the right properties. 13:57:27

So there is some uncertainty in our model of 13:57:38
benthic community health, and -- umm -- therefore, the 13:57:47
-- the -- I think it was the Scientific Steering 13:58:00
Committee and -- was adamant that we not just use 13:58:04
benthic community by itself no matter what the situation 13:58:12
was. 13:58:17

Q. Okay. Fair enough. 13:58:17

But I'm speaking to this sentence itself. 13:58:23

A. Oh. Yeah. Yeah. Yeah. 13:58:26

Okay. Yeah. Yes. 13:58:27

Q. This sentence itself -- 13:58:28

A. Sure. 13:58:30

Q. Excuse me. 13:58:31

This sentence itself does not provide a 13:58:32
rational basis to use chemistry or toxicity data coupled 13:58:34
with benthic community data when the benthic community 13:58:39
is in a reference or healthy condition? 13:58:43

A. Yes, I would agree with that. 13:58:45

Q. Thank you. 13:58:47

And at the bottom of the page, which carries over to page 5-11, there's a discussion of the BPJ we discussed before. 13:58:48 13:58:59 13:59:04

Do you see that? 13:59:05

A. Uh-huh. Yes. 13:59:06

Q. And the carryover sentence says "BPJ will be ineffective for use in SQOs." 13:59:07 13:59:12

Do you see that? 13:59:15

A. Uh-huh. 13:59:16

Q. And why is BPJ ineffective for use in SQOs? 13:59:17

A. Umm -- one expert would make an assumption about which categories to apply to -- umm -- an individual Line of Evidence or even the selection of the Lines of Evidence or -- umm -- experts will do slightly different things or -- umm -- assess sediment differently. 13:59:25 13:59:48 13:59:55 13:59:59 14:00:11 14:00:21

They'll have different ideas. 14:00:23

They may interpret the data slightly differently, which could result in differences in, you know, how you would rank a site or prioritize a site -- umm -- in -- 14:00:27 14:00:31 14:00:40 14:00:48

That could happen between water bodies. It could happen between regions. 14:00:53 14:00:56

We are -- 14:00:58

Q. And the particular MLOE approach required by Part 1 is in part designed to deal with the ineffective use of BPJ; right? 14:01:15 14:01:26 14:01:35

A. Yes. It gets rid of some of the BPJ -- umm -- and it probably -- quite a bit of the BPJ in the assessment process, but there's -- in terms of sediment quality and management there's a whole slough of places where it doesn't address. 14:01:38 14:01:46 14:01:51 14:01:56 14:02:02

Q. And this Part 1, by the way, it's not some menu where sediment quality specialists can pick and choose that which they want to do; right? 14:02:06 14:02:10 14:02:15

A. Right. Correct. 14:02:17

Q. It is an attempt to prescribe a method; right? 14:02:18

A. Yeah, it prescribes a method. 14:02:22

It -- yeah. 14:02:26

It's -- 14:02:29

Yes. Yes. 14:02:31

I would agree with that. 14:02:32

Q. And so, if one were to take a different approach and pick and choose that which they wanted to do in your MLOE, would it introduce the subjectivity associated with the BPJ? 14:02:33 14:02:39 14:02:42 14:02:47

MR. FUCHS: Calls for speculation. 14:02:50

Lacks foundation. 14:02:52

You can go ahead and answer if you -- if you can provide an answer 14:02:56 14:02:58

THE WITNESS: Umm -- yes. 14:02:59

BY MR. SINGARELLA: 14:03:04

Q. Okay. On page 5-12 there's a discussion of these different alternatives for the form of the SQO. 14:03:15 14:03:19

Do you see that? 14:03:25

A. Uh-huh. 14:03:26

Q. And the staff recommendation is Alternative 3; right? 14:03:26 14:03:29

A. Yes. 14:03:29

Q. And that is the narrative approach; correct? 14:03:32

A. Yes. 14:03:34

Q. An Alternative 4, the numeric approach, was rejected; correct? 14:03:36 14:03:39

A. Correct. 14:03:40

Q. And one of the reasons that it was rejected is that there isn't enough data collected; right? 14:03:40 14:03:45

A. Umm -- yeah. 14:03:49

I mean, there's a far simpler reason. 14:04:05

Q. Which is? 14:04:09

A. Umm -- we don't know -- 14:04:09

If you were to assign numerical values to those categories, unimpacted, like unimpacted, possibly impacted, likely impacted, clearly impacted, say 1 14:04:15 14:04:19 14:04:32

through 5, you have no way of evaluating those relationships, and what I mean by there's -- there's -- there would be an assumed mathematical relationship that possibly impacted is three times worse than unimpacted, and -- umm -- we don't have any information to be able to state one way or another whether that's true or not. 14:04:36 14:04:42 14:04:47 14:04:51 14:04:59 14:05:08

But those values, once they start being used for statistical purposes, would make some assumptions about those relationships, and they're simply not -- there's no rationale or no basis. 14:05:12 14:05:16 14:05:20 14:05:24

It's an arbitrary scale. 14:05:30

Q. Did you use the three times as an example -- 14:05:32

A. Yes. 14:05:35

Q. -- to illustrate your point? 14:05:35

A. Oh, yes. Absolutely. 14:05:36

It was -- yeah. Yeah. 14:05:39

Q. Whether it's three times worse or 30 times worse, there's just no rational basis to get at that; right? 14:05:40 14:05:46 14:05:50

A. Correct. 14:05:50

Q. Or it could be just 1.2 times worse; right? 14:05:51

A. Correct. 14:05:56

Q. We just don't know? 14:05:56

A. Right. 14:05:58

Q. You can't -- you can't take the relative 14:05:58

rankings by category and convert it in to some numeric expression? 14:06:04 14:06:08

A. Correct. 14:06:09

Q. Here in Alternative 4, which was rejected, there's a reference to a numeric scale. 14:06:09 14:06:17

Do you see that? 14:06:21

A. Yes. 14:06:23

Q. And is this what you were describing, this numeric scale? 14:06:23 14:06:26

A. Yes. 14:06:27

Umm -- yes. 14:06:29

Q. And it is concluded here that a scientifically defensible numeric cannot be developed. 14:06:30 14:06:35

Do you see that? 14:06:38

A. Yes. Yes. 14:06:38

Q. What does -- what does the "numeric" mean there? 14:06:39 14:06:43

A. I don't know. There's probably a missing word in there. 14:06:43 14:06:45

Q. Ahh. 14:06:46

A. Like -- between the various lines of evidence to create a valid numeric scale -- 14:06:47 14:06:50

Well -- umm -- 14:06:54

So to me -- geez. 14:06:55

Umm -- obviously, that could be better edited. 14:07:14

But -- umm -- what that sentence means to me is we don't have the data to develop a -- a -- these mathematical relationships between the categories. 14:07:20 14:07:26 14:07:34

At some point, if we collect enough data, perhaps we'll have enough information to develop some way to establish a numerical categoric goal ranking system. 14:07:37 14:07:41 14:07:47 14:07:55

Q. Does that mean that the more data you have the better chance you have of locating a particular station or site in the right category? 14:07:55 14:08:05 14:08:09

A. No. No. 14:08:11

That's not at all what I was trying to get at. 14:08:14

Q. What were you trying to get at? 14:08:18

A. Umm -- I was trying to -- umm -- describe what this sentence is attempting to address in terms of converting a narrative ranking, a station category system, in to a numeric category system -- umm -- those five categories, assign a value to them. 14:08:19 14:08:27 14:08:34 14:08:42 14:08:51

Q. Okay. At the bottom of page 5-12, three lines up there's a reference to sediment toxicity tests, and it says that they cannot reliably predict effects to the benthic communities. 14:08:54 14:09:05 14:09:09 14:09:14

Do you see that? 14:09:16

MR. FUCHS: Counsel, is that the sentence that begins "While this concept is logical"? 14:09:32 14:09:35

MR. SINGARELLA: That's right. 14:09:37

THE WITNESS: Umm -- okay. I see it. 14:09:38

BY MR. SINGARELLA: 14:09:45

Q. And what is it about sediment toxicity tests that make them an unreliable predictor of these effects? 14:09:48 14:09:56

MR. FUCHS: Calls for speculation. 14:10:01

MR. SINGARELLA: If you know. 14:10:03

THE WITNESS: Many of the factors we've talked about this morning. 14:10:04 14:10:16

BY MR. SINGARELLA: 14:10:17

Q. Okay. Such as the confounding factors? 14:10:17

A. Yes. 14:10:20

Q. Anything else? 14:10:21

A. Umm -- it's -- umm -- most of these factors -- umm -- I think I said this this morning -- affect the results at -- umm -- low -- low responses. 14:10:22 14:10:36 14:10:42

So the higher the magnitude of response the more the different Lines of Evidence start to respond in the same way. 14:10:52 14:10:55 14:11:04

Q. But this sentence here just refers to sediment toxicity tests in general; right? 14:11:05 14:11:10

A. Yes. 14:11:13

Q. And it appears to make the blanket statement that they're not reliable as the predictor to the effects to benthic communities; right? 14:11:21 14:11:24 14:11:27

A. Umm -- right. 14:11:30

Q. And then on to page 5-15, please. 14:11:33

I'd like to ask you a couple of questions about the alternatives considered for the sediment toxicity tests; okay? 14:11:49 14:11:51 14:11:57

A. Okay. 14:11:59

Q. And it turns out that Alternative 4 was recommended by staff; right? 14:12:01 14:12:04

A. I'm sorry. Go back to -- 14:12:06

What page are we on? 14:12:08

Q. I'm sorry. 14:12:09

Page 5-15 of the Staff Report. 14:12:11

A. Yes, Alternative 4. 14:12:17

Q. And that included the combination of acute and sublethal toxicity methods; right? 14:12:19 14:12:22

A. Yes. 14:12:26

Q. And staff rejected Alternative 2; correct? 14:12:26

A. Umm -- yes. 14:12:33

Q. And that would have specified only acute toxicity methods; right? 14:12:36 14:12:42

A. Correct. 14:12:44

Q. And two paragraphs up, the paragraph that says "Two sublethal test methods were recommended," do you see that? 14:12:44 14:12:53 14:12:56

A. Yes. 14:12:56

Q. And further down in that paragraph it indicates that the sublethal tests were recommended to complement the ability of acute tests to detect; right? 14:12:56 14:13:00 14:13:05

A. Correct. 14:13:11

Q. To detect toxicity; right? 14:13:12

A. Yes. 14:13:14

Q. It was important to complement the acute toxicity results; right? 14:13:14 14:13:21

A. Yes. 14:13:22

Q. And that's why you recommended Alternative 4, including the sublethal test methods; right? 14:13:22 14:13:25

A. Uh-huh. 14:13:28

Q. Yes? 14:13:29

A. Yes. 14:13:30

Q. And rejected Alternative 2, which would have been acute only? 14:13:30 14:13:33

A. Yes. 14:13:35

Q. Let's turn to page 5-22, chemistry line. 14:13:35

Now, this first paragraph refers to these complicating factors. 14:13:53 14:14:02

Do you see that? 14:14:04

A little bit more than midway down through this first paragraph in Section 5.4.4.1. 14:14:08 14:14:10

A. Oh. Right. Right. 14:14:14

Q. What is that referring to? 14:14:15

A. That's probably referring to -- 14:14:17
I'm sorry. 14:14:19
Q. Please proceed. 14:14:20
A. Okay. 14:14:23
Confounding factors. 14:14:24
Q. Well, it looks a little broader than that, Mr. Beegan. 14:14:24 14:14:30
Let's just walk through them so we make sure we understand what the complicating factors are. 14:14:31 14:14:33
The first one is a lack of guidance. 14:14:36
Do you see that? 14:14:39
A. Oh, yes. Yes. 14:14:39
Q. What does that refer to? 14:14:41
A. Umm -- there's not a whole lot of material out there that describes how sediment quality guidelines are to be used. 14:14:43 14:15:06 14:15:14
Actually, probably in the past. 14:15:15
And -- umm -- or the limitations have been -- umm -- not well described by those documents. 14:15:19 14:15:27
I'm making an assumption here that -- I don't remember specifically -- umm -- this so I'm basically reading it and trying to remember -- umm -- 14:15:36 14:15:43 14:15:51
Q. Is it fair to ask you to help us given that you were a principal author of this Staff Report? 14:15:59 14:16:03
A. No. Yeah. 14:16:06

Q. Thank you. 14:16:06

A. Again, this is a long time ago. 14:16:07

Q. I understand. 14:16:10

A. That's -- umm -- I haven't moved -- I haven't -- I haven't put much effort in to direct effects over the last year or so. Everything is focused on bioaccumulation. 14:16:11 14:16:16 14:16:23 14:16:29

But I acknowledge or at least I've read the fact that these sediment quality guidelines have been misused for purposes other than those intended by the developing author. 14:16:30 14:16:35 14:16:38 14:16:44

Q. And so these complicating factors are with reference to these sediment quality guidelines; right? 14:16:49 14:16:52

A. Yeah. 14:16:56

I just -- "Sediment quality guidelines, tools that, SQGs, tools that relate contaminant concentrations to the potential for adverse effects on sediment-dwelling organisms, are often used to help interpret sediment chemistry data. SQGs have been used for over 30 years to assess sediment contamination, yet there are many factors that make their use a complex and challenging task. These complicating factors include a lack of guidance on how to evaluate the many types of SQGs in order to select the approach best suited for a particular application." 14:16:57 14:17:00

Okay.

So -- "Uncertainty regarding how to asses complex mixtures of contaminants, and uncertainty in how to establish thresholds for SQG interpretation that define acceptable and unacceptable sediment quality." 14:17:20 14:17:22 14:17:36

Q. And so the complicating factors with regard to sediment quality guidelines include the lack of guidance; right? 14:17:36 14:17:43 14:17:47

A. Yep. 14:17:47

Q. The uncertainty regarding how to assess the complex mixtures; right? 14:17:48 14:17:51

A. Correct. 14:17:53

Q. The inability to reliably predict the contaminant bioavailability; right? 14:17:53 14:18:00

A. Yes. 14:18:01

Q. And also the uncertainty how to establish thresholds for SQG interpretation; right? 14:18:01 14:18:05

A. Correct. 14:18:07

Q. And with respect to those thresholds the uncertainty is with respect to distinguishing between acceptable and unacceptable sediment quality; right? 14:18:08 14:18:10 14:18:16

A. Yes. 14:18:18

Q. And those are all complications; right? 14:18:19

A. Correct. 14:18:25

Q. And challenges; right? 14:18:27

A. Correct. 14:18:28

Q. With regard to sediment quality guidelines; right? 14:18:29 14:18:33

A. Correct. 14:18:34

Q. Is this with regard to empirical SQGs? 14:18:34

A. Umm -- yes. 14:18:45

This is specific to -- 14:19:04

Umm -- empirical. 14:19:06

It doesn't look that way. 14:19:10

Q. It's -- could be broader than that? 14:19:11

A. It looks like. 14:19:13

Q. It's a broad critique of SQGs; correct? 14:19:14

A. Yes. 14:19:19

Q. And then the second paragraph refers to "particular challenges when there are intermediate levels of contamination." 14:19:19 14:19:22 14:19:27

Do you see that? 14:19:28

A. Umm -- yes. 14:19:29

Q. That's where SQGs can produce the highest error rates; correct? 14:19:33 14:19:38

A. Yes. 14:19:39

Q. In other words, where there are intermediate levels of contamination reliance on an SQG can produce an error; right? 14:19:40 14:19:44 14:19:50

A. Correct. 14:19:50

Q. And in that circumstance the rate of error is at its highest? 14:19:50 14:19:54

A. Correct. 14:19:55

Q. So those types of predictions might be erroneous; right? 14:19:56 14:20:02

A. Correct. 14:20:03

Q. And then in the next paragraph there's a reference to the "misuse of SQGs." 14:20:04 14:20:08

Do you see that? 14:20:12

A. Uh-huh. Yes. 14:20:13

Q. And you understand that there's considerable concern over that misuse; correct? 14:20:15 14:20:18

A. Uh-huh. Yes. 14:20:20

Q. And that's with regard to the implementation of narrative water quality objectives in Basin Plans; correct? 14:20:21 14:20:31 14:20:37

A. Yes. 14:20:38

Q. And then the next sentence of that paragraph refers to the uncertainty of using SQGs; right? 14:20:39 14:20:49

A. Yes. 14:20:55

Q. And it indicates that that uncertainty is substantial; right? 14:21:00 14:21:04

A. Yes. 14:21:05

Q. And it also refers to the controversy over the use of chemical SQGs. 14:21:13 14:21:17

Do you see that? 14:21:20

A. Yes. 14:21:21

Q. And is that controversy in the scientific community? 14:21:21 14:21:24

A. Yes. 14:21:24

Q. And that controversy is substantial as well; correct? 14:21:25 14:21:29

A. Yes. 14:21:29

Q. And this all runs from the fact that no single SQG is able to account for all of the factors; right? 14:21:29 14:21:33

A. Correct. 14:21:37

Q. All of the factors that influence contaminant effects; correct? 14:21:37 14:21:41

A. Correct. 14:21:42

Q. Let's turn to the next page, please. 14:21:42

Now, is sediment chemistry another surrogated measure of exposure? 14:21:53 14:22:10

A. Yes. 14:22:14

Well, yeah, it -- yes. 14:22:16

It's an estimate -- I guess. 14:22:19

It's a surrogate. 14:22:24

Yeah, sure. 14:22:26

Q. Now, in the carryover paragraph, first full sentence there refers to "the lack of plans or policies in California." 14:22:27 14:22:35 14:22:39

Do you see that? 14:22:40

A. Umm -- where are we? 14:22:41

I'm sorry. 14:22:49

Q. Oh. The carryover paragraph, Mr. Beegan? 14:22:49

A. Oh. "In California there are no current --" 14:22:53

okay "-- plans or policies that define what guidelines 14:22:55

shall be used, how the guidelines should be applied --" 14:22:59

Q. Do you see that? 14:23:05

A. Yeah. 14:23:10

Q. Was the Part 1 an effort to fill this void? 14:23:10

A. Umm -- I never thought of it like that. 14:23:21

Umm -- 14:23:39

Q. Why was it relevant to indicate that there are 14:23:42

no current plan or policies in California that define 14:23:44

what guidelines shall be used? 14:23:48

A. Umm -- I do not know. 14:23:51

Umm -- I would probably have to read this 14:24:02

paragraph a little more closely to understand where it 14:24:08

was getting at, because -- umm -- it doesn't make sense. 14:24:14

Q. Why doesn't it make sense? 14:24:23

A. Because there are guidelines used in -- umm -- 14:24:24

the 303(d) listing policy, and -- umm -- 14:24:32

Yeah, so I -- 14:24:44

Like I said, I know that the 303(d) listing 14:24:45

policy was adopted while we were in development, and 14:24:52

maybe that was something that's left over from a very early document, but, again, without reading this paragraph, it -- I may be taking something out of context. 14:25:01 14:25:05 14:25:08 14:25:12

Q. Don't want you to do that, so we'll move on. 14:25:13

A. Okay. 14:25:16

Q. Turning to page 5-27, this refers to the alternatives considered for sediment chemistry; right? 14:25:16 14:25:36

A. Umm -- top of the page? 14:25:42

Q. Yeah. 14:25:44

A. Yes. 14:25:45

Q. And Alternative 2 refers to the use of existing national empirical SQGs; right? 14:25:45 14:25:50

A. Yes. 14:25:54

Q. Without consideration of actual predictive ability when applied to California; right? 14:25:57 14:26:00

A. Correct. 14:26:02

Q. And that was rejected; right? 14:26:03

A. Yes. Yes. 14:26:05

Q. In favor of new empirical SQGs? 14:26:05

A. Yes. 14:26:09

Q. And as applicable to Part 1 those would be the CSI and the CALRM; right? 14:26:09 14:26:14

A. Yes. Yes. 14:26:17

Q. And a number of SQGs were -- were considered 14:26:18

in this Staff Report; right? 14:26:27

A. Yes. 14:26:29

Q. Including those by McDonald, et al, 1996; 14:26:29

right, going back to 5-23? 14:26:37

A. Umm -- correct. 14:26:40

Q. And McDonald et al, 2000; right? 14:26:41

A. Uh-huh. 14:26:47

Q. Yes? 14:26:48

A. Yes. 14:26:48

Q. And those were rejected in favor of 14:26:48

Alternative 3; correct? 14:26:52

A. Umm -- yes. 14:26:53

MR. SINGARELLA: Mr. Beegan, would you mind if 14:27:04

we took a quick break? 14:27:06

THE WITNESS: No. 14:27:08

MR. SINGARELLA: Okay. Thank you. 14:27:08

VIDEOGRAPHER: We are going off the record at 14:27:09

2:26 p.m. 14:27:11

This is the end of disk three. 14:27:12

(Thereupon a recess was taken at 2:27 p.m.

and the deposition resumed at 2:35 p.m.) 14:35:31

VIDEOGRAPHER: We are back on the record at 14:35:31

2:35 p.m. 14:35:35

This is the beginning of disk number four. 14:35:36

EXAMINATION 14:35:38

Q. Hi, Mr. Beegan. 14:35:39

My name is Bill Brown. 14:35:41

I represent the Port of San Diego. 14:35:42

I'm going to ask you a few questions. I think it's going to be relatively short. 14:35:44 14:35:47

My guess is you're going to tell me you don't know the answers to a lot of these specifics, and I'm going to be asking you if you can direct me to the person who would know. 14:35:48 14:35:51 14:35:53 14:35:54

The reason I'm going to ask you these questions is because I noticed that you're listed as a point of contact information on a website for the Bay Protection and Toxic Cleanup Program. 14:35:56 14:35:57 14:36:01 14:36:04

Are you aware of that? 14:36:06

A. Uh-huh. 14:36:07

Q. One of the areas that it lists is an economic analysis, and that's one of the documents that's listed. 14:36:08 14:36:14

Are you aware of that? 14:36:18

A. Umm -- there are a couple Bay Protection-related websites. 14:36:19 14:36:24

If you give me a time frame -- 14:36:26

Q. Are you aware of a report that was done by SAIC in 19 -- I mean in 2008? 14:36:29 14:36:32

A. Oh, yeah. Yes. 14:36:35

Umm -- as -- the -- economic analysis for -- 14:36:37

umm -- support of SQG development? 14:36:43

Is that the same one? 14:36:47

Q. Yes.

And it's also referred to in the Staff Report. 14:36:49

A. Yeah, yeah, yeah. 14:36:51

Q. And it's named as 704? 14:36:52

A. Right. 14:36:54

Q. The document doesn't list an author, but just 14:36:55
that rather large corporation. 14:36:58

If I wanted to know some of the specifics 14:37:00
about the analysis that they did in that report, who 14:37:03
would I be talking to? 14:37:06

A. Umm -- 14:37:07

MR. FUCHS: If you know. 14:37:12

MR. BROWN: If you know. 14:37:14

THE WITNESS: There -- there are two people at 14:37:18
SAIC that were principal authors. 14:37:21

One of them I know is no longer there. She 14:37:26
works for another consulting company. 14:37:28

But -- umm -- I can't -- remember her name. 14:37:31

It's been a couple years. 14:37:38

Q. Okay. 14:37:41

A. But I can provide that to you. 14:37:41

Q. Right. 14:37:43

And that would be one of my follow-up 14:37:43

questions is asking you if I can. 14:37:46

A. Yeah.

Q. Because we're in some administrative 14:37:49
proceedings and everything, and I want to make sure we 14:37:51
do it in a way that doesn't disturb you or the counsel 14:37:54
that's representing you. 14:37:57

I'm asking questions that appear to be 14:37:57
available through a State website, but because of the 14:38:00
predicament we're in I'm just being cautious. 14:38:03

Do you remember who the other person is at 14:38:06
SAIC who may have contributed to that report? 14:38:08

A. I just remember the main point of contact. 14:38:10

Like I said, I don't know her name off the top 14:38:13
of my head, but she was the primary author, Project 14:38:15
Manager. 14:38:20

If it helps you, she was the same person who 14:38:20
performed the economic analysis for the State 14:38:26
Implementation Policy, the SIP, back in '98, '99. 14:38:30

Q. Okay. 14:38:37

A. Sorry. 14:38:39

Q. All right. 14:38:39

But, in any event, if I E-mail you and include 14:38:40
your counsel on the E-mail, you could get back to me 14:38:42
with the names of these people? 14:38:45

A. Oh, I'll do it. 14:38:46

I could potentially do it tonight if I get home at a decent hour. 14:38:47 14:38:51

Q. If that's okay with your counsel, that would be fine with me. 14:38:53 14:38:56

A. But I can dig it up. 14:38:56

It's -- 14:38:58

Q. Okay. And these are some general questions that you may or may not know the answer to. 14:38:59 14:39:02

Is it a correct statement that in preparing SQOs that the State does have to take in to account economic impacts? 14:39:04 14:39:09 14:39:13

A. Umm -- broadly, yes. 14:39:14

Yes. 14:39:19

Q. Are you involved in that in any way? 14:39:19

A. Umm -- yes, to a general extent. 14:39:22

Umm -- I -- it was -- umm -- it's myself, the former attorney at the State Water Board, Sheila Vassey, who had a lot of experience on that, and -- 14:39:33 14:39:46 14:39:50

Eloise Castille. That's the author. 14:39:57

Q. At the SAIC? 14:40:00

A. Yes. 14:40:03

But, again, she's not there anymore. 14:40:03

Q. Okay. What was your involvement -- and I'm not trying to get in to your thought process or anything. 14:40:05 14:40:09 14:40:11

I'm just trying to figure out where you come in to the picture. 14:40:11 14:40:14

What was your involvement with the economic analysis? 14:40:15 14:40:17

A. Umm -- putting together a -- a scope -- umm -- of work. 14:40:18 14:40:27

Again, as the Project Manager, Program Manager -- umm -- with the economic analysis I relied quite a bit on -- umm -- the -- the Water Board attorney, Sheila Vassey, to help me with that -- 14:40:28 14:40:35 14:40:41 14:40:53

Umm -- so that was -- that was -- I -- I kind of -- umm -- pushed it through, made sure -- made sure it made sense, sent the scope out, made sure that the -- umm -- econ analysis fulfilled the scope of work requirements. 14:40:56 14:41:05 14:41:09 14:41:16 14:41:24

That was about it. 14:41:24

Q. And was that scope of work ultimately performed by SAIC? 14:41:25 14:41:28

A. Umm -- yes. Yes. 14:41:31

Q. Okay. Did you use any of their materials in coming up with any SQOs? 14:41:37 14:41:45

A. Oh, no, absolutely not. 14:41:47

Q. Okay. 14:41:49

A. Their -- their -- their role only related to -- umm -- economic analysis. It was limited. This was 14:41:52 14:41:58

nothing else. 14:42:06

They -- they did not have -- they were not 14:42:08

part of the technical team, per se. 14:42:12

So -- umm -- if you read all those technical 14:42:14

reports -- umm -- SAIC or Eloise had no -- umm -- no -- 14:42:19

she had no participation in the development of any of 14:42:29

that stuff. 14:42:33

Q. And that's where I'm kind of confused, and I'm 14:42:33

not trying to suggest anything. 14:42:37

I'm just trying to get the general frame -- 14:42:39

framework. 14:42:41

If economic analysis is considered in 14:42:42

conforming -- in preparing SQOs -- I'm sorry I 14:42:46

misspoke -- where does it come in at? 14:42:51

MR. FUCHS: Hang on a second. 14:42:53

I'm going to object that calls for a legal 14:42:55

conclusion. 14:42:57

MR. BROWN: If you know. 14:42:58

MR. FUCHS: If you can answer it, go ahead. 14:42:59

THE WITNESS: The -- umm -- the economic 14:43:02

analysis is performed on whatever is being proposed in 14:43:24

relation to baseline. 14:43:32

BY MR. BROWN: 14:43:37

Q. Let me give you a few different examples, and 14:43:37

you can tell me when I'm getting warm, if this works for 14:43:40

you. 14:43:44

Does it come in -- I don't think it comes in, 14:43:44

but does it come in during the MLOE phase? 14:43:47

A. Umm -- I -- for me I have a hard time 14:43:52

understanding -- 14:44:01

Are you talking about in the development of 14:44:04

the MLOE? 14:44:06

Q. Yes. 14:44:07

A. Okay. Umm -- yes. 14:44:08

Q. At what juncture? 14:44:17

A. Umm -- I don't recall specifically. 14:44:18

Q. Who would be the person who would know the 14:44:22

most about this subject at the Water Board? 14:44:25

A. Umm -- it probably should be me -- umm -- in 14:44:29

terms of when particular things happened, and -- umm -- 14:44:37

I just don't -- umm -- I -- 14:44:43

Like I had indicated to Mr. Singarella, there 14:44:52

are a lot of hoops that I jumped through or had to jump 14:45:02

through, or a lot of information that I had to put 14:45:06

together, assess, evaluate, five, six years ago. 14:45:10

Since that time there's a lot of new 14:45:19

information that I'm trying to deal with. 14:45:22

So asking me something like that -- umm -- you 14:45:26

know, at one time I probably had a good understanding of 14:45:32

the econ or better understanding, had a better 14:45:36

understanding of the timeline, what took place when. 14:45:39

Right now I -- umm -- I can't remember that 14:45:44

type of detail. 14:45:52

It would be guesswork or -- it would be 14:45:53

guessing. 14:45:55

Q. Let me ask it another way. 14:45:56

Do you come up with a scientific basis for a 14:45:58

SQO and then adjust it for economic considerations? 14:46:03

MR. FUCHS: Hang on. 14:46:08

Let me -- let me just object that this is 14:46:08

getting pretty far afield from the scope of this 14:46:11

deposition, which is how in the abstract in general the 14:46:15

SQOs get applied. 14:46:18

This sounds an awful lot like how they were 14:46:20

formed, how they were developed, at what point the 14:46:24

economic analysis came in. 14:46:27

So I guess I would suggest that, if you really 14:46:29

want to pursue this line of questioning, you send your 14:46:31

own deposition notice, and we can talk to Mr. Gallagher 14:46:34

about whether that gets quashed. 14:46:39

MR. BROWN: Okay. 14:46:42

BY MR. BROWN:

Q. Okay. Let's put it another way. 14:46:43

How does the economic analysis get applied? 14:46:45

And, more importantly, when? 14:46:49

I'm not so -- 14:46:51

I don't want to get in to the thought patterns 14:46:53
of how you do it so much as -- I'm trying to figure out 14:46:55
do you come up with an analysis first based on science 14:46:59
and then factor in economics, or is it all done at the 14:47:02
same time? 14:47:06

A. Umm -- I think -- 14:47:06

I believe it was developed by framework, 14:47:12
scientific-based framework, and then considered the -- 14:47:18
or performed the economic analysis. 14:47:27

Q. Okay. And who performed -- is that done by 14:47:30
you or is it done by somebody else? 14:47:35

A. The -- the economic analysis? 14:47:39

That was performed by -- this -- umm -- I just 14:47:44
mentioned her name -- Eloise at SAIC. 14:47:51

Q. And after the economic analysis is done how is 14:47:54
it applied to come up with the end product of SQOs? 14:47:57

MR. FUCHS: I'm sorry. 14:48:02

We're still not talking about applying the 14:48:03
SQOs, so -- I'm going to have to instruct Mr. Beegan not 14:48:04
to respond to any more questions regarding how the 14:48:12
economic analysis went in to developing the SQOs at what 14:48:16
point chronologically or logically. 14:48:23

MR. BROWN: Okay. Let me jump to another 14:48:26
subject, although they're interrelated, and then I 14:48:28

promise I will be done relatively shortly. 14:48:31

BY MR. BROWN:

Q. I'm curious about the interplay of TMDLs and SQOs and how they are applied on a statewide basis. 14:48:33 14:48:37

Are they -- 14:48:42

Are they developed jointly or does one inform the other? 14:48:43 14:48:47

A. The SQOs are applied -- as would any water quality objective to a water body or watershed situation. 14:48:49 14:49:06 14:49:12

And I'll attempt to explain. 14:49:13

Q. Okay. If you could explain, that would be great. 14:49:15 14:49:17

A. The -- the SQOs establish this means to differentiate good sediment from bad sediment. That's all they do. 14:49:18 14:49:26 14:49:30

So you're -- by assessing sediment quality in a segment, if you have enough impacted stations, you could list that segment for impairment of the direct effects, quote, "Sediment Quality Objective." 14:49:31 14:49:41 14:49:49 14:49:59

Once that listing got approved and went through -- jumped through the hoops, the State Water Board, it would be put on a list as what you need to do. 14:50:02 14:50:07 14:50:11

If it's on the TMDL list, the next step would be essentially going through the stressor identification 14:50:15 14:50:21

process and the target cleanup process. 14:50:26

That's how Part 1 is intended in the big 14:50:34

picture. 14:50:40

But -- umm -- there is, as I mentioned 14:50:41

earlier, when you -- I don't know if you were here, 14:50:45

there's a section in there that says that there's 14:50:48

nothing in that plan or in the specific section that 14:50:52

shall impinge upon the authority of the Regional Board 14:50:58

to set TMDL targets. 14:51:01

Something -- the language is something like 14:51:06

that. I don't remember it specifically, but I do know 14:51:08

that it's there. 14:51:11

So -- how did they relate? 14:51:12

It's a stepwise process. Use the SQOs to 14:51:17

assess and use the TMDLs in a kind of watershed water 14:51:22

body wide approach to restore sediment quality. 14:51:30

Q. In applying the TMDLs and the SQOs it appeared 14:51:36

in the Staff Report that they compared them for economic 14:51:45

analysis. 14:51:48

Are you aware of that? 14:51:49

A. Umm -- they -- umm -- they used -- umm -- 14:51:51

I was under the impression we used 303(d) 14:52:02

listings to make some comparisons and the TMDLs to -- 14:52:07

umm -- put estimates together as far as what restoration 14:52:18

would be required. 14:52:25

Q. Did you try to determine for economic analysis purposes whether SQOs would be more or less expensive than the SQO process? 14:52:25 14:52:30 14:52:34

A. Could you rephrase that? 14:52:36

Q. Did you compare the costs of TMDM -- TMDL implementation to the cost of SQO implementation for the economic analysis? 14:52:41 14:52:46 14:52:51

A. Umm -- I would have to reread the Staff Report. 14:52:53 14:53:00

Q. And I read the Staff Report and I saw the underlying document earlier in the day. 14:53:00 14:53:04

If I wanted to talk to the person who may know this subject most in depth, would it be the people you hired from SAIC or would it be you after you reviewed those documents? 14:53:06 14:53:09 14:53:14 14:53:18

A. It would probably be a combination of myself, Steve Bay at SCCWRP, Eloise Castille at SAIC. 14:53:19 14:53:29

Yeah. I mean, that's -- it's -- one of those three, but -- we considered a lot of things -- 14:53:32 14:53:36

Umm -- basically we looked at baseline conditions and moved forward from there. 14:53:45 14:53:48

Q. Okay. I promised everybody I wouldn't take long on this, so this is going to be very short, but I just am going to have you look at this because I think it's in here in a very summary fashion. 14:53:50 14:53:55 14:53:58 14:54:01

Could you look at Exhibit 704. 14:54:04

A. I think that's what I have. 14:54:12

MR. FUCHS: Yes, that's the Staff Report. 14:54:14

BY MR. BROWN:

Q. Or the one that's called "Staff Report," and then section is called Section 7.4. 14:54:16 14:54:18

MR. FUCHS: It's on page 7-2. 14:54:33

MR. BROWN: Okay. 14:54:37

BY MR. BROWN: 14:54:43

Q. I'm looking at the last -- second to the last paragraph on page 7-3. 14:54:43 14:55:16

And on the second to last sentence in that paragraph it mentions the 303(d) listings. 14:55:23 14:55:30

Do you see where I'm referring to? 14:55:34

A. Uh-huh. 14:55:35

Q. Does that refresh your recollection that in looking at the economic impact of SQOs that you compared it to listings with 303(d)? 14:55:35 14:55:39 14:55:45

A. Umm -- yes. 14:55:48

Q. And who did that work? 14:55:51

A. Umm -- well -- I developed a list -- listings of 303(d) as to water bodies, and then I believe -- umm -- the -- Eloise looked at -- 14:55:58 14:56:18 14:56:29

Actually, well -- it was probably -- it was probably a combination of people, I think. 14:56:46 14:56:52

I put together an initial list of what was -- 14:56:55
umm -- what was -- what the -- where -- where the 14:56:59
existing listings were. 14:57:06
SCCWRP put together a list or a document 14:57:11
describing sediment quality in -- in bays of California 14:57:17
and then -- umm -- Eloise probably looked at the 14:57:30
differences or the changes. 14:57:37
Q. Okay. And then just one last generalization 14:57:39
question. I'm going to be off very quickly. 14:57:45
I'm still trying to separate in my mind, 14:57:47
Mr. Beegan, the difference between the TMDL track and 14:57:50
the SQO track. 14:57:53
Did they run parallel or do they intersect at 14:57:56
some point? 14:57:59
MR. FUCHS: Objection. Vague and ambiguous. 14:58:00
Also calls for a legal conclusion. 14:58:04
If you understand the question, you can take a 14:58:07
stab at answering it. 14:58:10
THE WITNESS: Well -- I'm sorry. 14:58:12
I must not have -- umm -- answered the 14:58:15
question -- umm -- clearly before, because -- 14:58:18
MR. BROWN: I wouldn't presume that, but I'm 14:58:27
trying to take in a lot of information all at once. 14:58:29
You may have answered it very clearly. 14:58:32
THE WITNESS: No. No. 14:58:34

So -- umm -- the -- Sediment Quality Objectives are used to assess sediment. 14:58:35 14:58:45

Once you've assessed sediment -- umm -- and you have a sediment quality related listing -- umm -- your -- 14:58:51 14:58:59 14:59:09

In order to restore it you would go down the TMDL path. 14:59:15 14:59:19

You've demonstrated that your sediment quality isn't meeting the narrative. 14:59:25 14:59:28

From there stressor identification, target -- umm -- some sort of sediment target or load, waste load allocation would be -- umm -- appropriate. 14:59:30 14:59:36 14:59:42

I -- 14:59:48

A TMDL is developed based on a degradation or an impairment of a water body. 14:59:51 15:00:00

A TMDL usually must include and identify -- must identify what beneficial use or what criteria you're basing this all on. 15:00:02 15:00:07 15:00:12

So there's a relationship there. 15:00:14

If your sediment quality is impaired, or you've demonstrated that it's impaired due to a specific narrative objective, that becomes part of the TMDL, and it kind of forms the basis of where you go. 15:00:17 15:00:20 15:00:24 15:00:31

I -- I -- I'm trying to think of what -- what relationship beyond that exists, and just off the top of 15:00:36 15:00:44

my head I can't. 15:00:48

I wish I could help you more. I -- 15:00:50

Q. Oh, no. 15:00:53

I think you're probably being very helpful. 15:00:54

Let me put it to you another way. 15:00:57

To some extent in the economic analysis we just read it does appear that they're contrasting the 303(d) listing and the SQO process for purposes of economic analysis, and to some extent that implies that they're two different processes, but to -- based on what you just said it appears that one feeds in to the other. 15:01:00 15:01:04 15:01:08 15:01:13 15:01:17 15:01:20

Is that correct? 15:01:23

A. Umm -- well, I think your -- you're comparing apples and oranges. 15:01:24 15:01:28

So the TMDL process is not the same as a 303(d) listing process. 15:01:30 15:01:34

Q. Okay. 15:01:38

A. We were comparing -- the -- existing 303(d) list, or the existing 303(d) policy, or whatever baseline policies were out there, and listings with what could potentially occur through the adoption of SQOs. 15:01:38 15:01:49 15:02:01 15:02:07

Q. Do you know if they did a similar process for comparing TMDLs to SQOs, or was it only 303(d)s to SQOs? 15:02:18 15:02:20

A. Umm -- I think -- I -- umm -- 15:02:27

They may have been projections on forthcoming 15:02:42

TMDLs, but, again, the SQO is not a TMDL. 15:02:46

So -- 15:02:53

I -- I'm having a hard time answering that 15:03:05

question. 15:03:09

Umm -- I know that listings were -- form the 15:03:09

basis. 15:03:14

I know that costs for TMDLs were -- umm -- 15:03:15

were used in some cases. 15:03:21

I don't recall the specifics, but I think 15:03:24

there were some in there. 15:03:27

Umm -- how those were used, they would have to 15:03:30

be used in some sort of -- umm -- comparison of, you 15:03:33

know, cost to restore a water body. 15:03:38

Q. And in preparing the Staff Report did they try 15:03:42

to -- compare the incremental costs of SQOs above and 15:03:45

beyond what would be required by 303(d) or TMDL? 15:03:54

A. What do you mean by "incremental costs"? 15:04:00

Q. I'll try to define it for you. 15:04:02

If to implement a TMDL for a particular site 15:04:04

would cost X, and to implement the SQO process would 15:04:08

cost Y, did they try to determine what the difference 15:04:13

was between X and Y? 15:04:15

A. Umm -- off the top of my head I would say no. 15:04:18

MR. BROWN: Okay. Well, without making it any 15:04:27

further murkier I think they may have done that, -- 15:04:29

THE WITNESS: Okay. 15:04:33

MR. BROWN: -- but I don't think you're the 15:04:33
person that I should bugging about this, so I'm going to 15:04:34
turn the questioning back to Mr. Singarella. 15:04:37

THE WITNESS: Okay. 15:04:40

MR. BROWN: All right. Thank you. 15:04:41

FURTHER EXAMINATION 15:04:43

BY MR. SINGARELLA: 15:04:44

Q. Okay. Mr. Beegan, back to the Staff Report. 15:05:12

Can you turn to page 5-31, please. 15:05:16

And let's talk a little bit about best 15:05:25
professional judgments. 15:05:29

And you see the bullets on page 5-31? 15:05:31

A. Yes. 15:05:37

Q. And the lead in to the bullets indicates that 15:05:37
there are many reasons why the utility of BPJ is 15:05:43
limited. 15:05:49

Do you see that? 15:05:49

A. Yes. 15:05:50

Q. And those four bullets list some of those many 15:05:50
reasons; right? 15:05:54

A. Umm -- yes. 15:05:55

Q. And the first reason is that BPJ may result in 15:05:57
inconsistent decisions; right? 15:06:05

A. Yes. 15:06:08

Q. Within a single region itself; right? 15:06:09
A. Yes. 15:06:13
Q. Or in between different regions; right? 15:06:13
A. Correct. 15:06:16
Q. And inconsistent decisions with regard to what, Mr. Beegan? 15:06:17 15:06:22
A. Umm -- whether -- sediments are impacted or not impacted, I would assume without reading the rest of the section. 15:06:23 15:06:35 15:06:38
Q. You think that's a safe assumption? 15:06:39
A. Yeah. Yeah. Yeah. Yeah. 15:06:43
Q. And BPJ's also limited because it can be time consuming and resource intensive; right? 15:06:44 15:06:49
A. Absolutely. 15:06:51
Q. And BPJ is limited because it may not always lead to transparent results; right? 15:06:53 15:06:57
A. Right. 15:06:59
Q. Or unbiassed decisions; right? 15:06:59
A. Right. 15:07:02
Q. What does that mean, "transparent and unbiased decisions"? 15:07:02 15:07:05
MR. FUCHS: I'm going to start objecting here because we've been going through this Staff Report for several hours, and I've let it go on because I think to a certain extent the Staff Report can be used to aid 15:07:06 15:07:09 15:07:11 15:07:17

folks who may want to apply the SQOs, but we're really delving in to how the SQOs were developed here, which is clearly outside the scope of what has been delineated for this deposition. 15:07:22 15:07:27 15:07:33 15:07:38

Whether BPJs are appropriate or not has little to do with what one does to apply the SQOs. 15:07:40 15:07:48

So, you know, as I said, I've let this go on for quite a while, but I think it's time to bring it to an end. 15:07:52 15:07:55 15:07:59

Q. Is BPJ relevant to Part 1? 15:07:59

MR. FUCHS: That's vague and ambiguous. 15:08:05

You can answer that question -- if you can answer it 15:08:09 15:08:13

THE WITNESS: It's relevant to certain portions of Part 1. Other portions it's almost irrelevant. 15:08:14 15:08:24 15:08:29

BY MR. SINGARELLA: 15:08:30

Q. Is Part 1 an attempt to limit the problems with regard to BPJ? 15:08:32 15:08:38

A. Yes. 15:08:40

Q. And is it important to understand those problems in order to appreciate how to avoid them -- within the context of applying the SQOs? 15:08:41 15:08:45 15:09:01

A. Not -- necessarily. 15:09:08

Q. Is BPJ a methodology itself? 15:09:14

A. Umm -- yeah, I would say yes. 15:09:18

Q. And is there any BPJ whatsoever in Part 1? 15:09:33

A. Umm -- like I said, there are specific 15:09:36

portions of Part 1 that rely on -- umm -- BPJ -- umm -- 15:09:41

there's stressor identification requires -- umm -- 15:09:53

significant amount of best professional judgment in 15:09:59

terms of how to -- umm -- how to most effectively 15:10:05

determine which -- what stressor is causing the problem. 15:10:11

Study design would require best professional 15:10:18

judgment. Part 1 is other than it says to develop the 15:10:22

work plan, it's silent on those types of issues. 15:10:29

So -- there -- there's significant room in 15:10:32

Part 1 for BPJ, but within the application of the Lines 15:10:38

of Evidence for bays, marine bays, it's very limited, 15:10:46

but in the delta application, estuary applications, 15:10:56

there's a little more. 15:11:02

So, I mean, -- you could -- umm -- there's 15:11:03

portions, sections, where it's significant and sections 15:11:08

where it's less so, a lot less so. 15:11:14

Q. Why did the Staff Report spend so much time 15:11:18

discussing BPJ? 15:11:23

A. Umm -- because sediment quality assessments 15:11:25

are typically based on best professional judgment, and 15:11:34

in a state where there's multiple regions that act -- 15:11:42

can act somewhat independently, you could have very 15:11:51

different approaches. 15:11:59

None of those approaches are -- I think are 15:12:03
described in the basin plans or any other policies. 15:12:07

Q. Does the Staff Report help inform the use of 15:12:11
BPJ in the Part 1 SQO? 15:12:19

A. Does it help inform the use of BPJ -- in Part 15:12:23
1. 15:12:33

I guess it could. 15:12:33

That wasn't the intent. 15:12:44

Q. And what was the intent? 15:12:46

A. The intent is to describe -- umm -- the basis 15:12:47
for Part 1, not necessarily provide a -- an enduser 15:12:57
reference. 15:13:07

Q. And so one purpose of Part 1 is to prevent the 15:13:17
misuse of BPJ; right? 15:13:21

A. It's to -- 15:13:24

Well, yes. 15:13:30

Q. So to prevent the misuse of BPJ one needs to 15:13:30
understand how it can be misused; correct? 15:13:36

A. Umm -- the way I think of BPJ is -- umm -- 15:13:39
someone coming up with a method to assess sediment 15:13:58
quality, and Part 1 has a method to assess sediment 15:14:08
quality. 15:14:15

You don't necessarily need to know the 15:14:17
rationale for other approaches to follow Part 1. 15:14:21

Q. Well, for example, in Table 5 of Part 1, the benthic index categorization values -- is there a judgment that goes in to these different categories in the numeric ranges specified for each? 15:14:27 15:14:47 15:14:57 15:15:02

A. Umm -- 15:15:04

MR. FUCHS: Objection. Vague and ambiguous. 15:15:09

You mean in coming up with these numbers or in applying them? 15:15:14 15:15:16

MR. SINGARELLA: In coming up with them. 15:15:17

MR. FUCHS: Well, then that is outside the scope and invades the mental processes. 15:15:21 15:15:24

MR. SINGARELLA: I'm not asking him about the judgment itself. 15:15:29

I'm wondering if there is any judgment that goes in to this. 15:15:32 15:15:33

BY MR. SINGARELLA: 15:15:34

Q. Let me ask you a different way. 15:15:34

Do these ranges fall out of some mathematical equation that is known to be firm and precise in nature, for example, force equals mass times acceleration? 15:15:36 15:15:40 15:15:45

A. No. 15:15:49

Q. You're not just applying some basic principle of -- of physics or science to come up with these ranges; right? 15:15:50 15:15:52 15:15:57

A. Correct. 15:15:57

Q. You're not using a clean dose response relationship to come up with these ranges; correct? 15:15:58 15:16:00

MR. FUCHS: Once again, we're getting in to how things were developed, not how they're applied. 15:16:07 15:16:10

MR. SINGARELLA: We're asking what they are, actually. 15:16:12 15:16:14

MR. FUCHS: I mean, literally how they came up -- how he came up with them. 15:16:14 15:16:17

MR. SINGARELLA: No, what they are. 15:16:20

MR. FUCHS: Mr. Beegan, don't answer that question. 15:16:20 15:16:22

MR. SINGARELLA: So you're not going to let him tell us what's behind these numbers, what these numbers represent, are they -- are they based on physical principles or judgment? 15:16:23 15:16:24 15:16:27 15:16:30

MR. FUCHS: He's already answered that. 15:16:31

MR. SINGARELLA: What did he say? 15:16:33

MR. FUCHS: He said they're -- 15:16:34

You can read the record yourself. I'm not going to answer for him. 15:16:36 15:16:39

BY MR. SINGARELLA: 15:16:40

Q. So is there -- is there a judgment that went in to specifying the ranges? 15:16:40 15:16:44

MR. FUCHS: Asked and answered. 15:16:46

BY MR. SINGARELLA: 15:16:47

Q. Did you say that they weren't a product of a clean dose response relationship? 15:16:48 15:16:51

MR. FUCHS: He didn't answer that question because I told him not to. 15:16:54 15:16:56

We're done with figuring out how these numbers were derived. 15:16:57 15:17:02

MR. SINGARELLA: Okay. Let's call Gallagher. 15:17:02

This is silly. We'll be here until tomorrow the way this is going. 15:17:05 15:17:07

You've been interrupting me all day, and you're half the record, so let's call Gallagher -- if we can get him. 15:17:08 15:17:10 15:17:16

MR. RICHARDSON: Yeah. I'll probably call him and ask him to dial in to the main number here. 15:17:20 15:17:22

MR. SINGARELLA: Yeah.

MR. FUCHS: Go for it.

MR. RICHARDSON: Do you want to go off the record for just a moment? 15:17:25 15:17:26

MR. FUCHS: Yes. 15:17:27

VIDEOGRAPHER: We are going off the record at 3:17 p.m. 15:17:29 15:17:30

(Discussion off the record) 15:17:34

MR. SINGARELLA: Mr. Gallagher? 15:21:37

Mr. Gallagher, it's Paul Singarella. 15:21:38

Thanks for calling in. 15:21:40

MR. GALLAGHER: Hi. 15:21:41

Who do we have here? 15:21:42

MR. SINGARELLA: Well, we should probably go around the table and make appearances. 15:21:43 15:21:45

I was asking Kelly to see if we could ring you up. 15:21:47 15:21:49

Kelly is to my right. 15:21:50

VIDEOGRAPHER: Excuse me, sir. 15:21:52

Did you want this on the video? 15:21:53

MR. SINGARELLA: No. 15:21:55

VIDEOGRAPHRE: Okay. 15:21:56

MR. GALLAGHER: If we did, I couldn't see your faces. 15:21:58

Again, it's Paul, Kelly. 15:22:00

Who else? 15:22:00

MR. TRACY: Mike Tracy is here. 15:22:03

MR. GALLAGHER: Okay. 15:22:05

MR. FUCHS: This is Dan Fuchs. 15:22:08

MR. GALLAGHER: Hi, Dan. 15:22:09

Okay. 15:22:10

THE WITNESS: Chris Beegan, State Water Board. 15:22:10

MR. SINGARELLA: And we've got a few people on the line phoning in as well, Mr. Gallagher. 15:22:13 15:22:15

MR. GALLAGHER: Who is that next to Dan? 15:22:18

THE WITNESS: Chris Beegan. 15:22:21

MR. GALLAGHER: Oh, Chris. Okay. 15:22:22

MR. FUCHS: Our deponent. 15:22:24

MR. SINGARELLA: Mr. Gallagher, we -- 15:22:25

MS. REYNA: The witness. 15:22:25

MR. GALLAHGER: Who is this, I should say?

MS. TRACY: This is Jill. I'm on the phone. 15:22:33

MS. REYNA: And Kristin. I'm on the phone, 15:22:36
too.

MR. CONDER: Hi. This is Jason Conder.

How are you? 15:22:41

MR. GALLAGHER: Hi, Jason. 15:22:42

MR. SINGAREALL: And Bill Brown may be joining 15:22:44
us momentarily. He stepped out for a moment. 15:22:46

MR. GALLAGHER: Okay.

MR. SINGARELLA: Mr. Gallagher, Mr. Fuchs and 15:22:49
I have -- have reached an impasse over a few lines of 15:22:50
questioning. 15:22:53

I'm trying to -- to move this along so that we 15:22:53
can hopefully wrap this up today. 15:22:57

I must admit that -- umm -- the level of 15:22:59
speaking objections and statements on the record is 15:23:03
troubling me and has been preventing me from getting 15:23:07
through in an order early fashion. 15:23:12

Let me just give you a sense of where we are, 15:23:14
and then Mr. Fuchs, I'm sure, will have a contrary view 15:23:16

of things, but -- 15:23:21

I -- I have spent the vast majority of the day 15:23:23
on two exhibits that -- each of which requires very 15:23:26
material unpackaging to understand this rule, the 15:23:33
Sediment Quality Objectives, and those two exhibits 15:23:37
include the Sediment Quality Objective itself and as 15:23:43
adopted by the State Board, and then the second exhibit 15:23:45
is a very, very detailed and long Staff Report that the 15:23:48
State Water Board staff presented to the State Water 15:23:54
Board pursuant to the adoption hearing. 15:23:59

I'm not getting in to, you know, E-mails, and 15:24:01
ancient history, and personalities. 15:24:04

I'm spending my entire day trying to get at 15:24:07
the SQOs as those are understood in the SQO document 15:24:11
itself and -- 15:24:19

MR. GALLAGHER: So, counsel, the document is
the SQO document itself and the other is a Staff Report 15:24:25
presented to -- and sorry to interrupt -- just trying 15:24:25
not to get the exhibits wrong. 15:24:29

The other is the Staff Report presented to the 15:24:30
State Water Board at the adoption hearing. 15:24:31

MR. SINGARELLA: Exactly. 15:24:35

And Mr. Fuchs has objected on several grounds. 15:24:36

The first ground relates to this all important 15:24:40
category called possibly impacted, and I was trying to 15:24:44

get at the issue of whether that should be in the protective condition or not, meaning -- meaning if you're in possibly impacted are you flunking the SQO or are you passing it. 15:24:50 15:24:57 15:25:00 15:25:06

That was a very, very close call at the State Water Board. I'm not speaking from the deposition today, but just from my knowledge of it. 15:25:08 15:25:10 15:25:12

And I thought it was very, very important to -- an understanding of the methodology and explanation. 15:25:14 15:25:19

MR. GALLAGHER: So the first line of questioning, and you both can interrupt me at any time. 15:25:23 15:25:24

Possibly impacted -- is that a protective condition or not, did it pass or notpass. 15:25:28 15:25:33

Go on. 15:25:38

MR. SINGARELLA: Exactly. Exactly. 15:25:39

And how was -- how was -- how was that decision made at the State Water Board, how did they decide to put it on one side of the line or another. 15:25:41 15:25:44 15:25:48

It's critical because we have some of these possibly impacted stations. 15:25:51 15:25:53

The second issue deals with all these numbers inside the SQO itself. 15:25:55 15:26:00

There are a tremendous number of numbers, ranges and the like, and it's my belief that those ranges do not result from, you know, known scientific 15:26:03 15:26:06 15:26:10

formula, or principles, or equations, you know, like E=MC squared, but, rather, there is a good deal of judgment going in to these ranges, and I'm simply trying to ask questions to get an understanding as to where these numbers came from. 15:26:15 15:26:19 15:26:24 15:26:28 15:26:31

And to understand the SQO methodology we've got to know a little bit about these numbers. 15:26:32 15:26:36

It's not a rote application without any context, and I'm simply seeking that context, and I'm seeking a record that would clarify where these numbers came from. 15:26:39 15:26:42 15:26:46 15:26:49

And then we even had some trouble agreeing on whether I would be allowed to ask Mr. Beegan where certain data came from. 15:26:49 15:26:53 15:26:57

Here my belief is that the data that -- that Mr. Beegan has shown to the San Diego Regional Board on a couple of occasions is the data from the SQO, and it looks like a Rorschach test as opposed to something you draw a straight line through. 15:26:59 15:27:03 15:27:08 15:27:12 15:27:16

I'd like to know where those data come from and to what extent the SQO relies upon them. 15:27:19 15:27:21

So, you know, basic -- 15:27:25

MR. GALLAGHER: Let me -- the data that you're referring to is not data specific to the San Diego marine sediment. 15:27:26 15:27:31 15:27:35

It's other -- what -- what data are we talking about? 15:27:38 15:27:42

MR. SINGARELLA: It's statewide. 15:27:42

It appears to be everything that they looked at, for example copper. 15:27:44 15:27:46

There's -- there's a plot that -- that I believe is the data used to develop the -- the sediment chemistry prong of the SQO for copper, and I'm simply trying to link, you know, the data that I'm presenting to Mr. Beegan to SQO itself -- not for San Diego Bay. 15:27:49 15:27:52 15:27:58 15:28:03 15:28:08

It's not -- it probably has some San Diego Bay data in it. I have no idea. 15:28:11 15:28:14

This is some broad stroke stuff that we're trying to get our arms around here. 15:28:15 15:28:18

And so -- 15:28:20

MR. GALLAGHER: On the numbers inside the SQO not only are you, you know, trying -- 15:28:22 15:28:25

Just so I understand, not only are you trying to understand the judgment put in to the ranges, but when you -- but whether or not there's -- 15:28:29 15:28:32 15:28:36

In other words, A, you're trying to understand the numbers put in the -- with the judgment put in to the ranges, but then, B, you're trying to understand, you know, once you have some understanding of that judgment you're trying to understand where the data came 15:28:42 15:28:43 15:28:47 15:28:50 15:28:54

from for the judgment to put in the SQO numbers? 15:28:57

MR. SINGARELLA: Correct. 15:29:03

And I must be missing something, because 15:29:05
Mr. Fuchs has been repeatedly objecting and has issued a 15:29:07
series of limiting instructions limiting -- instructing 15:29:11
Mr. Beegan to not answer this or that. 15:29:15

MR. GALLAGHER: So those are two lines of 15:29:21
questioning. Those are the two exhibits. 15:29:23

Dan, do you want to clarify anything as far 15:29:27
as -- 15:29:34

MR. FUCHS: Oh, yeah, yeah, naturally. 15:29:34

I think it's very significant that Mr. 15:29:37
Singarella said that he wanted to, as he put it, get at 15:29:45
the SQOs. 15:29:48

My distinct recollection from our September 27 15:29:50
conference was that you had limited the questioning at 15:29:54
this deposition to how in the abstract the SQOs would be 15:29:59
or should be applied and not how they were arrived at, 15:30:06
because that -- would impermissibly invade the mental 15:30:14
processes of the decision-makers and would create an 15:30:23
opportunity for extra record evidence in the Cal Chamber 15:30:29
case which has been stayed and which is a record case 15:30:33
insofar as it is a -- a writ case. 15:30:37

MR. GALLAGHER: Right. 15:30:40

MR. FUCHS: So the -- Mr. Singarella is, of 15:30:41

course correct, that the majority of the questioning has been based on the SQO document itself and the Staff Report. There have been some others. 15:30:47 15:30:49 15:30:53

He didn't spend very much time on those, but those were certainly not the only two. 15:30:56 15:30:58

And -- and I've -- you know, it's obviously -- it's after 3:00 so -- we began at 8:00. 15:30:59 15:31:05

I've, obviously, let the questioning go on quite long today. 15:31:07 15:31:09

I've let Mr. Singarella ask a great many questions, many of which I think actually I probably should not have let him ask because they were outside the scope, as I've just described it. 15:31:13 15:31:17 15:31:21 15:31:24

So, for example, what he just -- the two examples he just gave, I think, are perfect examples of lines of questioning that should not be permitted, and I think that you did not permit, and those are, for example, how did the State Board decide how to put the possibly impacted category in to one side or the other? 15:31:27 15:31:30 15:31:35 15:31:39 15:31:42 15:31:46

That they did is what is relevant here, and one should do with a possibly -- 15:31:52 15:31:57

MR. GALLAGHER: Dan, say that last sentence again. 15:31:59 15:32:02

MR. FUCHS: Yeah. 15:32:02

What's relevant here is that they did put 15:32:03

possibly impacted in to one side or the other, and going on from there what one should do if one is applying the SQOs and one has a possibly impacted station. 15:32:06 15:32:10 15:32:15

How the State Board decided -- 15:32:21

MR. GALLAGHER: Say that second sentence, Dan. When you got you said they didn't, and the second sentence you said was? 15:32:24 15:32:26 15:32:30

MR. FUCHS: Right, what one should do when applying the SQOs -- 15:32:31 15:32:36

MR. GALLAGHER: Right. 15:32:41

MR. FUCHS: -- and -- and has a station that is possibly impacted. 15:32:41 15:32:45

That is a relevant line of questioning. 15:32:47

But how the State Board decided how to characterize or categorize, possibly impacted stations is not within the scope as you described it on the 27th and -- 15:32:50 15:32:56 15:33:03 15:33:10

MR. GALLAGHER: That's right. 15:33:11

MR. FUCHS: -- and is not a permissible avenue insofar as it invades the privileges and creates extra record evidence. 15:33:12 15:33:16 15:33:22

MR. GALLAGHER: Right. 15:33:25

MR. FUCHS: And the -- the second example that Mr. Singarella gave, I think, is also an example of an impermissible avenue. 15:33:25 15:33:29 15:33:36

For example, he said where the numbers came from, and the numbers here are the ranges of outcomes when various tests are performed. 15:33:39 15:33:41 15:33:48

So, for example, the health of the benthos, -- the benthic organisms, whether they're low disturbance or mid-disturbance, what I understood you to have said is that Mr. Singarella could ask how one who is applying the SQOs would decide whether something is low, or moderate, or heavily disturbed, but not how the State Board decided what range of values should qualify for each of those categories, because, again, to the extent that Mr. Singarella wants to explore the State Water Board's decision-making, that evidence is in the administrative record. 15:33:52 15:34:00 15:34:05 15:34:10 15:34:19 15:34:25 15:34:33 15:34:38 15:34:44 15:34:49 15:34:54

MR. SINGARELLA: Mr. Gallagher, I am not phrasing my questions based on, you know, deliberative process. 15:34:59 15:35:01 15:35:07

I'm not coming anywhere -- anywhere near deliberative process. 15:35:08 15:35:10

I am not asking Mr. Beegan, "How did the State Board decide this?" or "How did the State Board decide that?" 15:35:12 15:35:14 15:35:17

I'm simply looking at the words in these documents and asking questions about them. 15:35:17 15:35:20

For example, there are pages in the Staff 15:35:22

Report about best professional judgment and its limitations, and the idea, as I understand the SQO, is to overcome those limitations but, Mr. Beegan has testified there is some judgment that goes in to the SQOs, and I have been exploring that with him. 15:35:25 15:35:29 15:35:34 15:35:37 15:35:40

Where is it, show me where it is, not what did the State Board decide about best professional judgment. 15:35:43 15:35:46

And with respect to these -- this possible impacted category, you can't know how to use this tool correctly unless you understand how these categories were generated. 15:35:50 15:35:53 15:35:57 15:36:01

And whether something is on one side of the line or the other is the key issue here. 15:36:02 15:36:05

I'm simply trying to create a record of that so that no one relies on this thing as if it's handed down from Mount Sinai on tablets. 15:36:08 15:36:12 15:36:15

It's not Einstein's equation -- no -- no offense to the authors of the SQO here. 15:36:19 15:36:21

MR. FUCHS: Well, the -- 15:36:25

Again, I think it's -- what Mr. Singarella says is very significant. 15:36:27 15:36:30

He wants to -- reduce the credibility of the document. He just -- he just told you that. 15:36:33 15:36:40

And one of the ways he's doing that is by showing -- and this is the example we're using, because 15:36:43 15:36:46

it's the one that just -- we finished on, so it's the one freshest in our minds, I think. 15:36:50 15:36:54

The best professional judgment, there is some paragraphs in the Staff Report that suggest that best professional judgment may lead to inconsistent results, for example. 15:36:55 15:36:59 15:37:01 15:37:05

So then Mr. Singarella turns to the SQO document and says, "Well, essentially weren't these numbers derived using best professional judgment?" 15:37:06 15:37:09 15:37:13

That's not relevant to how one applies best professional judgment when using the SQOs. 15:37:17 15:37:23

He's exploring how best professional judgment was employed in deriving the SQOs. 15:37:28 15:37:32

It's very different. 15:37:35

MR. GALLAGHER: So -- so when you look at the Staff Report and you talk about best professional judgment, is it -- Mr. Beegan testified that it could lead to inconsistent results? 15:37:39 15:37:42 15:37:46 15:37:50

MR. SINGARELLA: Correct. 15:37:52

MR. FUCHS: Yes. 15:37:52

MR. SINGARELLA: The Staff Report says so, and I was -- 15:37:52 15:37:55

MR. GALLAGHER: And you -- and then now you, Paul, you want to understand that better? 15:37:56 15:37:59

MR. SINGARELLA: Absolutely. 15:38:01

I -- I spent the whole day basically trying to unpackage the sentences that are not self-explanatory and that led to a discussion of these concepts that are laced throughout these two exhibits. 15:38:02 15:38:06 15:38:10 15:38:17

MR. GALLAGHER: Then you may cross over to the deliberative process. 15:38:21 15:38:23

MR. SINGARELLA: Well, I think you cross over in to deliberative process if you say, "Mr. Beegan, you know, how did staff get together and decide, you know, how to develop these ranges?" 15:38:23 15:38:24 15:38:28 15:38:33

What I'm asking is are these ranges like E=MC squared or are they something else, the product of your judgment that you referred in to the Staff Report. 15:38:36 15:38:43 15:38:47

That's the nature of my question. 15:38:49

I'm not getting in to the -- the history of the proceedings. 15:38:51 15:38:53

There is a fine line here, Mr. Gallagher. I grant you that. 15:38:54 15:38:57

And I've been very solicitous of it, and I've been very mindful not to, you know, go too far. 15:38:57 15:39:01

There -- just like the SQOs, there is a bit of a line drawing going on here. 15:39:05 15:39:08

And -- and Mr. Fuchs characterized my questioning as "How did the State Board decide this? How did --" 15:39:09 15:39:13

That's not the nature of my questioning. 15:39:15

I am -- my questions are springing from these 15:39:17
materials in front of us here today very specifically, 15:39:20
and if you saw the transcript you'll see that I'm taking 15:39:24
specific sentences and asking four or five questions 15:39:27
about the sentences, because they don't explain 15:39:30
themselves. 15:39:32

There's -- there's a list of four reasons why 15:39:33
best professional judgment is dangerous and can lead to 15:39:36
spurious results. I think we're entitled to understand 15:39:40
that. 15:39:43

MR. GALLAGHER: In the -- in the Staff Report? 15:39:44

MR. SINGARELLA: In the Staff Report. 15:39:45

MR. GALLAGHER: And those four reasons are? 15:39:47

MR. SINGARELLA: Well, BPJ -- 15:39:50

Here we are on page 5-31 of the Staff Report. 15:39:53

BPJ, number one, may result in inconsistent 15:39:58
decisions. That can happen even within a single region. 15:40:00

BPJ number two, can be time-consuming and 15:40:04
resource intensive, and the utility of BPJ is limited 15:40:10
for a third reason, and that is it may not always lead 15:40:11
to transparency or unbiased decisions, and then number 15:40:14
4, BPJ is limited because it may not allow Regional 15:40:18
Board staff or interested parties to assess the outcome 15:40:23
independently. 15:40:27

And -- and what I understand is that staff were very aware of test problems with BPJ and did their best to try to tease those problems out of the SQO, but they couldn't do it fully, and I'm trying to figure out where that remaining judgment lies. 15:40:28 15:40:31 15:40:36 15:40:42 15:40:45

They were not -- 15:40:48

MR. GALLAGHER: So each of these issues 1 through 4 -- is a decision to -- to assess independence of it. 15:40:49 15:40:53 15:40:59

You're just trying to take each one of these and then you -- understand how -- how each one of these -- these conclusions -- 15:40:59 15:41:02 15:41:10

You're just trying to understand the discussion that took place in regards to these four BPJ points? 15:41:11 15:41:13 15:41:18

MR. SINGARELLA: Yes. 15:41:18

That was the last line of questioning before we called you. 15:41:19 15:41:21

MR. GALLAGHER: Okay. And then the legal documents on the possibly impacted, you know, there obviously -- the possibly impacted, you know, protected condition or not, pass or no pass -- umm -- trying to make you understand how that decision was based, but they're -- they're obviously -- you know, just like BPJ, there's a series of factors, you know, obviously taken 15:41:22 15:41:26 15:41:28 15:41:34 15:41:39 15:41:42 15:41:46

in to consideration in determining the station or whatever it is that's possibly impacted. 15:41:49 15:41:57

So what -- how did that line of questioning go? 15:42:06 15:42:09

I mean, where did you -- what in the Staff Report or in the SQO document itself -- where did you take off? 15:42:09 15:42:12 15:42:16

How did that line of questioning proceed? 15:42:16

MR. SINGARELLA: Well, and I -- I will admit that that one I did not launch as well as I could have from the document itself. And -- 15:42:19 15:42:23 15:42:27

MR. GALLAGHER: Okay. 15:42:30

MR. SINGARELLA; -- let me tell you where I'd like to launch from so we can discuss it, and -- and then maybe we can resolve this issue. 15:42:31 15:42:33 15:42:36

But I have some more questions on possibly impacted, and the reason is the Staff Report says that if you've got a site that's possibly impacted, the biological effect may be nominal or transient, and then it also says that for possibly impacted sites the ability to differentiate, you know, natural stresses, something just naturally happening in the environment or random noise or variability from the actual impact may be difficult. 15:42:39 15:42:42 15:42:45 15:42:49 15:42:55 15:42:58 15:43:02 15:43:06 15:43:10

Now, that's right in the Staff Report. 15:43:10

And so the State Board was -- and staff here, Mr. Beegan, they were very aware that this possible impact, that it's kind of on the cusp, and I was trying to get at that much more directly, and I think perhaps, you know, the way I did it led to the objection. 15:43:12 15:43:15 15:43:18 15:43:23 15:43:25

And the way I did it directly is I asked Mr. Beegan if at one point possibly impacted was considered by staff to be part of the protective condition, and then it switched over, and -- and really I can get at this point simply by discussing page 5-46 of the Staff Report, because it's right here. 15:43:29 15:43:32 15:43:36 15:43:37 15:43:41 15:43:48

I mean, they're saying -- I think we're entitled to understand, well, what do you mean by the affecting nominal or transient? 15:43:50 15:43:52 15:43:54

What do you mean by gee, I can't tell the difference between a real effect and random variability of possible impacted stations? 15:43:57 15:43:59 15:44:04

Those are the kinds of questions I would like to ask and haven't had the opportunity to. 15:44:05 15:44:08

MR. FUCHS: Well, those are the kind of questions that -- 15:44:10

Are you done, Paul? 15:44:10

I don't want to interrupt you. 15:44:11

MR. SINGARELLA: Yes, Dan. 15:44:13

MR. FUCHS: Okay. Those are the kind of 15:44:14

questions that do not address how someone who wants to use the SQOs would do so. 15:44:15 15:44:21

I want to just call your attention back to the rationale given originally in correspondence from Mr. Singarella's office as to why they wanted to take Mr. Beegan's deposition. 15:44:25 15:44:28 15:44:38 15:44:41

They said to address the Regional Board's rationale for selecting its methodology and application thereof. 15:44:42 15:44:45 15:44:49

So it's a very important to remember that this is all -- 15:44:50 15:44:53

MR. GALLAGHWER: Now, Dan, read that again.

Dan, read that again. 15:44:54

MR. FUCHS: Pardon me? Oh. 15:44:56

MR. GALLAGHER: That sentence again. 15:44:59

MR. FUCHS: Right. 15:45:01

The -- it was the Regional Board's rationale for selecting its methodology and application thereof. 15:45:02 15:45:06

And I don't have the -- the whole sentence here. I could find it. 15:45:11 15:45:14

But that's the -- the reason given for taking Mr. Beegan's deposition, the reason given in a letter to me from Mr. Richardson. 15:45:15 15:45:18 15:45:22

MR. GALLAGHER: All right. And you feel that, you know -- that you've allowed to identify rationale in 15:45:24 15:45:26

the application, but -- the rationale -- 15:45:33

Let's -- let's take -- take one of the 15:45:39

examples. 15:45:44

Take an example of how you believe he -- 15:45:45

you've allowed the deponent to discuss the rationale of 15:45:48

the application, just, I mean, BPJ, or possibly 15:45:52

impacted, just one of those or something else, whatever 15:45:58

you feel comfortable with. 15:46:01

You gave him rationale, you gave him 15:46:03

application, application. 15:46:05

Can you give me something -- 15:46:10

MR. FUCHS: Well, it -- the -- 15:46:13

What we're here for are the -- the case we're 15:46:17

here in is the San Diego Regional Board's Tentative 15:46:21

Cleanup And Abatement Order and -- 15:46:25

MR. GALLAGHER: Which I wasn't going allow you 15:46:28

to dig in to at all. 15:46:32

MR. FUCHS: Well, right. 15:46:34

So what -- we're not here to explore the -- 15:46:36

the background of the SQOs except that I've allowed, 15:46:42

frankly, a lot of questioning on the background because 15:46:48

Mr. Singarella made the case that someone who wants to 15:46:52

go to apply the SQOs might be interested or might be 15:46:56

aided by knowing some of the background. 15:47:01

So I've allowed an enormous amount of 15:47:04

questioning on the background. 15:47:07

But there comes a point when -- when we've 15:47:08
done enough on that, and when we're really invading the 15:47:11
mental processes, not -- not just the deliberative 15:47:15
process, but the broad category of mental processes of 15:47:18
folks who are involved. 15:47:22

And so, again, you know, I think Mr. 15:47:24
Singarella and I are in great agreement as to what the 15:47:28
questioning is relevant and what his basis is, and my 15:47:32
point is that the precise arguments he's made for why he 15:47:35
should be allowed to continue the questioning are why he 15:47:41
should not be allowed to continue the questioning. 15:47:46

MR. SINGARELLA: Which I find rather ironic 15:47:49
because -- 15:47:51

Mr. Gallagher, may I be heard? 15:47:53

MR. GALLAGHER: Yeah, go ahead. Please. 15:47:55

MR. SINGAREALLA: Yeah.

I mean, my client is facing a, you know, 15:47:57
potential action here with this cleanup order that, as 15:48:00
you know, is -- is very, very substantial, and we are 15:48:05
getting at the methodology used by the Regional Board, 15:48:12
and it's not by directly -- asking about the CAO today. 15:48:18

You put that off limits, and I understand 15:48:23
that. 15:48:25

But what is at issue is this SQO and that 15:48:25

Staff Report and whether this agency is going to try to wrap itself in the cloak of those documents and say, "Well, you know, the SQO didn't apply as a matter of law in San Diego Bay, but we used methods that are similar or the same to what was laid out in those materials, and that gives us the cloak of -- of, you know, an appropriate approach and an approach blessed by the State Board." 15:48:30 15:48:33 15:48:37 15:48:42 15:48:46 15:48:52 15:48:56

And I can imagine when we get to briefing here that they're going to be using these sentences from these materials, and they'll have their viewpoint on what they mean, and they will be using that to support a very substantial cleanup order. 15:48:59 15:49:02 15:49:06 15:49:10 15:49:15

And what I'm trying to do is create a record in this evidentiary proceeding so that these statements don't get misconstrued to prejudice my client. 15:49:17 15:49:20 15:49:23

So am I trying to get at the SQOs? 15:49:28

Of course, I am. 15:49:32

Am I trying to get at the deliberative process of the State Board? 15:49:33 15:49:37

Of course not. 15:49:37

Those are two separate things, and I think I've been at this long enough to understand how to judge that line. 15:49:39 15:49:41 15:49:44

MR. GALLAGHER: On the BPJ line of 15:49:46

questioning, and I know you said 5-31, but -- 15:49:49

Dan, has -- there's been discussion of how -- 15:49:58

how BPJ is employed? 15:50:03

MR. FUCHS: There's been a discussion as to 15:50:06

whether BPJ -- 15:50:11

Well, I stopped the questioning when Mr. 15:50:14

Singarella started asking whether Mr. Beegan had applied 15:50:18

BPJ in developing the -- Benthic index. 15:50:21

MR. GALLAGHER: Okay. 15:50:31

MR. FUCHS: Sorry. 15:50:34

Go ahead. 15:50:35

MR. GALLAGHER: The Staff Report -- the Staff 15:50:35

Report says BPJ is applied when? 15:50:38

What is the sentence on page 5-31? 15:50:44

I understand this can be time-consuming 15:50:46

inconsistent decisions, maybe not a lot of transparency, 15:50:50

you know, and -- may -- may not allow the Regional Board 15:50:55

to assess the outcome independently. 15:50:59

So I understand that, and I probably would 15:51:03

have stopped the line of questioning. 15:51:06

I wouldn't allow a line of questioning 15:51:07

understand how the decisions made, blah, blah, blah. 15:51:11

But have -- there's -- 15:51:12

Has there been some discussion how BPJ is 15:51:16

applied in the context of what you just said, Dan? 15:51:20

MR. FUCHS: How BPJ would be -- 15:51:22

No. 15:51:24

I would allow Mr. Singarella to ask how 15:51:24

someone using the SQOs would apply BPJ, and, in fact, I 15:51:29

did allow such questioning without any complaint or 15:51:35

objection. 15:51:38

It's how BPJ was employed in generating or 15:51:39

deriving the SQOs that -- where I put my foot down. 15:51:44

MR. GALLAGHER: But the line of questioning 15:51:50

that you did allow -- 15:51:51

Go on, Dan. 15:51:55

Fill that in for me. 15:51:56

MR. FUCHS: And -- and would continue to allow 15:51:57

is how someone, anyone, who is going to use the SQOs 15:51:59

should or could use their own best professional 15:52:10

judgment. 15:52:16

MR. GALLAGHER: Okay. 15:52:19

MR. FUCHS: It all comes back to the -- the 15:52:21

parameters that we all agreed on two weeks ago. 15:52:26

MR. GALLAGHER: Yeah. All right. 15:52:30

And then -- umm -- 15:52:31

Let's see. 15:52:39

MR. FUCHS: But, you know, I don't want you to 15:52:42

be mistaken. 15:52:44

Mr. Sangarella gave you a couple of examples 15:52:45

of instances where I have -- I've refused to let Mr. Beegan answer, and it's not limited to that. 15:52:47 15:52:51

I've -- I've told him not to answer about other things as well. 15:52:54 15:52:56

MR. GALLAGHER: Right. 15:52:58

MR. FUCHS: But generally I think, you know -- 15:52:58

So he's actually portraying me as more reasonable than I've been. 15:53:01 15:53:04

MR. GALLAGHER: Okay. 15:53:06

MR. FUCHS: So I think I've been reasonable, but -- 15:53:07 15:53:09

MR. SINGARELLA: Well, I'd like to just get through this, Mr. Gallagher. 15:53:12 15:53:14

You know, Dan's right, he has been interrupting, quite a bit, and I've got more stuff in this Staff Report that springs right from the language of the Staff Report that is the document used to adopt these SQOs and help people understand them, and I'd simply like to get through it. 15:53:16 15:53:18 15:53:22 15:53:26 15:53:31 15:53:37

MR. FUCHS: And I absolutely share -- 15:53:39

MR. GALLAGHER: Go ahead, Dan. 15:53:41

MR. FUCHS: I absolutely share the desire to just get through this. 15:53:43 15:53:46

I thought we would have been done in the morning, and I thought we would have been done if Mr. 15:53:46 15:53:48

Singarella had limited his questioning to the -- to be within the parameters that were set forth on September 27th. 15:53:49 15:53:54 15:53:57

MR. GALLAGHER: All right. Possibly impacted, page 5-46 saying it's nominal or transient -- can be nominal or transient -- 15:53:58 15:54:01 15:54:11

What was the next step with that? 15:54:15

What was the -- the -- questioning, Paul? 15:54:18

MR. SINGARELLA: Sorry to interrupt, sir. 15:54:24

Yeah. 15:54:26

My line of questioning was to understand what "possibly impacted" means with regard to these statements by the staff about, you know, nominal and transient biological effects and the fact that you can have these other things, natural influences, and just noise, statistical noise as -- 15:54:26 15:54:31 15:54:35 15:54:41 15:54:44 15:54:47

MR. GALLAGHER: Right. 15:54:50

MR. SINGARELLA: -- misleading you and thinking there's a pollutant-related stress there. 15:54:51 15:54:53

And, you know, I wish these words just spoke for themselves, but I think this possibly impacted category needs some understanding lest it be, you know, misconstrued. 15:54:55 15:54:58 15:55:02 15:55:08

MR. GALLAGHER: Well, how do you want to do this? 15:55:09 15:55:11

How do you want to go forward? 15:55:12

MR. SINGARELLA: Well, I -- 15:55:13

You know, if I'm limiting my questions to the 15:55:14
Staff Report, then in my mind I just -- I'm having a lot 15:55:17
of trouble finding this -- this distinction. 15:55:22

This is methodology. 15:55:25

I certainly have no intent to cross over any 15:55:27
line that you set, Mr. Gallagher, and I thought I was 15:55:30
vigilantly respecting it by limiting my questions 15:55:37
principally to these two seminal documents. 15:55:39

And I -- I've got probably another hour max in 15:55:42
-- in the Staff Report, and then I have some additional 15:55:47
questions about executive summaries and conclusions and 15:55:50
the documents that Mr. Beegan pointed us to last week, 15:55:55
and I'm done. 15:56:00

I don't know if I can finish today given where 15:56:01
we are, but I've done my level best. That's for sure. 15:56:03

MR. GALLAGHER: Okay. So let me just give you 15:56:07
a -- I lean a bit in favor of what Dan's saying in terms 15:56:10
of BPJ and page 541 and getting in to inconsistent 15:56:26
decisions and getting in to each one of those four 15:56:31
categories. 15:56:33

I'm not so sure where do you cross the line 15:56:34
between methodology and the mental process and -- you 15:56:38
know, jumping to possibly impacted, and, you know, 15:56:44

nominal or transient, and understand what that means or at least -- identifying factors such as statistical noise. I'm not exactly sure where you'll go -- 15:56:50 15:56:54 15:57:00

I'm happy -- I won't say I'm happy, but I'm more than pleasantly willing to -- or unpleasantly willing to be on the phone to, you know, deal with these questions to help you get through it for the next hour if that's what you want to do. 15:57:08 15:57:10 15:57:17 15:57:22 15:57:26

And, obviously, you know, the objective, and it doesn't mean what I decide, if it's methodology or mental process it's hundred percent right, leaning one direction or another, but because it does get a little difficult. 15:57:28 15:57:34 15:57:39 15:57:44 15:57:48

MR. SINGARELLA: We certainly don't want to impose, or I don't want to impose, but I do think that perhaps if you are available, perhaps taking advantage of -- of your kind offer to sit in on this for the next hour might not be a bad idea. 15:58:00 15:58:01 15:58:06 15:58:12 15:58:16

MR. GALLAGHER: I think so, too. 15:58:19

I'm in Court doing my Special Master functions on another matter, so I'm not available, you know, tomorrow morning, so why don't we just hop to it now. 15:58:21 15:58:24 15:58:28

MR. SINGARELLA: Okay. 15:58:32

MR. FUCHS: All right. Mr. Beegan stepped out briefly. So he should -- he should be back in a minute 15:58:32 15:58:34

or two. 15:58:40

MR. GALLAGHER: Okay. He ran somewhere else? 15:58:40

MR. FUCHS: He ran off to the restroom, I think. 15:58:43 15:58:45

MR. GALLAGHER: Yeah. And please don't hesitate to interrupt me, and say "I don't think you have it right" and explain, and I take no offense, and so, you know, we've talked it out a little, but I want to move as expeditiously as possible. 15:58:45 15:58:48 15:58:53 15:58:57 15:59:02

MR. SINGARELLA: I appreciate that, sir. 15:59:06

So we'll just wait for Mr. Beegan to return. 15:59:12

MR. FUCHS: Yeah. 15:59:15

MR. GALLAGHER: Okay. 15:59:15

(Discussion off the record) 16:01:24

VIDEOGRAPHER: We are back on the record at 4:01 p.m. 16:01:25 16:01:28

BY MR. SINGARELLA: 16:01:29

Q. Mr. Beegan, could you turn to Part 1, Attachment B, pages 26 and 27. 16:01:29 16:01:38

A. Okay. I'm there. 16:01:49

Q. And on page 27 there's a Line of Evidence category combination number 52. 16:01:50 16:01:55

Do you see that? 16:01:59

A. 52. 16:02:00

Umm -- yes. 16:02:02

Q. Now, what are these category combinations? 16:02:04

A. These -- category combinations are -- the sum total of the individual line of evidence categories integrated in to a station assessment category. 16:02:15 16:02:23 16:02:33

Q. And the station assessment category is whether the station passes or fails the SQO? 16:02:39 16:02:45

A. Well -- umm -- yes. 16:02:49

Q. And likely impacted as a station assessment means failure of the SQO; right? 16:02:55 16:02:59

A. Umm -- not necessarily. 16:03:01

Q. Sure. 16:03:06

Please explain. 16:03:09

A. So you don't make a pass/fail decision on the SQO based on a single station. 16:03:10 16:03:16

So there's multiple stations involved, and so I guess you can say that -- umm -- there's a line drawn at some point in these categories between possibly impacted and -- likely unimpacted. 16:03:19 16:03:27 16:03:31 16:03:34

That doesn't necessarily mean you failed the SQO. It's not conducted at a station-by-station basis. 16:03:41 16:03:43

Okay? 16:03:50

Q. If you had a series of stations that you formally fell in to the category of likely impacted and nothing else, would you fail the SQO? 16:03:50 16:03:53 16:03:58

A. Umm -- yes, that would be defined as an 16:04:00

exceedance, yeah. 16:04:04

Q. That would not be a protective condition; 16:04:05

correct? 16:04:08

A. No. No. 16:04:09

Q. And in category combination 52 -- 16:04:09

Are you with me? 16:04:14

A. 52? 16:04:14

Yes. 16:04:16

Q. You see how reference benthic community 16:04:16

condition can produce an SQO result of likely impacted? 16:04:22

A. Yes. 16:04:26

Q. And turning to page 26, can I turn your 16:04:26

attention to categories -- category combination 20 and 16:04:42

category combination 36? 16:04:46

Do you see those two? 16:04:48

A. 20 and 36? 16:04:50

Q. Yes. 16:04:51

A. Yes. 16:04:57

Q. And do you see how benthic community condition 16:04:57

of reference can result in a station assessment of 16:05:01

possibly impacted for those two combinations? 16:05:04

A. Yes. 16:05:07

Q. And if all you had were possibly impacted 16:05:08

stations, you would conclude that there is an exceedance 16:05:10

of the SQO for that site; right? 16:05:15

A. Yes. 16:05:18

MR. SINGARELLA: Okay. 16:05:25

MR. GALLAGHER: May I interrupt, folks, for a minute? 16:05:29 16:05:32

MR. SINGARELLA: Please. 16:05:32

MR. GALLAGHER: This is Tim Gallagher speaking, Discovery Referee. 16:05:33 16:05:35

This line of questioning, Dan, you can correct me, but really goes to methodology, so at least up to this point, so I didn't have a degree of difficulty. 16:05:38 16:05:41 16:05:45

Obviously, Dan didn't either, but, you know, clearly methodology. 16:05:48 16:05:51

MR. FUCHS: Agreed. 16:05:52

This is Dan. Thank you. 16:05:53

MR. SINGARELLA: Thank you. 16:05:54

MR. GALLAGHER: I don't need to say that, and I apologize, but I -- you know. 16:05:55 16:05:58

Within that framework I don't have a problem. 16:06:01

MR. SINGARELLA: Thank you. 16:06:04

No, that's helpful. 16:06:04

BY MR. SINGARELLA: 16:06:05

Q. So let's turn back to the Staff Report, page 5-46. 16:06:06 16:06:11

This is on the section regarding receiving water limits. 16:06:18 16:06:23

Do you see that? 16:06:24

A. Yes. Yes. 16:06:25

Q. And the third paragraph discusses performing 16:06:30
stressor identification; right? 16:06:34

A. Yes. 16:06:36

Q. And it indicates that stressor identification 16:06:38
can be particularly useful for those sites classified as 16:06:45
possibly impacted; right? 16:06:51

A. Yes. 16:06:52

Q. And one of the reasons that stressor 16:07:02
identification at possibly impacted sites is helpful is 16:07:06
that biological effects at such sites might be nominal; 16:07:14
right? 16:07:20

A. Correct. 16:07:20

Q. Or transient; right? 16:07:21

A. Correct. 16:07:23

Q. What does it mean when a biological effect is 16:07:24
not or transient? 16:07:29

A. It means it is -- 16:07:30

Maybe it's -- 16:07:35

That's -- 16:07:38

It occurs on a temporal basis or over time. 16:07:39
It -- it comes and goes, or it's measurable, and then 16:07:44
it's not. 16:07:48

It's at the low end of the -- umm -- 16:07:50

detectible response where -- noise that is regular -- or regular -- umm -- variability in organism response may affect the result, various factors such as that. 16:07:56 16:08:11 16:08:19

Q. And all those things you just described could be happening at possibly impacted sites; right? 16:08:27 16:08:31

A. They could be happening -- umm -- at -- Yes. Yes. 16:08:34 16:08:41

Q. Now, the next sentence refers to natural stressors; right? 16:08:42 16:08:46

A. Yes. 16:08:48

Q. And random variability; correct? 16:08:50

A. Right. 16:08:52

Q. And those are distinguished, on the one hand, from pollutant-related stressors on the other; correct? 16:08:53 16:08:56

A. Yes. 16:09:00

Q. And this sentence indicates that it might be difficult to distinguish the natural stressors and the random variability from pollutant-related stress at possibly impacted sites; correct? 16:09:01 16:09:08 16:09:13 16:09:17

A. Correct. 16:09:19

Q. What is meant by the reference to "natural stressors"? 16:09:19 16:09:24

A. Umm -- scour, currents, salinity, habitat factors, grain size, where those factors aren't caused by anthropogenic inputs or -- 16:09:25 16:09:39 16:09:49

Q. Are these natural stressors the same as those confounding factors that we spoke about earlier? 16:09:58 16:10:04

A. They could -- they -- confounding factors could include natural factors. 16:10:07 16:10:16

Q. And "random variability," what does that refer to, Mr. Beegan? 16:10:19 16:10:25

A. Umm -- 16:10:26

Q. Let me help out. 16:10:30

Random variability in what? 16:10:33

A. Right. 16:10:35

I'm going to read the paragraph. 16:10:36

Q. Oh, please do. 16:10:37

MR. GALLAGHER: Can somebody put a speaker to the phone if you could? 16:10:45 16:10:47

THE WITNESS: Random variability may have to do with -- umm -- your toxicity test organism may exhibit some variability. 16:10:53 16:10:55 16:11:03

The benthic community could exhibit some variability. 16:11:05 16:11:10

Umm -- basically what this sentence is describing is -- umm -- being able to differentiate a pollutant-related stressor from the background noise within the system for -- all three Lines of Evidence, chemistry, sediment toxicity, and benthic community. 16:11:14 16:11:22 16:11:30 16:11:36 16:11:45

BY MR. SINGARELLA: 16:11:50

Q. And that's a particular challenge for possibly impacted sites? 16:11:50 16:11:53

A. It's more of a challenge for possibly -- 16:11:54

Yes, I would agree. 16:11:57

Q. And the point of this paragraph is that's why you go through stressor identification; correct? 16:11:59 16:12:05

A. Umm -- 16:12:07

Q. Let me rephrase. 16:12:34

The first sentence of that paragraph refers to using stressor identification to address confidence; correct? 16:12:35 16:12:39 16:12:42

A. Yes. 16:12:42

Q. And does that word "confidence" refer to confidence that a possibly impacted station is truly affected by toxic pollutants? 16:12:44 16:12:48 16:12:53

A. Yes. 16:12:56

Q. And the idea isto avoid mistaking toxic pollutants as the causative agent when, in fact, it might be these other things; right? 16:12:57 16:13:12 16:13:16

A. Correct. 16:13:18

Q. And stressor identification helps you get to the requisite level of confidence in that determination; right? 16:13:18 16:13:28 16:13:31

A. Yes. 16:13:31

Q. Turning to page 5-47, under "Potential 16:13:32

Response Actions for Exceedances," do you see that? 16:13:40

A. Yes. 16:13:42

Q. This is a new term here that we haven't talked about today. 16:13:44 16:13:48

It refers to this "simple co-occurrence of pollutants." 16:13:49 16:13:52

Do you see that in the first sentence? 16:13:53

A. Umm -- yes. 16:13:55

Q. And it says that sediment management actions typically are based on the simple co-occurrence guidelines; right? 16:13:56 16:14:01 16:14:05

A. Yes. 16:14:07

Q. What is "simple co-occurrence" as used in this context? 16:14:07 16:14:12

A. Going back to the development of empirical sediment guidelines that we talked about -- umm -- we discussed the fact that those are based on mixtures and -- umm -- so they're not causal -- they're not -- there's no establishment of cause. 16:14:12 16:14:22 16:14:26 16:14:33 16:14:41

Umm -- and the reason that is is because these are, again, mixtures. 16:14:48 16:14:52

There are typically multiple chemicals at any one station that's used in the development of these empirical guidelines. 16:14:55 16:15:01 16:15:04

So oftentimes you can -- you may see a -- some 16:15:06

sort of relationship between a chemical and biological effects, but it doesn't necessarily relate to cause. 16:15:13 16:15:26

That's probably -- and I guess what I'm getting at is it's a demonstration of the weakness associated with these empirical quality sediment guidelines. 16:15:29 16:15:35 16:15:39 16:15:44

Q. And that paragraph -- 16:15:44

I'm sorry. 16:15:46

Did I cut you off? 16:15:47

A. No. 16:15:49

The -- the regulatory decisions that are referred to are referring to the exceedance of a sediment quality guideline and biological effects, and it's attempting to explain that these are not good -- indicators of cause, they merely establish occurrence or co-occurrence, or, you know, an association. 16:15:50 16:15:53 16:15:59 16:16:04 16:16:13 16:16:22

Q. So they would build more or less a circumstantial case against a particular compound? 16:16:27 16:16:30

A. Right. 16:16:35

Q. When there might be a host of other potential causative agents at play; right? 16:16:36 16:16:44

A. Correct. 16:16:48

Q. So going down through that paragraph, the paragraph says that "Those relationships," referring to these sediment quality guidelines, "don't demonstrate 16:16:48 16:16:55 16:16:58

causality;" right? 16:17:02

Second sentence. 16:17:08

A. I'm -- 16:17:15

Q. The second sentence says "This relationship does not demonstrate causality;" correct? 16:17:16 16:17:20

A. Yes. 16:17:23

Q. What does "this relationship" refer to? 16:17:24

A. Umm -- a co-occurrence of biological effects with sediment quality guideline. 16:17:26 16:17:35

Q. Okay. Thank you. 16:17:38

And then third sentence refers to enormous resources applied instead of focusing on the causes; correct? 16:17:39 16:17:45 16:17:51

A. Right. 16:17:51

Q. What does that mean? 16:17:52

A. It means that -- umm -- that TMDLs -- to develop -- 16:17:54 16:18:09

TMDLs develop for stressors -- and I use -- 16:18:10

I shouldn't use the term "stressors." 16:18:19

TMDLs develop for pollutants based on a -- an exceedance of a sediment quality guideline, with associated biological effects -- may not result in an improvement of sediment quality. 16:18:21 16:18:28 16:18:37 16:18:45

Q. And then further on in paragraph -- there's a reference to the performance of stressor identification; 16:18:55 16:19:03

correct? 16:19:05

A. Umm -- what is that sentence? 16:19:06

Q. It's the sentence that begins -- six lines up, 16:19:14

"If stressor identification is performed and a stressor 16:19:20

is identified." 16:19:22

Do you see that? 16:19:25

A. Oh, yes. Yes. Yes. 16:19:26

Q. And that refers to the stressor identification 16:19:28

section in Part 1; correct? 16:19:30

A. It refers to the stressor identification 16:19:32

section and the -- umm -- the section -- the two 16:19:38

sections later, I think, that we talked about, 16:19:45

management guidelines. 16:19:48

I think it refers to both of those. 16:19:50

Q. It's the next section. 16:19:53

A. Oh, okay. Okay. 16:19:55

Q. It follows right after. 16:19:56

A. Okay. 16:19:58

Q. The site specific guideline specification? 16:19:59

A. Right. 16:20:03

There was the cleanup and abatement section. 16:20:03

Q. I'm sorry. I should have known better. 16:20:06

Yes, Section F is stressor identification. 16:20:09

Section G is cleanup and abatement, and 16:20:13

Section H is development of site specific sediment 16:20:17

management guidelines; right? 16:20:19

A. Correct. 16:20:21

Q. Sorry. I misspoke, Mr. Beegan. 16:20:21

My apologies. 16:20:25

And so this paragraph on page 5-47 refers to 16:20:28
stressor identification and also the development of site 16:20:33
specific sediment management guidelines; correct? 16:20:36

A. Yes, correct. 16:20:38

Q. And those can lead to remediation goals; 16:20:39
correct? 16:20:47

A. They can develop -- lead to TMDL development 16:20:47
or remediation goals. 16:20:54

Q. And then finally at the end of the paragraph 16:20:58
there's a statement that the SQGs would not fulfill this 16:21:01
role; correct? 16:21:08

MR. FUCHS: I object. 16:21:14

That actually misstates the sentence. 16:21:15

BY MR. SINGARELLA: 16:21:17

Q. And then what does the last sentence mean, 16:21:18
Mr. Beegan? 16:21:21

Rather than leave it that way and have me 16:21:26
botch it. 16:21:29

A. Okay. So this is not absolutely one hundred 16:21:32
percent clear. 16:21:44

The second to the last sentence, headline 16:21:45

development, would account for site receptor specific factors that control by variability refers to Section H, development of site specific sediment management guidelines. 16:21:49 16:21:52 16:21:59 16:22:02

And then the next sentence is -- saying that the adoption of Sediment Quality Guidelines to fill this role does not account for factors -- those guidelines are the national guidelines, or statewide guidelines, or nonsite specific. 16:22:04 16:22:11 16:22:16 16:22:20 16:22:24

So I can see where that would be confusing. 16:22:26

But I believe that's my intent. 16:22:31

Q. In the last sentence your intent was to refer to the national guidelines that were discussed in the earlier part of the Staff Report? 16:22:34 16:22:37 16:22:43

A. Either the national guidelines -- 16:22:44

Yeah, it was probably the national guidelines. 16:22:47

But you could -- the chemistry guidelines used in the MLOE approach also -- you also would want to use those chemical values for the same reasons, because they don't account for those factors. 16:22:49 16:22:55 16:23:04 16:23:09

Q. Referring to the CSI and California LRM? 16:23:11

A. Yes. 16:23:15

Q. And so on page 5-48, staff recommended Alternative 2, which incorporated in to Part 1 the stressor identification steps of Section F; right? 16:23:16 16:23:20 16:23:23

A. Yes. 16:23:28

Q. And the biologically relevant guidelines in Section H; correct? 16:23:30 16:23:35

A. Correct. 16:23:36

Q. And those were ultimately adopted in to the SQO? 16:23:36 16:23:40

A. Correct. 16:23:41

Q. Okay. Let's turn to the next chapter, Chapter 6, 6-4. 16:23:41 16:23:48

6-4, first paragraph, the last sentence indicates the expectation that the Regional Boards would likely control -- control strategies and remediation only for highly impacted localized sites. 16:23:57 16:24:04 16:24:09 16:24:17

Do you see that? 16:24:20

A. Umm -- yes. 16:24:22

Q. And what is meant by the phrase in reference to "highly impacted localized sites"? 16:24:35 16:24:42

A. I guess -- what was meant by that was not -- umm -- 16:24:45 16:24:58

We were -- the Board was unlikely to require remediation for whole water bodies or large areas within a water body. 16:25:05 16:25:13 16:25:27

Q. Okay. Turning to page 6-6, this first paragraph refers to the primary limitation of Part 1; is that right? 16:25:29 16:25:43 16:25:47

A. I'm sorry. 16:25:47

Correct. 16:25:50

Q. And the primary limitation of the Part 1 Line of Evidence approach is that it doesn't provide any direct information on potential cause of exceedance; correct? 16:26:00 16:26:07 16:26:09 16:26:14

A. Right. 16:26:14

Q. And when it says "an exceedance," it's referring to exceedance of the SQO? 16:26:15 16:26:22

A. Yes. Correct. 16:26:25

Q. So the multiple Line of Evidence approach just doesn't go to the issue of cause; correct? 16:26:26 16:26:31

A. It does not identify pollutants that are causing impacts. 16:26:34 16:26:44

Q. Does the next sentence of this paragraph identify an additional limitation? 16:26:48 16:26:52

A. Yes. 16:26:55

Q. And what is that limitation? 16:27:06

A. It does not provide nor does the proposed SQO provide pollutant specific concentrations that would be protective of aquatic life in sediment. 16:27:08 16:27:14 16:27:17

Q. So the proposed SQO doesn't give you that level of a constituent that would be protective; right? 16:27:21 16:27:25

A. Not -- not on a single pollutant-by-pollutant basis. 16:27:29 16:27:42

Q. Could you develop that level of constituent using Section H of Part 1; right? 16:27:43 16:27:47

A. Umm -- correct. 16:27:50

Actually, you know, if you were to apply those pollutant-specific concentrations singularly to sediments where you knew the concentrations and the makeup of all the pollutants, if you applied the reference concentrations, you would likely have a low probability for biological effects. 16:28:17 16:28:25 16:28:35 16:28:42 16:28:48 16:29:00

Is that protective? 16:29:05

I don't know. 16:29:10

Q. What -- 16:29:11

I'm sorry. 16:29:14

What don't you know to be protective? 16:29:14

A. Well, I was trying to tell you that -- umm -- 16:29:16

I'll go back to just agreeing with you as far as what that sentence says. 16:29:54 16:29:59

Q. Okay. Okay. 16:30:02

Mr. Beegan, you steered us in the direction of a number of technical reports, and I'd like to ask you some questions about a few of them. 16:30:10 16:30:13 16:30:19

MR. GALLAGHER: Paul, can you speak up just a little? 16:30:28 16:30:30

MR. SINGARELLA: Yes. Yes. 16:30:30

Moving on to a -- new exhibit. 16:30:31

(Exhibit 706 was marked for Identification.) 16:30:45

BY MR. SINGARELLA: 16:30:45

Q. Mr. Beegan, I've placed in front of you what has been marked Exhibit Number 706 to your deposition. 16:30:45 16:30:48

Do you see that? 16:30:51

A. Yeah. 16:30:52

Q. And this document is entitled "Sediment Quality in California Bays and Estuaries." 16:30:58 16:31:02

Do you see that? 16:31:05

A. Yes. 16:31:05

Q. By Arthur Barnett, et al.; correct? 16:31:06

A. Correct. Yeah. Right. 16:31:08

Q. And this was work funded by the State Board; is that right? 16:31:10 16:31:15

A. Correct. 16:31:15

Q. As part of the SQO? 16:31:16

A. As part of the SQO and SCCWRP. 16:31:20

Q. Are you familiar with this document? 16:31:27

A. Yes. 16:31:28

Q. What did the authors do as -- as part of this exercise reflected in Exhibit 706? 16:31:29 16:31:38

A. They -- umm -- they compiled recent data that met certain criteria, generally regional monitoring data that had chemistry, toxicity, and benthic community measures, and as -- as best as possible, they applied 16:31:43 16:31:55 16:32:07 16:32:16

the SQO framework to that data set to get a -- an estimate of how the framework would apply. 16:32:26 16:32:39

Q. Do you have any understanding how the investigators would have used replicate samples and information from -- in this particular study? 16:32:46 16:32:49 16:32:54

A. No. 16:33:05

Q. Could you turn to page 22 of Exhibit 706, "Conclusions and Recommendations," last paragraph, please. 16:33:05 16:33:10 16:33:13

This last paragraph, once again, addresses these possibly impacted stations, and in particular the second half of that last paragraph on page 22. 16:33:18 16:33:23 16:33:26

Are you with me? 16:33:30

A. Umm -- what's it begin with? 16:33:31

Q. "Future statewide and regional assessments can be improved." 16:33:34 16:33:38

A. Oh, okay. 16:33:39

Yes. I'm there. 16:33:39

Q. You see that? 16:33:40

A. Yes. 16:33:41

Q. And then halfway through it discusses the environmental significance of sediments classified as possibly impacted. 16:33:41 16:33:48 16:33:52

Do you see that? 16:33:53

A. Uh-huh. 16:33:53

Q. And it characterizes the environmental significance of possibly impacted sediments as uncertain. 16:33:54 16:33:58 16:34:03

Do you see that? 16:34:03

A. Yes. 16:34:05

Q. And that's consistent with what was said in the Staff Report; right? 16:34:05 16:34:09

A. That's consistent with what was said in the Staff Report and the process defined in Part 1. 16:34:10 16:34:13

Q. And this paragraph goes on to refer to the minor level of contaminant effect that may be present at a possibly impacted site; right? 16:34:19 16:34:23 16:34:27

A. Correct. 16:34:30

Q. It also refers to the fact that there may be substantial disagreement among the Lines of Evidence at possibly impacted sites; right? 16:34:30 16:34:35 16:34:37

A. Correct. 16:34:39

Q. In fact, we saw that, didn't we, in Attachment B, that you can use -- you can have reference benthic community and generate a category assessment of possibly impacted; right? 16:34:43 16:34:49 16:34:52 16:35:00

A. Right. 16:35:02

Q. And, then, finally, the last sentence here refers to those stressor identification studies that are needed at possibly impacted sites; right? 16:35:03 16:35:10 16:35:12

A. Correct. 16:35:16

Q. And they're needed to determine whether 16:35:18

sediment quality at these sites is adversely impacted by 16:35:21

contaminants; correct? 16:35:26

A. Correct. 16:35:28

Q. So the stressor identification process itself 16:35:28

is where the determination of adverse impact at possibly 16:35:41

impacted sites is -- is made; right? 16:35:46

A. Correct. 16:35:48

Q. Is it just plain feasible to develop a numeric 16:35:50

objective for sediment quality? 16:36:09

MR. FUCHS: I have to object there. 16:36:12

MR. GALLAGHER: I agree with Dan. 16:36:17

MR. SINGARELLA: Well, I have a document to 16:36:21

prove this up, Mr. Gallagher. 16:36:24

MR. GALLAGHER: Okay. 16:36:26

MR. SINGARELLA: I don't think this is part of 16:36:28

deliberative process because it actually wasn't 16:36:34

exchanged between one agency and another. 16:36:38

MR. GALLAGHER: Let's see the document. 16:36:41

Okay. 16:36:43

(Exhibit 707 was marked for Identification.) 16:36:54

BY MR. SINGARELLA: 16:36:55

Q. Mr. Beegan I've caused to be placed in front 16:36:56

of you Exhibit 707 to your deposition. 16:36:58

Do you see that, sir? 16:37:01

A. Yes. 16:37:02

Q. And do you recognize this as an E-mail between you and a member of another California agency, the Office of Administrative Law? 16:37:11 16:37:14 16:37:20

A. Yes. 16:37:22

Q. And this is actually an E-mail from Mr. Mentink? 16:37:23 16:37:28

Did I say his name right? 16:37:30

A. Umm -- I -- that sounds right. 16:37:31

Q. M-e-n-t-i-n-k, dated April 10th, 2008; is that right? 16:37:35 16:37:40

Is that right, sir? 16:37:47

A. Yes. Yes. 16:37:47

Q. And in that last full paragraph he indicates that you mentioned to him that when numeric criteria are unfeasible the Water Code in the Clean Water Act authorizes the use of narratives; correct? 16:37:48 16:37:51 16:37:57 16:38:02

A. Hold on. 16:38:07

Last paragraph? 16:38:09

Q. Yes. 16:38:10

A. Wait. 16:38:18

Which -- 16:38:18

MR. FUCHS: Counsel, where are you on this? 16:38:25

MR. SINGARELLA: Physically on the page? 16:38:30

MR. FUCHS: Yeah. 16:38:31

MR. SINGARELLA: Oh. I'm on the bottom of page 1. 16:38:32 16:38:33

MR. FUCHS: Okay. 16:38:34

THE WITNESS: Oh, okay. 16:38:36

Umm -- 16:38:57

MR. FUCHS: Hang on. 16:39:05

Was there a question pending? 16:39:07

MR. SINGARELLA: No. 16:39:10

BY MR. SINGARELLA: 16:39:14

Q. Do you recall mentioning to Mr. Mentink that you can proceed with narrative objectives when numeric criteria are unfeasible? 16:39:15 16:39:20 16:39:24

MR. FUCHS: I still think the objection I made before you handed out the document stands. 16:39:26 16:39:28

MR. SINGARELLA: Which is? 16:39:31

MR. FUCHS: Which is that this is outside the scope of applying the SQOs. 16:39:32 16:39:34

MR. GALLAGHER: I agree with Dan. 16:39:37

MR. SINGARELLA: Okay. 16:39:40

MR. GALLAGHER: Maybe you want to ask a question later when -- we're already done with this. 16:39:41 16:39:43

MR. SINGARELLA: Sure. 16:39:49

I will attempt that. 16:39:51

MR. GALLAGHER: Okay. Sorry, Paul. 16:39:52

MR. SINGARELLA: I understand. 16:39:55

MR. GALLAGHER: Let's cut to the chase here. 16:39:56

MR. SINGARELLA: Sure. 16:39:58

I'm doing my level best here. 16:39:58

BY MR. SINGARELLA: 16:40:00

Q. Would you agree that it was not feasible to develop a numeric sediment quality objective? 16:40:00 16:40:02

MR. FUCHS: Same objection. 16:40:07

BY MR. SINGARELLA: 16:40:09

Q. Was it feasible to develop a numeric quality objective? 16:40:10 16:40:13

MR. FUCHS: Same objection. 16:40:16

MR. SINGARELLA: Are you instructing him not to answer? 16:40:26 16:40:28

MR. FUCHS: Oh, yeah. 16:40:29

THE WITNESS: Yes what? 16:40:29

MR. FUCHS: I'm instructing you not to answer. 16:40:31

THE WITNESS: Okay. 16:40:33

(Exhibit 708 was marked for Identification.) 16:40:33

MR. SINGARELLA: I'll move on. 16:40:41

MR. FUCHS: Thank you. 16:40:43

BY MR. SINGARELLA: 16:40:43

Q. I'm placing in front of you what has been marked as Exhibit 708. 16:40:44 16:40:47

Do you see that, sir? 16:40:51

A. Yes. 16:40:53

Q. Exhibit 708 is another one of these technical reports, this one called "Evaluation of Methods for Measuring Sediment Toxicity in California Bays and Estuaries;" right? 16:40:55 16:41:00 16:41:07 16:41:12

A. Correct. 16:41:12

Q. Could you turn to the Executive Summary, please. 16:41:12 16:41:15

Q. First page of the Executive Summary iii, three paragraphs down? 16:41:15 16:41:26

A. iii on the Executive -- 16:41:29

MR. FUCHS: Page iii. 16:41:34

THE WITNESS: Okay. 16:41:36

BY MR. SINGARELLA: 16:41:36

Q. Third full paragraph, last sentence, there's a -- reference to sublethal tests and acute tests; right? 16:41:37 16:41:41

A. Yes. 16:41:47

Q. And those were found to be complementary rather than redundant; correct? 16:41:51 16:41:54

A. Correct. 16:41:56

Q. Indicating that they're both important as part of your Part 1 SQO; right? 16:42:00 16:42:03

A. Correct. 16:42:06

Q. And then on the second page, iv, that paragraph below the top table, that starts "The use of 16:42:06 16:42:19

multiple toxicity tests," do you see that? 16:42:26

A. Yes. 16:42:29

Q. And then there's a second sentence "The use of a diversity of test methods provides two key advantages." 16:42:29 16:42:33 16:42:38

Do you see that? 16:42:38

A. Yes. 16:42:39

Q. And first it says that "The use of two test methods reduces the influence of spurious results from a test." 16:42:41 16:42:46 16:42:50

Do you see that? 16:42:51

A. Yes. 16:42:51

Q. And the two test methods referred to here are a test for lethality and a test for a sublethal effect; right? 16:42:52 16:42:58 16:43:05

A. Correct. 16:43:05

Q. And so, on the other hand, proceeding with one of the other would increase the potential influence of the spurious result; correct? 16:43:06 16:43:15 16:43:19

A. Correct. 16:43:22

Q. If you would turn to page 17, please -- the paragraph underneath the table. 16:43:23 16:43:39

And that first sentence refers to the important features of the two sublethal tests that were incorporated in to Part 1; correct? 16:43:50 16:43:52 16:43:56

A. Yes. 16:43:58

Q. I'm sorry? 16:44:01

A. Yes. 16:44:02

Q. And those important features were not present in the suite of amphipod acute tests; correct? 16:44:02 16:44:04

A. Correct. 16:44:09

Q. Including the amphipod acute tests incorporated in to Part 1; correct? 16:44:13 16:44:16

A. Correct. 16:44:19

Q. Okay. Next page, please. 16:44:22

A. Okay. 16:44:24

Q. Page 18. 16:44:25

Bottom paragraph, first sentence, "The use of multiple toxicity tests," do you see that? 16:44:28 16:44:35

A. Correct. Yes, I do. 16:44:39

Q. And that says that "Multiple toxicity tests is needed for a complete confident evaluation;" correct? 16:44:41 16:44:45

A. Correct. 16:44:49

Q. Suggesting that the absence of the multiple toxicity tests would not be as complete or confident; right? 16:44:49 16:44:53 16:44:57

A. Correct. 16:44:57

Q. Thank you. 16:44:58

Could you go back to Exhibit 703, please, the October 5 document that you prepared for us last week. 16:45:08 16:45:21

A. Okay. 16:45:28

MR. FUCHS: You can just use my copy. 16:45:28

BY MR. SINGARELLA: 16:45:30

Q. On page 2, Mr. Beegan, you referred us to the three sediment chemistry documents here; right? 16:45:30 16:45:34

A. Correct. 16:45:38

Q. You thought that perhaps we could find the dose response relationship in these documents; is that right? 16:45:40 16:45:42 16:45:46

A. Umm -- yes, or a description of the relationship that was being evaluated. 16:45:47 16:45:58

I mean -- when you describe the dose response relationship, I don't know what exactly you're looking for. 16:46:00 16:46:05 16:46:10

Q. Okay. 16:46:10

A. What does that mean to you? 16:46:13

Q. Well, is it a -- 16:46:14

What does it mean to you? 16:46:18

Do you have a working definition of "dose response relationship"? 16:46:22 16:46:31

A. The -- dose -- "dose response relationship" implies cause. 16:46:32 16:46:37

These are -- umm -- developed based on associations, not -- not necessarily causal, and these relationships are looking just at the concentrations of 16:46:40 16:46:47 16:46:57

a chemical within a mixture as they relate to biological effects, over, you know, the spectrum of concentration ranges that exist within the bays. 16:47:05 16:47:16 16:47:20

And I think the way those relationships were evaluated is described in those documents. 16:47:29 16:47:38

Q. And -- 16:47:50

Thank you. 16:47:56

Just turning back to the SQO, Part 1 -- 16:47:57

MR. GALLAGHER: Yeah.

I just want to make note it's 10 to 5:00. 16:48:02

MR. SINGARELLA: Thank you, Mr. Gallagher. 16:48:06

MR. GALLAGHER: Thank you, Paul. 16:48:13

MR. SINGARELLA: I think we're -- I'm very close to winding up here. 16:48:15 16:48:17

THE WITNESS: Part 1? 16:48:21

MR. SINGARELLA: Yes. 16:48:22

THE WITNESS: Okay. 16:48:24

BY MR. SINGARELLA: 16:48:24

Q. If I wanted to find the level of constituent that's protective of the critters in the -- in here, can you point me to it? 16:48:24 16:48:28 16:48:34

A. No. 16:48:35

Q. If it were in here, you'd be able to point me to it; right? 16:49:00 16:49:12

A. Correct. 16:49:13

MR. SINGARELLA: I have no further questions for Mr. Beegan. 16:49:30 16:49:31

Thank you, Mr. Beegan, for your time and patience today. 16:49:33 16:49:34

Thank you, Mr. Gallagher, for listening in. 16:49:35

MR. GALLAGHER: Thank you, folks. 16:49:43

Mr. Beegan, thank you. 16:49:46

MR. FUCHS: Thank you. 16:49:46

MR. RICHARDSON: Thank you. 16:49:48

MR. GALLAGHER: All right. Go in peace. 16:49:51

VIDEOGRAPHER: Can we go off the record? 16:49:53

MR. FUCHS: Yes. 16:49:55

Off the record? 16:49:56

MR. SINGARELLA: Yes. 16:49:57

VIDEOGRAPHER: We are going off the record at 4:49 p.m. 16:49:58 16:50:00

This is end of disk number four and the end of the deposition. 16:50:01 16:50:04

(Thereupon the deposition was adjourned at 4:49 p.m.)

		APPENDIX E	COMMENTS AND RESPONSES	
No.	Subject	Comment	Response	Author
		VERBAL COMMENTS (02 05 08)		
V1		SQO is a complex policy	Staff agree. Incorporating multiple lines of evidence into a draft Water Quality Control Plan requires a unique and complex approach	WSPA, CASQA
V2		Appreciate the clarifications, and figures in the January 2006 draft Part 1	Comment noted.	WSPA, CASQA
V3		There are inconsistencies between some items and we will talk to staff about those issues, however we support the Draft Part 1	Comment noted.	WSPA, CASQA
V4		We are disapointed with the loophole associated with the Possibly Impacted response actions between Section V.I and Section VII.F. Concerned about option to postpone stressor ID pending further monitoring. We disagree with the this text.	Comment noted. As with any attempt to be protective, the draft Part 1 must realistically address those areas of uncertainty. An unsuccesful TIE is a real possibility and continuing to spend time and money on a study that results in a inconclusive results is not an appropriate use of resources. Staff believe the proposed course of action is prudent and responsible.	SFBK
V5		Implementation langauge still vague, lacks clarity, Staff need to clarify the implementation langauge to make the document stronger	Comment noted. See comment V2. Staff believe that the nessecary clarifications have been made.	SFBK
V6		Permitees should not be allowed to delay categorizing sites for cleaning up pollutions; document still lacks a scheme to prioritize sites for cleanup	The Draft Part 1 requires stressor identification because only after the stressor is identified can beneficial uses be effectively restored. If the stressor is no longer being discharged then some sort of remedial action may be appropriate. However if the stressor is being discharged, then any remedial action would only result in a short term benefit. In this situation, the ongoing discharges would continue to contribute the causative pollutants to the water body. Stressor identification reduces this risk and provides the Regional Boards with a better means to focus both cleanup actions and TMDLs on the pollutants causing problems.	SFBK
V7		The draft Part 1 should ensure that sites are prioritized for cleanup actions not just stressor ID	See response to comment V7	SFBK

No.	Subject	Comment	Response	Author
60 co			These changes are the result of the response of individual species to the presence of stressors with those most sensitive showing the greatest and earliest response. The benthic indices developed and validated for use as the metric for the benthic line of evidence are designed to track this response. Along a stress gradient within a given habitat type, the progressive reduction or loss of members of the benthic community, beginning with those species most sensitive, drives the index values, allowing that change to be quantified and rated. A site that is within the reference condition as defined by the benthic indices is one in which stressors have not detectably altered the assemblage of species expected for the habitat. This provides a standard to assure that the sensitive species within the assemblage are protected.	RB5

No.	Subject	Comment	Response	Author
1003	5.3.2	If narrative objectives are to be used to protect all benthic species, they need to clearly state the level of protection for all benthic species that simply provide for protection at the community level. As Dr. Schaffner stated in her peer review "protecting at the community level and protecting all species are different." To try to rectify the differences, state board staff have greatly exaggerated the sensitivity of the benthic metrics making unsubstantiated claims that are misleading at best.	The diversity and abundance of the benthic invertebrates that compose the benthic community varies from location to location based upon habitat factors such as dissolved oxygen, depth, salinity, grain size, hydrodynamics and available food and anthropogenic factors such as the toxic pollutants and nutrients. The presence and absence of individual species will vary as the natural conditions change from location to location. As a result, the utility of individual organisms as an indicator or as the receptor of concern is limited. However, a healthy benthic community will still exhibit distinct characteristics that differentiate it from a community that has been stressed in most cases regardless of the habitat. These characteristics include functionality, balance, presence of sensitive species, and limited abundance of highly tolerant species. As a result, staff have focused on the protection of benthic communities.	HBK
1003			In regards to exaggerated claims, it is difficult to respond to the commenter with out knowing what statements the commenter feels are in question. Staff have based the technical portions of the draft Staff Report and draft Part 1 on information and conclusions drawn from external scientific articles or documents prepared by state or federal agencies, or from studies and reports prepared by the science team during the course of the SQO development process. Staff do not feel that exaggerating or misleading claims were made in the staff report or draft Part 1.	HBK

No.	Subject	Comment	Response	Author
61	5.3.2	The Delta could have a lower level of protection for benthic organisms from toxicity than the rest of the water bodies in the Central Valley Region. A higher level of impact would be allowed if the level of protection were set at the community level as opposed to the organism or population level. Showing "toxicity to benthic communities" would be much more difficult than showing detrimental effects to sediment-associated aquatic life. Toxic effects could occur to organisms and species before such impacts were manifested at the community level. We recommend that the proposed aquatic life SQO be amended to replace the term "benthic communities" with "aquatic organisms". The relationship of the proposed narrative SQO to existing narrative objectives in the Central Valley Water Board's Basin Plans should be specified and changes in the level of protection resulting from the SQO Plan should be analyzed.	Staff disagree. The regulatory baseline information provided by Central Valley Region staff for preparation of Section 4 of the staff report does not support the commenters assertion. Furthermore, staff requested by email that the Regional Board provide some evidence for the record that would support this claim. To date, no response has been provided.	RB5
1105	5.4.1	Section 5.4.1: Support Staff Alternative 3 (Page 79)	Comment noted	TJ
1106	5.4.2	Section 5.4.2: Support New Alternative 5--combination of Alternative 3 and 4 (Page 80)	Comment noted	TJ
155	5.4 (5.4.2)	Numeric objectives would create a bright line test that would eliminate the confusion caused by the vague narrative objectives and muddled integration of multiple lines of evidence. Specific numeric objectives would create consistency among regional boards and consistency over time because inherently numeric objectives are clear, transparent, cautious and easy to use regardless of the approach. Moreover, numeric objectives eliminate the need to use MLOE that introduce more variability and less transparency	Staff agree that numeric objectives would be easier to implement; however, there is no single tool or measure that can be used at this time to assess sediment quality reliably and confidently. Without a single robust tool, numeric objectives are not possible.	SFBK
156	5.4 (5.4.2)	We have grave concerns with the use of narrative objectives. Coupled with the multiple lines of evidence (MLOE) assessment approach, they are an ineffective way to determine if sediments are contaminated and impaired	Staff disagree. A narrative objective coupled with indicators to interpret the narrative objectives represents a logical means to assess sediment quality.	SFBK

State Water Board's Program to Develop Sediment Quality Objectives

San Diego Regional Water Board
Workshop
August 10, 2005

Chris Beegan
cbeegan@waterboards.ca.gov
916 341 5577

Challenges

- Shifting away from a pollutant-specific concentration-based approach
- Integration with other programs that address sediment quality but have very different goals or objectives (dredged materials)
- Need to minimize BPJ

Program Goals

- Develop scientifically defensible SQOs that are protective of specific beneficial uses.
- Provide consistent sediment quality assessment tools and ecologically relevant thresholds throughout the state.
- Include numeric targets or thresholds that would be applied to each indicator
- Develop approach to integrate the multiple responses into a station quality value or quality category.
- Develop approach for assessing multiple stations.

Schedule

- By June 30 2003 adopt Workplan
- By August 5, 2005 circulate draft objectives and policy*
- By February 28, 2007 submit SQO policy to Office of Administrative Law.

Boundaries

- California Water Code – Bay Protection Chapter
  - Bays and Estuaries
- The program approach could be applied to all these waterbodies.
- However the MLOE indicators have only been developed for marine embayments
  - Enough existing data present to support development

Numeric versus Narrative SQOs

- Numeric Objectives
- Narrative Objectives

How Narrative SQOs Could Be Implemented

- **Example** of Narrative Objective for Direct Effects

Sediment quality shall be maintained at a level that protects benthic communities from degradation or toxicity do to exposure to bio-available pollutants in bottom sediments... This narrative shall be implemented using the multiple lines of evidence described in....

Programs

- Dredging - Effects of disposal versus in-place effects
- Non dredge-related programs
  - Waterbody Assessments
  - Conventional NPDES permits
  - Stormwater NPDES Permits
  - Nonpoint Source Programs
  - TMDLS
  - Cleanup Efforts

Sequential Approach

The general approach would consist of four steps

- Assessment - multiple sites
- Confirmation – What's the Stressor
  - Chemical Pollutant?
  - Which pollutant
- Source Identification and Loading
  - Source Identification
  - Load Evaluation,
  - Load Allocation
- Permits and Regulatory Tools
  - Options

Development of Sediment Quality Objectives for Enclosed Bays and Estuaries

BPJ Best Professional Judgment

Standard:.

Legally: Water Code uses much of the same language for WQO as SQOs

Development: no established process for developing SQOs

Implementation: very different WQ regulatory programs focuses on control of effluents.....

Two reasons this works:

1. Linkage to the pipe or plant.....and
2. dose response in water we know what will happen to organisms exposed to at or above specific levels

With Sediments we have neither.....

Sediments are in the receiving water.

Does response relationships not predictable because the bioavailability of pollutants in sediments is highly variable.....

Draft Plan

Overview of Plan

- Narrative SQOs
- Interpreted using specific indicators and thresholds
- Implementation language describing;
  - Application of SQOs within specific programs
    - NPDES Permits
    - 303(d) listings (waterbody impairment)
    - dredging
  - Exceedence of SQOs
  - Response Actions
    - Stressor Identification
    - Biological based pollutant targets

Draft Plan

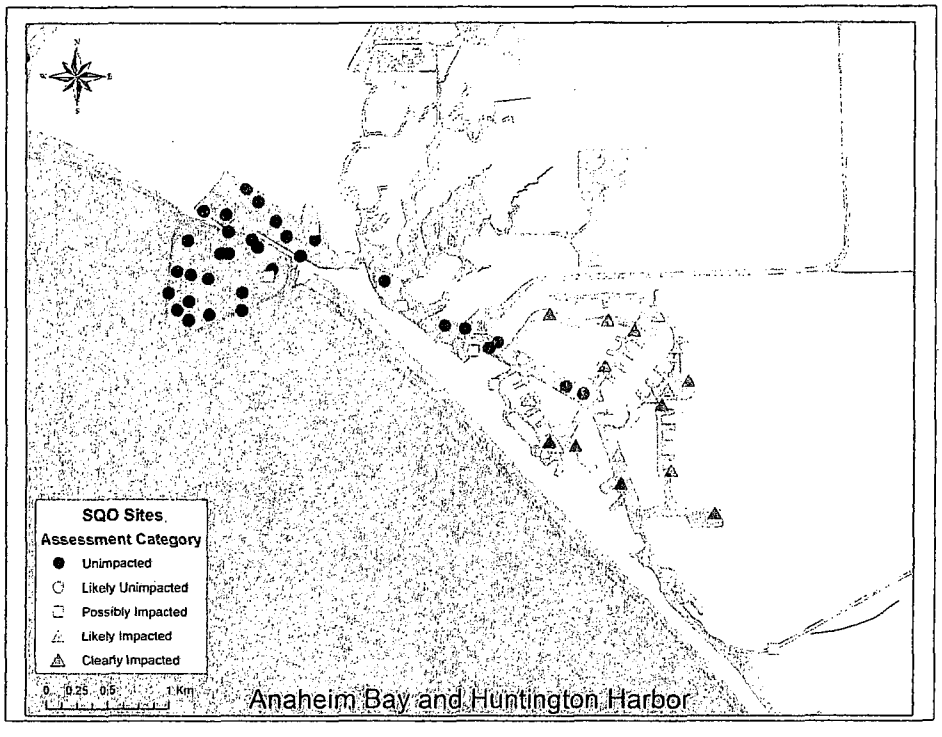
To protect benthic communities in bays and estuaries of California, the proposed plan describes

- MLOE Approach
  - Sediment Toxicity
  - Sediment Chemistry
  - Benthic Community Analysis
- Approach to integrate the MLOE into a station level assessment
- Appendix C Example Problem in draft Staff Report

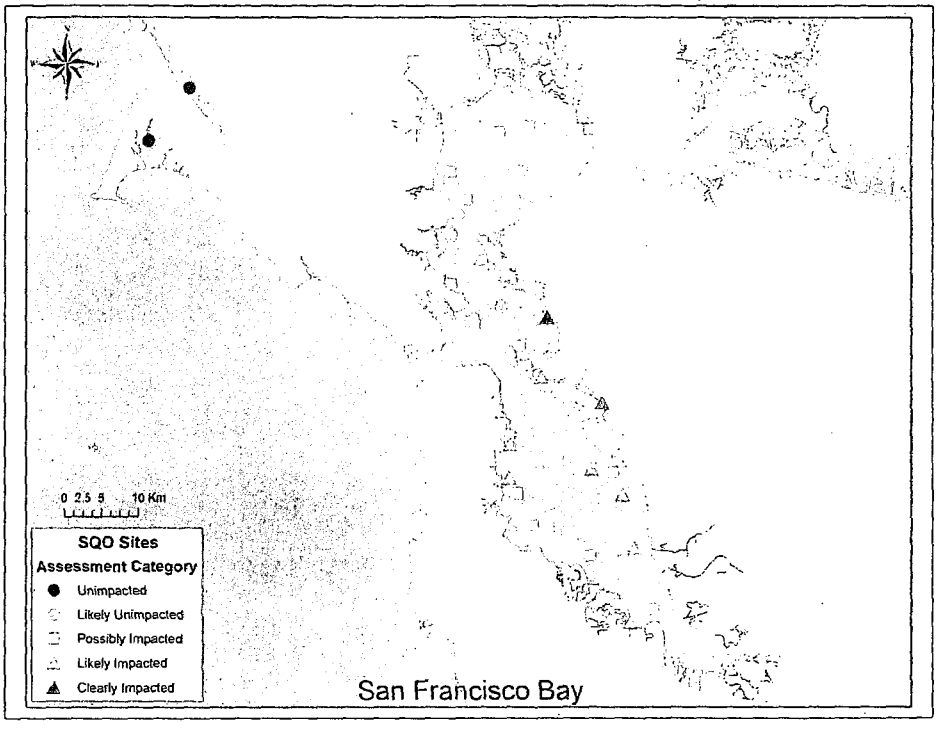
Draft Plan

Station Assessment categories

- Unimpacted
- Likely Unimpacted
- Possibly Impacted
- Likely Impacted
- Clearly Impacted
- Inconclusive



Data for Anaheim Bay and Huntington Harbor (Southern California) shows a gradient of greater response at inner harbor locations that is relatively consistent.



Most stations are possibly impacted, although greater impacts indicated near port/commercial areas.

1. INTRODUCTION

1.1 PURPOSE

This report represents the State Water Resources Control Board (State Water Board) formal water quality planning and substitute environmental document for the adoption of sediment quality objectives (SQOs) and program of implementation that would apply to enclosed bays and estuaries of California. The title of the proposed plan where the SQOs and policy of implementation would reside is *Water Quality Control Plan for Enclosed Bays and Estuaries of California, Part 1 Sediment Quality* (Part 1). SQOs would provide the State and Regional Water Quality Control Boards stakeholders and interested parties with a technically robust mechanism to differentiate sediments impacted by toxic pollutants from those that are not consistently through out the coastal regions. The proposed SQOs developed through this program do not address excessive sediment loading (siltation or sedimentation) related impairment or degradation.

Sediments in enclosed bays and estuaries are, with few exceptions, the most highly polluted sediments in the State. Historically, areas adjacent to bays and estuaries were the first heavily industrialized regions in the State; and, as a result, wastes have been discharged into bays either directly as point sources, indirectly as runoff, or accidentally through releases and spills for many years. Sediment carried down rivers and creeks also contributes to the contaminant loading into bays and estuaries. Many contaminants, such as metals and pesticides, readily attach to the sediments. Through this mechanism, contaminants from inland sources can be transported long distances. Poor flushing and low current speeds allow the sediments and contaminants to settle out in the bays and estuaries before reaching the open ocean. Few states have attempted to develop SQOs due to the lack of ecologically relevant tools, difficulties interpreting and integrating the results, and an inability to establish causality. In 2003, the State Water Board initiated a program to protect these water bodies through the development of SQOs for enclosed bays and estuaries.

1.2 MANDATE TO DEVELOP SQOS

In 1989, the Legislature added chapter 5.6 to Division 7 of the California Water Code. The legislation required the State Water Board to develop sediment quality objectives as part of a comprehensive program to protect beneficial uses in enclosed bays and estuaries. The objectives are required "for toxic pollutants" that were identified in toxic hot spots or that were identified as pollutants of concern by the State Water Board or the Regional Water Quality Control Boards (Regional Water Boards).[1] The waters targeted for protection are enclosed bays and estuaries.

The Legislature defined a "sediment quality objective" (SQO) as "that level of a constituent in sediment which is established with an adequate margin of safety, for the reasonable protection of the beneficial uses of water or the prevention of nuisance."[2] The SQOs have to "be based on scientific information, including, but not limited to, chemical monitoring, bioassays, or established modeling procedures."[3] They must "provide adequate protection for the most

[1] See Wat. Code sec. 13392.6.
[2] *Id.* sec. 13391.5.
[3] *Id.* sec. 13393.

sensitive aquatic organisms."[4] The State Water Board is not precluded from adopting SQOs for a pollutant even though additional research may be needed.[5]

In addition, if there is a potential for human exposure to pollutants through the food chain, the State Water Board must base SQOs on a health risk assessment.[6] A health risk assessment is an analysis that evaluates and quantifies the potential human exposure to a pollutant that bioaccumulates in edible fish, shellfish, or wildlife.[7] A health risk assessment "includes an analysis of both individual and population wide health risks associated with anticipated levels of human exposure, including potential synergistic effects of toxic pollutants and impacts on sensitive populations."[8]

The Legislature required the State Water Board to develop a workplan by July 1991 for the adoption of SQOs and to adopt the SQOs pursuant to the workplan.[9] In 1991, the State Water Board developed a seven year conceptual approach, which is described in the Workplan for the Development of Sediment Quality Objectives for Enclosed Bays and Estuaries of California (91-14 WQ) (1991 Workplan).

This 1991 Workplan included a schedule and specific tasks to develop direct effects tools that would protect benthic communities and an element to assess the human and ecological risk in bays and estuaries from pollutants in sediments. This conceptual approach embodied in the workplan was never implemented because available resources were primarily focused on identifying toxic hot spots using multiple lines of evidence.

In 1999, a lawsuit was filed against the State Water Board for failing, among other things, to adopt SQOs. The Court sided with the petitioners and ordered the State Water Board to develop SQOs and implementation measures. The Court also required the State Water Board to prepare a revised workplan. The draft revised workplan was circulated for public comment and adopted by the State Water Board on May 21, 2003. The targeted receptors, proposed objectives and indicators described in this staff report are based upon the technical elements described in that workplan.

1.3 Scientific Peer Review

In 1997, Section 57004 was added to the California Health and Safety Code. Section 57004 requires external scientific peer review of the scientific basis for any rule proposed by any board, office, or department within California Environmental Protection Agency (Cal/EPA). Scientific peer review ensures that public resources are managed effectively. Scientific peer review was requested through a contract with the University of California at Berkeley in November 2008. The following scientists agreed to review the technical issues associated with the staff report and Part 1:

- Dr. Dominic Di Toro, Edward C. Davis Professor of Civil and Environmental Engineering Department of Civil and Environmental Engineering, University of Delaware
- Dr. John P. Knezovich, PhD, Director, Center for Accelerator Mass Spectrometry, L-397 Lawrence Livermore National Laboratory

Peer reviews are posted at http://www.waterboards.ca.gov/bptcp/sediment.html. Responses to peer review comments are presented as Appendix XXX

1.4 Advisory and Scientific Committees

Advisory Committees

The 1989 amendments to the Water Code required the State Water Board to form an advisory committee to assist in the implementation of chapter 5.6. State Water Board staff invited stakeholders and interested parties to participate in this committee, which was intended to focus on SQOs development and implementation within bays. The organizational meeting for this committee was held on July 29, 2003. A second advisory committee was formed on April 13, 2006 to advise the State Water Board on issues associated with the development and implementation of SQOs within the Sacramento-San Joaquin Delta and other estuarine waters in the State. Dr. Brock Bernstein serves as Chairperson and facilitator on both committees.

Scientific Steering Committee

The Scientific Steering Committee (SSC) was formed for the purpose of independently assessing the soundness and adequacy of the technical approach and ensuring that all findings and conclusions are well supported. The SSC provided the State Water Board's technical team with a very high level of expertise and experience from around the nation. The members on this committee are:

- Dr. Peter Landrum, Committee Chair: .Research Chemist NOAA/Great Lakes Environmental Research Laboratory Ann Arbor, MI
- Ed Long, Former NOAA Scientist and developer of empirically derived sediment quality guidelines for NOAA's Status and Trends Program.
- Tom Gries, Environmental Scientist Washington Dept. of Ecology, Sediment Management Section, Olympia, WA
- Dr. Todd Bridges, Research Biologist and Director of the Center for Contaminated Sediments, Waterways Experiment Station (WES) U.S. Army Corps of Engineers, ERDC, Vicksburg, MS
- Dr. Robert F. Van Dolah, Benthic Ecologist and Director of the South Carolina Marine Resources Research Institute.
- Dr. Robert Burgess, Research Scientist, EPA's Office of Research and Development (Atlantic Ecology Division-Narragansett)

Agency Coordination Committee

The Agency Coordination Committee is an informal committee composed of staff from agencies that assess, regulate or manage contaminated sediments. Participants include staff from the coastal Regional Water Boards, Department of Toxic Substances Control, Department of Fish and Game, U.S EPA, and U.S Fish and Wildlife Service. The role of this committee was

to assist Water Board staff in the integration of other programs and policies related to sediment quality and identify potential areas of conflict.

1.5 CEQA Analysis and Impact of the Proposed Policy

When developing water quality objectives and water quality control plans, the State Water Board must comply with the California Environmental Quality Act (CEQA), Public Resources Code §21000 et seq. The objectives of CEQA are to: 1) inform the decision makers and public about the potential significant environmental effects of a proposed project, 2) identify ways that environmental damage may be mitigated, 3) prevent significant, avoidable damage to the environment by requiring changes in projects, through the use of alternatives or mitigation measures when feasible, and 4) disclose to the public why an agency approved a project if significant effects are involved. (Cal. Code Regs., tit. 14, § 15002(a).)

Although state agencies are subject to the environmental impact assessment requirements of CEQA, CEQA authorizes the Secretary of the Resources Agency to exempt specific state regulatory programs from the requirements to prepare Environmental Impact Reports (EIRs), Negative Declarations, and Initial Studies, if certain conditions are met (Public Resources Code, §21080.5). The water quality control (basin)/208 planning program of the State Water Board has been certified by the Secretary for Resources as meeting the requirements for exemption (California Code of Regulations (CCR), title 14, §15251(g)). Agencies qualifying for this exemption must comply with CEQA's goals and policies; evaluate environmental impacts; consider cumulative impacts; consult with other agencies with jurisdiction; provide public notice and allow public review; respond to comments on the environmental document; adopt CEQA findings; and provide for monitoring of mitigation measures. State Water Board regulations (CCR, tit. 23, §3777) require that a document prepared under its certified regulatory programs include:

- A brief description of the proposed project;
- Reasonable alternatives to the proposed project; and
- Mitigation measures to minimize any significant adverse environmental impacts of the proposed activity.

Accordingly, the State Water Board prepares programmatic substitute environmental documents (SEDs) in lieu of EIRs or other environmental documents when proposing statewide water quality objectives and a program of implementation. This Staff Report fulfills these requirements of a substitute environmental document. Until recently, the State Water Board referred to these formal planning documents as functional equivalent documents. There is no substantive difference between these documents.

Responses to comments and consequent revisions to the information in the Draft Staff Report are subsequently presented in a draft Final Staff Report for consideration by the State Water Board. After the State Water Board has certified the document as adequate, the title of the document becomes the Final Staff Report.

1.6 Compliance with CWC Sections 13241 and 13242

Chapter 5.6 requires that the State Water Board adopt sediment quality objectives in accordance with the procedures proscribed in the Water Code for adopting and amending water quality control plans. The procedures include notice and a public hearing prior to plan adoption. In addition, Section 13241 of the Water Code requires that the Water Boards consider specified

factors when they establish water quality objectives to ensure the reasonable protection of beneficial uses. These factors include:

(a) Past, present, and probable future beneficial uses of water.

(b) Environmental characteristics of the hydrographic unit under consideration.

(c) Water quality conditions that could reasonably be achieved through control of all factors affecting water quality.

(d) Economic considerations.

(e) The need for developing housing within the region.

(f) The need to develop and use recycled water.

Water Code section 13242 requires that the Water Boards formulate a program of implementation for the water quality objective under consideration by the Board. The program of implementation for achieving water quality objectives must include, at least:

(a) A description of the nature of actions that is necessary to achieve the objectives, including recommendations for appropriate action by any entity, public or private.

(b) A time schedule for the actions to be taken.

(c) A description of surveillance to be undertaken to determine compliance with objectives

1.7 Authors and Contributors

Mr. Chris Beegan from the Division of Water Quality – Ocean Unit prepared this staff report and Part 1. Principal Scientist Mr. Steve Bay, Mr. Ana Ranasinghe, Dr. Kerry Ritter, Dr. Art Barnett and Dr. Steve Weisberg with the Southern California Coastal Water Research Project provided the technical analysis and studies in support of the proposed SQP. Drs. Mike Connor and Bruce Thompson and Mr. Ben Greenfield at San Francisco Estuary Institute also contributed technical analysis and studies for this program. Mr. Dominic Gregorio and Mr. Craig J. Wilson from the Division of Water Quality and Ms. Sheila Vassey from the Office of Chief Counsel provided valuable input during the preparation of this document. Ms. Eloise Castillo and Ms Lauren Praesel from Science Application International Corporation (SAIC) prepared the economic analysis of the Part 1.

1.8 Proposed Project and Description

The State Water Board is proposing the following project: the adoption of a Water Quality Control Plan for Enclosed Bays and Estuaries of California, Part I Sediment Quality (Part 1)." Part 1 contains narrative SQOs indicators and threshold used to interpret the narrative objectives and a program of implementation. Part 1 if adopted would be applicable to all enclosed bays and estuaries of California.

Enclosed bays are defined in Water Code section 13391.5 as:

> *indentations along the coast which enclose an area of oceanic water within distinct headlands or harbor works. Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes, but is not limited to: Humboldt Bay, Bodega Harbor, Tomales Bay, Drakes Estero, San Francisco Bay, Morro Bay, Los Angeles Harbor, Upper and Lower Newport Bay, Mission Bay, and San Diego Bay.*

This section defines estuaries as:

> *waters at the mouths of streams that serve as mixing zones for fresh and ocean waters during a major portion of the year. Mouths of streams that are temporarily separated from the ocean by sandbars shall be considered as estuaries. Estuarine waters will generally be considered to extend from a bay or the open ocean to the upstream limit of tidal action but may be considered to extend seaward if significant mixing of fresh and salt water occurs in the open coastal waters. The waters described by this definition include, but are not limited to, the Sacramento-San Joaquin Delta as defined by Section 12220 of CWC, Suisun Bay, Carquinez Strait downstream to Carquinez Bridge, and appropriate areas of the Smith, Klamath, Mad, Eel, Noyo, and Russian Rivers.*

If adopted, the regulatory provisions of Part 1 would be enforced by the State Water Board and coastal Regional Water Boards, consisting of the North Coast, San Francisco Bay, Central Coast, Los Angeles, Central Valley, Santa Ana and San Diego Regional Water Boards.

Those regulated under Part 1 would include individual or organization that discharges toxic pollutants to enclosed bays and estuaries of California or rivers or streams draining into enclosed bays and estuaries.

1.9 Statement of Goals

The Water Code defines a sediment quality objective as that level of a constituent in sediment established with an adequate margin of safety for the reasonable protection of beneficial uses or prevention of nuisances. The Water Code does not define the term "reasonable"; however, the American Heritage Dictionary defines the term as governed by or in accordance with reason or sound thinking, within the bounds of common sense, not excessive or extreme; fair moderate (American Heritage Dictionary of English Language, New College Edition 1976).

The objective of this program since 2002 has been to develop SQOs and robust indicators in conjunction with a program of implementation that protects two beneficial uses, aquatic life and human health. The goals of this program are to:

- Establish narrative receptor-specific SQOs.
- Establish a condition that is considered protective for each targeted receptor.
- Identify appropriate lines of evidence for each receptor that when integrated can support a confident interpretation of the narrative objective.
- Develop and/or refine and validate specific indicators for each line of evidence so that the condition of each station can be measured relative to the protected condition.
- Build a program of implementation based upon these tools and the current level of scientific understanding to promote the protection of sediment quality related beneficial uses.
- Define a process that will result in better management and more effective restoration of polluted sediments

Staff believes the approach developed to assess aquatic life via benthic communities for Southern California's enclosed bays and marine lagoons and polyhaline San Francisco Bay has met these goals. For other bays on the central and north coast such as Morro Bay, Humboldt Bay, Tomales Bay, and all estuaries including the Sacramento-San Joaquin Delta, the lack of

available data prevented the staff and technical team from achieving these goals. In response, State Water Board staff have proposed a less robust means to determine if sediment quality is meeting the narrative aquatic life – benthic community SQO in these waters. However, State Water Board staff believe that work conducted in the next phase will provide superior indicators, which could replace these tools if adopted and be comparable to those developed for Southern California Bay and polyhaline San Francisco Bay in Phase II of the SQO program.

Although extensive progress was also made on developing an approach to interpret the human health-based narrative objective, Staff are proposing in this first phase to use existing site-specific human health risk methodology to interpret the narrative. As State Water Board staff stated in the May 2003 Workplan, developing sediment quality objectives that protect human health from consumption of contaminated fish is extremely complex for several reasons.

- The fate and transport of pollutants from sediment to tissue and the water column pollutants is highly site specific.
- Indirect exposure to pollutants from sediments transported up the food web is difficult to relate directly to specific sites or stations of area of a waterbody.
- The home range, habitat, feeding strategies, and lipid content of each fish species may vary seasonally and as the fish matures, all of which affects the rate of contaminant accumulation in the tissue.
- The type and size of prey-fish targeted by sport-fisherman and subsistence fisherman also varies considerably as do the methods of preparation, types of tissue consumed and consumption rates.

A more detailed approach to support the human health based SQOs will require greater time and effort. Staff expects this effort to be completed in the next phase, which would trigger a new proposed methodology for State Water Board consideration.

1.10 Document Organization

This document is organized as follows. A conceptual model describing the fate and transport of pollutants in sediments, potentially affected receptors and exposure mechanisms is described in Section 2. Section 3 describes the environmental setting of the coastal and estuarine Regional Water Board basins. The regulatory baseline is described in Section 4. Issues and Alternatives evaluated during the formulation of Part 1 are discussed in Section 5. Section 6 describes the CEQA analysis and Water Code section 13241 factors. Part 1 is presented in Appendix A. The CEQA Checklist is included in Appendix B. Appendix C presents the application of a data set assessed by applying the indicators and appropriate thresholds included in Part 1. Summary Maps of Toxic Hot Spots are presented by Region in Appendix D.

Comments on the staff report received by the State Water Board and staff's responses are presented in Appendix E.

2. CONCEPTUAL MODEL FOR SEDIMENT QUALITY

Sediment is a complex and dynamic environment, which can influence the fate and effects of the contaminants it contains. Sediment particles can vary from coarse sand with a diameter of about 1 millimeter (mm) to fine silts and clays with diameters less than 0.01 mm. Variations in the size and composition of these particles have an effect on the binding of contaminants to them, with the finer particles generally containing higher contaminant concentrations due to a much greater surface area and greater number of chemical sorption sites.

The assessment of sediment quality in bays and estuaries relies on information regarding the sources, fates and effects of contaminants of concern. The types of sources determine the overall magnitude, and spatial and temporal patterns of contaminant input to these nearshore environments. Contaminants in the receiving water environment are influenced by many processes that ultimately determine the type and amount of contaminant exposure to organisms. There are many gaps in our knowledge of contaminant sources and fate. Consequently, measurement of biological effects is often needed to determine the ecological significance of chemical measurements.

Multiple sources contribute to sediment contamination in embayments (Figure 2.1). Runoff and discharge from rivers, creeks, and drainage channels that carry storm water and dry weather runoff from the upland watershed are major nonpoint contaminant sources. Contaminants may also come from point source discharges, such as municipal wastewater and industrial discharges that are located within embayments, as well as spills. Additional nonpoint contaminant sources include atmospheric deposition and groundwater. A large portion of the contaminants from most of these sources may be associated with particles, either as suspended particles in the discharge or receiving water body. However, each of these discharges influences water and sediment quality on different spatial and temporal scales. This diversity of sources, combined with various physical mixing processes such as currents, tidal exchange, and ship traffic, can produce complex and widespread patterns of sediment contamination.

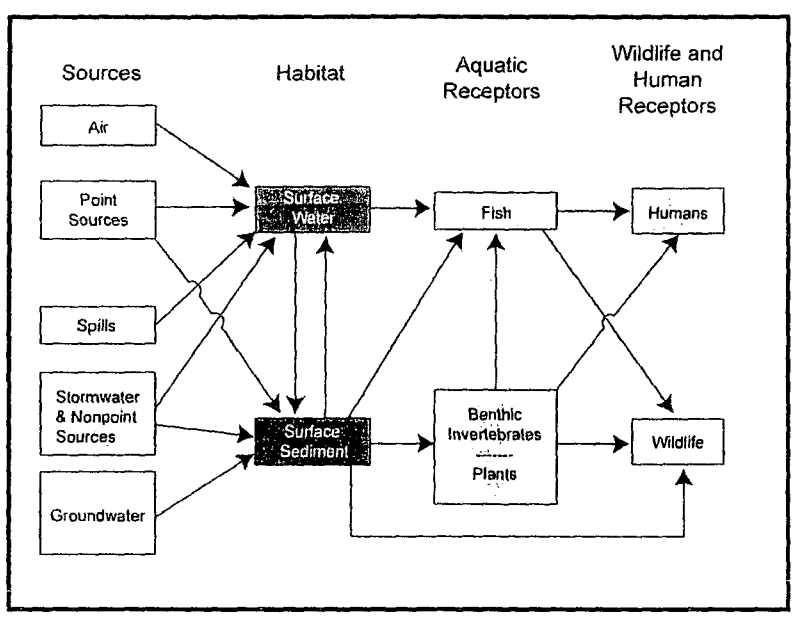

Figure 2.1. Principal Sources, Fates, and Effects of Sediment Contaminants in Enclosed Bays and Estuaries (Adapted from Brides et al. 2005)

There are a number of processes occurring in embayments that affect the fate and distribution of sediment contaminants (Figure 2.1). Upon introduction into the water body, dissolved contaminants in the source may bind to suspended particles in the water column or particle associated contaminants may desorb back into the water column. In brackish embayments in particular, flocculation and aggregation of small-suspended particles into large agglomerates that then settle out of the water column is a primary mechanism for introduction of contaminants to surface sediments. Where river or tidal currents are present, some contaminants will be transported (advected) out of the system. The fraction that remains and eventually settles forms the sediment's surface, a layer (5-20 centimeters (cm)) of high physical, chemical, and biological activity. Most of the benthic infauna resides in this surface layer. The layer of sediment below is less active and contaminants that are contained in this layer generally exert little influence on organisms. However, contaminants in the deep sediment layer can affect habitat quality if they are transported to the surface by deep burrowing organisms, transformed into different chemical species under anaerobic conditions, or resuspended by physical processes such as sediment erosion or dredging.

Sediment contaminants in the surface layer are not static, their concentration, distribution, and chemical form are being continually modified. For example, particle bound contaminants can move into the water column by diffusion (desorption from particles), resuspension, or from the burrowing and feeding activities of many benthic organisms (bioturbation).

The form and biological availability of contaminants is influenced by many factors in the sediment. The sediment particles contain variable amounts and types of organic carbon, including natural plant or animal detritus, microbial films, and anthropogenic materials such as ash, soot, wood chips, oils, and tars. The partitioning of many contaminants between sediment particles, water, and biota is strongly influenced by the nature of sediment organic carbon (Figure 2.2). The predominant forms for metals (or speciation) are largely governed by the reduction-oxidation (redox) potential (or E_h) and the co-occurrence of binding constituents such as sulfides, organic material, metal oxides, and clay minerals. Although the general mechanisms affecting partitioning and speciation of contaminants are known, it is often difficult to predict such changes from chemical measurements with sufficient accuracy to determine their bioavailability, which in turn is key for assessing biological effects.

Microbial activities also influence the characteristics of sediment contaminants. The microbial degradation of sediment organic matter can alter the pH and oxygen content of sediments, which may in turn affect the rates of metal desorption/precipitation. Bacterial metabolism or chemical processes can also transform or degrade some contaminants to other forms. In some cases, the transformation product may have greater biological availability or toxicity, such as methyl mercury. In other cases, such as for some pesticides, degradation may alter the contaminant so that it is no longer toxic.

California's bays and estuaries are home to a tremendous diversity of life. As such, there are multiple routes by which these organisms can be exposed to and affected by sediment contaminants. There are two general types of contaminant exposure: direct and indirect. Most of the direct exposure results from the contact of organisms with the sediment and sediment ingestion. Organisms living in the sediment are exposed through the uptake of contaminants from the pore water, which is the water associated with the sediment particles. This process is analogous to the exposure of water column organisms from dissolved contaminants. Organisms that ingest sediments may accumulate contaminants that are desorbed by digestive processes in the gut. Indirect contaminant exposure results from the consumption of contaminated prey. Examples include fish feeding on benthic invertebrates, birds feeding on benthic invertebrates or fish, and humans consuming fish (Figure 2.1).

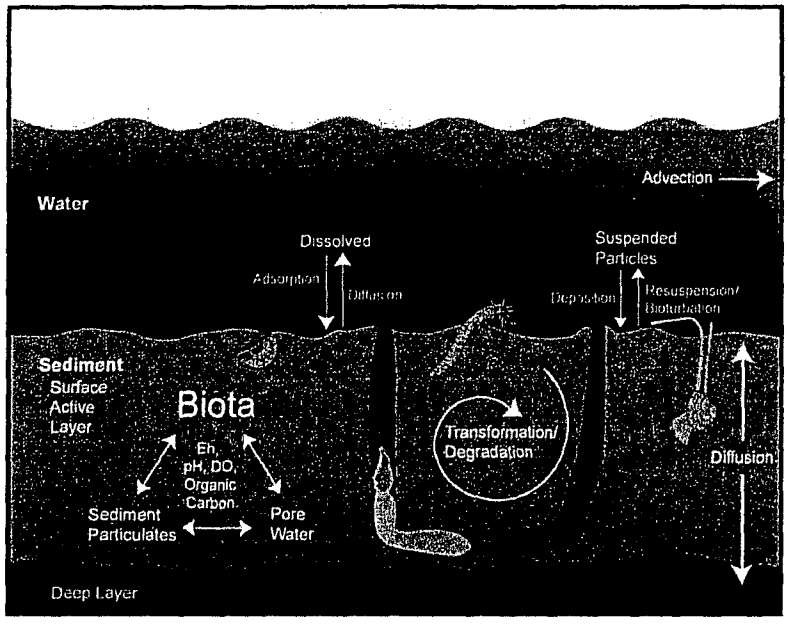

Figure 2.2. Sediment Processes Affecting the Distribution and Form of Contaminants

Benthic organisms are generally at greatest risk for adverse effects from direct sediment contaminant exposure, because these organisms often live in continual direct contact with sediment/pore water, and many species ingest significant quantities of sediment as a source of nutrition. The relative importance of sediment ingestion vs. sediment contact for contaminant exposure varies depending upon the life history of the species. In addition, there are species-specific differences in contaminant uptake rates and metabolism that affect the amount of contaminant (or dose) accumulated by benthic organisms. As a result, benthic species vary in their sensitivity to sediment contamination. This in turn produces a gradation of benthic community composition change that corresponds to the magnitude of contaminant exposure.

A variety of biological methods are needed to assess the direct effects of sediment contamination. Measurement of changes in the benthic community, such as abundance and species composition, are a sensitive measure of the direct effects of sediment contamination because these organisms live in the surface sediment layer. However, variations in sediment composition complicate this assessment because benthic organisms often have specific preferences or tolerances for variations in sediment grain size and organic content, in addition to other environmental factors such as water depth, salinity, and temperature. Consequently, the benthic community present at a site may be altered by a variety of environmental factors in addition to adverse effects from contaminants. It is necessary to understand how these environmental factors affect benthic communities before the effects of contaminants can be discerned.

Laboratory toxicity tests are also useful for assessing the direct effects of sediment. These tests measure the lethal or sublethal response of a test species exposed to the sediment under controlled conditions. Toxicity tests provide a measure of the bioavailability and toxicity of sediment contaminants from direct exposure and are not affected by many of the environmental factors that confound benthic community analyses or other measurements of effect in the field.

The magnitude of indirect contaminant exposure is affected by several key factors: biomagnification potential, feeding rate, and trophic level. Some contaminants, such as PCBs and methyl mercury, have an affinity for tissue lipids and tend to be retained and biomagnified in organisms. The tissue concentration of such contaminants often increases at higher trophic levels, such as fish-eating birds and mammals. The indirect exposure to some contaminants, such as inorganic forms of metals, may be relatively more significant for species that feed directly on benthic organisms, where the tissue concentrations are higher.

Feeding rate and movement also affect the amount of indirect exposure to contaminants. Unlike benthic organisms, fish, birds and mammals are often highly mobile and may spend a substantial portion of their lives away from the area of sediment contamination. Consequently, it is often difficult to determine the amount of contaminant exposure in these organisms that is due to feeding in the area of interest. Assessing the amount of indirect exposure resulting from sediment contamination is much more difficult than for direct exposure, as all of the complexities associated with the effects of sediment processes on contaminant exposure are compounded by additional variations in feeding and life history.

3. ENVIRONMENTAL SETTING

California encompasses a variety of environmental conditions ranging from the Sierra Nevada to deserts (with a huge variation in between these two extremes) to the Pacific Ocean. Specific geographical features that form basins, the availability of natural resources coupled with climate and topography have created a very broad range of land use patterns and population densities throughout California. Because of these unique differences around the State, the Legislature in the Porter-Cologne Water Quality Control Act, Water Code section 13000 et seq. (Porter-Cologne) divided the State into nine different hydrologic regions or basins. These regions consist of the North Coast , San Francisco Bay, Central Coast, Los Angeles, Central Valley, Lahontan, Colorado River, Santa Ana and San Diego Regions. Though many regions share some common environmental problems, each of the regions has a unique suite of factors, such as types of discharges, pollutants, potential risks to beneficial uses and receptors that are specific to that region.

The following section provides a brief description of the regions and waters within the regions. For each region, the section includes a summary of bays and estuaries within the region that have been listed on the State Water Board's 2006 Clean Water Act section 303(d) list for impairments related to sediment quality. The listings described below include water column, tissue and sediment quality impacts associated with toxic pollutants identified on the 2006 Section 303(d) list. Tissue listings are discussed because the food web exposure pathway frequently begins in the sediment. Water column listings are also included because the toxic pollutants eventually settle out and are deposited in the surface sediments. Many of these sediment- and tissue-related listings were designated previously by the State Water Board as Toxic Hot Spots and proposed for cleanup. Toxic Hotspots are identified in Table 4.2. Maps of hot spots are presented by Region in Appendix D.

The Lahontan and Colorado River Regions do not include enclosed bays[10] and estuaries[11] and are not considered further in this document. Descriptions of the regions were obtained from the individual water quality control plans (basin plans).

3.1 NORTH COAST REGION

The North Coast Region comprises all regional basins, including Lower Klamath Lake and Lost River Basins, draining into the Pacific Ocean from the California-Oregon state line southern

[10] ENCLOSED BAYS are indentations along the coast which enclose an area of oceanic water within distinct headlands or harbor works. Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes but is not limited to: Humboldt Bay, Bodega Harbor, Tomales Bay, Drakes Estero, San Francisco Bay, Morro Bay, Los Angeles Harbor, Upper and Lower Newport Bay, Mission Bay, and San Diego Bay.

[11] ESTUARIES AND COASTAL LAGOONS are waters at the mouths of streams that serve as mixing zones for fresh and ocean waters during a major portion of the year. Mouths of streams that are temporarily separated from the ocean by sandbars shall be considered as estuaries. Estuarine waters will generally be considered to extend from a bay or the open ocean to the upstream limit of tidal action but may be considered to extend seaward if significant mixing of fresh and salt water occurs in the open coastal waters. The waters described by this definition include but are not limited to the Sacramento-San Joaquin Delta as defined by Section 12220 of the California Water Code, Suisun Bay, Carquinez Strait downstream to Carquinez Bridge, and appropriate areas of the Smith, Klamath, Mad, Eel, Noyo, and Russian Rivers.

boundary and includes the watershed of the Estero de San Antonio and Stemple Creek in Marin and Sonoma Counties (Figure 3.1). Two natural drainage basins, the Klamath River Basin and the North Coastal Basin, divide the Region. The Region covers all of Del Norte, Humboldt, Trinity, and Mendocino Counties, major portions of Siskiyou and Sonoma Counties, and small portions of Glenn, Lake, and Marin Counties. It encompasses a total area of approximately 19,390 square miles, including 340 miles of coastline and remote wilderness areas, as well as urbanized and agricultural areas.

Beginning at the Smith River in northern Del Norte County and heading south to the Estero de San Antonio in northern Marin County, the Region encompasses a large number of major river estuaries. Other North Coast streams and rivers with significant estuaries include the Klamath River, Redwood Creek, Little River, Mad River, Eel River, Noyo River, Navarro River, Elk Creek, Gualala River, Russian River, and Salmon Creek (this creek mouth also forms a lagoon). Northern Humboldt County coastal lagoons include Big Lagoon and Stone Lagoon. The largest enclosed bay in the North Coast Region is Humboldt Bay in Humboldt County. Another enclosed bay, Bodega Bay, is located in Sonoma County near the southern border of the Region.

Distinct temperature zones characterize the North Coast Region. Along the coast, the climate is moderate and foggy with limited temperature variation. Inland, however, seasonal temperature ranges in excess of 100°F (Fahrenheit) have been recorded. Precipitation is greater than for any other part of California, and damaging floods are a fairly frequent hazard. Particularly devastating floods occurred in the North Coast area in December 1955, December 1964, and February 1986. Ample precipitation in combination with the mild climate found over most of the North Coast Region has provided a wealth of fish, wildlife, and scenic resources. The mountainous nature of the Region, with its dense coniferous forests interspersed with grassy or chaparral covered slopes, provides shelter and food for deer, elk, bear, mountain lion, fur bearers, and many upland bird and mammal species. The numerous streams and rivers of the Region contain anadromous fish, and the reservoirs, although few in number support both cold water and warm water fish.

Tidelands and marshes are extremely important to many species of waterfowl and shore birds, both for feeding and nesting. Cultivated land and pasturelands also provide supplemental food for many birds, including small pheasant populations. Tideland areas along the north coast provide important habitat for marine invertebrates and nursery areas for forage fish, game fish, and crustaceans. Offshore coastal rocks are used by many species of seabirds as nesting areas.

Major components of the economy are tourism and recreation, logging and timber milling, aggregate mining, commercial and sport fisheries, sheep, beef and dairy production, and vineyards and wineries. In all, the North Coast Region offers a beautiful natural environment with opportunities for scientific study and research, recreation, sport, and commerce.

Approximately two percent of California's total population resides in the North Coast Region. The largest urban centers are Eureka in Humboldt County and Santa Rosa in Sonoma County. The most common factors affecting beneficial uses in the North Coast Region are temperature, nutrients and sedimentation in creeks and rivers that drain the region. Few toxic pollutants have been identified at levels causing degradation of beneficial uses in the bays and estuaries of the North Coast Region. Humboldt Bay was added to the 2006 303(d) List by the State Water Board due to dioxin compounds reported in fish tissue caught from that bay. Although some lakes are impaired do to mercury, there are no other toxic pollutant-related listings in bays and estuaries in this Region.

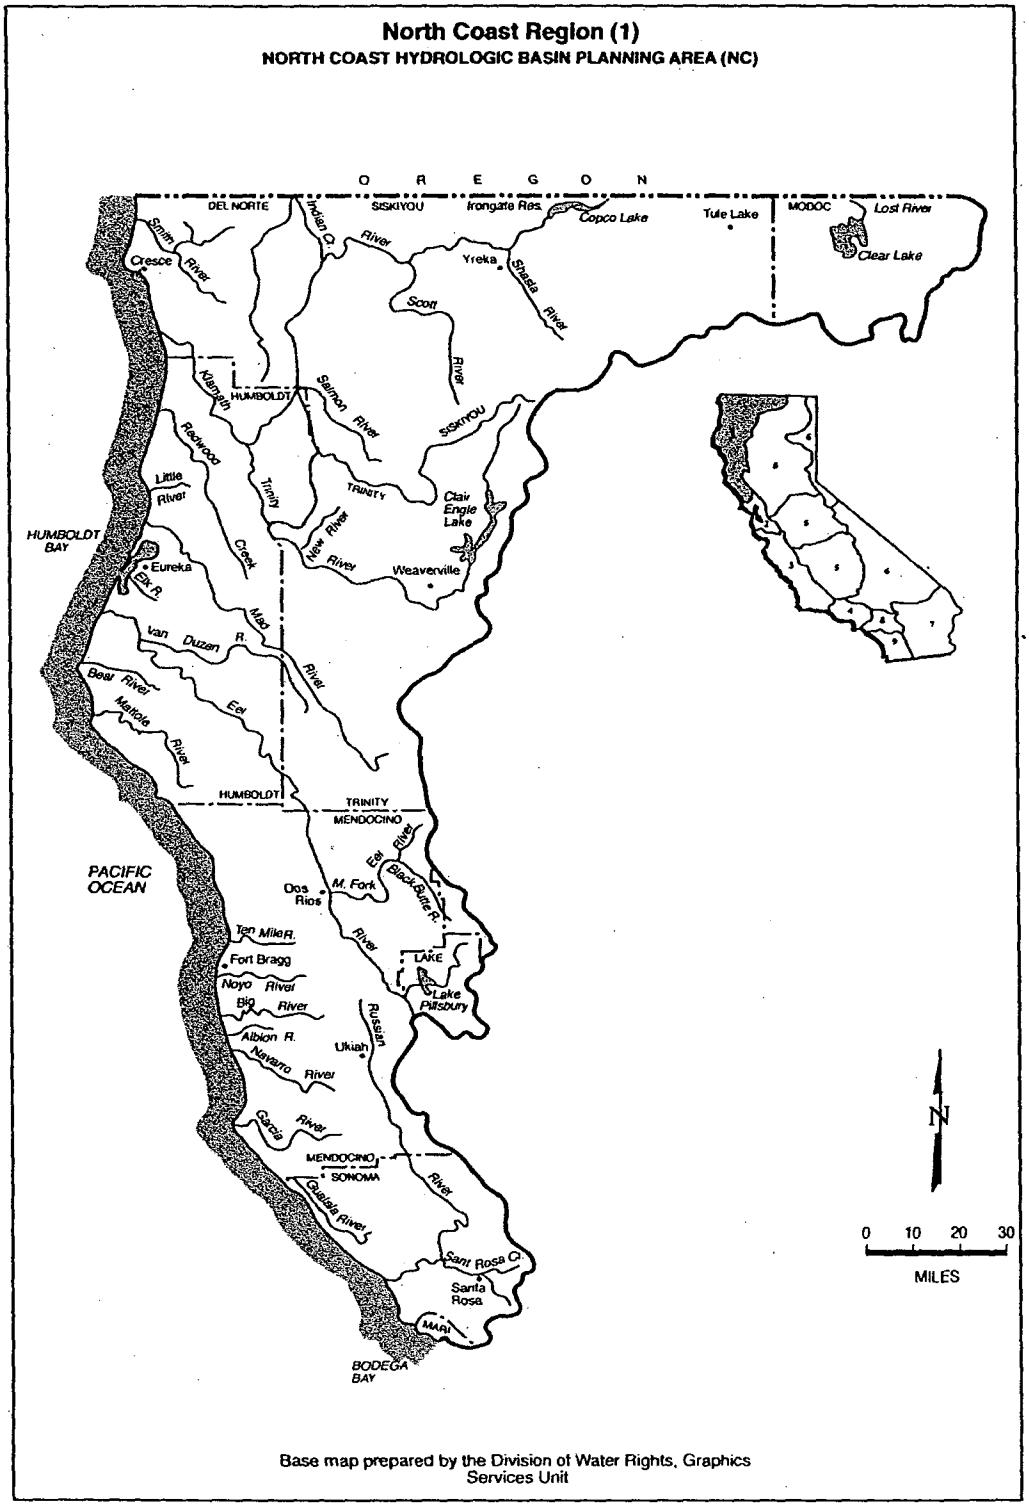

Figure 3.1. North Coast Region

3.2 SAN FRANCISCO BAY REGION

The San Francisco Bay Region comprises San Francisco Bay, Suisun Bay beginning at the Sacramento River, and San Joaquin River westerly, from a line which passes between Collinsville and Montezuma Island (Figure 3.2). The Region's boundary follows the borders common to Sacramento and Solano Counties and Sacramento and Contra Costa Counties west of the Markely Canyon watershed in Contra Costa County. All basins west of the boundary, described above, and all basins draining into the Pacific Ocean between the southern boundary of the North Coast Region and the southern boundary of the watershed of Pescadero Creek in San Mateo and Santa Cruz Counties are included in the Region.

The Region comprises most of the San Francisco Estuary to the mouth of the Sacramento-San Joaquin Delta. The San Francisco Estuary conveys the waters of the Sacramento and San Joaquin Rivers to the Pacific Ocean. Located on the central coast of California, the Bay system functions as the only drainage outlet for waters of the Central Valley. It also marks a natural topographic separation between the northern and southern coastal mountain ranges. The Region's waterways, wetlands, and bays form the centerpiece of the fourth largest metropolitan area in the United States, including all or major portions of Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano, and Sonoma Counties.

The San Francisco Bay Regional Water Board has jurisdiction over the part of the San Francisco Estuary, which includes all of the San Francisco Bay segments extending east to the Delta (Winter Island near Pittsburg). The San Francisco Estuary sustains a highly dynamic and complex environment. Within each section of the Bay system lie deepwater areas that are adjacent to large expanses of very shallow water. Salinity levels range from hypersaline to fresh water and water temperature varies widely.

The Bay system's deepwater channels, tidelands, marshlands, fresh water streams and rivers provide a wide variety of habitats within the Region. Coastal embayments including Tomales Bay and Bolinas Lagoon are also located in this Region. The Central Valley Regional Water Board has jurisdiction over the Delta and rivers extending further eastward.

The San Francisco Estuary is made up of many different types of aquatic habitats that support a great diversity of organisms. Suisun Marsh in Suisun Bay is the largest brackish-water marsh in the United States. San Pablo Bay is a shallow embayment strongly influenced by runoff from the Sacramento and San Joaquin Rivers.

The Central Bay is the portion of the Bay most influenced by oceanic conditions. The South Bay, with less freshwater inflow than the other portions of the Bay, acts more like a tidal lagoon. Together these areas sustain rich communities of aquatic life and serve as important wintering sites for migrating waterfowl and spawning areas for anadromous fish.

Sediment quality-related impairments are summarized in Table 3.1. Tissue listings potentially related to pollutants in sediment are summarized in Table 3.2. Water column listings are presented in Table 3.3.

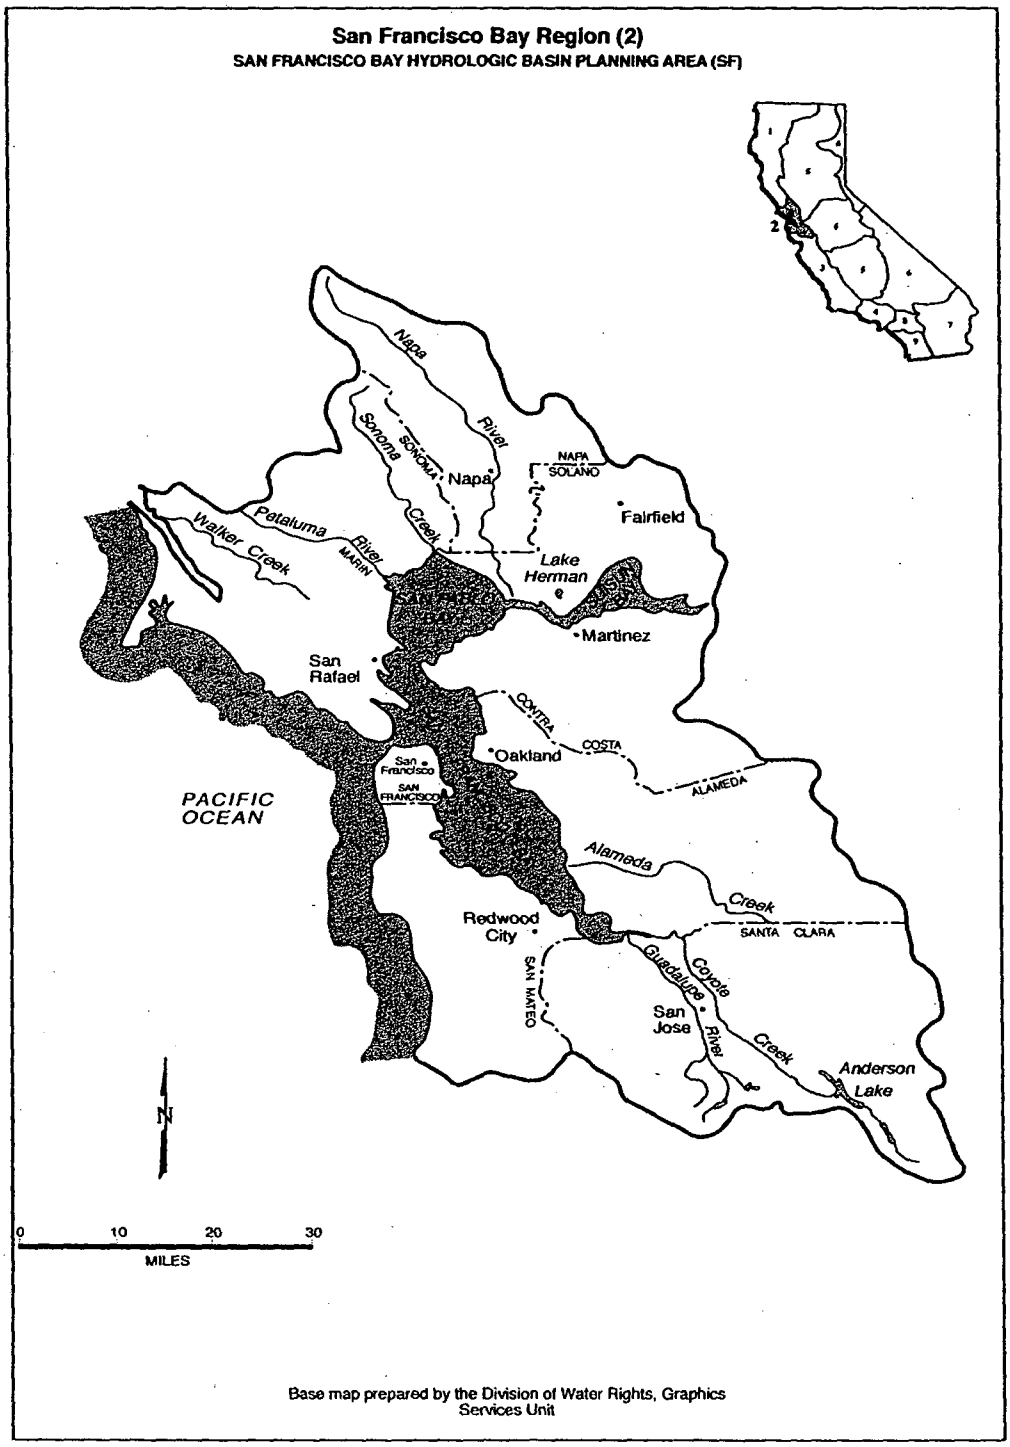

Figure 3.2. San Francisco Bay Region

Table 3.1. Summary of sediment Quality Related 303(d) Listing of Bays and Estuaries in the San Francisco Region (SWRCB, 2006)

Water Body	Type[1]	Basis For Impairment
Stege Marsh	Estuary	Chlordane, Copper, Dacthal, Dieldrin, Mercury, PCBs[2], Zinc, Sediment Toxicity, Benthic Community Impacts
Islais Creek	Estuary	Chlordane Dieldrin, PAH[3], Sediment Toxicity, Benthic Community Impacts
Mission Creek	Estuary	Chlordane, Dieldrin Lead, Mercury, PAHs[3], PCBs[2], Silver, Zinc, Lead, Mercury, Sediment Toxicity, Benthic Community Impacts
Petaluma River (tidal portion),	Estuary	Nickel
Oakland Inner Harbor (Fruitvale Site)	Bay	Chlordane, PCBs[2], Sediment Toxicity
Oakland Inner Harbor (Pacific Dry-dock Yard)	Bay	Chlordane, Copper, Dieldrin, Lead, Mercury, PCBs[2], Zinc, Sediment Toxicity
Castro Cove, Richmond	Bay	Dieldrin, Mercury, PAHs[3], Selenium
Central Basin, San Francisco Bay	Bay	Dieldrin, Mercury, PAHs[3], Selenium, Sediment Toxicity
San Leandro Bay	Bay	Lead, Mercury, PAHs[3], Chlordane, Dieldrin, Zinc, Sediment Toxicity, Benthic Community Impacts
San Pablo Bay	Bay

3.3 CENTRAL COAST REGION

The Central Coast Region comprises all basins (including Carrizo Plain in San Luis Obispo and Kern Counties) draining into the Pacific Ocean from the southern boundary of the Pescadero Creek watershed in San Mateo and Santa Cruz Counties; to the southeastern boundary of the Rincon Creek watershed, located in western Ventura County (Figure 3.3). The Region extends over a 300-mile long by 40-mile wide section of the State's central coast. Its geographic area encompasses all of Santa Cruz, San Benito, Monterey, San Luis Obispo, and Santa Barbara Counties as well as the southern one-third of Santa Clara County, and small portions of San Mateo, Kern, and Ventura Counties. Included in the region are urban areas such as the Monterey Peninsula and the Santa Barbara coastal plain; prime agricultural lands such as the Salinas, Santa Maria, and Lompoc Valleys; National Forest lands; extremely wet areas such as the Santa Cruz Mountains; and arid areas such as the Carrizo Plain. Water bodies in the Central Coast Region are varied. Enclosed bays and harbors in the Region include Morro Bay, Elkhorn Slough, Tembladero Slough, Santa Cruz Harbor, Moss Landing Harbor, San Luis Harbor, and Santa Barbara Harbor. Several small estuaries also characterize the Region, including the Santa Maria River Estuary, San Lorenzo River Estuary, Big Sur River Estuary, and many others. Major rivers, streams, and lakes include San Lorenzo River, Santa Cruz River, San Benito River, Pajaro River, Salinas River, Santa Maria River, Cuyama River, Estrella River and Santa Ynez River, San Antonio Reservoir, Nacimiento Reservoir, Twitchel Reservoir, and Cuchuma Reservoir. The economic and cultural activities in the basin have been primarily agrarian. Livestock grazing persists, but has been combined with hay cultivation in the valleys. Irrigation, with pumped local groundwater, is very significant in intermountain valleys throughout the basin. Mild winters result in long growing seasons and continuous cultivation of many vegetable crops in parts of the basin.

While agriculture and related food processing activities are major industries in the Region, oil production, tourism, and manufacturing contribute heavily to its economy. The northern part of the Region has experienced a significant influx of electronic manufacturing; while offshore oil exploration and production have heavily influenced the southern part. Total population of the Region is estimated at 1.22 million people.

Water quality problems frequently encountered in the Central Coastal Region include excessive salinity or hardness of local groundwaters. An increase in nitrate concentrations is a growing problem in a number of areas, in both groundwater and surface water. Surface waters suffer from bacterial contamination, nutrient enrichment, and siltation in a number of watersheds. Pesticides are a concern in agricultural areas and associated downstream water bodies. Sediment quality-related impairments and water column listings associated with toxic pollutants are summarized in Tables 3.4 and 3.5 respectively.

3.4 LOS ANGELES REGION

The Los Angeles Region comprises all basins draining into the Pacific Ocean between the southeastern boundary of the watershed of Rincon Creek, located in western Ventura County, and a line which coincides with the southeastern boundary of Los Angeles County, from the Pacific Ocean to San Antonio Peak, and follows the divide, between the San Gabriel River and Lytle Creek drainages to the divide between Sheep Creek and San Gabriel River drainages (Figure 3.4).

The Region encompasses all coastal drainages flowing into the Pacific Ocean between Rincon Point (on the coast of western Ventura County) and the eastern Los Angeles County line, as well as the drainages of five coastal islands (Anacapa, San Nicolas, Santa Barbara, Santa Catalina and San Clemente). In addition, the Region includes all coastal waters within three miles of the continental and island coastlines.

Water Body	Type[1]	Basis For Impairment
Monterey Harbor	Bay	Metals, Toxicity
Moss Landing Harbor	Bay	Pesticides

1. Based upon beneficial uses provided in fact sheets (SWRCB, 2006)

Two large deepwater harbors (Los Angeles and Long Beach Harbors) and one smaller deepwater harbor (Port Hueneme) are contained in the Region. There are small craft marinas within the harbors, as well as tank farms, naval facilities, fish processing plants, boatyards, and container terminals.

Several small-craft marinas also exist along the coast (Marina del Rey, King Harbor, Ventura Harbor); these contain boatyards, other small businesses and dense residential development.

Several large, primarily concrete-lined rivers (Los Angeles River, San Gabriel River) lead to unlined tidal prisms, which are influenced by marine waters. Salinity may be greatly reduced following rains since these rivers drain large urban areas composed of mostly impermeable surfaces. Some of these tidal prisms receive a considerable amount of freshwater throughout the year from publicly owned treatment works discharging tertiary-treated effluent. Lagoons are located at the mouths of other rivers draining relatively undeveloped areas (Mugu Lagoon, Malibu Lagoon, Ventura River Estuary, and Santa Clara River Estuary). There are also a few isolated coastal brackish water bodies receiving runoff from agricultural or residential areas.

Santa Monica Bay, which includes the Palos Verdes Shelf, dominates a large portion of the open coastal water bodies in the Region. The Region's coastal water bodies also include the areas along the shoreline of Ventura County and the waters surrounding the five offshore islands in the region.

Sediment quality, tissue and water quality listings for toxic pollutants are summarized in Tables 3.6, 3.7 and 3.8 respectively.

Table 3.6. Summary of Sediment Quality Related 303(d) Listing of Bays and Estuaries in the Los Angeles Region (SWRCB, 2006)

Water Body	Type[1]	Basis For Impairment
Ballona Creek Estuary	Estuary	Chlordane, DDT, Lead, PCBs[2], PAHs[3], Zinc, Sediment Toxicity, Benthic Community Impacts
Calleguas Creek Reach 1 (Mugu Lagoon)	Estuary	DDT, Sediment Toxicity
Channel Islands Harbor	Bay	Lead, Zinc
Dominguez Channel	Estuary	DDT, Zinc, Sediment Toxicity, Benthic Community Impacts
Los Angeles Harbor – Fish Harbor	Bay	Benzo[a]anthracene Dibenz[a,h]anthracene, Chlordane, Chrysene (C1-C4) Copper, Lead, Mercury, Phenanthrene, Pyrene, Zinc, Sediment toxicity
Los Angeles River Estuary (Queensway Bay)	Estuary	Chlordane, DDT, Lead, PCBs[2], Sediment Toxicity
Los Angeles Harbor – Inner Cabrillo Beach	Bay	Copper
Los Angeles Harbor – Consolidated Slip	Bay	Cadmium, Chlordane, Chromium, Copper, DDT, Lead, Mercury, PCBs[2], Zinc, Sediment Toxicity Benthic Community Impacts
Los Angeles/Long Beach Inner Harbor	Bay	Benthic Community Impacts, Sediment Toxicity
Los Cerritos Channel	Estuary	Chlordane
Malibu Lagoon	Estuary	Benthic Community Impacts
Marina del Rey Harbor – Back Basins	Bay	Chlordane, Copper, DDT, Lead, PCBs[2], Zinc, Sediment Toxicity
McGrath Lake	Estuary	Dieldrin, PCBs, Sediment Toxicity

2. Polychlorinated biphenyls

3.5 CENTRAL VALLEY REGION

The Central Valley Region includes approximately 40 percent of the land in California stretching from the Oregon border to the Kern County/ Los Angeles county line. The Region is divided into three basins. For planning purposes, the Sacramento River Basin and the San Joaquin River basin are covered under one Basin Plan and the Tulare Lake Basin is covered under a separate distinct one (Figures 3.5, 3.6 and 3.7).

The Sacramento River Basin covers 27,210 square miles and includes the entire area drained by the Sacramento River. The principal streams are the Sacramento River and its larger tributaries: the Pitt, Feather, Yuba, Bear, and American Rivers to the East; and Cottonwood, Stony, Cache, and Putah Creek to the west. Major reservoirs and lakes include Shasta, Oroville, Folsom, Clear Lake, and Lake Berryessa.

The San Joaquin River Basin covers 15,880 square miles and includes the entire area drained by the San Joaquin River. Principal streams in the basin are the San Joaquin River and its larger tributaries: the Consumnes, Mokelumne, Calaveras, Stanislaus, Tuolumne, Merced, Chowchilla, and Fresno Rivers. Major reservoirs and lakes include Pardee, New Hogan, Millerton, McClure, Don Pedro, and New Melones.

The Tulare Lake Basin covers approximately 16,406 square miles and comprises the drainage area of the San Joaquin Valley south of the San Joaquin River. The planning boundary between the San Joaquin River Basin and the Tulare Lake Basin is defined by the northern boundary of Little Pinoche Creek basin eastward along the channel of the San Joaquin River to Millerton Lake in the Sierra Nevada foothills, and then along the southern boundary of the San Joaquin River drainage basin. Main rivers within the basin include the King, Kaweah, Tule, and Kern Rivers, which drains the west face of the Sierra Nevada Mountains. Imported surface water supplies enter the basin through the San Luis Drain- California Aqueduct System, Friant-Kern Channel and the Delta Mendota Canal.

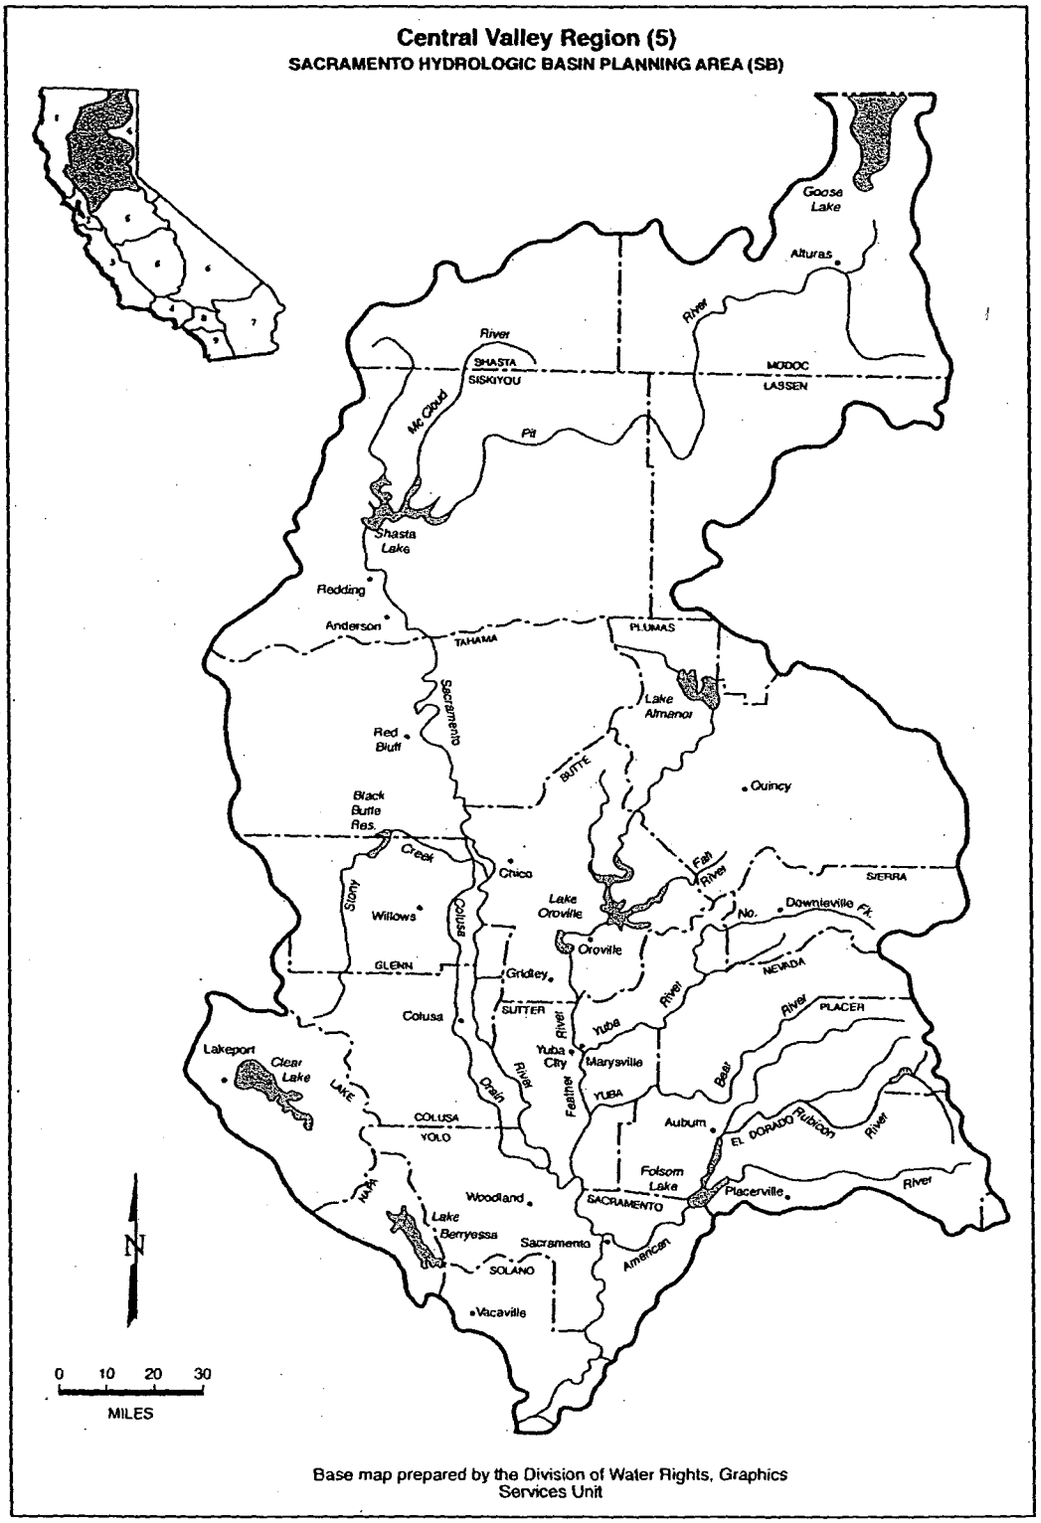

Figure 3.5. Central Valley Region Sacramento Hydrologic Basin

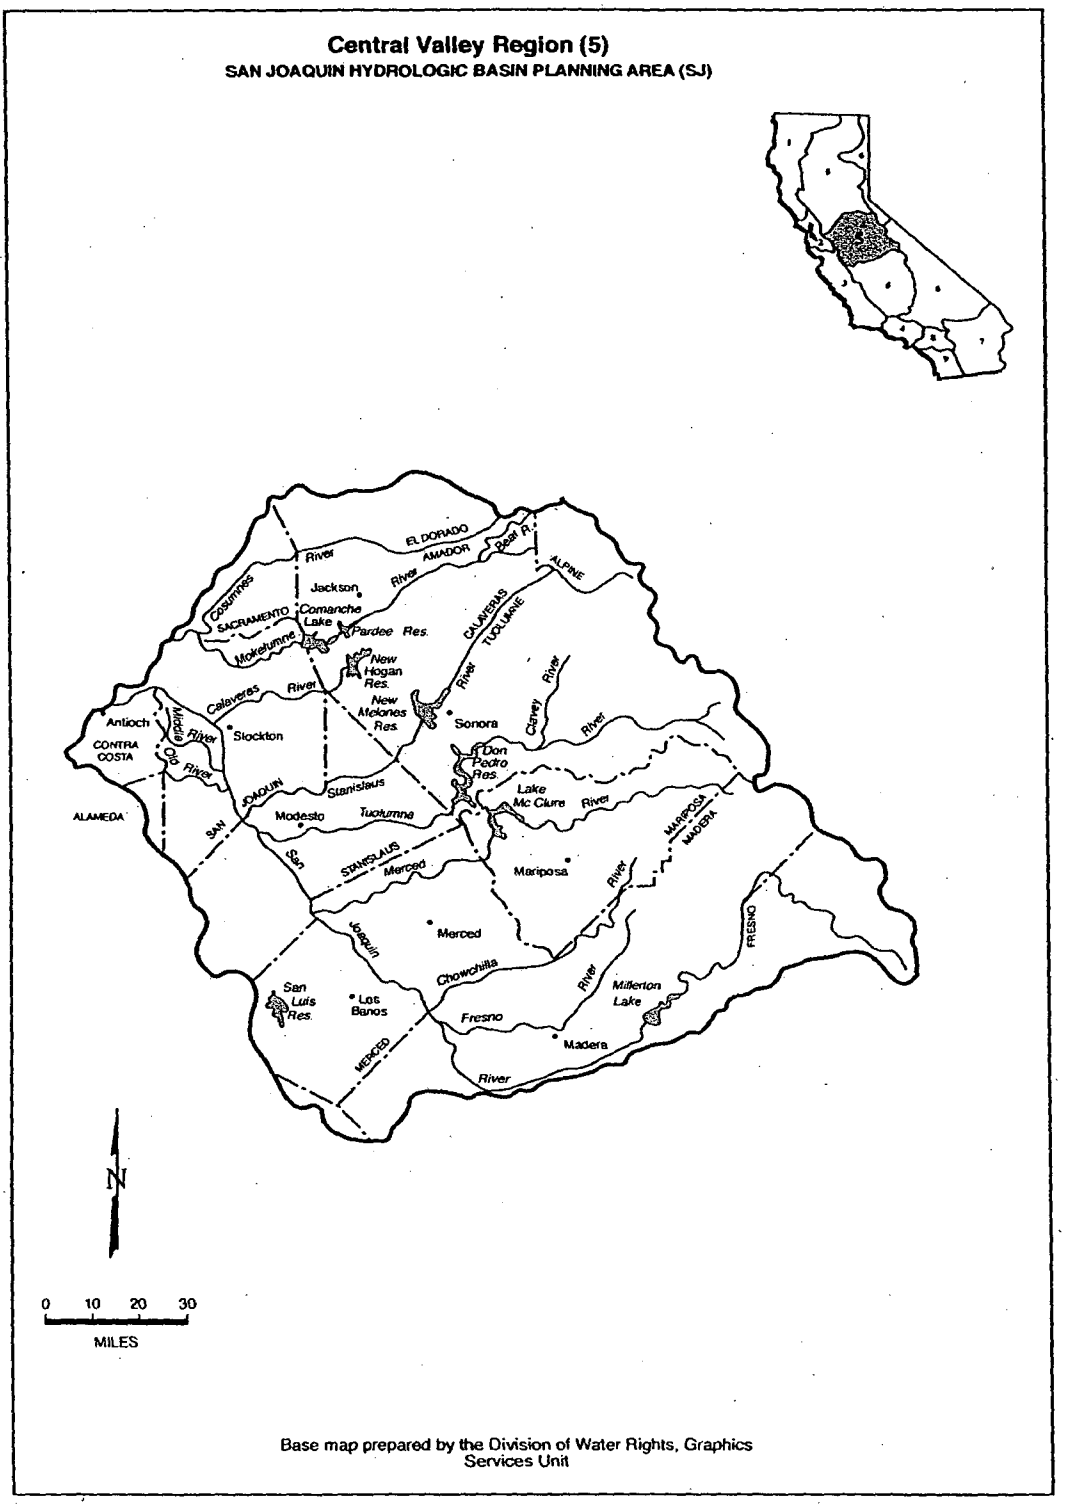

Base map prepared by the Division of Water Rights, Graphics Services Unit

Figure 3.6. Central Valley Region San Joaquin Hydrologic Basin

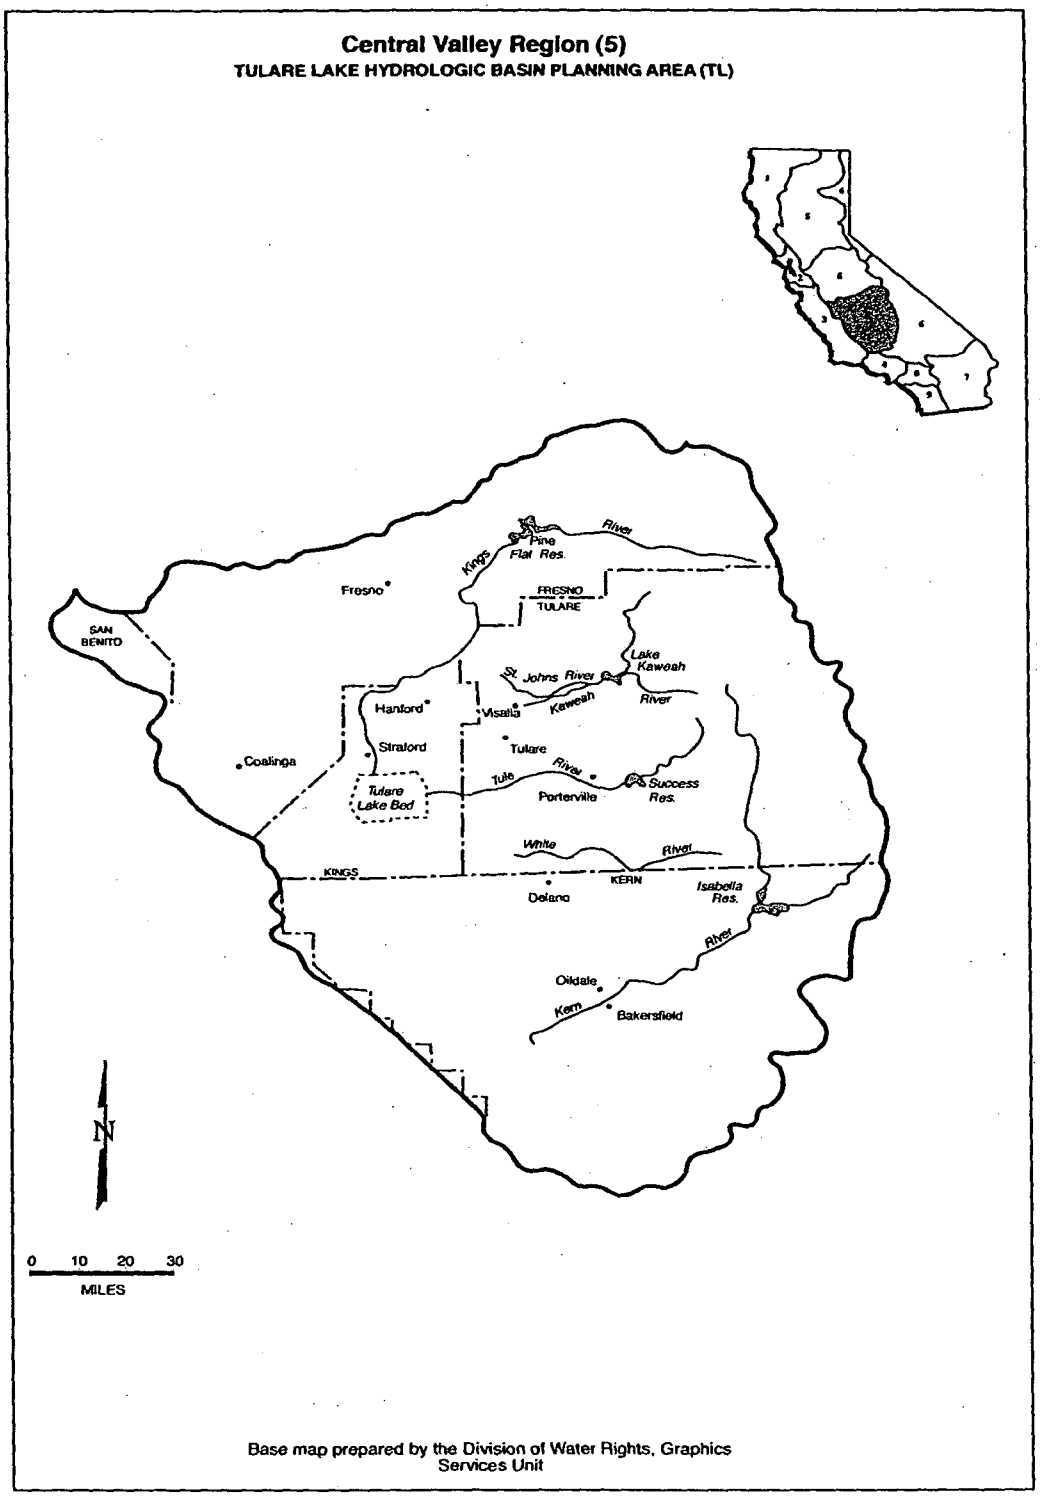

Figure 3.7. Central Valley Region Tulare lake Hydrologic Basin

The two northern most basins are bound by the crests of the Sierra Nevada on the east and the Coast Range and Klamath Mountains on the west. They extend about 400 miles from the California-Oregon border southward to the headwaters of the San Joaquin River. These two river basins cover about one fourth of the total area of the State and over 30 percent of the State's irrigable land. The Sacramento and San Joaquin Rivers furnish roughly 50 percent of the State's water supply. Surface water from the two drainage basins meet and form the Delta, which ultimately drains into the San Francisco Bay. The Delta is a maze of river channels and diked islands covering roughly 1,150 square miles, including 78 square miles of water area. Two major water projects located in the South Delta, the Federal Central Valley Project and the State Water Project, deliver water from the Delta to Southern California, the San Joaquin Valley, Tulare Lake Basin, the San Francisco Bay Area, as well as within the Delta boundaries. The legal boundary of the Delta is described in Water Code section 12220.

Tissue and water quality listings for toxic pollutants are summarized in Tables 3.9 and 3.10. The major pollutants affecting estuarine waters in the Central Valley include nutrients, metals, pathogens, and pesticides among others (SWRCB, 2003a).

Table 3.9. Summary of 303(d) Tissue Listings in Estuaries of the Central Valley Region (SWRCB, 2006)

Water Body	Type[1]	Basis For Impairment
Delta Waterways Northern Portion	Estuary	DDT, PCBs[2], Mercury
Delta Waterways Southern Portion	Estuary	DDT, Mercury
Delta Waterways Central Portion	Estuary	DDT, PCBs[2], Mercury
Delta Waterways Eastern Portion	Estuary	DDT, Mercury
Delta Waterways Western Portion	Estuary	DDT, Mercury
Delta Waterways Stockton Ship Channel	Estuary	DDT, Dioxins, Mercury, PCBs[2]

2. Polychlorinated biphenyls
3. Polyaromatic hydrocarbons

Table 3.10. Summary of 303(d) Water Quality Listings in Estuaries of the Central Valley Region (SWRCB, 2006)

Water Body	Type[1]	Basis For Impairment
Delta Waterways Northern Portion	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene
Delta Waterways Southern Portion	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene
Delta Waterways Central Portion	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene
Delta Waterways Eastern Portion	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene
Delta Waterways Western Portion	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene
Delta Waterways Stockton Ship Channel	Estuary	Chlorpyrifos, DDT, Diazinon, Mercury, Aldrin, Dieldrin, Chlordane, Endrin, Heptachlor, Heptachlor Epoxide, Hexachlorocyclohexane (including Lindane), Endosulfan, and Toxaphene

1. Based upon beneficial uses provided in fact sheets (SWRCB, 2006)

There are also a number of sediment quality-related 303(d) listings for waters upstream of affected bays and estuaries (see SWRCB, 2006). Impaired sediments can be carried downstream and settle into bays and estuaries, contributing to existing impairments or causing new impairments.

3.6 SANTA ANA REGION

The Santa Ana Region comprises all basins draining into the Pacific Ocean between the southern boundary of the Los Angeles Region and the drainage divide between Muddy and Moro Canyons, from the ocean to the summit of San Joaquin Hills; along the divide between lands draining into Newport Bay and Laguna Canyon to Niguel Road; along Niguel Road and Los Aliso Avenue to the divide between Newport Bay and Aliso Creek drainages; and along the divide and the southeastern boundary of the Santa Ana River drainage to the divide between Baldwin Lake and Mojave Desert drainages; to the divide between the Pacific Ocean and Mojave Desert drainages (Figure 3.8). The Santa Ana Region is the smallest of the nine regions in the state (2,800 square miles) and is located in southern California, roughly between Los Angeles and San Diego.

Although small geographically, the region's four-plus million residents (1993 estimate) make it one of the most densely populated regions. The climate of the Santa Ana Region is classified as Mediterranean: generally dry in the summer with mild, wet winters. The average annual rainfall in the region is about fifteen inches, most of it occurring between November and March.

The enclosed bays in the Region include Newport Bay, Bolsa Bay (including Bolsa Chica Marsh), and Anaheim Bay. Principal Rivers include Santa Ana, San Jacinto and San Diego. Lakes and reservoirs include Big Bear, Hemet, Mathews, Canyon Lake, Lake Elsinore, Santiago Reservoir, and Perris Reservoir.

The section 2002 303(d) list for the Santa Ana Region included nine water bodies affecting an estimated 7,886 acres (bays, estuaries, lakes, and wetlands) and 24 water bodies affecting 191 miles of rivers and shoreline. The major pollutants affecting these water bodies included nutrients, metals, pathogens, pesticides, and sediments among others (SWRCB 2003a). Sediment quality-related impairments are summarized in Table 3.11. Tissue listings potentially related to pollutants in sediment are summarized in Table 3.12.

Table 3.11. Summary of Sediment Quality Related 303(d) Listing of Bays and Estuaries in the Santa Ana Region (SWRCB, 2006)

Water Body	Type[1]	Basis for Impairment
Anaheim Bay	Bay	Sediment Toxicity
Huntington Harbour	Bay	Chlordane, Lead, Sediment Toxicity
Newport Bay – Lower	Bay	Chlordane, Copper, DDT, PCBs, Sediment Toxicity
Newport Bay – Upper (Ecological Reserve)	Bay	Chlordane, DDT, PCBs, Metals, Benthic Community Degradation, Sediment Toxicity
Rhine Channel	Bay	Sediment Toxicity

3. Polyaromatic hydrocarbons

Table 3.13. Summary of 303(d) Water Quality Listings for Toxic Pollutants in Bays and Estuaries of the Santa Ana Region (SWRCB, 2006)

Water Body	Type[1]	Basis for Impairment
Huntington Harbour	Bay	Copper
Bolsa Bay	Bay	Copper
Upper Newport Bay	Bay	Copper, PCBs[2], Chlordane, DDT, Metals
Lower Newport Bay	Bay	Copper, PCBs[2], Chlordane, DDT
Rhine Channel	Bay	Copper, Lead, Mercury, Zinc, PCB[2]

1. Based upon beneficial uses provided in fact sheets (SWRCB, 2006)
2. Polychlorinated biphenyls
3. Polyaromatic hydrocarbons

3.7 San Diego Region

The San Diego Region comprises all basins draining into the Pacific Ocean between the southern boundary of the Santa Ana Region and the California-Mexico boundary (Figure 3.9). The San Diego Region is located along the coast of the Pacific Ocean from the Mexican border to north of Laguna Beach. The Region is rectangular in shape and extends approximately 80 miles along the coastline and 40 miles east to the crest of the mountains. The Region includes portions of San Diego, Orange, and Riverside Counties.

The population of the Region is heavily concentrated along the coastal strip. Six deepwater sewage outfalls and one across the beach discharge from the new border plant at the Tijuana River empty into the ocean. Two harbors, Mission Bay and San Diego Bay, support major recreational and commercial boat traffic. Coastal lagoons are found along the San Diego County coast at the mouths of creeks and rivers.

The 2002 section 303(d) list for the San Diego Region included 26 water bodies affecting an estimated 6,907 acres (bays, estuaries, lakes, and wetlands) and 40 water bodies affecting 148 miles of rivers and shoreline. The major pollutants affecting these water bodies included nutrients, metals, pathogens, pesticides, and sediments among others (SWRCB, 2003a).

Weather patterns are Mediterranean in nature with an average rainfall of approximately ten inches per year occurring along the coast. Almost all the rainfall occurs during wet cool winters. The Pacific Ocean generally has cool water temperatures due to upwelling. This nutrient-rich water supports coastal beds of giant kelp. The cities of San Diego, National City, Chula Vista, Coronado, and Imperial Beach surround San Diego Bay in the southern portion of the Region.

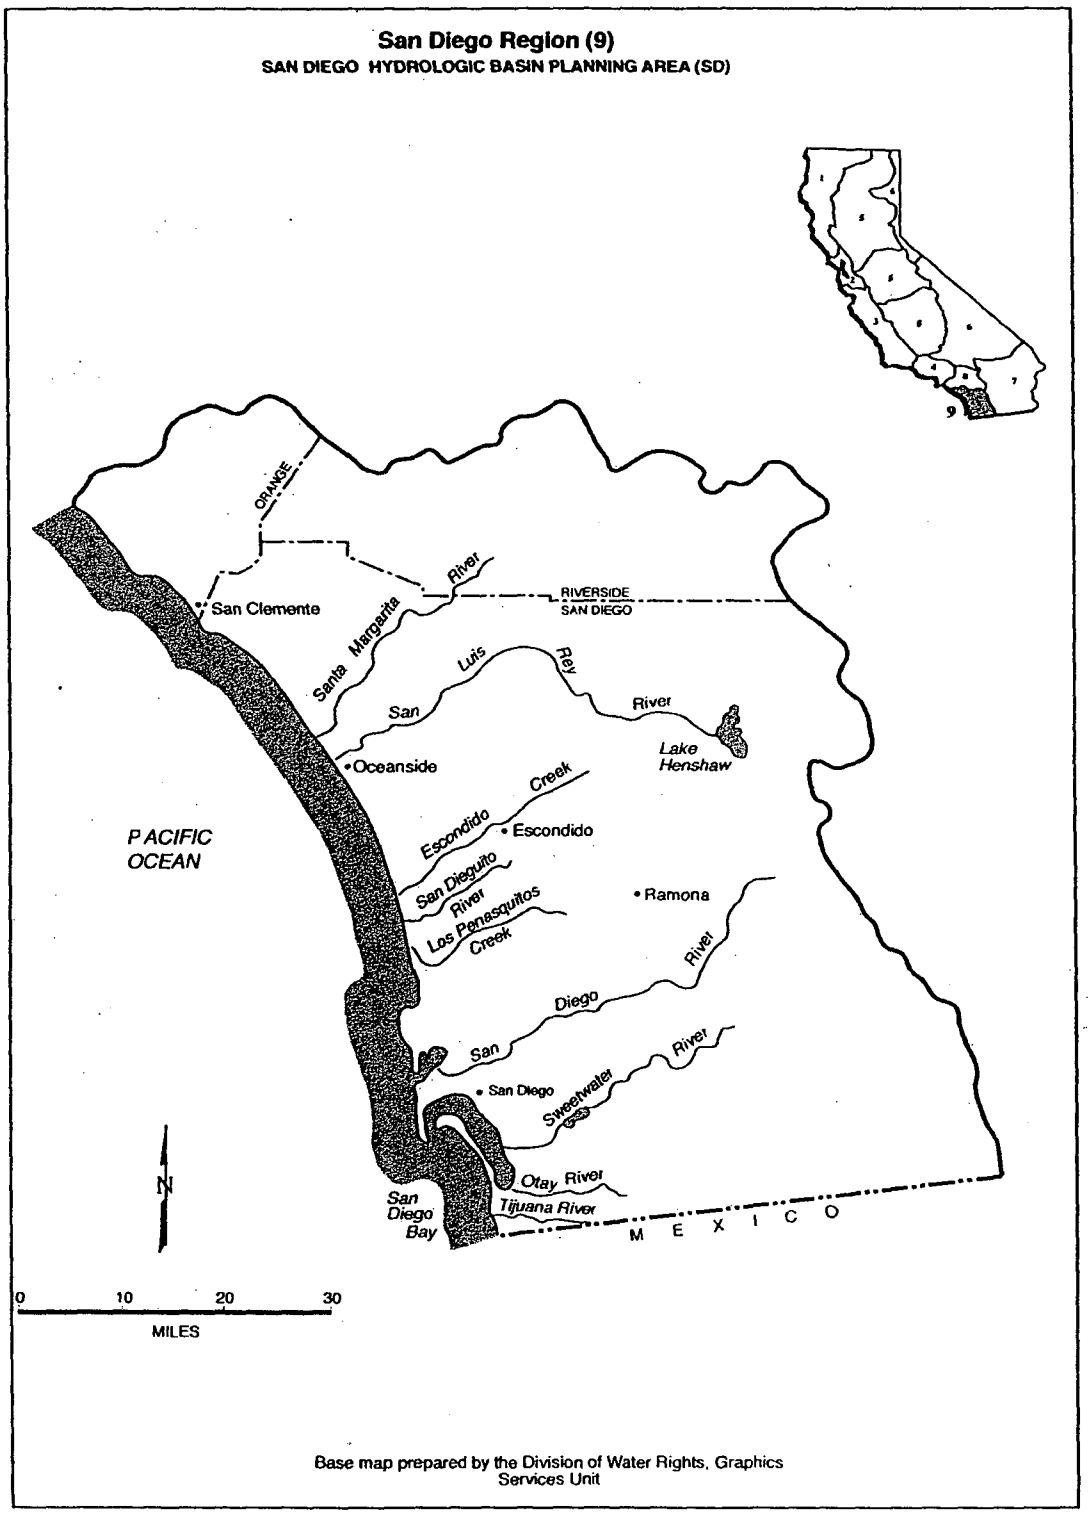

Figure 3.9. San Diego Region

San Diego Bay is long and narrow, 15 miles in length and approximately one mile across. A deep-water harbor, San Diego Bay has experienced waste discharge from former sewage outfalls, industries, and urban runoff. Up to 9,000 vessels may be moored there. San Diego Bay also hosts four major U.S. Navy bases with approximately 80 surface ships and submarines. Coastal waters include bays, harbors, estuaries, beaches, and open ocean. Sediment quality-related impairments are summarized in Table 3.14. Tissue listings potentially related to pollutants in sediment are summarized in Table 3.15.

Table 3.14. Summary of Sediment Quality Related 303(d) Listing of Bays and Estuaries in the San Diego Region (SWRCB, 2006)

Water Body	Type[1]	Basis for Impairment
San Diego Bay Shoreline, 32nd St San Diego Naval Station	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, Downtown Anchorage	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, near Chollas Creek	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, near Coronado Bridge	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, 9 B near sub base	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, near Switzer Creek	Bay	Chlordane, Lindane/Hexachlorocyclohexane (HCH), PAHs
San Diego Bay Shoreline, North of 24th Street Marine Terminal	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, Seventh Street Channel	Bay	Benthic Community Effects, Sediment Toxicity
San Diego Bay Shoreline, Vicinity of B St and Broadway Piers	Bay	Benthic Community Effects, Sediment Toxicity

2. Polychlorinated biphenyls
3. Polyaromatic hydrocarbons

4. REGULATORY BASELINE

This section describes current state and federal laws, programs, and practices that govern sediment quality in bays and estuaries. These laws, programs and practices represent the regulatory baseline for measuring incremental impacts of Part 1. As explained in greater detail in the following discussion, the basin plans for the coastal Regional Water Boards all contain narrative water quality objectives that apply to sediment quality in bays and estuaries. These narrative objectives provide the basis for sediment cleanup activities under current state and federal law.

The section begins with a brief overview of Porter-Cologne and the Clean Water Act, 33 U.S.C. section 1251 et seq. A more detailed discussion of relevant laws, programs, and practices follows. Porter-Cologne is the primary water quality control law for California. It addresses two key functions – planning and waste discharge regulation. The State Water Board adopts state policy for water quality control, which is binding on the Regional Water Boards. (Wat. Code §13140 et seq.) The State Water Board is also authorized to adopt water quality control plans for waters that require water quality standards under the Clean Water Act and must adopt plans for ocean waters and for enclosed bays and estuaries. (Wat. Code §§13170, 131702., 13391.) The Regional Water Boards are required to adopt water quality control plans, or basin plans, for waters within their respective regions. Water quality control plans designate beneficial uses of water, establish water quality objectives to protect those uses, and contain a program to implement the objectives. (*Id.*§13050(j).) The beneficial use designations and water quality objectives (together with an antidegradation policy) constitute water quality standards for purposes of the Clean Water Act. (See Clean Water Act §303(c)(2)(A); 40 C.F.R. §§131.3(i), 131.6.)

The Water Boards have designated for protection a variety of beneficial uses for bay and estuarine waters, including, among others, the preservation and enhancement of fish, wildlife, and other aquatic resources and habitats; commercial and sport fishing; and shellfish harvesting. They have also adopted water quality objectives to protect the uses, which can be either numeric or narrative. All regional basin plans include narrative toxicity objectives.

Porter-Cologne establishes a program to regulate waste discharges that could affect water quality through waste discharge requirements, conditional waivers, or prohibitions. (See Wat. Code §§13243, 13263, 13269.) This program is the principal way in which water quality control policies and plans are implemented. The term "waste" is broadly defined in Porter-Cologne and includes toxic pollutants, as well as other waste substances. (*Id.* §13050(d).) The term "waters of the state" is similarly broadly defined to include all surface waters, including bays and estuaries, and groundwater within state boundaries. (*Id.* §13050(e).)

Porter-Cologne also authorizes the Water Boards to investigate water quality and to require waste dischargers to submit monitoring and technical reports. (*Id.* §13267, 13383.) In addition, Porter-Cologne gives the Water Boards extensive enforcement authority to respond to unauthorized discharges, discharges in violation of applicable requirements, discharges that cause pollution or nuisance, and other matters. The enforcement options include, among others, cleanup and abatement orders, cease and desist orders, and administrative civil liability orders. (*Id.* §13301, 13304, 13323.)

In 1989, Porter-Cologne was amended to specifically address the threat posed to bays and estuaries from toxic pollutants. The legislation, which added chapter 5.6 to Division 7 of the Water Code, mandated that the State Water Board develop a consolidated toxic hot spot cleanup plan and adopt sediment quality objectives for bays and estuaries. The State Water

Board established the Bay Protection and Toxic Cleanup Program to implement the requirements of chapter 5.6.

The Water Boards also implement the federal Clean Water Act. As required under section 303(c) of the Act, the Water Boards adopt water quality standards for waters of the United States. In addition, the Water Boards issue National Pollutant Discharge Elimination System (NPDES) permits pursuant to section 402 of the Clean Water Act. Section 402 of the Clean Water Act requires that all point source discharges of pollutants to waters of the United States be regulated under a permit. The State Water Board is the state water pollution control agency for all purposes stated in the Clean Water Act. (*Id.* §13160.) As such, the State Water Board is authorized to issue water quality certifications under Clean Water Act §401 . The Water Boards also implement the total maximum daily load (TMDL) program, which is required under section 303(d) of the Clean Water Act.

4.1 Existing Water Quality Standards Related to Sediment Quality

As explained above, water quality standards consist of beneficial uses, criteria (which are the federal equivalent of water quality objectives) and an antidegradation policy. All basin plans for the coastal regions contain water quality objectives or prohibitions that apply to sediment quality. None of the Regional Water Boards has adopted numeric water quality objectives for sediments. Rather, the Regional Water Boards typically rely on narrative toxicity objectives to protect and manage ambient sediment quality. The current narratives and prohibitions used to regulate sediment quality are listed below in Section 4.1.1. These narratives (and associated beneficial uses) provide the bases for permit requirements, cleanup actions, Clean Water Act §303(d) listings, and other regulatory activities. Section 4.1.2 explains how the Regional Water Boards currently assess sediment quality to ascertain compliance with water quality standards. Section 4.1.3 describes state policies and federal regulations for toxic pollutant standards applicable to bay and estuarine waters.

4.1.1 Applicable Basin Plan Narrative Objectives or Prohibitions

Water Quality Control Plan for the North Coast Region

Regional Water Quality Control Board 5550 Skylane Blvd., Suite A Santa Rosa, CA 95403 (http://www.waterboards.ca.gov/northcoast/programs/basinplan/bpdocs.html).

- *All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal, or aquatic life. Compliance with this objective will be determined by use of indicator organisms, analyses of species diversity, population density, growth anomalies, bioassays of appropriate duration, or other appropriate methods as specified by the Regional Water Board.*
- *No individual pesticide or combination of pesticides shall be present in concentrations that adversely affect beneficial uses. There shall be no bioaccumulation of pesticide concentrations found in bottom sediments or aquatic life.*

Water Quality Control Plan (Basin Plan) for the San Francisco Bay Basin

San Francisco Regional Water Quality Control Board, 1515 Clay St. Suite 1400, Oakland, CA 94612 (http://www.waterboards.ca.gov/sanfranciscobay/basinplan.htm).

- Many pollutants can accumulate on particles, in sediment, or bioaccumulate in fish and other aquatic organisms. Controllable water quality factors shall not cause a detrimental increase in concentrations of toxic substances found in bottom sediments or aquatic life. Effects on aquatic organisms, wildlife, and human health will be considered.
- *Controllable water quality factors shall not cause a detrimental increase in the concentrations of toxic pollutants in sediments or aquatic life.*
- *All waters shall be maintained free of toxic substances in concentrations that are lethal to or that produce other detrimental responses in aquatic organisms. Detrimental responses include, but are not limited to, decreased growth rate and decreased reproductive success of resident or indicator species.*
- *There shall be no chronic toxicity in ambient waters. Chronic toxicity is a detrimental biological effect on growth rate, reproduction, fertilization success, larval development, population abundance, community composition, or any other relevant measure of the health of an organism, population, or community. Chronic toxicity generally results from exposures to pollutants exceeding 96 hours. However, chronic toxicity may also be detected through short-term exposure of critical life stages of organisms.*
- *The health and life history characteristics of aquatic organisms in waters affected by controllable water quality factors shall not differ significantly from those for the same waters in areas unaffected by controllable water quality factors.*
- *Bottom deposits or aquatic growths to the extent that such deposits or growths cause nuisance or adversely affect beneficial uses*
- *Toxic or other deleterious substances to be present in concentrations or quantities, which will cause deleterious effects on wildlife, waterfowl, or other aquatic biota, or which render any of these unfit for human consumption, either at levels created in the receiving waters or as a result of biological concentration.*

Water Quality Control Plan for the Central Coastal Basin

Central Coast Regional Water Quality Control Board
895 Aerovista Place, Suite 101
San Luis Obispo, CA 93401
http://www.swrcb.ca.gov/rwqcb3/BasinPlan/Index.htm.

- *All waters shall be maintained free of toxic substances in concentrations which are toxic to, or which produce detrimental physiological responses in, human, plant, animal, or aquatic life. Compliance with this objective will be determined by use of indicator organisms, analyses of species diversity, population density, growth anomalies, toxicity bioassays of appropriate duration, or other appropriate methods as specified by the Regional Board.*
- *No individual pesticide or combination of pesticides shall reach concentrations that adversely affect beneficial uses. There shall be no increase in pesticide concentrations found in bottom sediments or aquatic life.*

Water Quality Control Plan Los Angeles Region

Los Angeles Regional Water Quality Control Board
320 W. 4th St., Suite 200
Los Angeles, CA 90013

http://www.waterboards.ca.gov/losangeles/html/meetings/tmdl/Basin_plan/basin_plan_doc.html

- *No individual pesticide or combination of pesticides shall be present in concentrations that adversely affect beneficial uses. There shall be no increase in pesticide concentrations found in bottom sediments or aquatic life*
- *Toxic pollutants shall not be present at levels that will bioaccumulate in aquatic life to levels which are harmful to aquatic life or human health*

Water Quality Control Plan for the Sacramento and San Joaquin River Basins

Central Valley Regional Water Quality Control Board
Sacramento Main Office 11020 Sun Center Drive, Suite 200
Rancho Cordova, CA 95670-6114
Fresno Branch Office 1685 E Street Fresno, CA 93706-2007
Redding Branch Office 415 Knollcrest Drive, Suite 100 Redding, CA 96002
http://www.waterboards.ca.gov/centralvalley/available_documents/index.html#anchor616381

- *All waters shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal or aquatic life.*
- *Compliance with this narrative objective will be determined by analyses of indicator organisms, species diversity, growth anomalies, and biotoxicity tests of appropriate duration or other methods as specified by the Regional Water Board.*
- *The Regional Water Board will also consider all material and relevant information submitted by the discharger and other interested parties and numerical criteria and guidelines for toxic substances developed by the State Water Board, the California Office of Environmental Health Hazard Assessment, the California Department of Health Services, the US Food and Drug Administration, the National Academy of Sciences, the US Environmental Protection Agency, and other organizations to evaluate compliance with this objective.*
- *No individual pesticide or combination of pesticides shall be present in concentrations that adversely affect beneficial uses. Discharges shall not result in pesticide concentrations in bottom sediments or aquatic life that adversely affect beneficial uses*
- *Where compliance with these narrative objectives is required (i.e., where the objectives are applicable to protect specified beneficial uses), the Regional Water Board will, on a case-by-case basis, adopt numerical limitations in orders which will implement the narrative objectives. To evaluate compliance with the narrative water quality objectives, the Regional Water Board considers, on a case-by-case basis, direct evidence of beneficial use impacts, all material and relevant information submitted by the discharger and other interested parties, and relevant numerical criteria and guidelines developed and/or published by other agencies and organizations.*
- *In considering such criteria, the Board evaluates whether the specific numerical criteria, which are available through these sources and through other information supplied to the Board, are relevant and appropriate to the situation at hand and, therefore, should be used in determining compliance with the narrative objective.*

Water Quality Control Plan Santa Ana River Basin

Santa Ana Regional Water Quality Control Board
3737 Main St., Suite 500
Riverside, CA 92501
http://www.waterboards.ca.gov/santaana/html/basin_plan.html

- Toxic substances shall not be discharged at levels that will bioaccumulate in aquatic resources to levels which are harmful to human health.
- The concentrations of toxic substances in the water column, sediments or biota shall not adversely affect beneficial uses

Water Quality Control Plan for the San Diego Basin

San Diego Regional Water Quality Control Board
9174 Sky Park Court, Suite 100
San Diego, CA 92123
http://www.waterboards.ca.gov/sandiego/programs/basinplan.html

- All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal, or aquatic life. Compliance with this objective will be determined by use of indicator organisms, analyses of species diversity, population density, growth anomalies, bioassays of appropriate duration, or other appropriate methods as specified by the Regional Board
- The survival of aquatic life in surface waters subjected to a waste discharge or other controllable water quality factors, shall not be less than that for the same water body in areas unaffected by the waste discharge or, when necessary, for other control water that is consistent with requirements specified in US EPA, State Water Resources Control Board or other protocol authorized by the Regional Board. As a minimum, compliance with this objective as stated in the previous sentence shall be evaluated with a 96-hour acute bioassay
- In addition, effluent limits based upon acute bioassays of effluents will be prescribed where appropriate, additional numerical receiving water objectives for specific toxicants will be established as sufficient data become available, and source control of toxic substances will be encouraged

4.1.2 Current Regional Water Board Approaches for Assessing Whether Sediment Quality Complies with Applicable Standards

Indicators and Interpretive Tools

The type of monitoring and testing currently required by the Regional Water Boards to assess sediment quality varies by region. Each Regional Water Board has the discretion to determine how much information is enough to initiate an enforcement action. To assess direct exposure within the regions, one, two or three lines of evidence, such as sediment chemistry, sediment toxicity and benthic community analysis may be used to initiate an action. In the Central Valley Region, one line of evidence is adequate justification for an action. The lack of assessment tools has limited the use of bioassessment data in regulatory programs within the Central Valley Region (Bruns et al. 2007).

The San Diego Regional Water Board has devoted extensive resources to the assessment of sediment quality in San Diego Bay. Staff typically utilize sediment chemistry, sediment toxicity testing and benthic community analysis to assess direct effects to aquatic life. The selection of interpretative tools and thresholds are site specific and typically involve input from other organizations such as California Department of Fish and Game (DFG), U.S. Fish and Wildlife Service (U.S. FWS), California Department of Toxics Substance Control (DTSC), and National Oceanic and Atmospheric Administration (NOAA).

In the San Diego Region, sediment quality guidelines used recently to classify chemical concentrations in sediment are ERMs developed for metals (Long et al., 1998), Consensus midrange effects concentration developed for PAHs and PCBs (Swartz, 1999; MacDonald et al., 2000), and Sediment Quality Guideline Quotient (SQGQ) for chemical mixtures (Fairey et al., 2001). When attempting to distinguish localized impacts from regional or waterbody wide disturbances, these data are also compared with reference sites. The statistical procedure used by the San Diego Regional Water Board to identify stations where conditions are significantly different from the Reference Condition consists of identifying station sample values outside boundary established by the 95% prediction limit (PL) reference pool of data for each contaminant of concern. The sediment toxicity tests applied consisted of a 10-day amphipod survival test, a 48-hour bivalve larva development test exposed to the sediment-water interface, and 40-minute echinoderm egg fertilization test exposed to sediment pore water. The results of these toxicity tests are compared statistically to their respective negative controls using a one-tailed Student t-test ($\alpha = 0.05$). Toxicity results were ranked as low, moderate, and high toxicity based upon the magnitude of the response and type and significance of response and exposure (acute versus sublethal, whole sediment versus porewater). Benthic Community was classified as low, moderate, and high potential for benthic community degradation classifications. In this example, the benthic community structure indices at each station were compared to thresholds developed for the Bight'98 Benthic Response Index for Embayments (BRI-E) (Ranasinghe et al., 2003) and to the Reference Condition sample stations.

For the other Regional Water Boards, sediment chemistry is frequently interpreted by comparison with ambient levels or sediment quality guidelines. Sediment toxicity is characterized by a significant difference in mean survival between a sample and the control and if the magnitude of this difference was biologically significant or comparison to a waterbody specific reference envelope or more recent approaches developed to more effectively integrate the response with other lines of evidence. , Where benthic community tools have been developed, those applied include the Relative Benthic Index also developed for the BPTCP, the Index of Biotic Integrity (Thompson and Lows, 2004) and the Benthic Response Index (Smith *et al.*, 2003) utilized by Regional Boards, the regulated community, SCCWRP and others to monitor the southern California Bight.

Monitoring

The Regional Water Boards have varying approaches to sediment monitoring. Resolution 92-043 adopted by the San Francisco Bay Regional Water Board on April 15, 1992 officially established the Regional Monitoring Program (RMP) in San Francisco Bay. Resolution 92-043 authorized Regional Board staff to suspend some site-specific monitoring requirements for permittees, if the permittees would contribute to the development and support of a regional monitoring program. The Regional Board recognizing the advantages of a regional program cited the cost effectiveness and the greater ability to assess both the effectiveness of controls and overall waterbody health in comparison to data only collected from specific discharges. A component of includes sediment quality monitoring

Within the Los Angels Region, the City of Los Angeles' Terminal Island Treatment Plant, which discharges into the Los Angeles Long Beach Harbor, is required to perform both routine sediment quality monitoring and to participate in Regional Monitoring Studies. The routine monitoring studies are curtailed while regional monitoring studies are ongoing. Both of these efforts utilize sediment chemistry, sediment toxicity testing and benthic community analysis in addition to other indicators (trawls, tissue residue analysis) (For more information visit http://63.199.216.5/webdata/data/docs/2171_R4-2005-0024_MRP.pdf). Recently the Los Angeles Region has required five permittees to perform a joint sediment characterization study in Marina Del Rey in support of TMDL development. This monitoring program will be used to determine if the controls such as BMPS are effective alone or if sediment remediation will be required in addition to the controls to restore beneficial uses.

4.1.3 Toxic Pollutant Standards

Regulation of toxic pollutant discharges to bay and estuarine waters is important because these discharges can adversely affect sediment quality. In addition to the narrative objectives listed above, state water quality standards include numeric water quality objectives for toxic and other pollutants in water quality control plans and federally-promulgated criteria for toxic pollutants, which are contained in the California Toxics Rule. (See 40 C.F.R. §131.38.) The California Toxics Rule (CTR) criteria apply to inland surface waters, enclosed bays, and estuaries in the state. The numeric criteria and objectives establish permissible water column concentrations for the affected pollutants.

The State Water Board may also consider adopting a policy establishing a water quality objective for methylmercury in fish tissue in the future. In 2001, U.S. EPA issued a recommended fish tissue criterion for methylmercury. The State Water Board's proposed policy would modify the recommended criterion to reflect California-specific information on fish consumption. Elements of the proposed policy may include a methylmercury fish tissue objective, a total mercury water quality objective, a methylmercury water quality objective, or some combination of these objectives. The proposed policy may also include implementation procedures related to the NPDES permitting process.

In 2000, the State Water Board adopted state policy for water quality control to implement toxic standards in bays, estuaries and inland surface waters. The policy, entitled "Policy for Implementation of Toxic Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California," (SIP) provides a standardized approach for permitting discharges of toxic pollutants to non-ocean surface waters in a manner that promotes statewide consistency. The SIP describes: (1) applicable priority pollutant criteria and objectives; (2) data requirements and adjustments; (3) the identification of priority toxic pollutants requiring water quality-based effluent limitations; (4) the calculation of effluent limitations; (5) appropriate translators for metals and selenium;(6) factors to consider in the designation of mixing zones and dilution credits (7) ambient background concentrations and (8) intake water credits.

The SIP is not applicable to stormwater discharges nor does the SIP address sediment quality specifically. However, Section 1.4.2.1 does prohibit mixing zones from causing "objectionable bottom deposits" (SWRCB, 2000). This term is defined as "an accumulation of materials ... on or near the bottom of a water body which creates conditions that adversely impact aquatic life, human health, beneficial uses, or aesthetics. These conditions include, but are not limited to, the accumulation of pollutants in the sediment."

Additionally, the State Water Board's "Water Quality Control Policy for the Enclosed Bays and Estuaries of California" prescribes requirements pertaining to toxic pollutant discharges to enclosed bays and estuaries:

- Persistent or cumulative toxic substances shall be removed from the waste to the maximum extent practical through source control or treatment prior to discharge.
- New discharges of municipal wastewaters and industrial process waters (excluding cooling water) to enclosed bays and estuaries (excluding the San Francisco Bay Delta) are prohibited unless the effluent is discharged in a manner that enhances the quality of the receiving water.

4.2 CURRENT SEDIMENT CLEANUP AND REMEDIATION ACTIVITIES

Under current law, sediment cleanup activities may be undertaken in response to a Clean Water Act §303(d) listing, an enforcement order issued pursuant to Porter-Cologne, or the Bay Protection and Toxic Cleanup Program. In addition, cleanup of hazardous wastes may be driven by the California Health and Safety Code well as federal Laws such as Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) Superfund Amendments and Reauthorization Act (SARA).

4.2.1 Section 303(d) Activities

State Water Board Listing Policy

Clean Water Act section 303(d) requires that the states list waters that do not meet applicable water quality standards with technology-based controls alone. In 2004, the State Water Board adopted a Water Quality Control Policy for Developing California's Section 303(d) List. For sediments, the policy provides that a water segment will be listed as impaired if the sediments exhibit statistically significant toxicity based on a binomial distribution of the sampling data and exceedances. When applying this methodology, if the number of measured toxicity exceedances supports rejection of the null hypothesis, the water segment is considered impaired. The policy indicates that a segment should be listed if the observed toxicity is associated with a toxicant or toxicants, or for toxicity alone. If the toxicant causing or contributing to the toxicity is identified, the pollutant should be added to the 303(d) list as well.

Appropriate reference and control measures must be included in the toxicity testing. Reference conditions may include a response less than 90% of the minimum significant difference for each specific test organism. Acceptable methods include, but are not limited to, those listed in water quality control plans, the methods used by Surface Water Ambient Monitoring Program, the Southern California Bight Projects of the Southern California Coastal Water Research Project, American Society for Testing and Materials, EPA, the Regional Monitoring Program of the San Francisco Estuary Institute, and the Bay Protection and Toxic Cleanup Program (BPTCP) (SWRCB, 2004b).

Association of pollutant concentrations with toxic or other biological effects should be determined by one of the following (SWRCB, 2004b):

- Sediment quality guidelines are exceeded using the binomial distribution; in addition, using rank correlation, the observed effects are correlated with measurements of chemical concentration in sediments
- An evaluation of equilibrium partitioning or other type of toxicological response that identifies the pollutant that may cause the observed impact; comparison to reference conditions within a watershed or ecoregion may be used to establish sediment impacts
- Development of an evaluation (such as a TIE) that identifies the pollutant that contributes to or caused the observed impact.

TMDLs

Clean Water Act section 303(d) mandates that the state develop TMDLs for its listed waters. A TMDL, in general, identifies the maximum amount of a pollutant that a waterbody can assimilate while still meeting water quality standards. The TMDL identifies pollutant sources and includes an implementation plan that describes the actions necessary to achieve standards, including a schedule and monitoring and surveillance activities to determine compliance. Exhibit 3-10 of the report entitled "Economic Considerations of Sediment Quality Plan for Enclosed and Estuaries in California" (2008) summarizes sediment-related toxic pollutant TMDLs that have already been completed for enclosed bays and estuaries in California. Section 3 of this report identifies bays and estuaries in the coastal regions that are currently on the State Water Board's 2006 Section 303(d) list for water column, tissue and sediment quality impacts associated with toxic pollutants for which TMDLs must be developed.

TMDLs developed by the San Francisco Bay and Los Angeles Regional Water Boards illustrate application of the TMDL program to address sediment quality. The San Francisco Bay Regional Water Board recently adopted a TMDL to address bay-wide exceedances of the narrative bioaccumulation objective caused by excessive methyl-mercury levels. High mercury levels in sediments are due, in large part, to legacy gold mining operations and have resulted in bay-wide fish consumption advisories. The San Francisco Bay Regional Water Board has also listed bay waters for failure to achieve the bioaccumulation narrative objective due to PCBs, another legacy contaminant found in sediments, which was used in many high voltage applications as a dielectric fluid. For both pollutants, the mechanism to restore beneficial uses is through the development of TMDLs where all sources of loading regardless of media are evaluated and controlled to the extent practical. The mercury targets were derived based upon the estimated reduction in mercury mass in tissue that would be needed to be protective of human health and wildlife (California Regional Water Quality Control Board San Francisco Bay Region 2006). Unlike mercury, the movement of PCBs and other hydrophobic organochlorine compounds up through the food web can be predicted with food web models. Once a model has been validated by agreement with actual data, the model can also be used to predict the sediment concentrations that will lower prey tissue to levels that protect the target receptors (California Regional Water Quality Control Board San Francisco Bay Region 2007).

The Los Angeles Regional Water Board adopted the Marina del Rey TMDL in 2005 to address toxic pollutants in sediments and fish tissue. The TMDL established sediment chemistry targets for Marina del Rey, which address both sediment quality and fish tissue. The toxic pollutants include copper, lead, and zinc and chlordane and total PCBs. Numeric targets for these pollutants in sediments are based on ERLs developed by Long *et al.* (1995). In addition to sediment chemistry, the monitoring plan includes both acute and chronic toxicity tests as well as fish tissue testing to monitor progress (Technical Committee County of Los Angeles, Chair, 2007). Toxicity tests utilize three marine organisms; 28-day chronic and a10-day acute amphipod mortality test; pore water testing utilizing the sea urchin fertilization test; and the testing of overlying water using the red abalone larval development test. Toxic sediment will be identified by an average amphipod survival of 70% of less. During accelerated testing, if the response average of two tests is less than 90% survival, stressor identification is required.

4.2.2 Cleanup and Abatement Actions

Resolution No. 92-49

In 1992, the State Water Board adopted Resolution No. 92-49, "Policies and Procedures for Investigation and Cleanup and Abatement of Discharges Under Water Code Section 13304," The resolution describes the policies and procedures that apply to the cleanup and abatement of all types of discharges subject to Water Code section 13304. These include discharges, or threatened discharges, to surface and groundwater. The Resolution requires dischargers to clean up and abate the effects of discharges in a manner that promotes attainment of either background water quality or the best water quality that is reasonable if background levels of water quality cannot be restored, considering economic and other factors. In approving any alternative cleanup levels less stringent than background, Regional Boards must apply section 2550.4 of Title 23 of the California Code of Regulations.[12] Section 2550.4 provides that a Regional Water Board can only approve cleanup levels less stringent than background if the Regional Water Board finds that it is technologically or economically infeasible to achieve background. Resolution No. 92-49 further requires that any alternative cleanup level shall: (1) be consistent with maximum benefit to the people of the state; (2) not unreasonably affect present and anticipated beneficial uses of such water; and (3) not result in water quality less than that prescribed in the water quality control plans and policies adopted by the State and Regional Water Boards.

A Regional Water Board must apply Resolution No. 92-49 when setting cleanup levels for contaminated sediment if such sediment threatens beneficial uses of the waters of the state, and the contamination or pollution is the result of a discharge of waste. Contaminated sediment must be cleaned up to background sediment quality unless it would be technologically or economically infeasible to do so.

Examples of Cleanup Actions Related to Sediment Quality

The Regional Water Boards have issued enforcement orders, primarily cleanup and abatement orders, to address violations of narrative water quality objectives related to sediment quality. For example, the San Diego Regional Water Board issued a cleanup and abatement order to Paco Terminals, Inc. in 1985 to require cleanup of copper-contaminated sediments in San Diego Bay. In 1992, the State Water Board revised the order to impose more stringent cleanup levels. (State Water Board Order No. WQ 92-09.) The State Water Board determined that revised cleanup levels were necessary to ensure that sediments did not contain copper levels that would result in exceedance of either numeric water column objectives or narrative objectives for the protection of aquatic life and to comply with Resolution No. 92-49.

Similarly, in 2005, the San Diego Regional Water Board issued a tentative cleanup and abatement order to address discharges of metals and other pollutant wastes to San Diego Bay marine sediments and waters. The tentative order is based, in part, on alleged exceedances of the basin plan's narrative toxicity objectives. Proceedings to consider adoption of the order are ongoing.

Additional examples of ongoing or completed sediment quality related cleanup actions include Castro Cove, Stege Marsh, Moffet Field, Hamilton Air Base Salt Marsh, Peyton Slough in San Francisco Bay and Convair Lagoon, Bay City Marine, Kettenburg and America's Cup Harbor in southern California.

---

[12] Resolution No. 92-49, Section III.G.

4.2.3 Bay Protection and Toxic Cleanup Program

As stated above, chapter 5.6 mandated that the State Water Board fulfill two key tasks – adopt a consolidated hot spots cleanup plan and develop sediment quality objectives for enclosed bays and estuaries. The State Water Board focused initially on the former task.

4.2.3.1 Consolidated Hotspots Cleanup Plan

Chapter 5.6 Requirements

To address toxic hot spots, Water Code section 13392.5 required the Regional Water Boards to develop a consolidated data base that identified all known and potential toxic hot spot spots. In consultation with the State Water Board, the Regional Water Boards were directed to develop an ongoing monitoring and surveillance program that included suggested guidelines to promote standardized analytical methodologies and consistency in data reporting and identification of additional monitoring and analyses needed to complete the toxic hot spot assessment for each enclosed bay and estuary.

In addition, by January 1, 1998, the Regional Water Boards were required to complete and submit to the State Water Board a toxic hot spot cleanup plan for affected waters within their respective regions. (Wat. Code §13394.) Toxic hot spots are defined in Water Code section 13391.5 (e) "as *locations where hazardous substances have accumulated in the water or sediment to levels which (1) may pose a substantial present or potential hazard to aquatic life, wildlife, fisheries, or human health, or (2) may adversely affect the beneficial uses of the bay, estuary, or ocean waters as defined in water quality control plans, or (3) exceeds adopted water quality or sediment quality objectives.*

Each regional toxic hot spots cleanup plan had to include:

(a) A priority ranking of all hot spots, including the state board's recommendations for remedial action at each toxic hot spot site.

(b) A description of each hot spot site including a characterization of the pollutants present at the site.

(c) An estimate of the total costs to implement the plan.

(d) An assessment of the most likely source or sources of pollutants.

(e) An estimate of the costs that may be recoverable from parties responsible for the discharge of pollutants that have accumulated in sediment.

(f) A preliminary assessment of the actions required to remedy or restore a toxic hot spot.

(g) A two-year expenditure schedule identifying state funds needed to implement the plan.

(h) A summary of actions that have been initiated by the regional board to reduce the accumulation of pollutants at existing hot spot sites and to prevent the creation of new hot spots.

The State Water Board was mandated to submit a consolidated statewide toxic hot spot cleanup plan to the Legislature by June 30, 1999. The statewide plan had to include findings and recommendations on the need for establishing a toxic hot spots cleanup program.

Chapter 5.6 further required the Regional Water Boards to revise waste discharge requirements for dischargers that discharged all or part of the pollutants that caused the toxic

hot spot "*to ensure compliance with water quality control plans and water quality control plan amendments, including requirements to prevent the creation of new toxic hot spots and the maintenance or further pollution of existing toxic hot spots.*" (Wat. Code §13395.) A Regional Water Board could determine that it was unnecessary to revise waste discharge requirements only if the Regional Water Board determined that the discharger's contribution was insignificant or that the discharger no longer conducted the practices that led to creation of the toxic hot spot. Water Code section 13396 also prohibits any person from dredging or disturbing a toxic hot spot site without first obtaining a water quality certification under Clean Water Act section 401 or waste discharge requirements.

Program Goals and Actions

The BPTCP was driven by four major goals (SWRCB 2004a): (1) protect existing and future beneficial uses of bay and estuarine waters; (2) identify and characterize toxic hot spots; (3) plan for the prevention and control of further pollution at toxic hot spots; and (4) develop plans for remedial actions of existing toxic hot spots and prevent the creation of new toxic hot spots.

The BPTCP identified benthic organisms and human health as the key targets for protection (SWRCB, 1991) and used both exposure and effects-based measurements of the sediment quality triad (sediment toxicity, benthic community structure and measures of chemical concentrations in sediments) and other measures such as biomarkers and tissue residue to identify toxic hot spots. The sediment quality triad coupled with additional lines of evidence formed the basis for making hot spots determinations. The need for multiple lines of evidence was based upon the uncertainty and technical limitations associated with the tools (Stephenson, et al. 1994).

Sediment samples were taken only in summer months at a depth of 2-cm below the sediment surface. Evaluation of cause or stressor identification was not included in this program. As a result, biological effects at a site were determined to be associated with toxic chemicals if chemical analysis demonstrated significantly higher levels compared to the reference sites. The Bay Protection and Toxic Cleanup Program Quality Assurance Project Plan (Stephenson, et al. 1994) stated that, *because a strict determination of cause-and-effect will not have been achieved, we anticipate that responsible parties will have the opportunity to conduct Toxicity Identification Evaluations as an initial step in site remediation.* The technical team clearly understood the value of stressor identification **preceding** site remediation or restoration, however the difficulty associated with these studies was at the time considered far to expensive to be a requirement (Stephenson, et al. 1994).

Consolidated Hotspots Cleanup Plan

The Consolidated Toxic Hot Spots Cleanup Plan (Consolidated Plan) identified and ranked known toxic hot spots, and presented descriptions of toxic hot spots, actions necessary to remediate sites, the benefits of remediation, and a range of remediation costs. The plan is applicable to any point and nonpoint source discharges that the Regional Water Boards reasonably determine contribute to or cause the pollution at toxic hot spots. The Consolidated Plan required Regional Water Boards to implement the remediation action to the extent that responsible parties can be identified, and funds are available and allocated for this purpose. When the Regional Water Boards cannot identify a responsible party, the Consolidated Plan indicated that they are to seek funding from available sources to remediate the site. The Regional Water Boards determined the ranking of each known toxic hot spot based on the five general criteria specified in the Consolidated Plan as shown in Table 4.1. Table 4.2 describes the rank and reason for listing each hotspot identified in the Consolidated Plan.

Table 4.1. Toxic Hot Spot Ranking Criteria

Criteria Category	High	Moderate	Low
Human Health Impacts	Human health advisory for consumption of nonmigratory aquatic life from the site	Tissue residues in aquatic organisms exceed FDA/DHS action level or U.S. EPA screening levels	None
Aquatic Life Impacts[1]	Hits in any two biological measures if associated with high chemistry	Hit in one of the measures associated with high chemistry	High sediment or water chemistry
Water Quality Objectives	Objectives exceeded regularly	Objectives occasionally exceeded	Objectives infrequently exceeded
Areal Extent of Hot Spot	More than 10 acres	1 to 10 acres	Less than 1 acre
Natural Remediation Potential	Unlikely to improve without intervention	May or may not improve without intervention	Likely to improve without intervention

Source: SWRCB (1999).

1. Site rankings are based on an analysis of the sediment chemistry, sediment toxicity, biological field assessments (including benthic community analysis), water toxicity, TIEs, and bioaccumulation.

Table 4.2. Enclosed Bays Listed as Known Toxic Hot Spots

Rank	Site Identification	Reason for Listing	
		Definition trigger	Pollutants
High	Delta Estuary, Cache Creek watershed including Clear lake	Human health impacts	Mercury
High	Delta Estuary	Aquatic life impacts	Diazinon
High	Delta Estuary – Morrison Creek, Mosher Slough, 5 Mile Slough, Mormon Slough & Calaveras River	Aquatic life impacts	Diazinon & Chlorpyrifos
High	Delta Estuary – Ulatis Creek, Paradise Cut, French Camp & Duck Slough	Aquatic life impacts	Chlorpyrifos
High	Humboldt Bay Eureka Waterfront H Street	Bioassay toxicity	Lead, Silver, Antimony, Zinc, Methoxychlor, PAHs
High	Los Angeles Inner Harbor Dominguez Channel, Consolidated Slip	Human health, aquatic life impacts	DDT, PCBs, PAH, Cadmium, Copper, Lead, Mercury, Zinc, Dieldrin, Chlordane
High	Los Angeles Outer Harbor Cabrillo Pier	Human health, aquatic life impacts	DDT, PCBs, Copper
High	Lower Newport Bay Rhine Channel	Sediment toxicity, exceeds objectives	Arsenic, Copper, Lead, Mercury, Zinc, DDE, PCB, TBT
High	Moss Landing Harbor and Tributaries	Sediment chemistry, toxicity, bioaccumulation, and exceedances of NAS and FDA guidelines	Pesticides, PCBs, Nickel, Chromium, TBT
High	Mugu Lagoon/ Calleguas Creek tidal prism, Eastern Arm, Main Lagoon, Western Arm	Aquatic life impacts	DDT, PCBs, metals, Chlordane, Chlorpyrifos
High	San Diego Bay Seventh St. Channel Paleta Creek, Naval Station	Sediment toxicity and benthic community impacts	Chlordane, DDT, PAHs and Total Chemistry[2]
High	San Francisco Bay Castro Cove	Aquatic life impacts	Mercury, Selenium, PAHs, Dieldrin

Table 4.2. Enclosed Bays Listed as Known Toxic Hot Spots (Continued)

Rank	Site Identification	Reason for Listing	
		Definition trigger	Pollutants
High	San Francisco Bay Entire Bay	Human health impacts	Mercury, PCBs, Dieldrin, Chlordane, DDT, Dioxin Site listing was based on Mercury and PCB health advisory
High	San Francisco Bay Islais Creek	Aquatic life impacts	PCBs, chlordane, dieldrin, endosulfan sulfate, PAHs, anthropogenically enriched H_2S and NH_3
High	San Francisco Bay Mission Creek	Aquatic life impacts	Silver, Chromium, Copper Mercury, Lead, Zinc, Chlordane, Chlorpyrifos, Dieldrin, Mirex, PCBs, PAHs, anthropogenically enriched H_2S and NH_3
High	San Francisco Bay Peyton Slough	Aquatic life impacts	Silver, Cadmium, Copper, Selenium, Zinc, PCBs, Chlordane, ppDDE, Pyrene
High	San Francisco Bay Point Potrero/ Richmond Harbor	Human health	Mercury, PCBs, Copper, Lead, Zinc
High	San Francisco Bay Stege Marsh	Aquatic life impacts	Arsenic, Copper, Mercury, Selenium, Zinc, chlordane, dieldrin, ppDDE, dacthal, endosulfan, endosulfan sulfate, dichlorobenzophenone, heptachlor epoxide, hexachlorobenzene, mirex, oxidiazon, toxaphene and PCBs
Moderate	Anaheim Bay, Naval Reserve	Sediment toxicity	Chlordane, DDE
Moderate	Ballona Creek Entrance Channel	Sediment toxicity	DDT, zinc, lead, Chlordane, dieldrin, chlorpyrifos
Moderate	Bodega Bay-10006 Mason's Marina	Bioassay toxicity	Cadmium, Copper, TBT, PAH
Moderate	Bodega Bay-10028 Porto Bodega Marina	Bioassay toxicity	Copper, lead, Mercury, Zinc, TBT, DDT, PCB, PAH
Moderate	Delta Estuary Delta	Aquatic life impacts	Chlordane, Dieldrin, Lindane, Heptachlor, Total PCBs, PAH & DDT
Moderate	Delta Estuary Delta	Human health impacts	Chlordane, Dieldrin, Total DDT, PCBs, Endosulfan, Toxaphene
Moderate	Los Angeles River Estuary	Sediment toxicity	DDT, PAH, Chlordane
Moderate	Upper Newport Bay Narrows	Sediment toxicity, exceeds water quality objectives	Chlordane, Zinc, DDE
Moderate	Lower Newport Bay Newport Island	Exceeds water quality objectives	Copper, Lead, Mercury, Zinc, Chlordane, DDE, PCB, TBT
Moderate	Marina del Rey	Sediment toxicity	DDT, PCB, Copper, Mercury, Nickel, Lead, Zinc, Chlordane
Moderate	Monterey Harbor	Aquatic life impacts, sediment toxicity	PAHs, Cu, Zn, Toxaphene, PCBs, Tributyltin
Moderate	San Diego Bay Between "B" Street & Broadway Piers	Benthic community impacts	PAHs, Total Chemistry
Moderate	San Diego Bay Central Bay Switzer Creek	Sediment toxicity	Chlordane, Lindane, DDT, Total Chemistry
Moderate	San Diego Bay Chollas Creek	Benthic community impacts	Chlordane, Total Chemistry

Table 4.2. Enclosed Bays Listed as Known Toxic Hot Spots (Continued)

Rank	Site Identification	Reason for Listing	
		Definition trigger	Pollutants
Moderate	San Diego Bay Foot of Evans & Sampson Streets	Benthic Community Impacts	PCBs, Antimony, Copper, Total Chemistry
Moderate	San Francisco Bay Central Basin, San Francisco Bay	Aquatic life impacts	Mercury, PAHs
Moderate	San Francisco Bay Fruitvale (area in front of storm drain)	Aquatic life impacts	Chlordane, PCBs
Moderate	San Francisco Bay Oakland Estuary. Pacific Drydock #1 (in front of storm drain)	Aquatic life impacts	Copper, Lead, Mercury, Zinc, TBT, ppDDE, PCBs, PAHs, Chlorpyrifos, Chlordane, Dieldrin, Mirex
Moderate	San Francisco Bay, San Leandro Bay	Aquatic life impacts	Mercury, Lead, Selenium, Zinc, PCBs, PAHs, DDT, pesticides
Low	Huntington Harbor Upper Reach	Sediment toxicity	Chlordane, DDE, Chlorpyrifos

Source: SWRCB (1999).

As described in Table 4.2 a significant number of hotspots were identified in bays and estuaries. Although the program focused on specific sites, some hotspots encompass large portions of waterbodies and support many of the 303(d) listings described in the previous section. Under the Bay Protection program, all designated hotspots regardless of priority require corrective action, management action or delisting. Appendix D provides additional information on the enclosed bays listed as known toxic hot spots in the Consolidated Plan, including ranking and reason for listing. Appendix D also provides a summary of the remedial actions and estimated costs for the high priority toxic hot spots. Note that several of the remedial actions identified by the State and Regional Boards only characterize the problem at a hot spot. Thus, the costs identified for those actions do not include all actions necessary to fully remediate the toxic hot spot. Additional funds would be required for remediation after characterization studies are complete.

Depending on the source and areal extent of the known toxic hot spot, the actions to remediate the sites include: (1) Institutional controls/education, (2) Better characterization of the sites and problem, (3) Dredging, (4) Capping, (5) A combination of dredging and capping, (6) Source control, (7) Watershed management, and (8) Implementation of a no-action alternative (natural attenuation).

The estimated total cost to implement the Consolidated Plan ranges from $72 million to $812 million. According to the plan, much of this amount is considered recoverable from responsible dischargers. The un-funded portion of the cost to implement the Consolidated Plan ranges from approximately $40 million to $529 million. Although much of the Consolidated Plan can be implemented through existing Water Code authorities, no funding was obtained to fully implement the Consolidated Plan.

4.2.3.2 SQO Development

In addition to requiring the remediation of toxic hot spots, chapter 5.6 mandated that the State Water Board develop SQOs. The objectives were required for toxic pollutants that had been identified in know or suspected toxic hot spots and for toxic pollutants that the Water Boards had identified as pollutants of concern. The objectives had to be established with an adequate safety margin to reasonably protect beneficial uses and to prevent nuisance. (Wat.

Code §13391.5(d).) Further, the objectives had to ensure adequate protection for the most sensitive aquatic organisms. (Wat. Code §13393.) If humans could be exposed to pollutants through the food chain, the objectives had to based on a health risk assessment. (*Ibid.*)

After January 1, 1993, Water Code section 13396 prevents the Water Boards from approving a dredging project that involves the removal or disturbance of sediment which contains pollutants at or above the sediment quality objectives established pursuant to Section 13393 unless the board determines all of the following:

(a) *The polluted sediment will be removed in a manner that prevents or minimizes water quality degradation.*

(b) *Polluted dredge spoils will not be deposited in a location that may cause significant adverse effects to aquatic life, fish, shellfish, or wildlife or may harm the beneficial uses of the receiving waters, or does not create maximum benefit to the people of the state.*

(c) *The project or activity will not cause significant adverse impacts upon a federal sanctuary, recreational area, or other waters of significant national importance.*

Funding for the program was provided under former Water Code section 13396.5, which authorized the Water Boards to collect fees from point and nonpoint dischargers that discharged into enclosed bays, estuaries, or adjacent waters to fund the program. The fee period was limited under section 13396.5(h) to January 1, 1998. After that date. the program was no longer fee-funded.

4.2.4 Hazardous Waste Site Cleanups

U.S. EPA, Regional Water Boards and DTSC share responsibility for providing regulatory oversight for the cleanup of hazardous waste sites. The extent of site cleanup actions are based upon the desired goals and end uses established for the site, the evaluation of risks to human health and the environment at the site, and the selection of appropriate management alternatives that will reduce the risks to acceptable levels that are consistent with the desired goals and end uses. In order to evaluate existing risks and potential future risks, conceptual models are prepared that identify receptors potentially at risk and the probable exposure pathways. This conceptual model serves as the basis for formulating the human health and ecological risk assessment. At sites where polluted sediments are the primary concern, receptors commonly evaluated include:

- benthic communities exposed directly to pollutants in sediment,
- fish exposed directly to pollutants in sediment or indirectly through consumption of pollutants in prey tissue or
- birds, marine mammals and humans also exposed indirectly through consumption of pollutants in prey tissue.

For many receptors, risk is estimated by comparing pollutant concentrations in sediments and prey tissues to calculated risk thresholds developed specifically for those receptors. For other receptors, such as benthic invertebrates, direct measurements such as benthic community metrics, sediment toxicity and chemistry may be applied instead. Typically, those most sensitive receptors identified will become the focus of the remedial effort. Water quality objectives may be utilized to assess where the objective is based upon the receptor of concern and reflects the appropriate exposure pathway. However many aquatic life and human health based water quality objectives were not derived to protect these receptors from the exposure

pathways that exist at the site such as trophic transfer and bioaccumulation (U.S EPA 1985). Although risk assessments may guide the development of appropriate cleanup targets, the targets must comply with State Water Board Resolution No. 92-49.

4.3 Maintenance and Navigation Dredging

Dredging to maintain ports and waterways generates approximately 300 million cubic yards of material annually that requires characterization and disposal (U.S. EPA 1998). Maintenance dredging differs from sediment quality assessments described above because the goal of the programs is to maintain safe navigation. For dredging projects, the assessment is performed in order to identify appropriate disposal sites and controls that may be required to minimize environmental impacts associated with the disposal. Dredge materials are also characterized differently than ambient surface sediments. When assessing dredge materials, often only a small percentage of the material slated for disposal is present as surficial sediment. As a result, dredged materials characterization requires samples collected from multiple depths to adequately characterize the material.

4.3.1 Clean Water Act Section 404/MPRSA

There are three principal acts for the federal regulation of dredging and disposal operations in the United States. These are the Clean Water Act , the Marine Protection Research and Sanctuaries Act (MPRSA) and the Rivers and Harbors Act (RHA). Only the Clean Water Act and MPRSA prescribe the need to assess the quality of the sediment for disposal purposes.

The discharge of dredged or fill materials into "waters of the United States" is regulated under Section 404 of the Clean Water Act. Under section 404, applicants are required to seek permits from the U.S. Army Corp of Engineers (USACE) for proposed discharges of dredged material into waters of the U.S. with concurrence by U.S. U.S. EPA. Under Section 404, U.S. EPA and USACE have jointly developed an effect-based testing program to assess the suitability of dredged materials for inland waters in the USACE/U.S. EPA. Document titled "Evaluation of Dredged Material Proposed for Discharge in Waters of the U.S. – Inland Testing Manual (1998) commonly referred to as the Inland Testing Manual or ITM. USACE/U.S. EPA. 1998. The ITM utilizes a tiered, effects-based evaluation scheme to determine the suitability of dredged material for aquatic placement or disposal. Unlike other programs that only assess surficial sediments, dredge materials characterization requires that the sediment be evaluated to the anticipated maximum depth of the proposed activity. Therefore, none of the tools adopted in this program are depth dependent.

The ITM recognizes three distinct exposure pathways for a suitability determination

1. Water column toxicity
2. Benthic toxicity
3. Benthic bioaccumulation.

Suitability determinations for aquatic discharge of dredged material take into account not only the technical sediment test results from the ITM, but also the characteristics of the individual disposal sites and the practicability of alternatives to aquatic disposal (including beneficial reuse alternatives).

Tier I of the suitability determination consists of gathering all available chemical, biological, and physical data and information on the source area or waterbody. The information is assessed relative to the characteristics of the disposal site. If enough information is available, a

suitability determination can be made within Tier 1 without the need for additional testing. If insufficient information is available, the suitability determination would proceed to Tier 2.

The ITM requires Tier II to evaluate the potential for the disposal to cause an exceedance of water quality standards and the potential for the disposal to impact benthic organisms. To assess the potential exceedance of water quality standards outside the mixing zone, either a numerical mixing model or the chemical analysis of the sediment or elutriate are utilized. The Theoretical Bioaccumulation Potential (TBP) is used to screen potential impacts to benthic organisms. The TBP is a product of the chemical concentration in the sediment normalized to total organic carbon, the biota sediment accumulation factor, and the lipid content of the test organism. This result is compared to the results from a reference site.

The focus of Tier III is on toxicity and bioaccumulation tests. Water column toxicity is evaluated by exposing a sensitive test organism to the elutriate. To make a suitability determination, the LC50 or EC 50 concentrations are assessed after allowing for dilution/mixing to determine if there is potential for water column toxicity. Toxicity of the sediment is evaluated by exposing a benthic organism to the bulk sediment. Sediment toxicity suitability is based on comparison to a reference site. Results from the 28-day bioaccumulation are compared with accepted human health benchmarks such as those published by the Food and Drug Administration.

Tier IV is a more rigorous and site-specific evaluation of toxicity and bioaccumulation. This could include using tests of longer duration, or using other sensitive species and endpoints. Although Tier IV provides the greatest flexibility, the staff from USACE, U.S. EPA and the State must approve the proposed approach, test methods, and corresponding analysis before this study can be initiated.

None of the methods or analyses described in the ITM are intended to assess the quality of bedded undisturbed surface sediments, rather the methodology was developed solely to assess the risk associated with disposal.

Ocean disposal is not regulated under the Clean Water Act, these actions fall under the MPRSA. Section 103 regulates transportation of dredged material for the purpose of ocean disposal (i.e., outside the three mile baseline). Under the MPRSA, the U.S. EPA has the lead in the designation of suitable disposal sites and the USACE in consultation with U.S. EPA issues the permit. Since ocean disposal by definition falls outside state jurisdiction, the state generally has limited regulatory authority for permitting disposal under MPRSA. Like the ITM, the Ocean Testing Manual or OTM is also based upon a tiered, effects-based evaluation scheme to determine the suitability of dredged material for aquatic placement or disposal. The tiered scheme follows the same general approach and methodology utilized for the ITM. The OTM is also not intended for uses to assess the quality of bedded surface sediments.

Under the Clean Water Act there is an allowance for greater flexibility with the level of information required differing for different regions of the country. Differences in the regional implementation of the 404 requirements exist between Northern and Southern California as to the extent and nature of information required. In Northern California for example, suitability determinations for in-bay disposal in San Francisco Bay generally require solid and suspended phase toxicity data but rarely require information on bioaccumulation. In both Northern and Southern California, if an area proposed for dredging has been tested within the past 3 years, then there is an allowance for a "Tier I exclusion with confirmatory sediment chemistry" which means the material is exempted from any effects-based testing so long as the sediment chemistry is similar to what previously has been deemed suitable based upon results of earlier testing.

In Southern California, there are fewer options for a Clean Water Act section 404 disposal (i.e., most material is either ocean disposed under MPRSA, used beneficially for beach replenishment, or managed upland). Material being placed beneficially for beach nourishment generally does not require bioassay testing because only clean materials with grain size compatible with the proposed receiver site are eligible for beach replenishment. The clean sands typically required for stability in high energy environments have little or no ability to bind with pollutants because of the low organic carbon content and limited binding capacity of the minerals that make up most sand size particles.

When there are opportunities for confined or unconfined in-water placement at areas other than approved ocean disposal sites, the Corps' and U.S. EPA regulations allow for materials to be excluded from testing if acceptable engineering controls are available to contain potentially contaminated materials, or if the material is of such a large grain size that contaminants should not be present. When material is placed as a nearshore or upland fill and there is a return flow or exchange with water of the U.S., then typically sediment chemistry and possibly elutriate chemistry may be required. In those instances where there is little or no recent information and/or there is a reason to believe that sediment-associated contaminants are present, then a full suite of chemical and sediment toxicity and bioaccumulation testing may be required.

4.3.2 Water Quality Certifications

Clean Water Act section 401 allows states to deny or grant water quality certification for any activity which may result in a discharge to waters of the United States and which requires a federal permit or license. Certification requires a finding by the State that the activities permitted will comply with all water quality standards individually or cumulatively over the term of the permit. Certification must be consistent with the requirements of the Clean Water Act, CEQA, the California Endangered Species Act (CESA), and the State Water Board's mandate to protect beneficial uses of waters of the State.

The State Water Board considers issuance of water quality certifications for the discharge of dredged and fill materials. Clean Water Act section 401 allows the State to grant or deny water quality certification for any activity which may result in a discharge to navigable waters and which requires a federal permit. State Water Board regulations (Cal. Code Regs., tit. 23, §3830 et seq.) provide the regulatory framework under which the State Water Board issues water quality certifications. The Corps may not issue a Section 404 permit if the State denies water quality certification.

In order to certify a project, the State Water Board must certify that the proposed discharge will comply with all of the applicable requirements of Clean Water Act sections 301, 302, 303, 306, and 307 (42 U.S.C. §§ 1311, 1312, 1313, 1316, and 1317). Essentially, the State Water Board must find that there is reasonable assurance that the certified activity will not violate water quality standards. Clean Water Act section 401 requires the water quality certification process to comply with the Clean Water Act section 404(b)(1) Guidelines.

In California, wetlands are also regulated through under Clean Water Act section 401. Seasonally and permanently flooded wetlands are sites for methylmercury production due to the presence of sulfate-reducing bacteria in wetland environments (CVRWQCB, 2005a). Wetlands can be significant sources of methylmercury production; for example, the Central Valley Water Board (2005c) estimated that 21,000 acres of wetland in the Sacramento-San Joaquin River Delta produce about 16% of the annual methylmercury load to the watershed. A complicating issue is that wetland restoration efforts are ongoing because wetlands provide important services for ecosystems and human communities.

Management practices to reduce methylmercury discharge could include aeration, changing the stream channel, revegetation, sediment removal, and levees. Some of these practices may be applied upstream to reduce inorganic mercury in water flowing into the wetland, thus reducing methylmercury formation. Other practices may reduce the downstream transport of methylmercury formed in the wetland (CVRWQCB, 2005b).

In March of 2007, the State Water Board circulated a CEQA scoping document announcing the States intent to develop and propose for adoption a Wetland and Riparian Area Protection Policy.

4.4 Point Sources Regulated under Clean Water Act §402

As explained previously, the Water Boards issue and administer NPDES permits in California. Under the Clean Water Act, all point source discharges of pollutants to waters of the United States must be regulated under a permit. Thus, all point source discharges of toxic pollutants to enclosed bays and estuaries must be regulated under an NPDES permit.

Under the NPDES permit program, discharges are regulated under permits that contain both technology-based and water quality-based effluent limits. Water quality-based effluent limits are developed to implement applicable water quality standards As discussed in section 4.1 above, applicable water quality standards for toxic pollutants include narrative and numeric objectives and CTR criteria. The State Water Board's SIP addresses the implementation of numeric toxic pollutant criteria and objectives for bay, estuarine, and inland surface waters.

Typical discharges that are regulated under NPDES permits include discharges from publicly-owned treatment works and industrial facilities. In addition, storm water discharges are regulated under the permit program. The following subsection explains the State Water Board's storm water permit program.

4.4.1 Storm Water

The State Water Board has three distinct storm water programs – municipal, industrial, construction- and a fourth that encompasses parts of the other three because of the number, diversity and geographic extent of the discharges. This fourth program, referred to as Caltrans, describes the stormwater permits associated with the California Department of Transportation

Municipal Discharges

The municipal program regulates storm water discharges from municipal separate storm sewer systems (MS4s). Large (Phase I) and small (Phase II) MS4s implement best management practices (BMPs) to comply under the program. BMPs include both source controls and treatment measures. The Clean Water Act and implementing federal regulations require MS4s subject to NPDES permits to reduce pollutants in storm water to the maximum extent practicable (MEP). The regulations require implementation of BMPs to meet the MEP discharge standard. In California, MS4 permits also require permittees to reduce the discharge of pollutants so that water quality standards are met. This is usually accomplished under a storm water management plan (SWMP).

Industrial Discharges

Under the industrial program, the State Water Board issues a general NPDES permit that regulates discharges associated with ten broad categories of industrial activities. This general permit requires the implementation of management measures that will achieve the performance

standard of best available technology economically achievable (BAT) and best conventional pollutant control technology (BCT) and achieve the water quality standards. The permit also requires that dischargers develop a Storm Water Pollution Prevention Plan (SWPPP) and a monitoring plan. Through the SWPPP, dischargers are required to identify sources of pollutants, and describe the means to manage the sources to reduce storm water pollution. For the monitoring plan, facility operators may participate in group monitoring programs to reduce costs and resources.

Construction

The construction program requires dischargers whose projects disturb one or more acres of soil or whose projects disturb less than one acre but are part of a larger common plan of development that in total disturbs one or more acres to obtain coverage under the general permit for discharges of storm water associated with construction activity. The construction general permit requires the development and implementation of a SWPPP that lists BMPs the discharger will use to control storm water runoff and the placement of those BMPs. Additionally, the SWPPP must contain a visual monitoring program; a chemical monitoring program for non-visible pollutants to be implemented if there is a failure of BMPs; and a sediment monitoring plan if the site discharges directly to a water body impaired for sediment.

Caltrans

In 1996, Caltrans requested that the State Water Board consider adopting a single NPDES permit for storm water discharges from all Caltrans properties, facilities, and activities, which would encompass both the MS4 requirements and the statewide construction general permit requirements. The State Water Board issued the Caltrans general permit in 1999, requiring Caltrans to control pollutant discharges to the MEP for the MS4s and to the standard of BAT/BCT for construction activities through BMPs. The State Water Board also required Caltrans to implement more stringent controls, if necessary, to meet water quality standards.

4.5 Nonpoint Source Control

Under Porter-Cologne, all waste discharges that could affect water quality must be regulated, including nonpoint source discharges of pollution. Nonpoint source (NPS) pollution, unlike point source pollution from industrial and sewage treatment plants, comes from many diffuse sources. Some types of NPS pollution are caused by rainfall or snowmelt moving over and through the ground. As the runoff moves, it picks up and carries away natural and human-made pollutants, depositing them into lakes, rivers, wetlands, coastal waters, and groundwater. NPS pollution may originate from several sources, including agricultural runoff, forestry operations, urban runoff, boating and marinas, active and historical mining operations, atmospheric deposition, and wetlands.

Nonpoint sources in California must be regulated under waste discharge requirements (WDRs), conditional waivers of WDRs, or basin plan prohibitions. However, WDRs need not necessarily contain numeric effluent limits. The state's Policy for Implementation and Enforcement of the Nonpoint Source Pollution Control Program (NPS Policy) provides guidance regarding the prevention and control of nonpoint source pollutant discharges and enforcement of nonpoint source regulations (e.g., WDRs). In practice, the Regional Water Boards do not usually impose numeric effluent limits on nonpoint pollution sources; rather they primarily rely on implementation of BMPs to reduce pollution.

In 1998, California began implementing its Fifteen-Year Program Strategy for the Nonpoint Source Pollution Control Program, as delineated in the Plan for California's Nonpoint Source

Pollution Control Program (NPS Program Plan). The legal foundation for the NPS Plan is the Clean Water Act and the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA) (SWRCB, 2000), and state law. The agencies primarily responsible for the development and implementation of the NPS Program Plan are the State Water Board, the nine Regional Water Boards, and the California Coastal Commission (CCC). Various other federal, state, and local agencies have significant roles in the implementation of the NPS Plan.

The NPS Program Plan addresses six categories of nonpoint sources including agriculture, forestry, urban areas, marinas and recreational boating, hydromodification, and wetlands/riparian areas/vegetated treatment systems. For each category, the NPS Program Plan specifies management measures (MMs) and the corresponding management practices or BMPs. The NPS Program Plan provides five general goals:

- Track, monitor, assess, and report NPS Program activities
- Target NPS Program activities
- Coordinate with public and private partners in all aspects of the NPS Program
- Provide financial and technical assistance and education
- Implement MMs and associated BMPs

The following sections discuss the objectives and policies relevant to sediment quality for specific NPS sources.

4.5.1 Agriculture

Impacts from agricultural activities that may affect sediment quality include sedimentation and the runoff of pesticides. These impacts can be caused by:

- Farming activities that cause excessive erosion, resulting in sediment entering receiving waters
- Improper use and over-application of pesticides
- Over-application of irrigation water resulting in runoff of sediments and pesticides (SWRCB, 2006b).

Although wastewater discharges from irrigated land, including stormwater runoff, irrigation tail-water, and tile drainage are subject to regulation under Porter-Cologne, the Regional Water Boards have historically regulated these discharges under waivers as authorized by Water Code section 13269. This section allows the Regional Water Boards to waive the requirement to have waste discharge requirements if it is in the public interest and the waiver is consistent with any applicable water quality control plans. Although waivers are always conditional, the historic waivers had few conditions. In general, they required that discharges not cause violations of water quality objectives, but did not require water quality monitoring.

In 1999, Senate Bill 390 was enacted into law. The law amended section 13269 and required Regional Water Boards to review and renew their waivers, or replace them with waste discharge requirements. Waivers not reissued automatically expired on January 1, 2003.

To comply with SB 390, as well as to control and assess the effects of these discharges, the Los Angeles, Central Coast, Central Valley, and San Diego Water Boards have adopted comprehensive conditional waivers. An estimated 80,000 growers, who cultivate over 9 million acres, are subject to conditional waivers in the Central Coast, Los Angeles, and Central Valley regions. These Regional Water Boards have made significant strides to implement their waiver programs and are committed to continue their efforts to work with the agricultural community to protect and improve water quality. The number of acres and agricultural operations will

increase as other Regional Water Boards adopt conditional waivers for discharges from irrigated agricultural land. The North Coast, San Francisco Bay and Lahontan Water Boards have no immediate plans to adopt waivers for agricultural discharges, but may do so eventually to implement TMDLs. The Santa Ana Water Board is in the process of developing a conditional waiver for discharges from irrigated agricultural lands.

In conjunction with the conditional waivers, Regional Water Boards regulate agricultural discharges from cropland under NPS programs that rely on BMPs to protect water quality. For example, the State Water Board and the CCC oversee agricultural control programs, with assistance from the Department of Pesticide Regulation (DPR) for pesticide pollution and the Department of Water Resources for irrigation water management (SWRCB, 2006b).

The pesticide management measure (MM 1D) is likely to have the greatest impact on sediment toxicity. This MM reduces contamination of surface water and ground water from pesticides through:

- Development and adoption of reduced risk pest management strategies (including reductions in pesticide use)
- Evaluation of pest, crop, and field factors
- Use of Integrated Pest Management (IPM)
- Consideration of environmental impacts when choosing pesticides for use
- Calibration of equipment
- Use of antibackflow devices (SWRCB, 2006b).

IPM is a key component of pest control. IPM strategies include evaluating pest problems in relation to cropping history and previous pest control measures, and applying pesticides only when an economic benefit will be achieved. Pesticides should be selected based on their effectiveness to control target pests and their potential environmental impacts, such as persistence, toxicity, and leaching potential (SWRCB, 2006b).

There are many planned, on-going, and completed activities related to management of pesticides. However, as reported in the most recent NPS Program Plan progress report (SWRCB, 2004a), efforts to improve water quality impaired by agriculture activities are highly challenging because of the different perspectives that exist between the regulatory community and the agricultural community.

As of 2003, the SWRCB (2004a) reports the following progress:

- 16 watershed working groups are actively developing farm water quality plans, with 19 new groups being formed
- Of the over 90 farmers that attended a farm water quality course, half have developed comprehensive water quality plans for more than 10,700 acres of irrigated crops
- Over 750 farmers have attended 35 workshops designed to train farmers in specific conservation practices.

To address local issues, the Regional Water Boards adopted conditional waivers that use different regulatory models, as follow:

- **Central Coast Region:**
  - Requires the submittal of a Notice of Intent (NOI) for each grower;

- Several waiver conditions were based on recommendations developed by an advisory panel of agricultural and environmental representatives, including individual enrollment, education, farm plan development and a checklist of management practices.
- For group and individual waivers, the focus of monitoring is primarily nutrients and toxicity. A region-wide Monitoring and Reporting Program, adopted by the board, includes provision for follow-up monitoring when water quality objectives are exceeded or toxicity is detected.
- Requires 15 hours of training in farm water quality management. The training is funded through grants in some cases, in others education is provided by cooperators throughout region.
- Requires development of farm water quality management plans that address, at a minimum, irrigation management, nutrient management, pesticide management, and erosion control; and implementation of management practices identified in their plans (CCRWQCB, 2006a).

- **Los Angeles Region:**
  - Provision for individual growers to participate in a group. Groups will submit one NOI for all documented participants in the group. NOI to discharge for all dischargers includes individual grower description of location, crop type, and management practices. A Monitoring Plan is submitted with NOI;
  - Requires the submittal of NOI's for each individual grower that does not participate in an approved group;
  - Monitoring can be performed after the Regional Water Board issues a Notice of Applicability (NOA) to participate. NOA is provided within 6 months of NOI submittal;
  - Monitoring is conducted twice in wet weather and twice in dry weather for physical parameters, nutrients, and pesticides. Individual dischargers monitor surface water at the end of property. Group dischargers monitor surface water and watershed-wide receiving water;
  - A Corrective Action Plan (CAP) with time-specific management modifications is required when routine monitoring shows the basin plan, CTR, or TMDL limits are not attained;
  - Requires 8 hours of training in farm water quality management. Annual monitoring plan requires evidence of education.
- **Central Valley Region:**
  - Group participation emphasized;
  - NOI required of each grower that chooses to acquire an Individual Waiver. For a Group, the coalition submits one NOI on behalf of the participating growers.
  - Coalitions required to submit participant lists and update annually.
  - Two step communication report and then Management Plan request (via Executive Officer) to correct problems.
  - Monitoring plan submitted in second year after group receives approval to participate.
  - Timeline for compliance with water quality objectives is no later than 10 years.
  - The Central Valley does not require education or training.

- **San Diego Region:**
  - Conditional Waiver adopted by the R9 Water Board on October 10, 2007 that includes the following requirements.
  - Operators must perform a self assessment to identify the pollutants present on the site and assess the potential for runoff and/or infiltration to adversely affect the quality or beneficial uses of the waters of the state .
  - Agricultural and nursery operators must complete at least 2 hours of water quality management related training annually.
  - Agricultural and nursery operations must implement MMs/BMPs to minimize or eliminate the discharge of pollutants that may adversely impact the quality or beneficial uses of waters of the state.
  - Agricultural and nursery operators must maintain records pertaining to the water quality management efforts for the operation.
  - No later than December 31, 2010, agricultural and nursery operations must form or join a monitoring group.
  - No later than January 1, 2011, owners/operators of agricultural and nursery operations must file a Notice of Intent, as either an individual operation or as part of a monitoring group, with the San Diego Water Board.
  - Currently the County Farm Bureau is working with operators to form a region-wide monitoring group with the intent to submit a NOI to the Regional Water Board by December 31, 2010.

4.5.2 Forestry

Timber harvesting and associated activities can result in the discharge of chemical pollutants and petroleum products, in addition to other conventional pollutants. Chemical pollutants and metals can be discharged through runoff and drift. Potential sources of chemical runoff include roads that have been treated with oils or other dust suppressing materials and herbicide applications.

Forest chemical management focuses on reducing pesticides that are occasionally used for pest management to reduce mortality of desired tree species, and improve forest production. Pesticide use on state or private forestry land is regulated by DPR. However, a large proportion of California's forested lands are owned or regulated by the federal government (SWQCB, 2004a), and the U.S. Forest Service (USFS) Region 5 controls pesticide use.

In addition to the NPS Program MMs, forestry activities are also controlled through WDR and conditional waivers. Recently, Regional Water Boards have adopted conditional waivers for timber harvesting activities, which require compliance with applicable requirements contained in each region's basin plan.

DPR regulates the sale and use of pesticides and, through county agricultural commissioners (CACs), enforces laws pertaining to pesticide use. CACs inspect pesticide applications to forests and ensure that applications do not violate pesticide laws and regulations. Landowners must also submit timber harvest plans (THPs) to the California Department of Forestry (CDF) outlining what timber will be harvested, how it will be harvested, and the steps that will be taken to prevent damage to the environment. CDF will only approve those THPs that comply with all applicable federal and state laws.

4.5.3 Urban Runoff

Pollutants found in runoff from urban areas include, among others, sediments, heavy metals, petroleum hydrocarbons, and plastics. As population densities increase, pollutant loadings generated from human activities also increase. Most urban runoff enters surface waters without undergoing treatment.

Urban runoff is addressed primarily through the NPDES program, although the State Water Board's NPS Program applies where runoff is not regulated as a permitted point source. The NPDES program supersedes the Water Boards' NPS Program in the areas where there is overlap. As mentioned in Section 4.4.1, NPDES storm water permits typically require implementation of BMPs, which may or may not be similar to the MMs in the NPS Program.

The control of urban NPS pollution requires the use of two primary strategies: preventing pollutant loadings from entering waters and reducing the impact of unavoidable loadings. The major opportunities to control NPS loadings occur during the following three stages of development: (1) the siting and design phase, (2) the construction phase, and (3) the post-development phase. Before development occurs, land in a watershed is available for a number of pollution prevention and treatment options, such as setbacks, buffers, or open space requirements, as well as wet ponds or constructed urban runoff wetlands that can provide treatment of the inevitable runoff and associated pollutants. In addition, siting requirements and restrictions and other land use ordinances, which can be highly effective, are more easily implemented during this period. After development occurs, these options may no longer be practicable or cost-effective.

In 1976, the State Legislature enacted the California Coastal Act to provide for the conservation and planned development of the State's coastline. The Coastal Act directs each of the 73 coastal cities and counties to prepare, for review and certification by the CCC, a local coastal plan (LCP) consisting of land use plans, zoning ordinances, zoning district maps, and, other implementation actions. The CCC also works with local governments to incorporate urban MMs and MPs into their respective LCPs. Certified LCPs are important tools for implementing urban runoff MMs and MPs that prevent, reduce or treat polluted runoff from proposed developments. Storm water programs can become more effective because of local planning and permitting decisions throughout the State.

4.5.4 Marina and Recreational Boating

Poorly planned or managed boating and related activities (e.g., marinas and boat maintenance areas) may threaten the health of aquatic systems and pose other environmental hazards. Sources include poorly flushed waterways, pollutants discharged from boats (recreational boats and commercial boats), and pollutants generated from boat maintenance activities on land and in the water (SWRCB, 2006b). For example, as mentioned in Section 2.1.1, copper is often found in marina sediments due to the leaching of antifoulant paints.

There are many planned, on-going, and completed activities related to NPS pollution in marinas. The primary focus of these activities is to prevent discharges of waste oil, sewage, petroleum, solid waste, and hazardous substances from surface runoff, improper boat cleaning/maintenance activities, lack of disposal facilities, or improper maintenance of facilities at marinas. The state relies on education and outreach efforts aimed at marina owners and operators, and the boating public, to provide information on pollution problems and management practices that can be implemented to prevent or control improper disposal of pollutants into surface waters (SWRCB, 2006b).

The Federal Oil Pollution Act (OPA) is a comprehensive prevention, response, liability, and compensation regime for dealing with vessel- and facility-generated discharges of oil or hazardous substances. Under the OPA, any hazardous waste spill from a vessel must be reported by the owner of the vessel, and vessel owners are responsible for any costs of a resulting environmental cleanup and any damage claims that might result from the spill. Marinas are responsible for any oil contamination resulting from their facilities, including dumping or spilling of oil or oil-based paint and the use of chemically treated agents. The Department of Fish and Game's Office of Spill Prevention and Response enforces the laws designed to prevent spills, dispatches units to respond to spills, and investigates spills.

Note that commercial and military ports are subject to storm water NPDES permits regulating industrial and construction activities. Commercial ports are also required to submit a port master plan to the CCC. The master plan must include an estimate of the effect of development on habitat areas and the marine environment, a review of existing water quality, habitat areas, and quantitative and qualitative biological inventories, and proposals to minimize and mitigate any substantial adverse impact. In addition, the state has the opportunity to ensure that appropriate pollution prevention and control measures are in place at all military ports.

Obstacles facing the implementation of BMPs related to MMs for marinas can be primarily attributed to the insufficiency of the number of regulatory or inspection authorities relative to the number of registered boats and marinas, as well as other budgetary constraints that affect marina programs and activities. There are nearly 1 million registered boats and approximately 650 marinas in California. Marinas and boaters fall under the jurisdiction of multiple State and local agencies. In many cases, marina facilities are not being regulated and are rarely inspected. NPS pollution in marinas is often seen as a low priority for many regulatory agencies, and boating enforcement actions have primarily been in the area of boater safety (SWRCB, 2004a).

4.5.5 Abandoned and Active Mines

The State Water Board and Regional Water Boards have identified approximately 40 mines that cause serious water quality problems resulting from acid mine drainage and acute mercury loading (SWRCB, 2000). Although all mines may not be significant polluters individually, cumulatively mines may contribute to chronic toxicity due to increased metals loadings. Additionally, drainage structures and sluices associated with abandoned hydraulic gold mines are a potential source of mercury to surface waters. Mercury from abandoned mines poses a serious potential threat to coastal waters because mercury transported from these sites may bioaccumulate in fish.

The NPS Program Plan does not contain management measures for abandoned mines, and there is no specific, comprehensive program at either the state or federal level for cleaning up abandoned and inactive mines other than coal. Rather, abandoned and inactive mine cleanup is carried out under a variety of state, federal, and local programs. Regional Water Boards may issue WDRs to the most serious sites. The federal Superfund Program addresses only the most extreme pollution sites, such as Iron Mountain Mine. Federal land management agencies have specific, marginally funded programs for cleaning up abandoned mines on federal land, but most projects address safety hazards rather than water quality. California's Title 27 Program regulates discharges of wastes to land, and can be used to pursue mine cleanups.

Enforcement actions, however, are costly and have not been effective because responsible parties are difficult to locate, and current property owners either do not have, or will not spend money, to clean up their sites. The main barrier to a comprehensive program for

abandoned mines is liability. Under the federal Clean Water Act, a third party can sue an agency or private party that performs abatement actions at an abandoned mine if the discharge from the mine continues to violate the Clean Water Act.

In June 2000, the Department of Conservation (DOC) inventoried the number of abandoned mine sites in California. DOC estimates that of the 47,084 historic and inactive mine sites in the state, approximately 11% (5,200) present an environmental hazard. The most common hazards include heavy metals from acid rock drainage and methylmercury from mercury contaminated sediments. DOC (2000) indicates that some bays have been or could be impacted by acid rock drainage and mercury from abandoned mines.

As a land-managing agency, the USFS also has an abandoned mine reclamation program. The program includes an inventory of abandoned mines and locations, environmental and/or resource problems present, rehabilitation measures required, and potential sources of funding. The USFS has worked with various Regional Water Boards on numerous occasions in the rehabilitation of mine sites. Restoration funding comes from USFS funds, CERCLA, and RCRA sources. All lands disturbed by mineral activities must be reclaimed to a condition consistent with resource management plans, including air and water quality requirements (SWRCB, 2000; SWRCB, 2003). In addition, the Bureau of Land Management (BLM) has an extensive abandoned mine land program.

All active mining projects must comply with the Surface Mining and Reclamation Act (SMARA). The goal of SMARA is to have mined lands reclaimed to a beneficial end use. Local Enforcement Agencies (LEAs), usually counties, implement SMARA. The DOC's Office of Mine Reclamation provides technical support to LEAs but has limited enforcement authority.

Mining projects that could impair water quality or beneficial uses may also be subject to NPDES permits or conditions under the Clean Water Act section 401 Water Quality Certification Program.

4.5.6 Atmospheric Deposition

Atmospheric deposition may be a potential NPS to bays through either direct or indirect deposition. Indirect deposition reflects the process by which metals and other pollutants such as PAHs deposited on the land surface are washed off during storm events and enter surface water through storm water runoff (LARWQCB, 2005a). For example, Sabin (2005) concluded that atmospheric deposition potentially accounts for as much as 57–100% of the total trace metal loads in storm water within Los Angeles. In the Los Angeles Region (LARWQCB 2005a, 2005b), loadings associated with indirect atmospheric deposition are included in the storm water waste load allocations. Therefore, NPS pollution from atmospheric deposition is not directly addressed, but indirectly addressed through storm water management. Typically, direct deposition accounts for a very small fraction of NPS pollution (for example, see LARWQCB, 2005a and LARWQCB, 2005b).

Currently, there are no policies in California to directly address potential NPS pollution from atmospheric deposition. Atmospheric deposition is also not directly addressed in the NPS Program Plan, and only MM 2G (Fire Management) would address possible pollution of PAHs from forest fires.

5. ISSUES AND ALTERNATIVES

This section describes the major policy related issues identified and alternatives that have been considered by staff during the development of Part 1. Each issue analysis contains the following sections:

Issue—The subject matter or brief question framing the issue followed by an explanation or description of the issue and concerns.

Issue Description—A description of the issue or topic and (if appropriate) any additional background information, list of limitations and assumptions, descriptions of related programs or other information.

Baseline—A description of how the State and Regional Water Quality Control Boards (Regional Water Boards) currently act on the issue.

Alternatives—For each issue or topic, at least two alternatives are provided for consideration. Each alternative is evaluated with respect to the program needs and the appropriate sections within Division 7 of the California Water Code (CWC). For those issues that address scientific questions, the SQO Scientific Steering Committee's position is also stated.

Staff Recommendation—In this section, a recommended alternative (or combination of alternatives) is identified and proposed for adoption by the State Water Board.

Example Language—Following each recommendation, the reader is directed to proposed language in Part 1 presented in Appendix A where applicable. Presented in Appendix C is the analysis of a data set as applied using the indicators and thresholds described in Part 1.

5.1 PROJECT ALTERNATIVES

5.1.1 No Project Alternative

CEQA requires that the State Water Board consider the "No-Project" alternative. As explained in Section 4 above, the basin plans for all coastal regions have narrative water quality objectives or prohibitions that apply to sediment quality. These objectives currently provide the basis for Clean Water Act section 303(d) listings, cleanup orders, and other regulatory actions. If this project is not adopted, the assessment of sediment quality does and would continue to occur; however, the lines of evidence, test organisms, community indices and data reduction and analysis would continue to differ significantly by Region. These factors not only limit consistency amongst the regions, but also lower the confidence in, and technical basis for, these assessments. The No-Project" alternative does not comply with the mandate in chapter 5.6 or the judgment against the State Water Board for failure to comply with the mandate. The "No Project" alternative would not achieve the objectives of the proposed action. Additional discussion of this alternative is presented in Section 6.

Alternative 1—Adopt the no project alternative. As state above the "No Project" alternative would not achieve the objectives of the proposed action.

Alternative 2—Do not adopt the no project alternative.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A.

5.1.2 What Issues Should Part 1 Address?

At a minimum, the State Water Board is required to comply with the procedures in CWC §§13240 through 13247 in adopting SQOs. Section 13241 lists the factors that the State Water Board must consider when adopting water quality objectives, and section 13242 specifies the elements that must be included in a program to implement the objectives. State Water Board staff believes that sediment quality protection is significantly different from the tools and methods commonly applied to develop water column-based objectives. Therefore, additional information and implementation guidance should be provided to foster greater understanding and consistency when the SQOs are applied within the various regions.

Baseline—Not applicable.

Alternative 1—Include only the SQOs and tools and thresholds needed to implement the objectives.

Alternative 2—Include the narrative objectives and tools and thresholds needed to implement the objectives, and provide a framework that will better support the restoration of sediment quality and beneficial uses.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Section I.B.

5.2 Applicable Waters and Sediment

5.2.1 Applicable Waters

Chapter 5.6 requires the State Water Board to develop SQOs for bays and estuaries. Since 2003, State Water Board staff and the technical team have been developing SQOs and associated tools and thresholds for specific embayments in California. This focus on San Francisco Bay and enclosed bays south of Point Conception was based upon the large volume of data and an understanding of aquatic communities in these waterbodies. Sediment quality within these bays has been relatively well studied since the late 1980's when the State Water Board initiated the Bay Protection and Toxic Hotspots Cleanup Program. Through this program and others such as U.S. EPA's Environmental Monitoring and Assessment Program (EMAP), the San Francisco Estuary Institute Regional Monitoring Program (RMP), and the Southern California Coastal Water Research Project (SCCWRP) Bight 94, 98, and 03, and various site cleanup and dredging projects, a large volume of coupled biological effects and chemistry data existed for the major embayments in California. The technical team was able to rely on this data to evaluate potential indicators for use in this program and was able to refine each indicator and develop California specific thresholds to assess response. The database created for this program included over 150 studies and approximately 5,000 data points. In comparison, very few coupled data sets are available for all the estuaries, including the Sacramento San Joaquin Delta, San Pablo Bay (an estuary) and enclosed bays such as Morro and Humboldt Bays located on the central and north coast respectively.

The indicators and thresholds developed for bays cannot be applied to estuarine water bodies without undergoing rigorous assessment for a variety of reasons. Chapman et al. (2001) provides a detailed explanation of the fundamental physical and chemical differences between the two types of water bodies. The bioavailability of both hydrophobic organic and inorganic pollutants can be influenced by salinity. Chemical equilibrium may not exist within the highly dynamic environments of estuaries. While many of the organisms present in bays are also

found in estuaries, their tolerance to external stressors may vary greatly (Chapman et al. 2001). Within bays, even during wet years, the denser salt water can provide protection from osmotic shock to marine benthic organisms while estuarine organisms could be exposed to wide variations in salinity through tidal fluctuations. As result the indicators proposed for use within San Francisco Bay and enclosed bays south of Point Conception cannot be considered as reliable when applied to other water bodies until additional analyses are conducted.

Within estuaries, a different approach could be applied to interpret the narrative objective. This approach would utilize the same indicators as proposed for embayments, but would rely on a reference envelope approach to aid the assessment of sediment quality. The reference envelope approach has been applied most notably in San Francisco Bay (Hunt et al. 1998a).

This approach could be proposed for use within north and central coast bays as well. An approach for these bays could also be developed that relies on a combination of indicators developed for use in San Francisco Bay and enclosed bays south of Point Conception with the reference approach.

Baseline—Not applicable.

Alternative 1—Develop SQOs for both bays and estuaries as mandated under chapter 5.6 that utilize the same conceptual approach for all bays and estuaries, but relies on less robust interim tools in some water bodies as described above. These tools would be replaced under Phase II of the SQO program by more robust indicators and thresholds. This alternative is consistent with the Water Boards' negotiated settlement with the litigants associated with the original lawsuit described in Section 1.2.

Alternative 2—Develop SQOs and an implementation policy for bays first, followed by estuaries in a phased approach. This alternative would not fully comply with the negotiated settlement agreement approved by the Court.

Staff Recommendation—Alternative 1.

Proposed Language—See Appendix A, Sections II.B and V.C.

5.2.2 Applicable Sediments

Sediment quality programs are designed for specific needs. For example, dredged materials are frequently evaluated by collecting samples from multiple depths. This is performed because the properties of the sediment differ at depth, and characterization of the entire volume proposed for dredging is required before an appropriate disposal site can be selected (USACE/U.S. EPA. 1998). For dredged materials characterization, the USACE in coordination with U.S. EPA has designed a series of methods and tools that can be applied to deep sediments to assess risk associated with these materials relative to the disposal sites.

The State Water Board is most concerned with those pollutants that have the greatest potential to harm beneficial uses. Within contaminated sediments, the most direct exposure pathway for pollutants is through surficial sediments or the biologically active layer. In these surficial sediments, the presence of pollutants has the greatest potential to affect valuable and sensitive receptors either through direct exposure or indirectly as the pollutants in surface sediments are transferred up the food chain to piscivorous fish and birds and finally humans. This pathway was evaluated under the Bay Protection and Toxic Cleanup Program where only the upper two centimeters of sediment were sampled (Stephenson et al., 1994) and is also consistent with the conceptual approach used by Washington Department of Ecology in the regulation of polluted sediments in Puget Sound (WDOE, 1995).

Baseline—Previous assessment conducted through the Bay Protection and Toxic Hotspots Cleanup Program focused on the surficial sediments within the biological active layer. As stated in the Bay Protection and Toxic Cleanup Program Quality Assurance Project Plan, the target depth was designated as the upper two centimeters of sediment (Stephenson et al., 1994).

Alternative 1—Do not identify specific sediments applicable within the proposed Part 1. This alternative would severely limit the effectiveness of the program through inconsistent application of the indicators.

Alternative 2—Surficial sediments only. The tools that have been developed are intended solely to assess the biologically active layer.

Alternative 3—Specify a range of depths. As discussed above, the greatest risk from pollutants is with surficial sediments. Developing additional indicators and thresholds for deeper sediments would not provide enough additional value to offset the additional effort and costs to collect and evaluate this data.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Sections II.C.

5.3 Beneficial Uses and Receptors

5.3.1 Beneficial Uses Potentially Addressed in Part 1

Chapter 5.6 requires the State Water Board to develop SQOs for the reasonable protection of beneficial uses. The Water Boards are required to protect all beneficial uses designated within each water body. Beneficial uses established for bays and estuaries are identified in Table 5.1. Within the context of this program, State Water Board staff considered those beneficial uses that met the following criteria.

- Relationship between the beneficial uses and pollutants in sediment. Some beneficial uses are unaffected by pollutants in sediments. Other beneficial uses are clearly affected by pollutants in sediment but are also highly influenced by natural and anthropogenic water quality factors. Other beneficial uses are linked to pollutants in sediments that have not been considered within the context of this program such as indicator bacteria.
- Ability to utilize robust indicators to measure the potential risk to each beneficial use.
- Ability to consistently assess the risk to the beneficial use within the context of a sediment quality regulatory program.

The beneficial uses that best meet these criteria consist of Marine and Estuarine Habitat, Commercial and Sport Fishing, and Rare and Endangered Species. All of these beneficial uses can be severely affected by pollutants in sediment and assessed using the indicators described in the following Section.

Baseline—Not applicable.

Alternative 1—Attempt to develop SQOs indicators and thresholds to assess the health of all beneficial uses including Municipal, Industrial, Water Contact Recreation Non-contact Water Recreation and spawning reproduction and or early development.

Alternative 2—Beneficial uses linked to specific receptors (Examples—Marine and Estuarine Habitat, and Commercial and Sport Fishing).

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Sections III.

Table 5.1. Beneficial Uses for Enclosed Bays and Estuaries

Beneficial Uses	Description
Industrial Service Supply	Uses of water for industrial activities that do not depend primarily upon water quality including, but not limited to, mining, cooling water supply, hydraulic conveyance, gravel washing, fire protection and oil well repressurization.
Navigation	Uses of water for shipping, travel, or other transportation by private military or commercial vessels.
Water Contact Recreation (1):	Uses of water for recreational activities involving body contact with water where ingestion of water is reasonably possible. These uses include, but are not limited to, swimming, wading, waterskiing, skin and scuba diving, surfing, whitewater activities, and fishing, and uses of natural hot springs.
Non-contact Water Recreation (2):	Uses of water for recreational activities involving proximity to water but not normally involving contact with water where water ingestion is reasonably possible. These uses include, but are not limited to, picnicking, camping, boating, tide pool and marine life study, hunting, and sightseeing, or aesthetic enjoyment in conjunction with the above activities.
Ocean Commercial and Sport Fishing	Uses of water for commercial or recreational collection of fish, shellfish, or other organisms in oceans, bays, and estuaries including, but not limited to, uses involving organism intended for human consumption.
Aquaculture	Uses of water for aquaculture or mariculture operations including, but not limited to, propagation, cultivation, and maintenance or harvesting of aquatic plants and animals for human consumption or bait purposes.
Estuarine Habitat	Uses of water that support estuarine ecosystems including, but not limited to, preservation and enhancement of estuarine habitats, vegetation, shellfish or wildlife (e.g., estuarine mammals, waterfowl, shorebirds), and the propagation sustenance and migration of estuarine organism.
Marine Habitat	Uses of water that support marine ecosystems including, but not limited to, preservation or enhancement of marine habitats vegetation such as kelp, fish, shellfish, or wildlife habitats (e.g., marine mammals, shorebirds).
Preservation of Biological Habitats of Special Significance	Includes uses of water that support designated areas or habitats such as established refuges, parks, sanctuaries, ecological reserves, or Areas of Special Biological Significance where the preservation or enhancement of natural resources requires special protection.
Rare Threatened or Endangered Species	Uses of water that support habitats necessary for the survival and successful maintenance of plant or animal species established under State/or federal law as rare, threatened, or endangered.
Migration of Aquatic Organism	Uses of water that support habitats necessary for the migration, acclimatization between freshwater and salt water, and the protection of aquatic organism that are temporary inhabitants of waters within the region.
Spawning, Reproduction and/or Early Development	Uses of water that support high quality aquatic habitats suitable for the reproduction and early development of fish.
Shellfish Harvesting	Uses of water that support habitats suitable for the collection of crustaceans and filter-feeding shellfish (e.g., clams, oysters, and mussels) for human consumption and commercial or sport purposes

5.3.2 Choice of Receptors

Selection of appropriate receptors is a critical element of every standards development proposal. U.S. EPA's program to develop sediment quality criteria focused on the protection of

benthic organisms (EPA 2003 A and B). Other potential sediment-related receptors include demersal fish, aquatic macrophytes, marine birds, and mammals. Each of these receptors is essential to support a healthy ecosystem. Humans are also potentially affected through the consumption of fish tissue containing contaminant residues. Selecting a receptor as a primary indicator of beneficial use protection is relatively straightforward. For example, human health is an obvious receptor to assess Commercial and Sportfishing. Endangered species such as the least tern could be an appropriate receptor to assess Rare and Endangered Species Beneficial Uses protection. Selection of appropriate receptors to assess risk to other beneficial uses is more difficult because of the broad nature of these beneficial uses (See Table 5.1). For beneficial uses such as Estuarine Habitat and Marine Habitat, many different receptors could be applied. Within the context of this program, receptors were considered based upon the following criteria:

- Ecological Importance.
- Potential for direct or significant exposure.
- Strong link to pollutants in sediment.
- Understanding of response to pollutant exposure understood.
- Availability of tools that can reliably measure response.
- Successfully application in sediment monitoring programs within other sediment monitoring programs in the country.

Fish are an important receptor that can be affected by pollutants in sediments and pollutants that bioaccumulate up the food chain. Fish are ecologically and economically important and provide a source of food to many people. Fish are relatively long lived and exhibit a variety of responses to stress. In terms of a sediment specific receptor, fish exhibit many characteristics that limit their utility in a regulatory framework. Many fish are highly mobile, and, as a result, they can avoid highly impacted areas (Gibson et al. 2000). Their mobility also limits the ability to qualitatively assess exposure without detailed long-term studies. Mobility within unconfined water bodies such as bays and estuaries also makes it difficult to utilize community attributes as a measure of fish health. Fish populations also respond rapidly to environmental disturbance or habitat changes. External anomalies such as fin erosion, lesions, and external parasites can be more sensitive indicators of contaminant effects than community integrity and have been utilized within monitoring programs by coastal publicly owned treatment works (POTWs) or regional monitoring programs in the Southern California Bight (Schiff et al. 2001). However, these effects cannot be directly linked to pollutants in specific sediments without significant and detailed site-specific studies.

Aquatic macrophytes are the most important primary producers and provide stability to the substrate as well as critical habitat for fish and invertebrates. Aquatic macrophytes can respond to pollutants in sediments; however, water quality factors may play a more significant role (Gibson, 2000).

Benthic communities are recognized as the optimal sediment receptor for several reasons. They play a critical role in aquatic ecosystem health because they:

- Digest a significant portion of the organic detritus that settles out in bays and estuaries.
- Significantly enhance sediment mixing and oxygenate deeper sediments that stimulate bacteria-driven biogeochemical processes.
- Create habitat that enhances recruitment for other organisms.

- Provide food for most fish species that utilize bays and estuaries. Waterfowl and wetlands birds also rely on benthic invertebrates as a primary food source.

As an aquatic life indicator of sediment quality, benthic communities also exhibit the following characteristics (Jackson et al. 2000, Gibson et al. 2000):

- Benthic communities are an in-situ measure of actual conditions and biological effects that *are or have* occurred within surface sediments. Other tools commonly applied such as laboratory toxicity tests are at best surrogate measures that may or may not be reflective of actual conditions.
- Benthic invertebrates typically spend at least one or all life stages in direct contact with bottom sediments and characteristically exhibit limited range or mobility. This long-term exposure scenario allows for sublethal toxic effects to cause subtle changes in community structure. Other receptors such as fish and birds are more difficult to utilize because of their mobility and migratory life histories.
- The great variety of taxa within a healthy benthic community represents many different feeding and reproductive strategies that create a great range in sensitivity or tolerance to pollutants and other stressors. These tolerances can be used collectively to identify relatively subtle community responses above reference conditions creating a very robust tool.
- A variety of tools have been used to support the assessment of benthic community health in addition to community measures. These tools include sediment toxicity tests and empirical sediment quality guidelines (SQGs).
- Benthic communities are used by many State and federal agencies to evaluate the effects associated with impaired sediments, and to assess the effectiveness of mitigation actions. Existing data and assessment tools have been developed for many water bodies throughout the nation. While variability is always a factor when evaluating biological communities, compared to other indicators, the analysis of benthic community data does not rely on complex food web fate and transport studies and models to link a pollutant or stressor to a specific region or trophic level.

The State Water Board is required to protect all receptors associated with a specific beneficial use. However, many receptors are not understood well enough to develop tools and define appropriate thresholds for measuring the health of the receptor, or the linkage to pollutants in sediments is easily overshadowed by other factors. For these situations, ecological risk assessments are an appropriate means to assess the risk to other receptors.

Baseline—Selection of appropriate receptors for the assessment of sediment quality is site or water body specific with the final decision approved by the Regional Water Board.

Alternative 1—Consider all potential receptors including aquatic plants, plankton, and bacteria. In order to protect all receptors, detailed ecological risk assessments would be required for each water body of concern.

Alternative 2—Consider a variety of important and ecologically relevant receptors. The process could focus on only the most sensitive organisms; however, sensitivity is specific only to types or groups of pollutants. As with Alternative 1, the application of different indicators would require extensive use of best professional judgment and is counter to the argument for statewide consistency of assessment tools.

Alternative 3—Consider important, relevant, and understood receptors (benthic invertebrates, and human health) exposed either directly or indirectly to pollutants in sediments.

This alternative focuses on those sensitive and ecologically relevant receptors that have been evaluated and applied as sentinel organisms in sediment quality programs throughout the nation. This alternative would utilize the following sediment-related exposure receptor relationships:

1. Benthic communities exposed directly to pollutants in sediment.
2. Human health exposed indirectly through fish and shellfish tissue.

The receptors and corresponding exposures must be clearly described in the policy. The selection of these receptors is not intended to trivialize the importance of other receptors. Receptors such as fish and wildlife are assessed often during the assessment of contaminated sediments through ecological risk assessment. These detailed site-specific studies are the appropriate mechanism to evaluate risk to those receptors not considered within the proposed Part 1. Additional receptors can be evaluated in later phases of the program.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Sections III. and IV.

5.4 Benthic Communities Exposed Directly to Pollutants Within Enclosed Bays

5.4.1 Lines of Evidence

Water quality is routinely assessed based on a single line of evidence (LOE), chemical-specific concentration-based thresholds developed from toxicological studies. A single LOE is appropriate in the water column because the binding effects of other water column constituents are well understood, and the performance of these chemical-specific criteria is reproducible under a variety of conditions (U.S. EPA, 1985, 1991). Moreover, there is a single predominant means for chemical exposure in the water column, transport across the gills. As a result, scientists have been able to integrate this information to describe site-specific bioavailability of chemical contaminants using tools such as the Biotic Ligand Model (Paquin et al., 2002).

Sediment, however, is a more complex matrix that makes establishment of an objective based on chemical concentration alone problematic. There are two primary factors that create this complexity: variations in the bioavailability of sediment-associated contaminants, and multiple pathways of exposure resulting in both direct effects (from contact with the sediment) and indirect effects (as a result of bioaccumulation and transfer to higher trophic levels). Bulk measures of chemical concentration fail to differentiate between the fraction that is tightly bound to sediment and that which is found in interstitial waters and more available for transport across the gill. Further complicating interpretation of chemical data is that transport of chemicals in interstitial waters across the gill is not the only mechanism for exposure, as many benthic organisms ingest the sediment and can uptake chemicals sorbed onto particles. Thus, even chemical measurement approaches that attempt to differentiate interstitial chemical concentrations, such as using equilibrium partitioning models or direct measurement of pore water chemistry, do not fully describe chemical bioavailability in the sediment. Only the bioavailable fraction of pollutant has the potential to alter basic functional processes such as oxygen transfer or reproduction.

Factors that affect bioavailability of contaminants in sediment include the proportion of organic matter, grain size, hydrogen ion activity (pH), and aerobic state, salinity, chemical form of the pollutants, and the composition and mineralogy of the sediment itself (Chapman et al. 2001, U.S. EPA 2000A). These factors can create large spatial and temporal differences in

pollutant bioavailability within a given region or water body (Chapman et al., 2001, U.S. EPA 2001A).

Assessing the indirect effects of sediment contamination presents additional challenges besides those identified for direct effects. As predators consume many prey throughout their lifespan, bioaccumulative pollutants with an affinity for fatty tissue, such as DDT, polychlorinated biphenyls (PCBs), and methyl mercury can build up to levels many times greater then those observed in lower trophic levels or in the sediment (biomagnification). Numerous studies have demonstrated that the biomagnification of sediment-associated compounds can cause deleterious effects in fish and in wildlife or human consumers of seafood (Beyer et al. 1996). The presence of multiple trophic levels and different types of receptors for effects creates additional complexity and uncertainty in the interpretation of sediment contamination data.

A thorough understanding of fish communities, trophic structure and uptake, and the pollutant contribution from all sources must be assessed in order to quantifiably link sediment and fish tissue contaminant levels. Fish are highly mobile; at a given site, a portion of an organism's contaminant body burden may result from uptake from other locations, or from other sources such as the overlying water column. Although specific case studies indicate that certain contaminants are accumulated from the sediments (Gobas et al., 2002), this could vary on a site-by-site basis. Variation in home range can affect the relative impact of contamination at a specific site as a result of the heterogeneous distribution of chemicals in the sediment. Variations in food web structure among locations can also cause differences in contaminant bioaccumulation (Gobas et al., 2002).

As a result of the factors described above, sediment quality indicators based on pollutant concentrations in sediment have only limited utility when used by sediment managers unless bolstered by effects data such as toxicity and benthic community disturbance (Chapman 1990, Ingersoll et al. 2002c, Wenning et al. 2002). This limitation is acknowledged in the ecological risk assessment process, where measures of both chemical exposure and effects are required in order to evaluate the potential for adverse impacts due to either the direct or indirect effects of contaminants.

Other LOE applied to sediments also have potential flaws that make them inappropriate for establishment of SQOs when used alone. Toxicity tests improve in some ways on chemical measurements because they integrate the effects of multiple contaminants- even those chemicals that are not routinely measured. These tests measure individual organism responses relative to endpoints such as growth reproduction and mortality. In the hierarchal response scheme toxicity associated with these organism level endpoints should equate to some affect in community assuming that the indigenous and test species are similarly sensitive and similarly exposed. This paradigm formed the basis for water quality control by relying upon sensitive species and bioassays to establish water quality criteria that are protective of more tolerant organisms. Unfortunately the paradigm has never been proven in sediments. As Griffith (et al. 2008) states *organism-level effects are predictive to some extent of effects at the community level. However, this relationship is obscured by differences between these methods other than the hierarchical differences in the level of biological organization between their measurement endpoints.* This conclusion is supported by other authors including Chapman (et al. 2001, 2002) Ferraro (2002), Griffith (2008) Luoma (1996) and others. A number of factors weaken this relationship including.

- Toxicity test species and species that compose the benthic community have different sensitivities to different contaminants.

- Toxicity tests typically rely on short-term exposures using relatively few species and end points, making it difficult to interpret ecological significance of the results when used alone.
- Toxicity tests do not mimic the sediment structure, the bio-geochemical processes that influence bioavailability and the exposures that occurs in-situ.
- Presence of natural factors such as ammonia, hydrogen sulfide, or physical abrasion can lead to spurious results.

Benthic community condition is a good indicator because the benthos are directly exposed to sediment contamination and are one of the target biological resources the SQOs are intended to protect. However, their use alone is problematic because they are potentially affected by a large number of factors other than chemical contamination. Without chemistry or toxicity data for confirmation, it is difficult to distinguish whether degraded benthic communities resulted from chemical exposure or from physical disturbance, such as an anchor or prop-wash.

Bioaccumulation is also a useful measure, but sediments classified based on only a tissue uptake/bioaccumulation LOE would not account for toxicants that tend not to bioaccumulate in tissues of biota. Most trace metals and polynuclear aromatic hydrocarbons (PAHs) do not bioaccumulate in tissues, so their presence and toxicity would not be accounted for in such an approach. In addition, impacts from readily biotransformed pollutants would not be addressed by this LOE. The measurement of fish or shellfish tissue contamination provides an important measure of potential effects to wildlife or human consumers, but the mobility and varied life histories of the species makes it difficult to associate the effects with sediment contamination in specific locations.

For these reasons, multiple lines of evidence (MLOE) that represent both contaminant exposure and effects are frequently used in sediment assessments. The State Water Board's Bay Protection and Toxic Hotspots Cleanup Program relied primarily on MLOE to make critical decisions regarding management of sediment in bays and estuaries throughout the State (Anderson et, al 1997, 1998, Fairey, R, 1998, Hunt et al., 1998).

Virtually all of the estuarine ambient monitoring programs in this country rely on some form of the sediment quality triad, where chemistry and multiple measures of biological effect are used together to assess sediment quality (Crane, J.L., et al. 2000, Ingersoll, C. et al. 2002, MacDonald et al., 2003, U.S. EPA, 1998, 2004). These include the two largest nationwide estuarine monitoring programs, U.S. EPA's EMAP and the National Oceanic and Atmospheric Administration's (NOAAs) National Status and Trends Program, as well numerous regional monitoring programs, including those for the Great Lakes, Puget Sound, San Francisco Bay, Chesapeake Bay, Southern California Bight, Tampa Bay, and New York/New Jersey harbors.

The triad concept has been used and published in the United States, Canada, Australia, United Kingdom, France, the Netherlands, and Brazil, among others. Most regulatory programs, including those that control open water disposal of dredged material, require tests of sediment chemistry, toxicity, and bioaccumulation. Comprehensive ecological risk assessments invariably use a weight of evidence approach from multiple kinds of assays and tests to estimate and manage risks at waste sites. Even the national chemical benchmarks issued by U.S. EPA that rely on one LOE encourage users to apply them in concert with other sediment assessment tools in making management decisions.

While various MLOE approaches have been used to describe and classify sediment quality, they have typically been applied for site-specific or regional assessments. Moreover, MLOE applications are often based on use of BPJ for combining the individual LOE. BPJ will be

ineffective for use in SQOs because the expertise of the individuals applying them will vary considerably across the State, and there is a need for statewide consistency in their application. While there is no direct precedent for translation of MLOE into criteria, standards, or objectives, there are some applications that move in that direction from which lessons can be learned. The State of Washington's SQSs have provisions to use chemical, toxicological, and benthic composition data to classify sediments for multiple purposes, including disposal of dredged material. The Tampa Bay Estuary Program has adopted a triad of measures of sediment quality for management purposes there. The States of Minnesota and Illinois, in partnership with the U.S. EPA Assessment and Remediation of Contaminated Sediment (ARCS) Program of the Great Lakes National Program Office, use the triad of measures to assess sediment quality for management in the Great Lakes.

Baseline—Sediment quality assessment programs throughout the nation rely on MLOE to assess impacts to beneficial or designated uses.

Alternative 1—Do not specify LOE.

Alternative 2—Base policy on application of a single LOE. This alternative would base the policy on a single LOE, such as sediment toxicity, chemistry, or benthic community. Such an approach would be very simple to implement; however, any single LOE is affected by confounding factors, measurement errors, and variability and would contradict the approach recommended by U.S. EPA.

Alternative 3—Base policy on application of MLOE. The suite of tools and LOE would be specific to each receptor.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Sections I.A, V.A and B.

5.4.2 Form of Sediment Quality Objectives

The State Water Board has the option of establishing narrative or numeric objectives, or some combination of the two. In order to implement an approach based upon MLOE, as described above consideration must be given to the importance of each tool. Sediment quality is assessed with a combination of tools and results, in contrast to a numeric water quality objective for which a single specific measurement may be used. Within this approach, a narrative objective can be proposed that can be implemented with a high degree of confidence using a robust suite of tools; the MLOE approach. This approach would also minimize potential conflicts associated with discordant results. In addition, as better tools are developed to support the narrative objectives, these tools could be added as amendments to the plan while maintaining a consistent narrative objective.

Baseline—As described in Section 4 above, basin plans include narrative objectives that apply to sediment quality, as Implementation of the narrative objectives varies from region to region because the Regional Water Boards typically rely on best professional judgment (BPJ) applied on a case-by-case basis. There are no applicable numeric objectives in California that apply specifically to sediment quality.

Alternative 1—Do not adopt SQOs. This alternative would conflict with chapter 5.6, which requires the State Water Board to adopt SQOs.

Alternative 2—Numeric objectives could be developed and proposed for each LOE. However, each numeric objective would need to be integrated into a weight of evidence approach. The numeric objective would be meaningless without the other LOE.

Alternative 3—Narrative objectives could be proposed that would be implemented using MLOE and corresponding thresholds coupled to a logic based data integration process.

Alternative 4—Numeric objective based upon the integration of data from the three LOE. This alternative would provide greater utility for statistical analysis however until enough data is collected to evaluate the response relationships between the various LOE to create a valid numeric scale, a scientifically defensible numeric cannot be developed.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Section IV.

5.4.3 Sediment Toxicity

5.4.3.1 Sediment Toxicity to Support the Direct Effects of SQO

Sediment toxicity tests are considered an important component of sediment quality assessments (U.S. EPA 2001a, 2004a, 2004b, 2005, Wenning et al. 2005). Recent California assessment programs, such as the Bay Protection and Toxic Cleanup Program, and current programs, such as RMP and the Southern California Bight Regional Monitoring Program, use sediment toxicity as one of multiple measures of sediment quality. Much of the testing has employed acute amphipod survival methods using protocols established by U.S. EPA (U.S. EPA 1994). Many of the projects have also included a measure of sublethal toxic effects in sediments using a wide variety of test methods, including long-term growth tests, elutriate toxicity tests, porewater toxicity tests, and tests of toxicity at the sediment-water interface. The Environmental Monitoring and Assessment Program of U.S. EPA has used amphipod acute testing in conjunction with a variety of sublethal methods in different parts of the country (Ringwood *et al.* 1996, Bay *et al.* 1998). The State of Washington has a program for monitoring and assessing sediments that has been in place for nearly two decades using a combination of acute amphipod tests, polychaete growth tests, and modified elutriate testing with invertebrate larvae (Puget Sound Water Quality Authority 1995).

Laboratory toxicity tests consist of exposing test organisms to sediments within a controlled environment. The toxicity test response provides a direct measure of the combined effects of all chemicals present in the sample and can thus indicate the presence of toxic quantities of chemicals that were not detected or analyzed for in a chemical analysis. Because toxicity tests are conducted using sediments from the environment, the results incorporate the effects of sediment characteristics such as organic carbon that can alter the biological availability of the contaminant. The laboratory environment of the toxicity test allows for the control of confounding factors such as salinity, temperature, or dissolved oxygen that may vary in the field, thus permitting a distinction between toxic effects and effects due to natural habitat variability. For these reasons, some have argued that toxicity tests are the only line of evidence that is required to adequately asses sediment quality. Supporting this argument is the concept that a response causing mortality or reduced growth and reproduction in test organisms should translate to affects within resident community, such as decreased diversity and abundance (Griffith (2008). While this concept is logical and studies have demonstrated correlations between toxicity observed in laboratory organisms and community impacts, sediment toxicity tests cannot reliably predict effects to benthic communities (Chapman et al. 2001, 2002) (Ferraro (2002), Griffith (2008) Luoma (1996). Factors affecting this relationship are described

in Section 5.4.1. The toxicity test result may overestimate or underestimate effects occurring in the field due to variations in the sensitivity of the test organism or to changes in chemical exposure caused by sediment handling in the laboratory.

Baseline—The State and Regional Water Boards have relied upon sediment toxicity tests.

Alternative 1—Do not consider sediment toxicity tests for measuring direct effects.

Alternative 2—Propose sediment toxicity tests for inclusion in the implementation of direct effects narrative SQOs.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Section V.A.

5.4.3.2 Choice of Toxicity Tests Should Be used

The only means by which the State Water Board can maintain a high level of consistency and data quality is by limiting the tests that can be used in this program to those that meet specific criteria. Various methods for measuring sediment toxicity are available. Key differences between tests include: species, life history stage, duration, endpoint, and mode of exposure. Different species vary in their sensitivity to contaminants as a result of physiological differences, body type, and degree of exposure to the sediment. Crustaceans, bivalves, or polychaete worms are commonly used in toxicity tests, and there is no single species that is consistently the most sensitive to all contaminants of interest (Long *et al.* 1990, Burton *et al.* 1996, Anderson *et al.* 1998b, Bay *et al.* 2007a).

Various life history stages, including embryos, juveniles, and adults, are used in toxicity tests (Lamberson *et al.* 1992). Embryos and juveniles are generally more sensitive to contaminants than adults, but adult test organisms may be less sensitive to confounding factors that complicate test interpretation. There are a variety of endpoints that are specific to each test. The simplest endpoint is survival or lethality which is the endpoint associated with acute tests. Sublethal test endpoints include growth, reproduction, egg fertilization, embryo development, and biochemical responses such as DNA damage or cellular stress.

Test duration varies widely among toxicity test methods; tests generally range from 48 hours to 28 days in length. Longer duration tests may be more sensitive to the effects of chemicals that require bioaccumulation before toxicity is caused, but they also are more difficult and expensive to conduct. The method of exposure can also affect the sensitivity of the toxicity test or the data interpretation. Many tests expose the organism directly to whole sediment, which provides potential chemical exposure from direct particle contact, the pore water, and from sediment ingestion. Other test methods expose the organism to pore water extracted from the sediment, an elutriate, overlying water, or a solvent extract of the sediment (Anderson *et al.* 1996, Carr and Nipper 2003). These variations in exposure method are used to facilitate tests with organisms that cannot tolerate sediment contact (e.g., embryos) or to investigate specific mechanisms of exposure.

Because toxicity test responses are governed by so many different factors, a suite of standard test methods is often used to measure sediment toxicity in various assessment or regulatory programs. By requiring the use of specific test methods, (1) consistency is established throughout the State, (2) statewide thresholds can be developed that minimize subjective decision making, and (3) inappropriate tests will not be performed.

The process of selecting the recommended toxicity methods for the SQO program is described in Bay *et al.* (2007a). A review of the scientific literature and consultation with other scientists was used to identify a set of candidate sediment toxicity protocols that had the following characteristics: adopted or approved by U.S. EPA, USACE, American Society for Testing and Material Standards (ASTM), or other states; tolerance of expected sediment physical characteristics; diversity of taxonomic groups; association between response and sediment exposure; sensitivity to individual contaminants; and representative of benthic community species. The selection process resulted in a candidate test method list consisting of acute methods with the four commonly used amphipod species (*Ampelisca abdita, Eohaustorius estuarius, Rhepoxynius abronius,* and *Leptocheirus plumulosus*) plus six sublethal methods using amphipods (*Leptocheirus plumulosus),* polychaete worms *(Neanthes arenaceodentata),* sea urchins *(Strongylocentrotus purpuratus),* bivalves (*Mytilus galloprovincialis, Mercenaria mercenaria, Crassostrea virginica*), and copepods (*Amphiascus tenuiremis*). The tests are summarized in Table 5.2 from Bay *et al.* (2007a).

Table 5.2. List of Candidate Sediment Toxicity Tests, the Citations Containing Testing Protocols and Whether Quality Assurance and Test Acceptability Criteria Have Been Established

Species	Taxonomic Group	Duration (days)	Matrix	Endpoint(s)	Citations	State or National Program Use[1]
Ampelisca abdita/ Eohaustorius estuarius Rhepoxynius abronius Leptocheirus plumulosus	Amphipod	10	Whole sediment	Survival	(U.S. EPA 1994, ASTM 1996)	EMAP NOAA USACE WA, RMP
Leptocheirus plumulosus	Amphipod	28	Whole sediment	Growth, reproduction, survival	(U.S. EPA 2001)	
Neanthes arenaceodentata	Polychaete	28	Whole sediment	Growth, survival	(ASTM 2002b) modified	USACE[2] WA
Strongylocentrotus purpuratus	Sea urchin	3	Sediment-water Interface	Embryo development	(Anderson *et al.* 1996)	
Mytilus galloprovincialis	Mussel	2	Sediment-water Interface	Embryo development	(Anderson *et al.* 1996)	RMP
Amphiascus tenuiremis	Copepod	14	Whole sediment	Reproduction, survival	(Chandler and Green 1996)	NOAA
Mercenaria mercenaria	Clam	7	Whole sediment	Growth, survival	(Ringwood and Keppler 1998, Keppler and Ringwood 2002)	
Crassostrea virginica	Oyster	4	Whole sediment	lysosomal stability	(Ringwood *et al.* 1998, Ringwood *et al.* 2003)	

[1] EMAP: Environmental Monitoring and Assessment Program; NOAA: NOAA National Status and Trends Program; USACE (U.S. Army Corps of Engineers: dredged material evaluation for disposal under USACE or U.S. EPA guidance; WA: dredged material evaluation for disposal under Washington State guidance; RMP: San Francisco Bay Regional Monitoring Program

[2] The same species and endpoint is used in dredged material evaluations, but the duration and aspects of the test method differ

Toxicity tests on sediment pore water or elutriate samples were not considered for evaluation because of technical limitations in the methods. Pore water tests are widely used for testing sediment toxicity (Carr and Nipper 2003), but it is difficult to collect enough sample for testing. Other characteristics of pore water toxicity tests make these methods less suited for use in the SQO program, including potential changes in metal toxicity due to oxidation, change in sample pH, sorption of contaminants to test chambers, confounding effects of ammonia toxicity, and elimination of sediment ingestion as a route of uptake (Ho *et al.* 2002). Elutriate tests were also not included in the list of candidate methods. These tests, where sediments are added to water with agitation, allowed to settle, and then the water is removed for testing, are often used for testing the effects of sediment resuspension during dredged material disposal. The elutriate sample is subject to many of the confounding factors associated with pore water, and the relationship of the results to direct sediment exposure is not known. The decision to exclude pore water and elutriate tests was endorsed by the SQO Scientific Steering Committee.

Each of the candidate methods was ranked relative to the following characteristics: organism availability, method documentation, technical difficulty, sensitivity, precision, and cost. Results of these are shown on Tables 5.3 and 5.4. Survival tests using the amphipods *E. estuarius, R. abronius,* and *L. plumulosus* were recommended as the best choices for acute testing in California. *E. estuarius* and *R. abronius* have a substantial history of successful use in California for both monitoring and assessment studies. The *L. plumulosus* 10-day test has been conducted in California on a much more limited basis. However, it has long been used in other parts of the country, especially on the Gulf Coast for monitoring and assessment studies. *Leptocheirus* is also easily cultured in the laboratory and available year round from commercial suppliers.

Two sublethal test methods were recommended for use in the SQO program: a 28-day growth test using the polychaete worm *Neanthes arenaceodentata* and a 2-day development test using embryos of the mussel *Mytilus galloprovincialis* exposed at the sediment-water interface. These tests had the best combination of characteristics related to test feasibility, method documentation, and sensitivity. The recommended sublethal tests complement the ability of the acute tests to detect toxicity by providing diversity in test species, length of exposure, and mode of exposure. The other candidate sublethal tests were not recommended for a variety of reasons, including incomplete documentation of the method, high cost, and relatively low sensitivity to contaminated sediments

Baseline—The State and Regional Water Boards have used different amphipod species for acute tests within different programs, though *A. abdita* and *E. estuarius* are the species most commonly required. Sublethal sediment toxicity tests are not typically required by State and Regional Water Boards in NPDES programs.

Alternative 1—Do not specify toxicity methods.

Alternative 2—Specify only acute toxicity methods.

Alternative 3—Specify only sublethal toxicity methods.

Alternative 4—Specify a combination of acute and sublethal toxicity methods.

Staff Recommendation—Alternative 4.

Proposed Language—See Appendix A, Section V.F.

Table 5.3. Characteristics of Candidate Sediment Toxicity Test Methods from Bay et al. (2007a)

	Organism Availability[1]	Method Description[2]	Technical Difficulty[3]	Concordance at Clearly Clean or Impacted Sites[4]	More Sensitive than *Eohaustorius*[5]	Reproducibility Among Laboratories[6]	Reproducibility Within Laboratories[6]	Relative Precision of Response[7]	Documentation of Confounding Factors[8]	Cost of Method[9]
Amphipod Acute										
Eohaustorius	12 (+)	Standard	Low	NA	NA	Good	Good	NA	Good	Low
Rhepoxynius	12 (+)	Standard	Low	NA	Sometimes	Good	Good	NA	Good	Low
Leptocheirus	12 (+)	Standard	Low	NA	Often	Fair	Poor	NA	Fair	Low
Ampelisca	8 (+)	Standard	Moderate	NA	Rarely	Poor	Good	NA	Fair	Low
Sublethal Methods										
Mercenaria growth	8(+)	Published	Low	Fair	Sometimes	Fair	Fair	Similar	Good	Low
Neanthes growth and survival	12(1)	Published	Moderate	Fair	Sometimes	Good	Good	Low	Good	High

5.4.3.3 *Evaluation of Toxicity Test Responses*

To provide consistent interpretation and assessment of sediment toxicity, Part 1 should describe how the responses to the tests recommended above are assessed. If Part 1 did not include this information, the interpretation of sediment toxicity would have to be decided by individual staff at the Regional Water Boards using best professional judgment, which would create a greater risk of inconsistent assessment both within and across the regions.

Interpretation of sediment toxicity is commonly assessed using a binary approach (nontoxic/toxic) or by using three or more categories to distinguish different levels of response and confidence. The advantage of multiple categories versus the binary approach is that it provides greater information about the toxicity response and thus provides greater potential resolution when combining the toxicity data with other lines of evidence in a sediment quality triad approach. This is especially important when the end user must be able to distinguish not only the highly impacted stations from the unimpacted stations, but also those stations that exhibit low levels of impact as well. For this reason, members of the SSC strongly supported the development of multiple categories for all LOE.

In response to this need, the SQO technical team developed a multi-category system adapted from the three-category system commonly used to classify sediment toxicity (Long et al., 2000). In the three-category system, the test response is classified as nontoxic, marginal, or toxic. Within the SQO program, the technical team developed a system based upon four categories. Each of the four categories was based on a narrative description of condition that incorporated both the degree of confidence that a toxic effect was present and the magnitude of response (Bay et al., 2007).

Nontoxic—Response not substantially different from that expected in sediments that are uncontaminated and have optimum characteristics for the test species

Low Toxicity—A response that is of relatively low magnitude; the response may not be greater than test variability

Moderate Toxicity—High confidence that a statistically significant effect is present

High Toxicity—Highest confidence that a toxic effect is present and the magnitude of response is among the strongest effects observed for the test

The nontoxic and marginal categories used in previous studies such as the Water Boards' Bay Protection Program correspond to the nontoxic and low toxicity categories of the scoring system proposed for here. The category designated as toxic in past studies typically represented a reliably statistically significant response that encompassed a wide range of effects (*e.g.*, 0 – 80% survival) and as a result provided little discrimination among the majority of the toxic samples. The proposed approach described here divides this broad response category into two categories defined as moderate and high, in order to provide the ability to distinguish severe effects from more moderate responses.

Figure 5.1 illustrates the relationship between these four categories, the numeric thresholds and statistical criteria. In order to assess toxicity response within a given sample, the end user would simply compare test results (e.g., % survival) to Low, Moderate, and High thresholds and statistical significance criteria.

Basis for Thresholds

The thresholds were developed using test-specific characteristics, such as test variability (minimum significant difference (MSD)) and distribution of the toxicity response data. A statistical criterion was also used in the classification scheme (Figure 5.1). Samples qualifying for the Low or Moderate categories based on test response magnitude were classified into the next lower category if the response was not significantly different relative to the control (t test, $p \leq 0.05$). A statistical significance criterion was not applied to the highest toxicity category because the derivation of the high toxicity threshold already incorporated a high degree of statistical confidence.

The basis for establishing each of the sediment toxicity thresholds that bound each category is summarized below. The analyses used to derive the thresholds are described in Bay et al. (2007a). This report can be downloaded directly from www.sccwrp.org.

Low Toxicity Threshold

The threshold separating the nontoxic and low categories was defined as the lowest acceptable control response value for the given test, as established in the test protocols. The response value is defined as the mean value for the endpoint for a given test method (i.e. survival, growth). This threshold was based on the rationale that any response that fell within the range expected of animals exposed to optimum sediment conditions (i.e., controls) should indicate a nontoxic condition in the test sample. The control acceptability criteria were obtained from the appropriate protocol for each test method. Any test sample having a response value that is greater than or equal to the low threshold will be classified as nontoxic, regardless of whether a statistical difference from the control is present. A test response that is less than the low threshold will be classified as Low, Moderate, or High, depending on the magnitude of response and statistical significance (Figure 5.1).

Moderate Toxicity Threshold

The intent of the Moderate Threshold is to distinguish between samples producing a small response of uncertain significance and larger responses representing a reliably significant difference relative to the control. This threshold was based on the Minimum Significant Difference (MSD), which was specific to each test method. The MSD represents the minimum difference between the control and sample response that is necessary to be statistically different at $p \leq 0.05$ level. The moderate threshold was equal to the 90^{th} percentile of the MSD for a given toxicity test method. This approach for calculating a toxicity threshold has been used by other researchers (Phillips *et al.* 2001). Use of the 90^{th} percentile results in a threshold with a high degree of confidence that the sample is different from the nontoxic condition.

The MSD values were calculated using the replicate control and sample data from many toxicity tests. Details of this calculation can be found in Phillips *et al.* (2001). For each combination of a control and a sample, the variance of the replicates, number of replicates, and the t-critical value for the pair were used to calculate a single MSD value. All of the MSD values in the dataset for each toxicity test method were then sorted in rank order. The 90^{th} percentile value of this set of data was then calculated (MSD_{90}). The MSD_{90} values were calculated using all available data for each toxicity test method. Finally, the moderate threshold value was calculated by subtracting the MSD_{90} from 100% in order to produce a value that could be compared to the control-adjusted test response value.

Sample response values (i.e. survival or growth) between the low and moderate thresholds are classified as Low Toxicity if they are significantly different from the control

response (Figure 5.1). Sample response values that are less than the moderate threshold and are significantly different from the control are categorized as moderately toxic.

High Toxicity Threshold

The intent of the High Threshold is to identify samples producing a severe and highly significant effect from those samples producing lesser effects. No precedent for this threshold was available from the literature, so this threshold was based on a combination of test variability and response distribution that corresponded to the category definition. This approach was recommended by the SQO Scientific Steering Committee.

The 99th percentile MSD value was used to link the High threshold to test variability. A sample having a response that falls below this limit would be expected to be significantly different from the control 99% of the time. This value therefore represents a response that is associated with a very high level of confidence of statistical significance. The 99th percentile MSD for the high threshold was calculated using the same data and methodology described for the calculation of the MSD_{90} for the moderate threshold.

The response distribution component of the high threshold was based on the distribution of toxic samples from California. For purposes of this calculation, toxic samples were defined as samples having a mean response that was significantly different from the control response. The toxic samples were ranked in descending order based on the control-adjusted mean survival. The response magnitude component of the high threshold corresponded to the 75th percentile of the data. The value obtained from this calculation represents the response associated with the most strongly affected 25% of the toxic samples found in California. It was required that data for this calculation be from stations within California in order to obtain a response value that was relevant to the characteristics of sediments in California.

Both the variability and data distribution response values represented important, but partial, aspects of the High Threshold. Therefore, the mean of the two values was used as the High Threshold. Response values (i.e. survival or growth) below the high threshold are classified as high toxicity regardless of whether they are significantly different from the control response or not (Figure 5.1).

Sediment Toxicity Thresholds

The toxicity test thresholds developed for the SQO program are summarized in Table 5.5. These thresholds are similar to comparable thresholds utilized within the California Bay Protection and Toxic Cleanup Program and the Southern California Bight Regional Monitoring Programs.

Table 5.5. Proposed Toxicity Threshold Values for the Sediment Toxicity Test Methods

Species	Low (%)	Moderate (% Control)	High (%Control)
Eohaustorius	90	82	59
Rhepoxynius	90	83	70
Leptocheirus	90	78	56
Neanthes	90[1]	68	46
Mytilus	80	77	42

[1] % of control growth.

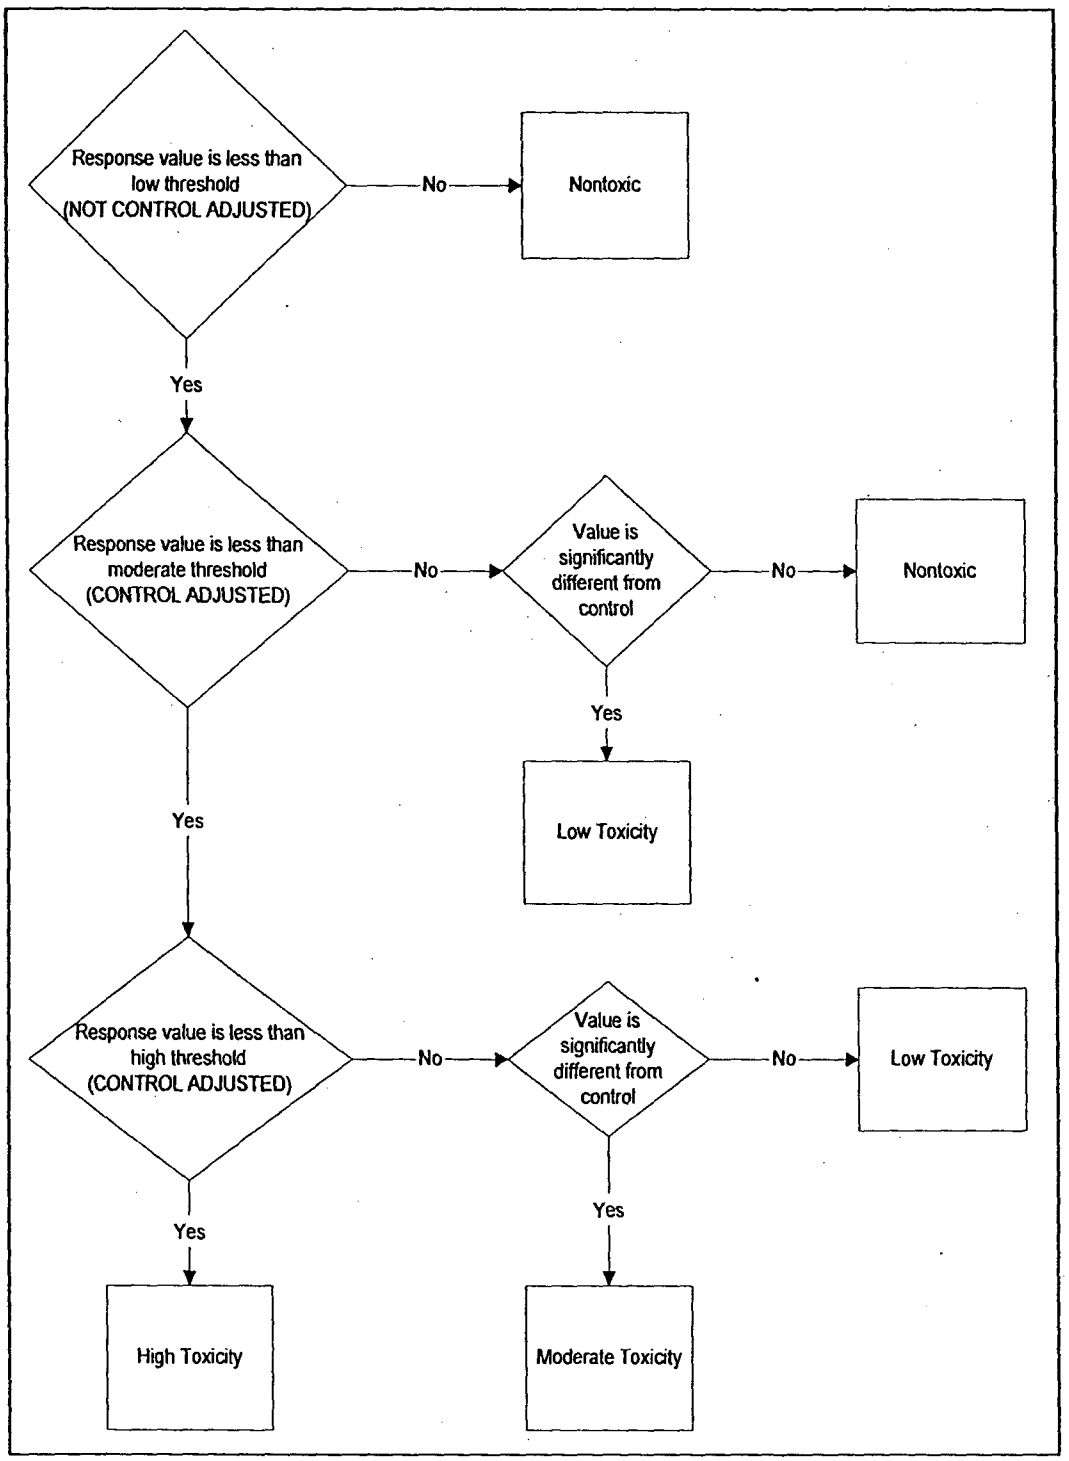

Figure 5.1. Conceptual Approach and Process for Assigning the Category of Toxicity from Laboratory Test Results

Baseline—Existing programs typically categorize response as either toxic or nontoxic where the toxic response is defined as a reliably statistically significant response that encompasses a wide range of effects (*e.g.*, 0 – 80% survival).

Alternative 1—Categorize toxicity response as toxic or nontoxic

Alternative 2—Categorize toxicity response by the toxicity thresholds identified in Table 5.5.

Staff Recommendation—Alternative 2

Proposed Language—See Appendix A, Section V.F. Presented in Appendix C is an example problem and solution based upon the proposed language.

5.4.4 Chemical Analysis

5.4.4.1 Chemical concentrations used to support the Direct Effects of SQOs

Many monitoring and assessment programs evaluate the effects of chemical contamination on sediment quality. Sediment quality guidelines (SQGs), tools that relate contaminant concentrations to the potential for adverse effects on sediment-dwelling organisms, are often used to help interpret sediment chemistry data. SQGs have been used for over 30 years to assess sediment contamination (Engler *et al.* 2005), yet there are many factors that make their use a complex and challenging task. These complicating factors include a lack of guidance on how to evaluate the many types of SQGs in order to select the approach best suited for a particular application, uncertainty regarding how to assess complex mixtures of contaminants, the inability to reliably predict contaminant bioavailability, and uncertainty in how to establish thresholds for SQG interpretation that define acceptable and unacceptable sediment quality (Wenning *et al.* 2005).

Numerous studies have shown that each type of SQG has predictive ability with respect to biological effects (Wenning *et al.* 2005). The predictive ability is often greatest in instances of high/low contaminant concentrations. Predictions of the biological effect based on SQGs have the highest error rates when applied to samples containing intermediate levels of contamination (Long *et al.* 1998, Fairey *et al.* 2001). The predictive ability of SQGs has also been shown to vary among datasets from different regions (Fairey *et al.* 2001, Crane *et al.* 2002), which complicates the selection of the most reliable approach and thresholds for a given application.

There is considerable concern over the misuse of sediment chemistry guidelines to implement narrative water quality objectives in Basin Plans. The use of chemical SQGs is often accompanied by substantial uncertainty and controversy, as no single SQG approach is able to account for all of the factors that influence contaminant effects. In sediments, if pollutant concentrations are very low or not detected but significant effects are observed, two possible scenarios exist: (1) a non-pollutant-related stressor, such as physical disturbance or habitat alteration, is the cause of impairment; or (2) a pollutant is present that was not identified by the suite of analytical methods selected (Chapman 1990, Ingersoll *et al.* 2001). Both scenarios assume that the effects data and the chemistry data accurately reflect the conditions at the station. Conversely, if pollutant concentrations are elevated but effects are not observed, the pollutant may not be bioavailable. Simple effective approaches to quantify the bioavailable fraction of a pollutant in sediment are not currently available and are not likely to be developed in the near future (U.S. EPA 2005).

Baseline—Sediment chemistry is frequently used as an indicator to assess potential impacts. In this role, sediment concentrations are compared to various SQGs (ERLs, ERMs, PELs, AETs) either independently or in conjunction with other LOEs to determine if the

pollutants in sediment pose a risk. In California, there are no current plans or policies that define what guidelines shall be used, how the guidelines should be applied, or what conclusions can appropriately be drawn based solely on chemistry.

Alternative 1—Do not consider sediment chemistry as a direct-effects implementation tool. As described previously, sediment chemistry is not a measure of the bioavailable fraction of pollutants in sediment. As a result, this tool would have little or no utility within a state sediment quality program.

Alternative 2—Propose specific sediment chemistry indicators for inclusion in the implementation of direct effects narrative SQOs. Within the policy, sediment chemistry would be proposed as a surrogate measure of exposure and used only with other LOEs.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Section V.A.

5.4.4.2 Choice of Chemistry Indicators

There are three principal types of SQGs, based on the approach used in their derivation: empirical, mechanistic, and consensus. Empirical SQGs are the most widely used type; these guidelines are derived from the statistical analysis of large databases of matched sediment chemistry and biological effects data. Examples of empirical SQGs for the marine environment include the effects range-median (ERM) probable effects level (PEL), apparent effects level (AET), and logistic regression models (LRM) (Long *et al.* 1995, MacDonald *et al.* 1996, Barrick *et al.* 1988, Field *et al.* 2002). Mechanistic SQGs take into account chemical and biological processes that affect contaminant bioavailability and toxicity. Current mechanistic SQGs are based on equilibrium partitioning theory and apply to selected classes of contaminants, primarily divalent metals and some types of nonionic organics (U.S. EPA 2004c, 2004d). Consensus guidelines are derived from the aggregation of several types of SQGs having a similar narrative intent (e.g., median effect). Marine consensus SQGs have been developed for a relatively small number of constituents, including metals, PCBs, and PAHs (MacDonald *et al.* 2000, Swartz 1999, Vidal and Bay 2005).

There are two potential applications of chemical SQGs in a SQO policy setting: overall assessment of the presence of impacts due to chemical pollutants, and determination of the cause of the impacts. The different types of SQGs vary in their effectiveness for these applications. Empirical and consensus SQGs provide an estimate of the probability of effects due to chemical contamination level and are thus well suited for overall assessment of impacts. Mechanistic SQGs use partitioning models to determine cause and effect and are thus well suited for applications where determination of cause is needed. The different SQG approaches are complementary in their uses and limitations and both have applications in the assessment and management of contaminated sediment (Di Toro *et. al.* 2005).

The utility and performance of SQGs based on mechanistic, empirical and consensus approaches were evaluated. The approaches included EqP models for nonpolar organics and metals, existing national empirical and consensus guidelines, regional guidelines calibrated to California data, and newly developed guidelines. The evaluation consisted of two phases: preliminary and final. The preliminary evaluation examined a wide range of SQG approaches and assessed the predictive ability (e.g., correlation with respect to sediment toxicity) and feasibility of each approach. Mechanistic SQGs based on EqP models were found to have no significant correlation with California sediment toxicity data in the preliminary analyses and insufficient data (e.g., sediment acid volatile sulfides and simultaneously extracted metals) were

available to enable further evaluation of EqP SQGs for metals. These results were consistent with previous analyses using southern California data that showed poor predictive ability of mechanistic SQGs (Vidal and Bay 2005).

The final evaluation of SQG performance examined several empirical and consensus approaches that were identified in the preliminary analyses as best meeting the needs of an SQO assessment framework. The results for the individual chemical components of each SQG were summarized for evaluation as either a mean quotient or maximum probability (Bay *et al.* 2007b, Ritter *et al.* 2007). These summary statistics integrate the effects of the mixture of chemicals present in each sample and have been shown to improve the predictive ability of empirical SQGs (Field *et al.* 2002, Long *et al.* 2006). The SQG approaches evaluated include:

National SQGs

Effects Range Median (National ERM)

The Effects Range Median (ERM; Long *et al.* 1995) represents the concentration above which adverse effects are frequently observed. This value corresponds to the 50th percentile (median value) of the distribution of chemical concentrations associated with adverse biological effects. The subset of National ERM values used in this study was the same as that used in other studies of ERM performance (Long *et al.* 2000). The mean ERM quotient was calculated for a sample by dividing each chemical concentration by its respective ERM and subsequently averaging the individual quotients.

Mean Sediment Quality Guideline Quotient 1 (SQGQ1)

The mean sediment quality guideline quotient 1 (SQGQ1) is based on a set of metal SQGs selected from ERM or PEL and consensus SQGs for PAHs and PCBs (Fairey *et al.* 2001). The suite of chemicals included in the SQGQ1 was selected by Fairey *et al.* to obtain high predictive ability with respect to the incidence of toxicity. The SQGQ1 quotient was calculated for a sample by dividing each chemical concentration by its respective SQG and subsequently averaging the individual quotients.

Consensus Midpoint Effect Concentration (Consensus)

The Consensus SQG approach is based on the integration of different SQG types. Consensus MEC values are the geometric mean of three or more SQGs that correspond to the same biological effect level. This study evaluated Consensus SQG values representing the midpoint effect concentration (MEC), an intermediate level of effect. Consensus values for PAHs and PCBs were obtained from Swartz (1999) and MacDonald et al. (2000), respectively. Values for DDTs, dieldrin, arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, and zinc were obtained from Vidal and Bay (2005). The mean Consensus quotient was calculated for a sample by dividing each chemical concentration by its respective SQG and subsequently averaging the individual quotients.

Logistic Regression Model (National LRM)

The Logistic Regression Model (LRM) approach was based on the statistical analysis of paired chemistry and amphipod toxicity data from studies throughout the U.S. (Field et al. 1999, 2002). A logistic regression model is developed for each chemical to estimate the probability of toxicity at a given concentration. LRM models for 18 chemicals having low rates of false positives were selected for use in this study. The LRM method does not establish specific concentration values for each chemical, but rather describes the relationship between

contaminant concentrations and the probability of toxicity. The maximum probability of effects obtained from the individual chemical models (P_{max}) was selected to represent the chemical mixture present in a sample (Field et al. 2002).

Regional SQGs

Regional chemical indicators were developed based on two national SQG approaches: ERM and LRM. Three versions of each regional indicator were developed: a statewide version that was calibrated to data from throughout California (CA ERM or CA LRM), and two region-specific versions. The region-specific versions were calibrated separately for northern California (NorCA ERM or NorCA LRM) and southern California (SoCA ERM or SoCA LRM) data sets.

CA ERM, SoCA ERM, NorCA ERM

Individual chemical values analogous to national ERMs were calculated using California data. The data were screened to select toxic samples (>20% mortality) with chemical concentrations >2x median concentration of nontoxic samples. After screening, the data were sorted in ascending order and the median concentration of each chemical was selected as the region-specific ERM value. CA ERM and So CA ERM values were calculated for 27 chemicals, and NorCA ERMs were calculated for 25 chemicals.

CA LRM, SoCA LRM, NorCA LRM

LRM models for individual chemicals were developed for the statewide and regional California data sets. The specific LRM models included in the CA LRM, SoCA LRM, and NorCA LRM approaches were selected from a library of candidate models that included national models as well as models derived using the California data sets. The selected models were chosen based on the goodness of fit with the observed probability of toxicity.

Mean Chemical Score Indicator (CSI)

The mean CSI is a new SQG developed for the SQO program that is based on the association between chemicals and the magnitude of benthic community disturbance (Ritter *et al.* 2007). Two types of data are combined to calculate the mean CSI: a set of predicted benthic community effects categories based on the individual chemical concentrations and a set of weighting factors reflecting the strength of association between the chemical and benthos response. The chemical values determining the benthic community effect categories were determined for each chemical by a statistical process that identified the chemical ranges producing the best agreement with the biological response categories. Each constituent's predicted effect level is then multiplied by its respective weighting factor to produce a CSI score. Individual CSI scores were combined as a weighted mean to represent chemical mixture effects.

The results of the SQG performance evaluations are described in Bay *et al.* (2007b) and Ritter *et al.* (2007) and summarized in Tables 5.6, 5.7, and 5.8. A regional SQG approach, the CA LRM, had the best ability to predict the toxicity of California sediments. Among the statewide-calibrated SQGs, the CA LRM ranked highest in all three performance measures (correlation, weighted kappa, % agreement). Some of the other statewide-calibrated SQG approaches performed similar to the CA LRM in some respects, but their performance was less consistent (Table 5.6). This study identified regional differences in SQG performance and found that the use of regional data to develop and calibrate SQGs produced a small, but inconsistent, improvement in performance (Table 5.7).

Table 5.6. Nonparametric Spearman Correlation (r) and Classification Accuracy of Statewide SQG Approaches for Amphipod Mortality

Region	Approach	Weighted Kappa	% Agreement	r
State	CA LRM	[illegible]	[illegible]	[illegible]
State	National ERM	0.17	32	0.25
State	Consensus	0.17	31	0.25
State	National LRM	0.15	[illegible]	0.22
State	CA ERM	0.17	[illegible]	0.20
State	SQGQ1	0.12	32	0.16

Note:
Values in the shaded cells are within the 90th percentile of the highest median value for the bootstrapped analyses. Analyses were conducted on the combined data for the north and south validation data sets and used thresholds calibrated statewide. (Table from Bay *et al.* 2007b)

Table 5.7. Classification Accuracy and Spearman Correlation of Regional SQG Approaches for Amphipod Mortality

Approach	Northern California			Southern California		
	Weighted Kappa	% Agreement	r	Weighted Kappa	% Agreement	r
Regional Calibration						
CA LRM	[illegible]	27	[illegible]	[illegible]	[illegible]	[illegible]
National ERM	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	0.28
Consensus	[illegible]	[illegible]	0.23	[illegible]	[illegible]	[illegible]
National LRM	[illegible]	[illegible]	0.15	[illegible]	[illegible]	[illegible]
CA ERM	[illegible]	[illegible]	0.22	0.13	33	0.18
SQGQ1	[illegible]	[illegible]	0.25	0.18	33	0.26
Nor/SoCA LRM	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	[illegible]
Nor/SoCA ERM	[illegible]	[illegible]	[illegible]	0.18	[illegible]	0.18

Note:
Values in the shaded cells are within the 90th percentile of the highest median value of the bootstrapped analyses. Analyses were conducted using thresholds for each region separately. (Table from Bay et al. 2007b)

Table 5.8. Classification Accuracy of CSI and Toxicity-based SQG Approaches for Benthic Community Condition

Region	Approach	Weighted Kappa	% Agreement
SoCA	CSI	0.44	52
SoCA	CA LRM	0.31	31
SoCA	National ERM	0.26	43

Note:
Analyses were conducted using thresholds and data for southern California. (Table from Ritter et al. 2007)

Different correlations with chemistry were obtained for toxicity and benthic condition, suggesting that these two indicators of biological effect are responding differently to contamination or other sediment characteristics. The new benthos-based CSI SQG had greater accuracy for predicting benthic community condition than did SQGs based on toxicity (Table 5.8). The results indicated that the accuracy and ecological relevance of chemical SQGs could be improved by incorporating benthic response data into SQG development.

Baseline—Sediment chemistry is typically evaluated by comparison to one or more national empirical SQGs, with little consistency in approach among regions.

Alternate 1: Establish narrative guidance.

Alternate 2: Use existing national empirical SQGs without consideration of actual predictive ability when applied to California data.

Alternate 3: Use either existing, regional, or new empirical SQGs derived from California data. Methodologies and thresholds for applications would be selected based upon how the approach performs within the SQO framework.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Section V.H. Presented in Appendix C is an example problem and solution based upon the proposed language.

5.4.5 Benthic Community

Benthic communities are found almost universally in aquatic soft sediments and are indicators of choice for monitoring and assessing anthropogenic effects for two main reasons. First, they possess many attributes considered desirable in indicator organisms, including limited mobility, diversity of organism types, life histories that are short enough to reflect recent changes in stressors, and direct exposure to sediment contamination. Second, they are important components of aquatic food webs, transferring carbon and nutrients from suspended particulates in the water column to the sediments by filter feeding and serving as forage for bottom-feeding fishes.

Despite these appealing characteristics, benthic infaunal monitoring data are maximally useful in a regulatory context only when they can be interpreted in relation to scientifically valid criteria or thresholds that distinguish "healthy" from "unhealthy" benthic communities. While reducing complex biological data to index values has disadvantages, the resulting indices remove much of the subjectivity associated with data interpretation. Such indices also provide a simple means of communicating complex information to managers, tracking trends over time, and correlating benthic responses with stressor data (Dauer *et al.* 2000, Hale *et al.* 2004).

During the past decade, several scientifically valid measures of marine and estuarine benthic community condition, often called benthic indices, have been developed for regulatory use. Benthic indices are increasingly accepted by regulators and incorporated into regulatory processes. The U.S. EPA's guidance for biocriteria development (Gibson *et al.* 2000) recognizes three types of benthic indices, and the agency included benthic assessments in a recent report on nationwide coastal condition to Congress (U.S. EPA 2004). In Maryland and Virginia, the Index of Biotic Integrity is one of the measures used to report on the condition of Chesapeake Bay waters under sections 305(b) and 303(d) of CWA. In California, the Relative Benthic Index (RBI) (Hunt *et al.* 2001) was one of the indicators used by the State Water Board to designate toxic hotspots (SWRCB 2004a) and the Benthic Response Index (BRI)(Smith *et al.* 2001, 2003 and Ranasinghe 2004 was applied by the San Diego Regional Water Board to

assess clean-up for three toxic hot-spots in San Diego Bay (Exponent 2002, SCCWRP and Space and Naval Warfare Systems Center San Diego 2004). Due to the presence of benthic communities in good condition as measured by the BRI and other reasons, Santa Monica Bay, which previously was listed as impaired under section 303(d) of the CWA due to sediment concentrations of six metals, was removed from the list in 2003. The BRI has also been used in southern California to assess the extent of bottom area supporting unhealthy benthic communities since 1994 (Bergen *et al.* 1998, Bergen *et al.* 2000, Ranasinghe *et al.* 2003).

5.4.5.1 Choice of Metrics Used to Support the Direct Effects SQO

There are several impediments to applying benthic indices statewide in California's bays and estuaries. First, several different habitats and benthic assemblages are present in California embayments, each of which requires metric development and calibration. Second, different benthic indices have been used in California at different times and different places, and results cannot be compared across regions because the various indices have not yet been rigorously compared and intercalibrated. Third, initial development of each existing benthic index was constrained by data limitations, and they would all benefit from refinement with additional data as well as independent validation. In addition, there is a lack of knowledge of the effects of differences in: (1) sampling procedures traditional in different regions, (2) habitat factors such as seasonality and sediment type, and (3) accuracy of identification of benthic organisms on performance of California benthic indices. As a result, significant work is required to develop benthic tools for all bays and estuarine habitats.

In order to select the appropriate benthic indices for this program, the technical team compared a number of indexes and combinations of indexes to a California data set validated by nine highly regarded benthic ecologists. This study is described in Ranasinghe *et al.* (2007) and consisted of the following tasks:

- Data for sampling sites in each of the two habitats were identified, acquired, and adjusted to create consistency across sampling programs.
- Five benthic indices were calibrated using a common set of data for all indices.
- Threshold values were selected for each index to assess benthic condition on a four-category scale.
- Performance of the indices and all possible combinations was evaluated by applying the calibrated indices to independent data and comparing the index condition assessments with benthic condition assessments of nine benthic experts.

The benthic indices evaluated in the study include:

Benthic Response Index (BRI), which was originally developed for the southern California mainland shelf and extended into California's bays and estuaries (Smith *et al.* 2001, 2003). The BRI is the abundance-weighted average pollution tolerance score of organisms occurring in a sample.

Index of Benthic Biotic Integrity (IBI), which was developed for freshwater streams and adapted for California's bays and estuaries (Thompson and Lowe 2004). The IBI identifies community measures that have values outside a reference range.

Relative Benthic Index (RBI), which was originally developed for California's Bay Protection and Toxic Cleanup Program (Hunt *et al.* 2001). The RBI is the weighted sum of: (a) several community metrics, (b) the abundances of three positive indicator species, and (c) the presence of two negative indicator species.

River Invertebrate Prediction and Classification System (RIVPACS), which was originally developed for British freshwater streams (Wright *et al.* 1993, Van Sickle *et al.* 2006) and adapted for California's bays and estuaries. The RIVPACS index calculates the number of reference taxa present in the test sample and compares it to the number expected to be present in a reference sample from the same habitat.

Benthic Quality Index (BQI)

The BQI was originally developed for the west coast of Sweden by Rosenberg *et al.* (2004) and applied in the United States for the first time in this project. The BQI is the product of the logarithm ($base_{10}$) of the total number of species and the abundance-weighted average tolerance of organisms occurring in a sample. Species tolerance scores are calculated differently than for the BRI; instead, they are based on relationships of the abundance distributions to Hurlbert's (1971) expected number of species.

Summary of Findings

Index performance was evaluated by comparing index assessments of 34 sites to the best professional judgment of nine benthic experts (Table 5.9). None of the individual indices performed as well as the average expert in ranking sample condition or evaluating whether benthic assemblages exhibited evidence of disturbance. However, several index combinations outperformed the average expert. When results from both habitats were combined, two four-index combinations and a three-index combination performed best.

Baseline—No methods have been approved or adopted by the Water Boards for the habitats under consideration. However, several tools have been applied by the Water Boards for the purposes of hot spot identification, water body assessment and site assessments. Those tools used most frequently in California are the BRI applied currently to embayments and nearshore waters south of Point Conception, (Ranasinghe et al. 2007a, 2007b), RBI used within the Bay Protection Program (Hunt et al. 1998, Hunt et al. 2001, Fairey et al. 1996) and IBI used in pilot studies in the San Francisco Bay Regional Monitoring Program (Davis, et al. 2006).

Alternative 1—Do not specify the methods.

Alternative 2—Select a single benthic index for all applicable water bodies.

Alternative 3—Select a combination of benthic indices for applicable water bodies.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A Section .V.G. Presented in Appendix C is an example problem and solution based upon the proposed language.

5.4.6 Integration of Direct Effects LOE Within Embayments

Sediment quality is frequently assessed using a triad of chemical concentration, sediment toxicity, and benthic infaunal community condition (Long and Chapman 1985). These are used in combination because sediments are a complex matrix and chemical concentration data alone fails to differentiate between the fraction that is tightly bound to sediment and that which is biologically available. Multiple approaches for integrating these multiple lines of evidence (MLOE) data have been developed (Chapman *et al.* 2002). These integration approaches mostly rely on a similar suite of indicators for each LOE, but differ in how the LOEs are combined into a single assessment. Some are based on combinations of binary responses for each LOE, while others use a more complex statistical summarization. Additionally, some

approaches weight the three LOEs equally, while others place differing weight among them. Even within an integration framework, thresholds need to be determined for each LOE. Consensus thresholds for these LOEs don't yet exist and these threshold decisions are particularly important when the integration is based on a binary decision for each LOE.

Table 5.9. Classification Accuracy and Bias for Indices and Index Combinations

No. of Indices	#	Measure	Southern California Bays (n=24)			Polyhaline San Francisco Bay (n=10)

		Maximum	87.5	+4, -3	100.0	100.0	+4, -2	100.0

Note:
Classification accuracy is presented for "undisturbed" vs. "disturbed" status and four condition categories. Each of 34 evaluation samples was assessed into one of four numeric categories by the index or index combination and compared with consensus categories from an independent assessment by nine benthic experts. Bias is the sum of differences between index combination and consensus categories; positive values indicate a tendency to score samples as more disturbed than the expert consensus, while negative values indicate a tendency to score samples as less disturbed. The categories were 1: Reference; 2: Marginal; 3: Affected; 4: Severely Affected. Categories 1 and 2 were considered "undisturbed" and 3 and 4 as "disturbed." Index results were combined as the median of the numeric categories; if the median fell between categories, it was rounded to the higher effect category. Means, minima and maxima for concordance between individual experts and the expert consensus are presented below to provide context for the index results. (Table from Ranasinghe et al. 2007a)

At present, no single, universally accepted method for interpreting triad data and classification of sediments based on an MLOE approach exists (Chapman *et al.* 2002; Wenning *et al.* 2005). Each regulatory or monitoring program uses an approach developed through their unique experience. As a result, most triad applications rely on some degree of best professional judgment (BPJ) (Burton *et al.* 2002, Chapman and Anderson 2005). Despite the many decisions inherent in integration of LOEs, BPJ has been found to be reasonably repeatable for interpretation of triad data (Bay *et al.* 2007c). Thus, BPJ can be an acceptable means of integration for site-specific assessments, but it is not easily applicable to large-scale assessments where many sites are involved. As discussed in Section 2, these approaches are rarely if ever applied within the context of a water quality control program.

Within a large and densely populated state like California, the utility of BPJ is limited for many reasons. Its use:

- May result in inconsistent decisions within a single region and from region to region.
- Can be time consuming and resource intensive.
- May not always lead to transparent and unbiased decisions.
- May not allow Regional Water Board staff, permittees, or interested parties to assess the outcome independently.

Logic systems are frequently used to integrate MLOE data; the sediment quality triad was one of the first examples of the use of a logic system to evaluate sediment quality data. Tabular decision matrices that provide an interpretation of various MLOE scenarios are used to apply a logic system. These logic systems are based on a transparent set of criteria used to infer the likelihood of causality for contaminant-related impacts and the system can accommodate various types of scoring systems within each LOE. The rules applied in a logic system can also be modified to reflect specific policy objectives or scientific assumptions, such as giving greater weight to benthic community disturbance relative to toxicity.

The State Water Board's technical team developed a logic-based framework for integrating MLOE to make a station level determination of the likelihood of biological effects due to sediment contamination (Bay and Weisberg 2007). This system was developed in consultation with a stakeholder advisory committee and an independent scientific steering committee. The framework for integrating the three lines of evidence (LOE) to create a station assessment involves a three-step process (Figure 5.2). First, the response for each LOE is assigned into one of four response categories: 1) no difference from background conditions, 2) a small response that might not be statistically distinguishable from background conditions, 3) a response that is clearly distinguishable from background, and 4) a large response indicative of extreme conditions.

Second, the individual LOEs are combined to address two key elements of a risk assessment paradigm: 1) Is there biological degradation at the site and 2) Is chemical exposure at the site high enough to potentially result in a biological response? To answer the first question, the benthos and toxicity LOE are integrated to assess the severity of effect (Table 5.10). Benthos is given greater weight in this assessment, as it is the ultimate endpoint of interest (Chapman 2007). The second question arises because the biological response may be attributable to factors other than chemical contaminants. The potential that effects are chemically mediated is assessed using the sediment chemistry and toxicity LOEs (Table 5.11). Chemistry is the more direct measure, but toxicity is also included in this step because of the potential that unmeasured chemicals are present and because of uncertainties in thresholds used to interpret chemical data (Ingersoll *et al.* 2005).

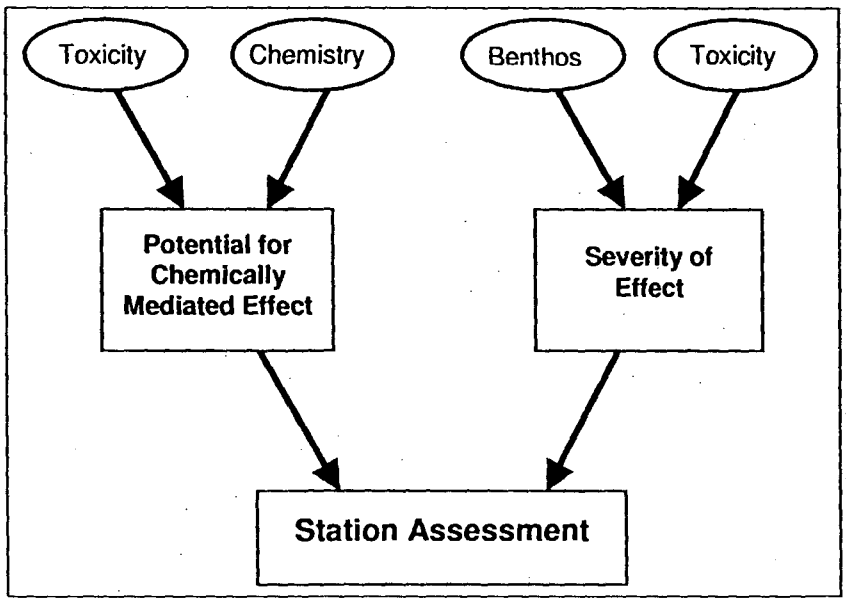

Figure 5.2. Schematic of Multiple Lines of Evidence (MLOE) Integration Framework

Table 5.10. Severity of Effect Classifications, Derived from Benthos and Toxicity LOE

		Toxicity			
		Nontoxic	Low Toxicity	Moderate Toxicity	High Toxicity
Benthos	Reference	Unaffected	Unaffected	Unaffected	Low effect
	Low disturbance	Unaffected	Low effect	Low effect	Low effect
	Moderate disturbance	Moderate effect	Moderate effect	Moderate effect	Moderate effect
	High disturbance	Moderate effect	High Effect	High Effect	High Effect

Table 5.11. Potential that Effects Are Chemically-Mediated Categories, Derived from Chemistry and Toxicity LOE

		Toxicity			
		Nontoxic	Low Toxicity	Moderate Toxicity	High Toxicity
Chemistry	Minimal exposure	Minimal potential	Minimal potential	Low potential	Moderate potential
	Low exposure	Minimal potential	Low potential	Moderate potential	Moderate potential
	Moderate exposure	Low potential	Moderate potential	Moderate potential	Moderate potential
	High exposure	Moderate potential	Moderate potential	High potential	High potential

The final data integration step combines the severity of effect and potential for chemically mediated effects to assign a site into one of six impact categories:

- ***Unimpacted***—Confident that sediment contamination is not causing significant adverse impacts to aquatic life living in the sediment at the site.
- ***Likely Unimpacted***—Sediment contamination at the site is not expected to cause adverse impacts to aquatic life, but some disagreement among the LOE reduces certainty in classifying the site as unimpacted.
- ***Possibly Impacted***—Sediment contamination at the site may be causing adverse impacts to aquatic life, but these impacts are either small or uncertain because of disagreement among LOE.
- ***Likely Impacted***—Evidence for a contaminant-related impact to aquatic life at the site is persuasive, even if there is some disagreement among LOE.
- ***Clearly Impacted***—Sediment contamination at the site is causing clear and severe adverse impacts to aquatic life.
- ***Inconclusive***—Disagreement among the LOE suggests that either the data are suspect or that additional information is needed before a classification can be made.

The decision process for determining the station assessment category is based on a foundation that there must be some evidence of biological effect in order to classify a station as impacted (Table 5.12). Additionally, there must be some evidence of elevated chemical exposure in order to classify a station as chemically impacted.

Table 5.12 Multiple lines of evidence station classifications.

		Severity of Effect			
		Unaffected	Low Effect	Moderate Effect	High Effect
Potential that effects are chemically-mediated	Minimal potential	Unimpacted	Likely unimpacted	Likely unimpacted	Inconclusive
	Low potential	Unimpacted	Likely unimpacted	Possibly impacted	Possibly impacted
	Moderate potential	Likely unimpacted	Possibly impacted or Inconclusive*	Likely impacted	Likely impacted
	High potential	Inconclusive	Likely impacted	Clearly impacted	Clearly impacted

* Inconclusive category when chemistry = minimal exposure, benthos = reference, and toxicity= high.

The efficacy of the framework was assessed by applying it to data from 25 sites and comparing the site classifications to that of six experts that were provided the same data. The framework produced an answer that better matched the median classification of the experts than did five of the six experts (Table 5.13). Moreover, there was little bias in response, as the errors were relatively evenly divided between sites classified as more impacted or less impacted than the median expert classification. The framework was also applied and found to distinguish well sites from known degraded and reference areas within California.

Table 5.13. Summary of Categorical Assessments for Each Expert

	Expert 1	Expert 2	Expert 3	Expert 4	Expert 5	Expert 6	Framework
# Sites	25	22	25	19	25	22	25
Disagreement	6	16	13	10	14	5	6
Bias	4	-14	12	7	-14	-1	2

Note:
Differences in the number of sites are due to the exclusion of sites classified as inconclusive. Disagreement values represent the total number of category differences between the expert's assessment and the median of all other experts' assessments. Bias values reflect the net of positive or negative assessment differences, with positive numbers indicating a bias toward rating the site as more impacted.

Baseline—MLOE is integrated based upon BPJ on a case-by-case basis.

Alternative 1—Support an approach based upon BPJ. As described above, using BPJ does provide some consistency when highly experienced sediment quality scientists are making the assessment, however discrepancies still occur. Water Board staff do not currently have the same level of expertise. A lack of qualified staff would limit the ability to implement this alternative

Alternative 2—Select an integration method that is based upon a transparent logic-based framework that has been evaluated for accuracy relative to experts and is supported by independent scientific peer review.

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Section VII. I. Presented in Appendix C is an example problem and solution based upon the proposed language.

5.5 Indicators Applicable in Estuarine Habitats

5.5.1 Potential Interim Tools and Methods for the Delta and Other Estuaries

The State Water Board initiated development of SQOs in 2003 in order to comply with Water Code section 13393 and a court-ordered compliance schedule (See Section 1.2). The schedule required the State Water Board to circulate draft objectives and an implementation policy by August 2006 and to approve and submit the package to the Office of Administrative Law by February 2008.

Section 13393 requires the State Water Board to develop SQOs for bays and estuaries of California. As described in Section 2.2, the State Water Board's Phase I effort focused on those water bodies where chemical and biological data were available to develop indicators and tools to assess sediment quality. Only within southern California bays and most of San Francisco Bay were enough data available to evaluate exposure and effects relationships. Most estuaries including the Sacramento-San Joaquin Delta have not been monitored routinely to assess the impact of toxic pollutants to sediment dwelling organisms; therefore, very little combined effects and exposure data exist within these water bodies. Where data is available, it often consists of only one to three data points. Clearly, the robust data sets required to assess the relationship between exposure and biological effects to benthic communities are far too sparse for the development of assessment tools.

Generally, the type of data required would consist of sediment chemistry-sediment toxicity and benthic community data that encompasses the range of pollutant impacts expected within

these water bodies. With such a data set, effects measures such as toxicity and community degradation can be assessed relative to pollutant loading and other disturbances. This is the general approach that has been applied to develop SQOs within California's embayments and is supported by the SQO Scientific Steering Committee. Although the State Water Board recognizes the need to collect additional data and provide funding to achieve this goal, the technical team will not have the data necessary to complete the appropriate analyses until 2008. As a result, there is a need to consider other interim options in order to comply with the court's decision.

Single LOE Chemistry or Toxicity

The State Water Board could propose the use of Sediment Chemistry Guidelines (SQGs) such as the ERMs (See Section 5.5.3.2) or apparent effects thresholds as a single LOE indicator of sediment quality in estuaries. SQGs are existing chemical thresholds that have been applied to assist managers when making decisions about sediment quality. Some of these approaches were developed in part from estuarine data. This approach would require little or no resources to prepare as existing sediment thresholds could be proposed and could be applied to determine whether sediment exceeds the narrative objective. As stated previously, there are significant problems when this LOE is used without the benefit of the other LOE.

Sediment toxicity could be proposed as a stand-alone tool for the assessment of sediment quality. There are two species within the proposed embayments suite of toxicity test methods that tolerate the salinity range of some estuarine waters. However, additional test methods need to be selected and calibrated in order to apply the recommended combination of acute and sublethal toxicity tests at most sites. As described above, this approach could be applied to determine whether sediment exceeds the narrative objective described in Section 2.11, or a toxicity-specific narrative objective could be proposed. Sediment toxicity has been applied within many different water bodies; however, similar limitations persist with this tool as well. The use of toxicity tests without other LOE would increase the likelihood of underestimating sediment that is due to seasonal events or contaminants that require chronic exposure to produce an adverse effect. Confounding factors and uncertainty also limit the ability to use this single LOE to assess sediment quality.

Combination of Sediment Chemistry and Toxicity

Sediment chemistry and toxicity could be integrated into a two-line of evidence approach. This approach would provide greater confidence in the assessment compared to a single LOE approach. However, the selection of appropriate thresholds would be difficult. Thresholds could be adopted from those proposed for sediment chemistry and toxicity in embayments. However, there may be little or no correlation between organism response in embayments and that in estuaries. The toxicity and chemistry lines of evidence could be interpreted relative to site-specific reference sites, providing only two possible outcomes for each LOE: good or bad. However, determination of reference sites is often contentious and typically requires a large amount of data to support the hypothesis. This approach gives more flexibility and responsibility to local agencies, and may be inconsistently applied.

The State Water Board would need to establish some thresholds to implement the two LOE approach in order to reduce the use of BPJ, which does not promote statewide consistency and promotes adversarial science. While it may not be possible to develop multiple thresholds that provide the same level of discrimination as those being developed for embayments, the

State Water Board could provide thresholds that would enable a manager to respond quickly to relatively high level of effects.

This approach would be developed based on the following considerations.

- Develop an integration approach that accounts for greater uncertainty associated with application in estuaries.
- Utilize fewer categories of effect or exposure to reflect present lack of knowledge.
- May require a greater number of inconclusive categories for situations where LOE are not in agreement, additional data collection (e.g., benthos) or analysis is needed before an assessment can be made. Current embayment chemical indicators and thresholds have not been validated for use in estuaries, and as a result may not be accurate or effective.
- Additional toxicity test methods that are compatible with freshwater (e.g., *Hyallella azteca* survival test and *Chironomus dilutus* growth test) may be needed, depending on salinities at time of collection.

Three LOE: Chemistry, Toxicity and Benthic Community

A more rigorous approach would be to use the sediment quality triad as it has been applied traditionally in areas where little prior sediment quality information was available. In this case, two independent data sets of chemistry, sediment toxicity and benthic community measures are required. The first data set would define the baseline conditions or reference envelope for the area of interest. A second data set would contain the sediment quality measures in the area of interest. Data from each line of evidence would be compared to the baseline data if adequate thresholds for data interpretation were not available. Statistically significant differences relative to the reference envelope among two of the three lines of evidence would trigger an impacted designation for the study site. This approach is consistent with the overall conceptual approach and underlying philosophy of the embayments approach and has been applied throughout the country.

Table 5.14. Potential Measures for LOE Evaluation in Estuaries

LOE	Measures	Comparison Value
Chemistry	Existing analyte list plus other chemicals of concern	Reference envelope or SQGs
Sediment Toxicity	Survival – *Hyalella azteca* Growth – *Chironomus dilutus*	Reference envelope or numeric threshold from similar programs
Benthic Community	Benthic macrofauna identification and abundance	Reference envelope

The sediment quality triad is commonly applied to assess sediment quality in habitats when little is known about the biological and toxicological characteristics of the study area. This approach requires an even greater use of BPJ compared to the two LOE approach. BPJ would be required to decide which measures to use, what thresholds or reference envelope to compare the results against, and how to integrate the LOE. The need to collect additional data in order to establish a reference envelope may also increase the cost and complexity of monitoring programs.

Baseline—Not applicable.

Alternative 1—Do not propose any tools for implementing the narrative SQOs until data is collected in Phase II, and the technical team has the time to develop appropriate tools.

Alternative 2—Propose the use of a single LOE for delta waters.

Alternative 3—Propose using sediment toxicity and chemistry to implement the narrative objective. The Scientific Steering Committee was critical of this approach.

Alternative 4—Propose using the sediment quality triad (chemistry, toxicity, benthic community condition) to implement the narrative objective. Additional development and evaluation will be required before a detailed approach is proposed.

Staff Recommendation—Alternative 4.

Proposed Language—See Appendix A, Section .V.J.

5.5.2 Sunset Date for Interim Tools

Some stakeholders have expressed concern that the State Water Board could adopt interim tools for the Delta and other estuaries without providing any guarantee that these tools will not be replaced by more fully developed implementation measures scheduled for development under Phase II. Although the State Water Board provided additional funding to develop Phase II tools, there is always some uncertainty associated with future planning efforts.

Baseline—Not applicable.

Alternative 1—Do not provide sunsetting language in Part 1 for the water bodies with less robust tools.

Alternative 2—Provide language that sunsets interim implementation tools if the State Water Board has not developed more robust tools by a specific date.

Alternative 3—Provide language in the resolution adopting Phase I that the State Board will revisit the interim implementation tools in Phase II

Staff Recommendation—Alternative 3.

5.6 Protective Condition

While proposing six categories to describe the condition of sediments provides for greater understanding of the sediment quality in a water body, the proposed Part 1 must define what categories are considered protective or degraded in order to fit the binary (pass/fail) model applied within all current regulatory programs. Section 13391.5(d) of Porter Cologne provides some guidance stating that the SQOs must be established with an adequate margin of safety for the reasonable protection of the beneficial uses of water. Defining what is protective versus what is considered the unprotective or degraded condition must meet this requirement.

As described previously, the six categories are:

- ***Unimpacted***—Confident that sediment contamination is not causing significant adverse impacts to aquatic life living in the sediment at the site.
- ***Likely Unimpacted***—Sediment contamination at the site is not expected to cause adverse impacts to aquatic life, but some disagreement among the LOE reduces certainty in classifying the site as unimpacted.

- ***Possibly Impacted***—Sediment contamination at the site may be causing adverse impacts to aquatic life, but these impacts are either small or uncertain because of disagreement among LOE.
- ***Likely Impacted***—Evidence for a contaminant-related impact to aquatic life at the site is persuasive, even if there is some disagreement among LOE.
- ***Clearly Impacted***—Sediment contamination at the site is causing clear and severe adverse impacts to aquatic life.
- ***Inconclusive***—Disagreement among the LOE suggests that either the data are suspect or that additional information is needed before a classification can be made.

Most would agree that from the definitions, *Unimpacted* would describe a protected condition while *"Clearly Impacted"* would represent a highly degraded condition. These two cases are the easiest to classify confidently as a result of strong concordance amongst all three LOE. The next two cases; *"Likely Unimpacted"* and *"Likely Impacted"* represent the protective and degraded condition albeit with a lower level of confidence as a result of some disagreement among the LOE, however within these categories, two of the LOE are compelling. The middle category designated *"Possibly Impacted"* represents the greatest uncertainty and disagreement amongst the LOE of the categories. Stations within this category may be either unimpacted or impacted.

There are five possible options that could be applied to provide a binary determination: Three of these options are considered below.

1. Protected sediments could be defined as those sediments within the *"Unimpacted"* Category only. All other categories would be considered as not representing the protective condition. This would represent a very conservative approach but does provide for an adequate margin of safety.
2. Protected sediments could be defined by the categories *"Unimpacted"* and *"Likely Unimpacted"*. All other categories would be considered as not representing the protective condition. This option also provides for a margin of safety as the next category *"Possibly Impacted"* indicates that there would be more sites in this category that are unimpacted then actually impacted.
3. Protected sediments could be defined by the categories *Unimpacted, Likely Unimpacted and Possibly Impacted.* All other categories would be considered as not representing the protective condition. While the *Possibly Impacted* category only suggests the possibility of the station being impacted, there is lower confidence that sediment quality at this site is protective relative to the proposed narrative objective.

Baseline—MLOE assessments applied sediment quality are typically decided by best professional judgment.

Alternative 1—Protected sediments could be defined as those sediments within the *"Unimpacted"* Category only.

Alternative 2—Protected sediments could be defined by the categories *"Unimpacted"* and *"Likely Unimpacted"*.

Alternative 3—Protected sediments could be defined by the categories *Unimpacted, Likely Unimpacted and Possibly Impacted*

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A Section .V.I and J.

5.7 Application of Proposed within Specific Programs

As explained in Section 4, the Basin Plans for all of the coastal Regional Water Boards contain water quality standards, including narrative water quality objectives, that apply to sediment quality in bays and estuaries. Under existing law, these standards are implemented through several regulatory programs. The standards are implemented in NPDES permits regulating the point source discharges and in waste discharge requirements, conditional waivers or prohibitions for nonpoint source discharges to bay and estuarine waters. The standards also provide the basis for enforcement actions, including cleanup and abatement activities, and for water quality certifications under Clean Water Act section 401. Bay and estuarine waters that do not meet the standards must be listed under Clean Water Act section 303(d), and appropriate TMDLs must be developed to attain the standards.

The proposed SQOs will add an objective that specifically addresses sediment quality in the coastal regions. The narrative SQOs and implementation tools were developed to assess whether pollutants in sediments pose a risk or are causing or contributing to the degradation of ecologically important and sensitive sediment dwelling organisms directly exposed to the pollutants in sediment. As a result, the SQO and tools will provide a robust measure of ambient sediment quality that directly relates to beneficial use protection.

The proposed SQOs will be implemented under the existing regulatory programs described in Section 4. This Section describes how the proposed SQOs could be implemented within these programs.

5.7.1 Applicability to Sediment Cleanup Actions

Part 1 could be applied to support site cleanup actions if the receptors addressed in Part 1 are consistent with those at risk. . Receptors that may be exposed include benthic invertebrates, fish, birds, marine mammals and humans through consumption of fish tissue. As a result human health and ecological risk assessments are used to both assess risk and assist in the derivation of receptor specific cleanup goals. The SQOs and supporting tools could be applied to determine what sediments within a specific area are protected or degraded for benthic communities. Stressor identification and development of site-specific management guidelines could also be applied to address potential cleanup actions focused on benthic communities.

As discussed in Section 4.2.2, Resolution *No. 92-49, "Policies and Procedures for Investigation and Cleanup and Abatement of Discharges Under Water Code Section 13304,* could be incorporated into Part 1 which encompasses both the investigation and development of cleanup goals. Under 92-49, cleanup levels range from background to the best water quality that is reasonable, but not to exceed applicable water quality standards. Development of biology based site-specific sediment management guidelines would assist Regional Boards in complying with this policy.

Baseline—Regional Water Boards require human health and/or ecological risk assessments to assess the exposure to all receptors. The relative risks posed to each receptor are calculated to determine which receptors are most sensitive to the pollutants of concern.

Alternative 1—Apply 92-49 to cleanups of sites not meeting the SQOs. Under 92-49, cleanup levels range from background to the best water quality that is reasonable, but not to

exceed applicable water quality standards. Stressor identification and development of site-specific sediment management guidelines could support this effort.

Alternative 2—Prepare language describing how and when the SQOs could be applied to cleanup actions. This policy could be applied to assist in characterizing risk at cleanup action sites when the receptors of interest, the exposure type, and scale of effort are identical or similar to those protected by this policy. The exposure receptor scenarios not protected by this policy would need to be evaluated using ecological and human health risk assessment guidance such as that prepared by the Department of Toxic Substances Control (DTSC), the Office of Environmental Health Hazard Assessment (OEHHA), and U.S. EPA.

Staff Recommendation—Alternative 1.

Proposed Language—See Appendix A, Section VII.G.

5.7.2 Applicability to dredged materials management

Water Code section 13396 states that the State and Regional Water Boards shall not grant approval for a dredging project that involves the removal or disturbance of sediment that contains pollutants at or above the (SQOs) established pursuant to Section 13393 unless the Water Boards determine all of the following:

(a) the polluted sediment will be removed in a manner that prevents or minimizes water quality degradation.

(b) polluted dredge spoils will not be deposited in a location that may cause significant adverse effects to aquatic life, fish, shellfish, or wildlife or may harm the beneficial uses of the receiving waters, or does not create maximum benefit to the people of the State.

(c) the project or activity will not cause significant adverse impacts upon a federal sanctuary, recreational area, or other waters of significant national importance.

California SQOs for enclosed bays and estuaries are being developed to protect sensitive aquatic organisms and other beneficial uses from the adverse effects of exposure to pollutants present in in-place surficial sediments. Section 13396 makes it clear that SQOs apply to dredged material. However, Section 13396 also allows dredged material that exceeds SQOs to be approved for discharge into waters of the State of California when conditions (a)-(c) are met. One difficulty is that some of the procedures used by California to determine the SQOs are not technically applicable to sediments below the biologically active layer (e.g., benthic community analysis). Dredged material, however, is typically composed *primarily* of sediments from below the biologically active layer. In addition, some of the test species used to determine the California SQOs are not necessarily appropriate to use for dredged material testing in all cases. The federal evaluation procedures discussed below were specifically developed to characterize the full spectrum of dredged material (not just surface sediments) in order to determine suitability for aquatic discharge in a variety of disposal or placement scenarios. Furthermore, the federal procedures emphasize conducting these dredged material evaluations in a nationally consistent manner.

Under the authority of the CWA and the Marine Protection, Research, and Sanctuaries Act (MPRSA), and their implementing regulations, the USACE and U.S. EPA jointly developed national testing guidance manuals for dredged material (the Inland Testing Manual or ITM for non-ocean waters, USACE and U.S. EPA 1998; and the Ocean Testing Manual or OTM for ocean waters, USACE and U.S. EPA 1991). These manuals utilize a tiered, effects-based evaluation scheme to determine the suitability of dredged material for aquatic placement or disposal. Each

of these national sediment-testing manuals is implemented under a national Technical Framework for Dredged Material Management ("Framework") also jointly published by the USACE and U.S. EPA. (1992). The purpose of the Framework is to facilitate consistency in how the sediment evaluation procedures are applied within and between various areas of the United States. In addition, the Framework describes the broader regulatory context within which sediment evaluations conducted under the ITM or OTM are carried out so as to meet the overall goals of the CWA and MPRSA. In particular, under the Framework, suitability determinations for aquatic discharge of dredged material take into account not only the technical sediment test results from the ITM or OTM, but also the characteristics of the individual disposal sites and the practicability of alternatives to aquatic disposal (including beneficial reuse alternatives).

Certain other federal programs that otherwise address contaminated sediments generally defer to this Framework when it comes to management of dredged material. For example, in U.S. EPA Region 9, U.S. EPA regularly allows navigation dredging to continue within the boundaries of sediment remediation study areas for projects in the Remedial Investigation/Feasibility Study (RI/FS) stage under the Comprehensive Environmental Recovery, Cleanup, and Liability Act (CERCLA), provided that the dredged material is first specifically evaluated under the Framework, and its discharge is managed under a CWA Section 404 or MPRSA Section 103 permit. Similarly, at the national level, U.S. EPA excluded dredged material from the definition of hazardous waste under Subtitle C of the Resource Conservation and Recovery Act (RCRA), when it is subject to a CWA Section 404 or MPRSA Section 103 permit. As U.S. EPA noted in the Hazardous Remediation Waste Management Requirements (HWIR-Media) Final Rule (U.S. EPA 1998A):

> "Dredged material that is subject to the requirements of a permit that has been issued under 404 of the Federal Water Pollution Control Act (33 U.S.C.1344) or section 103 of the Marine Protection, Research, and Sanctuaries Act of 1972 (33 U.S.C. 1413) is not a hazardous waste."
>
> "Testing procedures under the CWA and MPRSA ... are better suited to the chemical and biological evaluation of dredged material disposed of in the aquatic environment. These tests are specifically designed to evaluate effects such as the potential contaminant-related impacts associated with the discharge of dredged material into oceans and waterways of the United States. The Agency believes that the CWA and MPRSA permit programs protect human health and the environment from the consequences of dredged material disposal to an extent that is at least as protective as the RCRA Subtitle C program. These programs incorporate appropriate biological and chemical assessments to evaluate potential impacts on water column and benthic organisms, and the potential for human health impacts caused by food chain transfer of contaminants. As improved assessment methods are developed, they can be incorporated into these procedures. The programs also make available appropriate control measures (for example, 40 CFR 230.72) for addressing contamination in each of the relevant pathways."

Under the federal Framework (USACE and U.S. EPA, 1992) the ITM and OTM provide for application of relevant chemical sediment quality criteria (SQC) or Sediment Quality Standards (SQS) issued by U.S. EPA or by a state, respectively, as screening step in "Tier I" or "Tier II" of their evaluation procedures. Exceedance of SQC or SQS indicates the need for direct effects-based testing at a higher tier. Any numeric chemical SQOs that California promulgates could be applied in this manner. Section 13396 provides that even when California SQOs are exceeded, dredging and discharge may still be allowed when conditions (a)-(c) are met. As described

below, the higher-tier evaluation procedures of the ITM or OTM, and other considerations of the CWA and MPRSA as described in the Framework, provide an appropriate and consistent basis for the State to determine whether conditions (a)-(c) have in fact been met.

Condition (a) requires that the polluted sediment will be removed in a manner that prevents or minimizes water quality degradation. This condition focuses on the dredging (or removal) site itself, as opposed to the dredged material disposal site. It is addressed by any Best Management Practices (BMPs) or special conditions, incorporated in the dredging permit(s) or other authorizations, that federal or State agencies (including the State and Regional Water Boards) determine to be necessary for the protection of water quality and beneficial uses. These may include monitoring; constraints on dredging equipment type; operation; and timing, control technologies such as silt curtains, etc. The federal evaluation Framework generates specific information relevant to making determinations about the need for any controls at the dredging site, via physical-chemical characterization and via the water column (suspended-liquid phase) bioassays conducted on dredged material samples.

Condition (b) focuses on the discharge of dredged material at the disposal or placement site. The evaluation procedures in the ITM and OTM were specifically designed to address each of the relevant pollutant exposure pathways that may be associated with dredged material discharges at aquatic disposal sites. These procedures provide for the comprehensive physical, chemical, and biological evaluation of the specific sediments to be dredged and discharged. Biological testing includes both liquid-suspended phase and solid phase sediment testing using appropriately sensitive indicator organisms that cover a range of functional feeding types. There is flexibility to use appropriate species for different dredged material types and situations. When necessary, information from the bioaccumulation tests can be readily used to assess the environmental risk of food web transfer of pollutants to different trophic levels. The national testing manuals also provide for updating the specific tests used; for example, to include regionally important species or as more sensitive tests (possibly including chronic/sublethal assays) are developed sufficiently for reliable regulatory use nationwide.

Another important consideration is that dredged material that may pose a risk at a particular disposal site or when managed in a particular manner, may not pose such a risk at a different disposal site or if managed in a different manner. The overall federal Framework incorporates CWA and MPRSA provisions that ensure suitable determinations take into account all relevant sediment-specific and disposal site-specific factors, and any management actions necessary to minimize adverse impacts. SQOs as stand-alone factors cannot do this.

Condition (c) is consistent with already existing requirements of the CWA and MPRSA programs. In particular, the USACE generally may not authorize the discharge of dredged (or fill) material into waters of the United States that would cause the kinds of impacts listed in 40 C.F.R. §230.10, including significant impacts to designated marine sanctuaries, whether such impacts are caused by pollutants associated with the sediments or simply by the physical discharge of the sediments. In addition, the CWA program focuses on identifying and, to the maximum extent possible, avoiding impacts to "aquatic resources of national importance."

Baseline—USACE, under the authority of the federal CWA and MPRSA and in coordination with U.S. EPA, prepared the ITM (USACE and U.S. EPA 1998) and the OTM (USACE and U.S. EPA 1992) to address the suitability of dredged material for disposal. These manuals are not intended to assess in-place sediments; rather, these methodologies were designed to assess potential effects that may occur during or after disposal of the dredged materials. At the regional level, USACE, U.S. EPA, State Water Board staff, and staff from other State agencies have also prepared water body specific guidance and formed dredged materials management teams to streamline the onerous multi-jurisdictional regulatory process (USACE et al., 2001).

Alternative 1—SQOs should be applicable to dredged material. The proposed SQOs could be applied to dredged materials; however, collection of this information would not eliminate the need to perform the suitability tests described in the ITM or the OTM in accordance with the federal CWA or MPRSA.

Alternative 2—SQOs should not be applicable to dredged materials. These SQOs and supporting tools were intended to evaluate beneficial uses protection and, as a result, only focus on the in-place biologically active layer. The Dredged Materials program was designed to measure average bulk properties of sediment to determine both the appropriate method of disposal or reuse and assess potential effects caused by the dredging and disposal action. While some tools are similar, the application and implementation of the tools differs significantly.

Alternative 3—SQOs would only apply under specific conditions specified in section 13396.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Section VII.A.

5.7.3 Applicability to 303(d) Listings

As explained in Section 4.2.1 of this report, the State Water Board's Section 303(d) Listing Policy currently provides that a water segment shall be placed on the list if the segment exhibits statistically significant sediment toxicity based on a binomial distribution. The segment must be listed if the observed sediment toxicity is associated with a pollutant. The segment may also be listed for toxicity alone. The Section 303(d) Listing Policy predates Part 1; consequently, the policy does not specifically address listings based on the proposed SQOs.

A multi-station assessment tool will integrate the results of many single station assessments into a single watershed-based or water body assessment. This tool will help determine whether the water body is consistent with the narrative SQOs. The proposed MLOE approach uses evidence from chemistry, toxicity, and the benthic community structure to make a single station assessment. At each station, sediment quality will be categorized into one of five ordered categories: "unimpacted" "likely unimpacted" "possibly impacted" "likely impacted" "clearly impacted." This type of ordinal data is interpretable in terms of its arrangement in a given order, e.g., from lowest to highest.

Results measured on an ordinal scale, however, may limit the types of appropriate statistical methods that can be applied during a multi-station assessment. Nonparametric methods are usually used with ordinal data, while parametric methods are usually used with interval or ratio data (Stevens 1946). Some researchers, however, have concluded that treating ordinal data as if they were interval data is unlikely to lead to improper conclusions (Gardner 1975). The following is a list of preliminary ideas for statistical tests that could be used to assess multiple station sediment data:

- ***Tests of Exceedance***—Convert each single station assessment into binary yes-or-no type data value. A water body would then be characterized by a count of the number of exceedances and the number of non-exceedances. A binomial test can then be used to determine if the proportion of exceedances is significantly excessive. This is the approach taken in the State's current 303(d) Listing Policy (SWRCB 2004) for listings based on exceedances of numeric criteria or objectives for toxic pollutants. This approach does not consider the magnitude of the exceedance. For this alternative, it is important to understand that the application of SQOs cannot supersede all sediment listing criteria for several reasons
  - There are many waterbodies where SQOs do not apply, such as rivers, lakes, and ocean waters.
  - The SQOs were not developed to assess exposure associated with "non" priority pollutants
  - The SQOs were not developed to explicitly protect receptors such as fish, birds, marine mammals and the bioaccumulation from sediment up the aquatic food chain
- ***Goodness of Fit Tests***—The observed frequencies in each assessment category are compared to frequencies expected in each category under a specified null distribution. Sufficiently large deviations from the expected frequencies will support the conclusion that the data did not come from the hypothesized distribution. Chi-squared and Kolmogorov-Smirnov one-sample goodness-of-fit tests are examples. This option does not fully utilize the ordinal scale of the data.
- ***Tests of Location***—These tests work by subjectively assigning numeric integer values to ordinal data. For example, a value of 1 is assigned to stations classified as "unimpacted," a value of 2 is assigned to stations classified as "likely unimpacted," and so on. A one-sample parametric *t*-test can be used to test for a significant difference between the observed mean and the hypothesized mean. Similarly, a one-sample non-parametric Wilcoxon signed rank test can be used to test for a significant difference between the observed median and the hypothesized median. These tests of location account for magnitude.

Alternative 1—Do not consider the SQOs for listing purposes.

Alternative 2—Utilize an approach that is consistent with the approach for listing waters based on exceedances of numeric criteria or objectives for toxic pollutants, which is described in 303(d) listing policy (SWRCB 2004) and under a. above.

Alternative 3—Evaluate a variety of approaches such as b and c described above for applying SQOs to the listing process.

Staff Recommendation—Alternative 2. Under this alternative, the Water Boards will continue to list water segments for sediment toxicity under the current Section 303(d) Listing Policy, unless the listing is due to exceedance of the aquatic life SQOs in Part 1 in bays or estuaries. In the latter case, listings will follow the approach described in a. above. The State Water Board may reconsider the Section 303(d) Listing Policy, if appropriate, in the future to further address listings for sediment toxicity.

Proposed Language—See Appendix A Section VII.E.8.

5.7.4 Applicability to NPDES Permits

In general, under the Clean Water Act and implementing regulations, water quality objectives are typically translated into effluent limits when the discharge of specific pollutants has the "reasonable potential" to cause or contribute to water quality standards exceedances. In assessing reasonable potential, the permitting authority can consider a variety of factors and information. The State Water Board's SIP contains specific requirements for determining the need for numeric effluent limitations regulating the discharge of priority toxic pollutants. Additional guidance on determining reasonable potential is found in U.S. EPA's Technical Support Document for Water Quality-based Toxics Control (1991).

During the late 1980's, the State Water Board assessed the relationship between sediment deposition, pollutant loading, and effluent quality (Hendricks 1990) in an attempt to develop a process for deriving sediment-based effluent limits. The Washington Department of Ecology developed similar tools to calculate effluent limits based upon chemical concentrations in sediments within Puget Sound (Bailey 2005). Application of these tools to derive effluent limits has been limited for several reasons.

- Chemical concentrations in sediment do not represent the bioavailable fraction.
- Chemical thresholds are not based upon causal association.
- Pollutants discharged undergo chemical processes that vary depending upon the chemistry and physical properties of the effluent and receiving water.
- Sediment fate and transport must be well characterized.

In appropriate cases, water quality objectives can also be implemented in NPDES permits as receiving water limits. Receiving water limits are typically used when the water quality objective cannot be directly translated to effluent limits or when there is a clear need to monitor compliance within the receiving water. Examples include biological narratives and bacteria receiving water limits described in the California Ocean Plan (SWRCB, 2005).

Because it is not feasible at the present time to directly translate the SQOs into numeric effluent limits, the SQOs and implementation tools can be implemented as receiving water limits in NPDES permits. Receiving water limits should be included in permits if sediment quality in the vicinity of a permitted discharge to a bay or estuary is potentially at risk due to toxic pollutants in the discharge. In determining the need for receiving water limits, the Water Boards will have to use BPJ and consider all available and relevant information. This could include the location and characteristics of the discharge and the receiving waters.

Baseline—Not applicable.

Alternative 1—Do not address implementation of SQOs in NPDES permits.

Alternative 2—Develop translator tools that would enable the calculation of effluent limits from chemistry-based sediment thresholds.

Alternative 3—Propose that the narrative SQOs be implemented in NPDES permits as receiving water limits.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Section VII.B.

5.7.4.1 Defining Receiving Water Limit Exceedances

In general, demonstrating an exceedance of a numeric effluent limitation is fairly straightforward. Typically, there is an exceedance if the pollutant concentration in a monitoring sample is greater than the effluent limitation. Determining an exceedance of a receiving water limit implementing the proposed SQOs poses a greater challenge.

The proposed aquatic life SQO addresses pollutants in sediments that, alone or in combination, are toxic to benthic communities. The protected condition defined in Section 5.6 can be applied to individual stations. However integrating data from multiple stations is also necessary to ensure the evaluation of receiving water limits takes into consideration all available data. The protected condition defined in Section 5.6 could be coupled with the binomial statistic used by the Water Boards for 303(d) Listings to assess exceedances of receiving water limits using multiple stations designated in the permit. However coupling the MLOE based protected condition with the binomial statistic does not lead to the identity of a specific toxic pollutant stressor. In order to demonstrate an exceedance of the proposed SQO, a toxic pollutant or pollutants must be identified. Additional studies would be required to identify the specific cause. This effort requires stressor identification studies similar to the Toxicity Identification Evaluation process developed and utilized by U.S. EPA for the Whole Effluent Toxicity (WET) program (U.S. EPA 1999) and the process described in U.S. EPA's aquatic stressor identification guidance document (U.S. EPA 2002).

Performing stressor identification can also be tailored to address the confidence and magnitude of the assessment. For example sites classified as possibly impacted indicate that toxic pollutants may be causing adverse impacts to aquatic life (described in Section 5.6). In this case the exposure and biological effect maybe nominal or transient. In this example the ability to differentiate natural stressors and random variability from pollutant related stress might be difficult. However sites classified as likely or clearly impacted should clearly be prioritized for several reasons. First, the confidence in these assessment categories supports the need for priority response. Second, as the magnitude of the exposure and the biological effects increases, a greater number of tools could be applied to stressor identification, which increases the probability of establishing cause. Finally, resolving some of problems associated with likely and clearly impacted stations may help in resolving some of the problems associated with possibly impacted station clusters in the vicinity.

Baseline—Not applicable.

Alternative 1—Provide no guidance beyond the MLOE based protected condition as described in Section 5.6 to assess exceedances of receiving water limit.

Alternative 2—Provide guidance in Part 1 that would consist of a multi station assessment followed by stressor identification to determine the cause based upon the station categories. This language would also describe situations where findings support a conclusion that the narrative objective is met.

Staff Recommendation—Alternative 2

Proposed Language—See Appendix A, Section VII.C.

5.7.4.2 Monitoring Frequency in NPDES Permits

Sediment toxicity studies in southern California bays are indicate that there may be variable rates of temporal changes in sediment quality. Sediment toxicity in some bays has changed little over five years whereas conditions in other bays may change more frequently

(Bay et al. 2005). In San Francisco, sediment toxicity varies seasonally, yet the year-to-year sediment toxicity appears in many places to be relatively consistent (Anderson et al., 2007). The model monitoring program developed by SCCWRP for the southern California Bight recommends that the sediment monitoring frequency be based on the management objectives of the program, within a range of one to five years (Schiff et al., 2001). In order to monitor the impact of discharges the model-monitoring program suggests that the appropriate frequency be established after time series data has been collected for major dischargers. A frequency-limiting factor is the benthic community. The benthic indices proposed for use were developed using data collected in summer periods and as a result should only be applied during this season. Considering the above information the maximum frequency of once a year and a minimum frequency of once every five years (one permit cycle) would be appropriate.

Baseline—Not applicable.

Alternative 1—Do not specify a monitoring frequency. This alternative does not provide consistency throughout the coastal Regional Water Boards.

Alternative 2—Require permittees to collect time series data to determine appropriate frequency. This alternative may require the collection of a great deal of data before a monitoring frequency can be established.

Alternative 3—Require Phase I Stormwater Discharges and Major Discharges to monitor less frequently than twice per permit cycle. Require Phase II Stormwater and Minor Discharges to monitor more often then twice per permit cycle or less then once per permit cycle.

Staff Recommendation—Alternative 3.

Proposed Language—See Appendix A, Section VII.D.

5.7.4.3 Potential response actions for exceedances

Regulatory decisions or management actions are typically based upon the simple co-occurrence of pollutants that exceed a sediment quality guideline and biological effects measured at the same station or another station within the waterbody segment. Although this relationship does not demonstrate causality, TMDLs for each of these pollutants that exceed a sediment quality guideline are frequently required. As a result enormous resources are applied to develop control strategies for a large number of pollutants instead of focusing on the specific causes. There are also situations where routine chemical analysis does not include the identification of the pollutants that are responsible for the observed biological effects. In such situations, the true stressor is not considered in the development of control strategies. If stressor identification is performed and a stressor is identified, a logical application would be the development of biologically relevant guidelines that could be applied to support TMDL development or remediation goals. Guideline development would account for site and receptor specific factors that control bioavailability. Adopting sediment quality guidelines to fulfill this role does not account for these factors

Baseline—Not applicable.

Alternative 1—Do not provide guidance in Part 1 to support stressor identification and the development of additional biologically relevant guidelines in support of TMDLs or remediation goals

Alternative 2—Provide guidance in Part 1 to support stressor identification and the development of additional biologically relevant guidelines in support of TMDLs or remediation goals

Staff Recommendation—Alternative 2.

Proposed Language—See Appendix A, Section 3.VII.F and H.

5.7.4.4 Process Diagram for Application of the Direct Effects Narrative Objective

The Biological monitoring requires Sections 5.8.1 through 5.8.4 describe the potential means by which the direct effects narrative SQO and supporting tools could be applied within different water quality protection and control programs. However, members of the Advisory Committee have expressed a desire to include process figures to better communicate the basic approach and to further support consistent implementation and use across regions. The process figures would describe relevant response actions when an exceedance occurs and also describe situations where findings support a conclusion that the narrative objective is met.

Baseline—Not applicable.

Alternative 1—Do not include process figures in Part 1.

Alternative 2—Include process figures in Part 1

Proposed Language—See Appendix A, Figures 1 and 2.

6. ENVIRONMENTAL EFFECTS OF PART 1

6.1 REGULATORY REQUIREMENTS

This section presents the regulatory requirements for assessing environmental impacts under CEQA for the proposed *Water Quality Control Plan for Enclosed Bays and Estuaries of California Part 1 Sediment Quality* (Part I). Part I (Appendix A) is evaluated at a program level of detail under a certified regulatory program. As described in Section 1.5, state agencies are subject to the environmental impact assessment requirements of CEQA . However, CEQA authorizes the Secretary of the Resources Agency to exempt specific State regulatory programs from the requirements to prepare Environmental Impact Reports (EIRs), Negative Declarations, and Initial Studies, if certain conditions are met (Public Resources Code, §21080.5). While the "certified regulatory programs" of the State and Regional Water Boards are exempt from certain CEQA requirements, they are subject to the substantive requirements of California Code of Regulations, title 23, section 3777(a). This section requires a written report that includes a description of the proposed activity, an analysis of reasonable alternatives, and an identification of mitigation measures to minimize any significant adverse environmental impacts based on information developed before, during, and after the CEQA scoping process that is specified in California Public Resources Code section 21083.9.

Public scoping meetings were held in San Diego, Oakland and Rancho Cordova in the fall of 2006 to obtain input on the scope of this analysis. Comments received are posted on the Water Boards website at http://www.waterboards.ca.gov/bptcp/comments_sqo.html.

Section 3777(a) also requires the State Water Board to complete an environmental checklist as part of its substitute environmental documents. This checklist is provided in Appendix B of this document.

In addition, the State Water Board must fulfill substantive obligations when adopting performance standards, including water or sediment quality objectives. Public Resources Code section 21159 provides that an agency shall perform, at the time of the adoption of a rule or regulation requiring the installation of pollution control equipment, or a performance standard or treatment requirement, an environmental analysis of the reasonably foreseeable methods of compliance. The statute further requires that the environmental analysis, at a minimum, include all of the following:

- An analysis of the reasonably foreseeable environmental impacts of the methods of compliance.
- An analysis of reasonably foreseeable feasible mitigation measures to lessen the adverse environmental impacts.
- An analysis of reasonably foreseeable alternative means of compliance with the rule or regulation that would have less significant adverse impacts. (Pub. Resources Code, § 21159(a).)

6.2 DESCRIPTION OF ANALYSIS

Public Resources Code §21159(d) specifically states that the public agency is not required to conduct a "project level analysis." Rather, the project level analysis must be done by the lead agency that is required to comply with or implement the performance standard. Neither the State Water Board nor the Regional Water Boards can specify the manner of compliance with their regulations under Water Code §13360. Rather, the lead agency charged with complying

with or implementing the standard must conduct a project-level environmental review based on the particular compliance strategy.

Instead, this CEQA document represents a program level environmental analysis of thet Part 1 proposal. The document analyzes the reasonably foreseeable environmental impacts of the reasonably foreseeable methods of compliance within Part 1l. In conducting the program-level analysis, the State Water Board is not required to engage in speculation or conjecture. Reasonably foreseeable methods of compliance within Part 1 may include additional controls, remediation or the development of TMDLs to restore sediment quality. The corrective actions that require additional controls and or remediation will require a project level CEQA analysis (Pub. Res. Code § 21159.2.).

This analysis is based on the description of the environmental setting and existing conditions in Section 3, the regulatory baseline described in Section 4, the incremental changes that could result from the adoption of Part 1, the reasonably foreseeable environmental impacts associated with the reasonably foreseeable methods of compliance within Part 1, and reasonably foreseeable mitigation measures and alternatives.

As explained previously, the State Water Board's proposed program consists of the adoption of SQOs that address direct effects on benthic communities and indirect effects on human health of toxic pollutants in bays and estuaries. The primary outcome of this program will be the adoption of scientifically-defensible and environmentally-protective SQOs that can be consistently implemented throughout the state. As discussed in Section 4, the all coastal Regional Water Board basin plans currently contain narrative water quality objectives for toxicity or toxic substances, pesticides, bioaccumulation, or a combination of these that apply to sediment quality. In addition, existing basin plan prohibitions and numeric objectives and criteria for toxic pollutants, for example, the CTR criteria, affect sediment quality. Sediment cleanup and remediation programs are underway or planned in many regions because the sediments do not achieve the applicable objectives or other applicable requirements. These regulatory controls and activities would continue in the absence of this program. The extent to which additional controls on pollutant sources or additional remediation would be required under the proposed program, over the current baseline, is very difficult to determine. This analysis, nevertheless, assumes that adoption of Part I could potentially result in incremental controls or remediation activities over the current baseline.

If Part I is adopted, significant adverse environmental impacts are unlikely to occur from the Part 1 requirements for sampling, testing, sediment quality assessment, or stressor identification. If, however permittees or responsible parties are required to institute additional controls or corrective actions to comply with the proposed aquatic life SQOs for bays, over baseline conditions, these actions could result in potentially significant environmental impacts.

No potential significant adverse environmental impacts, over baseline conditions, are reasonably foreseeable if the proposed human health objective is adopted. Currently, waters are listed under CWA §303(d) as impaired if fish tissue advisory levels or other criteria are exceeded, and the levels or criteria are based on human health risk assessments. The proposed policy continues to use this approach.

Under Part I, compliance with the proposed aquatic life SQO for estuaries would be based on comparing coupled biological effects and chemistry data to reference site conditions. Due to a lack of existing coupled data and known reference sites, staff is unable to determine whether adoption of the proposed objective could result in potentially significant adverse environmental impacts. As noted above, the State Water Board is not required to engage in speculation. Nevertheless, the additional controls or corrective actions, if any, over baseline conditions,

stemming from adoption of the proposed objective for estuaries would likely be the same controls and actions required to comply with the proposed aquatic life objective for bays.

This report analyzes the reasonably foreseeable methods of compliance with Part I. This analysis takes into account the knowledge and understanding of baseline conditions and current Regional Water Board actions to restore beneficial uses. For example, it is not reasonably foreseeable that a project proponent would propose or that the Regional Water Board would approve, dredging and disposal of sediment from an entire water body as a result of sediment in the waterbody failing to meet a SQO. Dredging of this magnitude would be environmentally and economically infeasible. In the existing TMDL program, even legacy pollutants, those that are no longer in regular use or production, such as DDT, PCBs and mercury, are being controlled through means other than waterbody-wide dredging. Nor would staff anticipate a need for new wastewater treatment plants. All POTWs are required by the CWA to meet secondary treatment standards and many inland dischargers have or are in the process of upgrading to tertiary treatment. In addition, POTWs that discharge to bays and estuaries must comply with stringent CTR toxic pollutant criteria, which are implemented under the State Water Board's SIP, and must meet U.S. EPA's existing pretreatment program requirements. It is, therefore, unlikely that major modifications to existing POTWs or new POTWs would have to be constructed to meet the SQOs.

6.3 Summary of Baseline Conditions

Section 4 described the authority and means by which the State and Regional Boards initiate action to restore and protect beneficial uses through the control of existing discharges causing or contributing to the impact and/or the remediation of the impacted media itself by responsible parties. Currently, the risk to beneficial uses is evaluated based upon water, sediment and tissue data, which is compared to water quality criteria and objectives for priority pollutants in the CTR and basin plans, other numeric and narrative water quality objectives and prohibitions contained in basin plans, and other water quality control plans and policies, such as the 303(d) Listing Policy.

Section 3 described the beneficial uses designated for enclosed bays and estuaries that are impaired based upon the State Water Boards 303(d) List and/or designated as a Toxic Hotpots. Over one hundred segments are listed in bays and estuaries as a result of water-column, sediment or fish tissue-based impairments (Tables 3.1 through 3.16). There are also a number of sediment quality-related 303(d) listings for waters upstream of affected bays and estuaries. Impaired sediments can be carried downstream and settle into bays and estuaries, contributing to existing impairments or causing new ones. Unless de-listing occurs, all of these segments will require development of a TMDL to restore the beneficial use. The types of actions taken by permittees to comply with permit limits or wasteload allocations include additional pollution prevention education and awareness, modifications to pretreatment programs, construction or implementation of new BMPs or modification to existing BMPs, or process optimization or construction of additional treatment works.

Many Toxic Hotpots have been designated as 303(d) listed segments, however if existing sources are not contributing to the impairment, the extent of the impact is relatively localized and the listed segment or hotspot is significantly impacting beneficial uses, Regional Water Boards may require the area to be remediated. The types of action currently implemented by responsible parties to comply with cleanup and abatement orders include removal actions, capping and sequestering, in-situ remediation, natural attenuation or by other means described in the Consolidated Toxic Hotspots Cleanup Plan Amended Final Functional Equivalent Document (SWRCB 2004a).

6.4 INCREMENTAL IMPACTS ABOVE BASELINE CONDITIONS

If waters are identified as impaired because they fail to comply with the proposed SQOs, remediation activities or source control, or both, will be required to bring them into compliance. Many bays and estuaries are currently listed for sediment impairments and require controls under baseline conditions. Incremental sediment remediation, over baseline conditions, would be required under the proposed Part 1 only if monitoring data revealed biological impacts in areas that would not be designated for clean up under existing objectives. However, it is likely that most sites with sediment conditions that would require cleanup and remediation under Part 1 would also exceed current objectives. To the extent that results differ, it is possible that the additional assessment activities under Part 1 could lead to cleanup strategies that are more cost effective compared to baseline activities. In addition, based on the implementation plans for existing TMDLs, Regional Water Boards are likely to pursue source controls for ongoing sources and only require remediation activities for highly impacted localized sites affected by historical pollutants with no known, ongoing sources.

A review of available data and existing listings indicates that there is insufficient data to assess compliance with the SQOs for several enclosed bays and all estuaries. For enclosed bays with sufficient data, the review indicates that there are potentially eight bay segments that are not currently on the state's 303(d) list for sediment toxicity-related impacts for which the MLOE data indicates impairment under Part 1. Under baseline conditions, it is possible that the Regional Water Boards could identify these segments as impaired based upon existing narrative objectives even in the absence of Part 1. It should be noted that the Regional Water Boards identified the need for sediment cleanup and remediation for three of the eight segments under BPTCP. Assuming, however, that stressor identification and TMDL development are required for these segments under Part 1 and that these activities would not be pursued under baseline conditions, sediment remediation or other cleanup activities would be necessary.

In addition to the eight segments discussed above, the review indicated that three segments, which are currently listed on the 303(d) list for sediment-related degradation under the baseline, would not be impaired under Part 1. Adoption of Part 1 would result in cost savings for these sites.

Additional pollution control activities for on-going discharges under the proposed Part 1 could be required if the concentration of pollutants in discharges had to meet levels more stringent than required to achieve compliance with existing water quality objectives. Moreover, additional controls might be required to address previously unidentified chemical stressors. Without being able to identify the particular pollutants causing biological effects, however, or to determine the discharge concentrations necessary to achieve the proposed SQOs, it is difficult to determine whether, and to what extent, additional remediation or control activities will be necessary.

Assuming that additional controls on pollutant sources are necessary, the controls will likely focus on storm water sources, marinas, and wetlands. The degree to which incremental controls on these sources, over baseline conditions, would be required is uncertain. In any event, the reasonably foreseeable methods of compliance for storm water sources include increased or additional nonstructural and structural BMPs. For marinas and boating activities, reasonably foreseeable methods of compliance include the use of less toxic paint on boats and the use of containment or recovery equipment during hull maintenance activities. Wetlands controls may include aeration, channelization, revegetation, sediment removal, levees, or a combination of these practices.

6.5 PROGRAM ALTERNATIVES

Section 5 identified a series of issues and alternatives considered in the development of SQOs and Part 1. Of those Issues Staff have considered the following in this Tier I Programmatic Analysis:

1. No project alternative as described in Section 5.1.1
2. Selection of receptors as described in Section 5.3.2
3. The number of LOE as described in Section 5.5.1
4. Selecting alternative designation for the protected condition described in Section 5.6.1
5. The staff proposed Part 1 that protects specific receptors and utilizes MLOE to interpret the narrative objectives. The rationale and information supporting this approach that forms the foundation for Part 1 is described in Section 5.

No Project Alternative

Section 5.1.1 described the legal mandate that the State Water Board adopt SQOs. The State Water Board is bound by chapter 5.6 and the amended Settlement Agreement to develop and adopt SQOs. For this reason, the no project alternative is not feasible and is not considered further in this analysis.

Section of Alternate Receptors

The strengths and limitations of various receptors are examined in detail in Section 5.3.2. Although all receptors are important, the selection of receptors was based upon the type and magnitude of exposure based upon the life history of the organism, the ecological significance, sensitivity and response and the ability to evaluate the health of the receptor relative to pollutants in sediment. Selection of inappropriate receptors can have a significant impact on the environment. For instance, the selection of transient receptors may not respond to pollutants in sediment because the duration of the exposure is limited or the receptor may be exposed in other waterbodies and thus not represent an exposure at the area of concern. The selection of benthic communities and human health are both sensitive, relevant receptors and appropriate for Part 1

The Number of LOE to Assess Benthic Community Narrative Objective

The State Water Board could propose fewer LOE to support the narrative SQO, however the use of fewer LOE was not supported by the Scientific Steering Committee as an appropriate measure of sediment quality. As explained in Section 5.5.1, each LOE has strengths and weaknesses that must be considered in the application of the LOE as a measure of sediment quality. Through the application of three LOE, the weight of evidence can provide a more confident assessment that minimizes the weaknesses or limitations associated with the individual LOE used alone.

Alternative Designation for the Protected Condition

The selection of the protected condition clearly has significant potential to impact the environment. Staff has recommended that stations designated as Possibly Impacted, Likely Impacted and Clearly Impacted be considered as degraded. As discussed in Section 5.6.1, establishing this classification is consistent with chapter 5.7 , because the Possibly Impacted category represents the lowest level of impact. As described in Section 1.9, the purpose of the SQOs is to provide reasonable protection of beneficial uses, with an adequate margin of safety.

6.6 Reasonably Foreseeable Methods of Compliance

The primary limitation of the proposed SQOs is that the application of the indicators and thresholds to existing MLOE data from bays and estuaries does not provide any direct information on potential cause of an exceedance. Nor does the proposed SQO provide a pollutant-specific concentration that would be protective of aquatic life in sediment. As a result, evaluating reasonable means of compliance is difficult. It is also very difficult to determine whether there will be any reasonably foreseeable adverse environmental impacts stemming from the reasonably foreseeable methods of compliance over the current baseline.

There are an unlimited number of reasonable and foreseeable actions that could be implemented by permittees or responsible parties to comply with Part I. These actions can be categorized by controls that are applicable to the quality of water being discharged and remedial actions that are applied to reduce the risk associated with the pollutants already in the sediment. Controls may include the following:

Non-Structural Controls

- ***Public Education***—Education to promote pollution awareness on the proper use and proper disposal of products containing toxic pollutants, pollution prevention and minimization, and environmental stewardship
- ***Training***—Training programs can be used to support effective use of BMPs
- ***Water Conservation***—Water conservation reduces dry weather runoff that may carry sediment and pollutants directly into enclosed bays and estuaries or rivers draining into these waterbodies.
- ***Street cleaning (includes sweeping or washing)***—Frequent or more effective street sweeping or washing can reduce both sediment and pollutant runoff.

Structural Controls

Detention Basins/Retention Ponds—These ponds and basins can reduce the volume of suspended sediment and pollutants in stormwater by allowing suspended solids to settle out and reduce hydraulic load on the conveyance system.

Stormwater Diversions—Stormwater diversions have been constructed to divert dry season flows to wastewater treatment plants.

Vegetated Swales/Buffer Strips—Well maintained buffer strips constructed along roadsides and in medians can reduce the volume of sediment carried to storm drains.

Removal and Disposal of Polluted Soils—Soil containing toxic pollutant residuals may be removed from sewer lines and excavated out of stormwater channels or conveyances or public rights-of-way.

Treatment process optimization—Measures wastewater treatment plants can implement to modify or adjust the operating efficiency of the existing wastewater treatment process.

Pretreatment Program Assessment—Wastewater treatment plants can evaluate the effectiveness of the pretreatment programs and require upstream sources to reduce pollutant loading into the plant influent.

Treatment Plant Upgrades. Treatment plants may be upgraded to reduce pollutant concentrations in effluent.

Outfall Modifications—Treatment plants may relocate or redesign an outfall to reduce the potential impacts associated with the discharge of effluent. Redesign may include construction of a multi-port diffuser to increase dilution or relocation of the discharge into a location close to the ocean.

Remedial Actions

Remedial Actions are applied to restore the beneficial uses by reducing the risk of exposure to pollutants in sediment. The types of remedial action, potential environmental impacts and mitigation and relative costs are described in the Consolidated Toxic Hotspots Cleanup Plan Amended Final Functional Equivalent Document (SWRCB 2004a). Potential actions include:

- Capping/Sequestering of Polluted Sediments—If the polluted sediments are not limiting navigation and risk minimization is the objective, a well-engineered cap can reduce the mass of pollutants available for uptake or exposure.
- Dredging—Polluted sediments may be dredged from the water body for offsite disposal or remediation.
- In-situ Remediation
- Natural Attenuation

6.7 Potential Adverse Environmental Effects

For waterbodies identified as hotspots or placed on the CWA §303(d) list due to impaired sediment quality, the Regional Water Boards currently have the authority to issue and revise waste discharge requirements for ongoing pollutant sources, issue and implement enforcement actions to require remediation of these sites and/or develop TMDLs wasteload and load allocations to restore beneficial uses. Adoption of Part 1 will not alter this authority nor does adoption of Part 1 change the physical way in which the sites or waterbodies could be remediated or protected. Adoption of Part 1 could, however, result in incremental remediation activities or controls, or both, that could have reasonably foreseeable adverse environmental impacts.

Actions taken by the Regional Water Boards in response to sediment exceeding the proposed SQOs could result in degraded or adversely impacted biological resources, at least temporarily, during the construction of controls, treatment works, BMPs, or cleanup and mitigation efforts if these actions are not carefully planned and executed. Other impacts related to air quality, aesthetics, noise, hazardous materials, vehicle or vessel traffic could occur as well. Staff has determined that all of these potential impacts can be mitigated to less then significant levels with mitigation at the project level. When the SQOs are implemented on a project-specific basis, the agencies responsible for the project can and should incorporate the alternatives and mitigation measures into the project or project approvals.

Finally, it should be noted that Part 1 and management actions that occur as a result of adoption of Part 1 are intended to protect and restore the beneficial uses within bays and estuaries of California.

6.8 GROWTH-INDUCING IMPACTS

CEQA defines the expected discussion of growth-inducing impacts and indirect impacts associated with growth in section 15126(g) of the CEQA guidelines. That section states:

> "...Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects that would remove obstacles to population growth (a major expansion of a wastewater treatment plant might, for example, allow for more construction in service areas). Increase in the population may further tax existing community service facilities so consideration must be given to this impact. Also discuss the characteristics of some projects which may encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment."

Part 1 provides consistent approach to assess sediment quality relative to the narrative SQOs. The analysis of environmental impacts concludes that Part 1 will not have a significant effect on the environment. Part 1 is not expected to foster or inhibit economic or human population growth, or the construction of additional housing.

6.9 CUMULATIVE AND LONG-TERM IMPACTS

No cumulative adverse environmental impacts are expected at the program level from the adoption of Part I. Neither the State nor the Regional Water Boards have previously adopted SQOs. The State Water Board anticipates adopting refined SQOs for direct effects in estuaries and indirect effects in bays and estuaries in Phase II. The cumulative environmental impacts from the adoption of Phase I and Phase II are expected to be beneficial. The adoption of scientifically defensible and protective SQOs will ensure that aquatic life and human health beneficial uses are maintained and protected in coastal bays and estuaries. At the project level, the lead agency will have to analyze whether a compliance project could have environmentally cumulative effects. This analysis will depend on whether other related or unrelated projects are occurring in the same general time and space as the compliance project. Whether or not any potential significant adverse cumulative impacts could occur at the project level will depend on site-specific information related to the location, timing, and nature of the compliance action.

When considering cumulative and long-term impacts, Staff also considered the Part 1 potential contribution to global climate change. The State of California adopted Assembly Bill 32, the Global Warming Solutions Act of 2006. The Act requires the State to reduce its global warming emissions to 2000 levels by 2010 (11% below business as usual), to 1990 levels by 2020 (25% below business as usual), and 80% below 1990 levels by 2050. To that end, this CEQA analysis considers the potential of the proposed sediment quality objectives to impede efforts to achieve the mandated reductions.

Adoption of the proposed sediment quality objectives will not directly contribute to greenhouse gas (GHG) emissions, but consequent implementation of monitoring, clean-up and remediation activities could require the operation of equipment and vehicles that will generate emissions potentially contributing to GHG levels. Emissions from such operations are unknown but are unlikely to be significant when considered in the context of the state emissions inventory. In any event, due to the lack of data on potential emissions and their relative significance on global climate change, the potential cumulative impacts are far too speculative to analyze. At the programmatic level, it is not possible to estimate the number of monitoring

and remediation efforts that could be initiated, the equipment or vehicles that might be required, or the locations throughout the state where such actions might be undertaken. Efforts to assess the level of benefits or adverse impacts of such projects would be speculative at this time. Individual projects will be subject to the appropriate level of environmental review at the time they are proposed, and mitigation would be identified as warranted prior to approval.

6.10 Potential Environmental Impacts and Mitigation

In this section, Staff presents the rationale for the ratings of environmental impacts listed in the CEQA checklist presented in Appendix B and potential means to mitigate the impacts. As used in this analysis and as defined by CEQA (Article 20, Section 15370), mitigation can be divided into four types:

1. Avoiding the impact altogether by not taking a certain action or part of an action.
2. Minimizing impacts by limiting the degree or magnitude of the action and its implementation.
3. Rectifying or eliminating the impact over time by preservation and maintenance operations during the life of the action.
4. Compensating for the impact by replacing or providing substitute resources or environments.

It is likely that all of these mitigation strategies will be used alone or in a variety of combinations to address specific impacts associated with individual projects developed to restore or protect beneficial uses related to sediment quality.

It should be noted that Part 1 does not mandate any actions or projects that would lead to significant, permanent, negative impacts on the environment. However, this analysis also considers the reasonably foreseeable potential adverse environmental impacts stemming from the reasonably foreseeable methods of compliance with Part I, including additional controls or remediation or the development of TMDLs. Staff anticipate that all reasonably foreseeable potential environmental impacts will be mitigated to less-than-significant levels through a project-specific CEQA analysis, the Water Board's regulatory and permitting process or through other agencies with jurisdiction in relevant areas, such as U.S. EPA, USFWS, NMFS, OSHA, USACE, CDFG, DTSC, California Coastal Commission and San Francisco Bay Conservation and Development Commission (BCDC).

Aesthetics

Failure to meet the objectives could potentially result in construction activities for additional treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities. Thus, reasonably foreseeable short term impacts could occur during construction related activities. No long term impacts are anticipated that would result in substantial physical changes to the environment, including light or glare that would affect aesthetics. Construction activities could be limited to spring, fall, and winter week-days to avoid disrupting recreational, pleasure boating or site-seeing activities associated with the summer tourist season.

Agricultural Resources

Significant impacts would occur if a project substantially affected agricultural lands or production processes. There are no known or reasonably foreseeable impacts to agricultural resources due to the proposed adoption of Part 1. Furthermore, Part 1 relies on the Regional

Water Boards' Irrigated Lands Programs to determine how the SQOs will be implemented for those specific agricultural discharges that drain into bays and estuaries.

Air Quality

Failure to meet the proposed objectives could potentially result in construction activities for treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities. Emissions from this equipment vehicles and vessels have the potential for temporary adverse effects to air quality. The primary pollutants of concern in these emissions are NOx or nitrogen oxides. NOx are precursors to ozone formation, and many of the major embayments and the Sacramento San Joaquin Delta are located in areas designated as nonattainment areas for ozone. Other emissions of concern could be carbon monoxide and PM_{10} (particulate matter < 10 microns). Potential air quality impacts can be mitigated by operating equipment under permit, use of electric dredging equipment, planning the project for the time of year or day when emissions would be least likely to cause an exceedance of air quality standards, optimizing the mode of transportation, favoring disposal sites closer to dredge sites, and minimizing the number of trips necessary to transport dredged material to the disposal site or rehandling facility. Mitigation of air quality impacts will be considered under CEQA for each specific project.

Biological Resources

Failure to meet the proposed objectives could potentially result in construction activities for treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities. On land, there are no reasonably foreseeable impacts to biological resources from adoption of Part 1. The removal of soil could occur as part of land-based corrective action and control activities; however, many toxic pollutants found in sediments are typically found in highly urbanized, industrial areas where the presence of sensitive native species and habitats are improbable. Measures designed to intercept, divert, treat, and convey urban runoff to municipal wastewater treatment systems are only likely to occur at strategic locations in highly urbanized areas where the runoff requires additional controls.

In water, dredging, disposal, and capping all have the potential to cause adverse effects to biological resources in several ways: short-term habitat destruction and displacement of sensitive species, possibly during critical periods such as nesting, disturbance of sensitive spawning or migrating fish species due to turbidity, and "take" of endangered species.

Specific mitigation measures include adherence to established work windows to time dredging activities to avoid key seasonal activity of anadromous fish and bird species that inhabit nearshore areas either seasonally or year-round; use of electric dredge equipment; use of environmental (closed) clamshell buckets on dredges; and noise dampening material on equipment. Identification and mitigation of impacts to biological resources would be determined under CEQA for each specific project in consultation with the DFG and the USFWS.

Cultural Resources

Staff is not aware of any cultural resources present beneath subtidal sediments in bays and estuaries that could potentially be impacted through the adoption of Part 1. However, our lack of awareness does not preclude the possibility of previously unmapped cultural resources in near-shore locations that could be impacted by activities in response to exceedance of the narrative SQOs. As a result, any future actions that could impact cultural resources would be subject to CEQA on an individual case-by-case basis, and evaluated at that time.

Geology and Soils

Significant impacts to geology and soils would occur if a project exposed people or structures to potential, substantial adverse effects related to rupture of a known earthquake fault, other seismic events, or landslides. Significant impacts would also occur if a project caused substantial erosion or was located in areas with unsuitable soils or landslide-prone conditions. Although Part 1 does not mandate any specific remediation or corrective action, failure to meet the proposed objectives could potentially result in construction activities for treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging, excavation or construction activities. Dredging activities have the potential to destabilize channel slopes and undermine pilings. Standard engineering practices such as installation of sheet pile walls at the toe of the shore slope would reduce or avoid this impact.

Hazards and Hazardous Materials

This category refers to chemicals that have been discharged to the environment that may adversely impact the environment or human health and safety. Soil and groundwater impacted by such chemicals are also included. Significant impacts would occur if a project led to increased hazards to the public or environment from transport, handling, or emissions of such materials. Also included are projects located near airports and listed hazardous materials sites.

Failure to meet the proposed objectives could potentially result in construction activities for treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities. For these situations, potential impacts related to hazardous materials can be mitigated to less than significant levels with appropriate mitigation measures. In any action involving toxic pollutants, there is a potential for release of pollutants due to an accident or upset condition. The potential for such releases can be greatly reduced by proper planning. Measures to prevent releases of toxic pollutants include such things as pollution prevention technology (e.g., automatic sensors and shut-off valves, pressure and vacuum relief valves, secondary containment, air pollution control devices, double walled tanks and piping), access restrictions, fire controls, emergency power supplies, contingency planning for potential spills and releases, pollution prevention training and other types of mitigation appropriate to the cleanup plan.

Trucking hazardous wastes through neighborhoods has the potential to result in the possibility of fire or explosion; exclusion of hazardous waste from certain neighborhoods; inability to get bridge-crossing permits in a timely manner may limit the feasibility of remedial measures. It may be necessary to select a remediation measure such as capping to avoid such hazards. Fuels, lubricating oils, and other petroleum products will be used during cleanup activity. Well-established techniques for controlling spills, leaks, and drips will be incorporated in the work plans to assure the control of petroleum products and any other chemicals used during the cleanup activity.

Project workers and supervisors are required to comply with applicable Occupational of Health and Safety Administration (OSHA) training requirements for site clean-up personnel. In addition, site-specific health and safety plans would be prepared in accordance with California Code of Regulations, tit. 8, §5L92 and 29 C.F.R. § 1910.120, which govern site clean-up.

Potential management and remedial actions could include handling and transport of equipment, debris, scrap materials, soil and sediment containing potentially hazardous material. To protect people and the environment from potential impacts, the hazardous material must be handled, transported, and stored in accordance with applicable laws and regulations.

Hydrology and Water Quality

Significant impacts to hydrology and water quality would occur if a project substantially alters existing drainage patterns, alters the course of a river or stream, violates water quality standards, or creates or contributes to runoff that would exceed the capacity of local stormwater drainage systems. Significant impacts would also occur if a project placed housing or other structures within the 100-year flood plain, or exposed people or structures to significant risks from flooding, seiches, or tsunamis.

Failure to meet the proposed objectives could potentially result in construction activities for treatment works, BMPs, and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities.

Dredging equipment can cause turbulence in the water body, and, thus, the dredging process can cause short-term adverse impacts to water quality from turbidity or from stirring up pollutants in the sediment. These impacts can be regulated through WDRs and can be reduced by requiring use of dredging equipment or operations that minimize the discharge of chemical pollutants during dredging (e.g., use of clam shell dredger, etc.), use of settling tanks to reduce excessive turbidity in discharge, use of silt curtains to reduce dispersal of the turbidity plume beyond the dredge site, coffer dams in small channels, and accurate positioning of disposal equipment during dredging. DFG also has dredging regulations to protect against adverse biological impacts.

Some control or remedial actions could occur on the shoreline. Depending on the cleanup method selected for the shoreline activity, minor changes in absorption rates, drainage patterns, and the rate of surface runoff may change. On land, excavation can be mitigated by performing all work during the dry season and using BMPs for the control of erosion.

In addition, runoff from construction of BMPs, treatment works, excavation activities, or disposal of dredged materials above sea level can adversely affect surface water quality. Impacts from these activities can be reduced by doing work during the dry season or by implementing BMPs to reduce erosion. Most local governments also have erosion control ordinances and grading ordinances.

Stormwater diversions intended to improve water and sediment quality are not expected to degrade receiving water quality, rather these actions would improve water and sediment quality by means of additional treatment.

Changes in bottom contours brought by dredging or capping would probably have minimal effects on water circulation if properly managed. Relatively small areas are under consideration for modification at most of the sites. At larger sites, removal and placement will attempt to retain regional bottom depth and contour, except where bathymetry is planned for environmental improvement.

Land Use and Planning

Significant impacts to land use and planning would occur if a project physically divided a community, conflicted with a land use plan, policy or regulation, or caused conflict with a habitat conservation plan. General plans and zoning delineate those areas that will be developed, and the type and density of development to be allowed. There is nothing in Part 1 that requires the properties to be used in any way.

Mineral Resources

Significant impacts to mineral resources would occur if a project resulted in the loss of a mineral resource of value locally, regionally, or statewide. There is no evidence that the adoption of Part 1 would result in the loss of a known mineral resource or availability of the mineral resources.

Noise

Significant impacts from noise would occur if a project exposed people to noise or groundborne vibration in excess of established standards in a local general plan or noise ordinance or resulted in a substantial permanent increase to ambient noise levels. Significant impacts can also occur if a project causes substantial temporary or periodic increases in noise or if a project is located in the vicinity of an airport and would expose people residing or working in the project area to excessive noise levels.

Although Part 1 does not mandate any specific remediation or corrective action, failure to meet the objectives could potentially result in short-term noise related to construction activities and use of land or vessel-based heavy equipment for all projects involving dredging or construction activities. Mitigation would consists of compliance with local noise ordinances (typical standards include blackouts prohibiting use of heavy equipment on Sundays, early morning hours and evenings all week, and on holidays), use of noise dampening material or barriers around equipment, locating equipment as far as practical from noise-sensitive areas and selecting haul routes that affect the lowest number of people. These alternatives would be considered under CEQA for each specific project.

Population and Housing

Significant impacts to population and housing would occur if a project substantially encouraged population growth, displacing substantial numbers of people from existing housing and thereby necessitating construction of replacement housing elsewhere. Adoption of Part 1 will not result in the need for more housing or displace residents in existing communities. See discussion of growth-inducing impacts in Section 6 and Section 13241 factors in Section 7.

Public Services

Significant impacts to public services would occur if a project resulted in substantial physical impacts as a result of requirements for increased public services such as police, fire protection, schools, or other public facilities. Adoption of Part 1 will not result in the need for new government services for fire or police protection, education, or maintenance of public services.

Recreation

Significant impacts to recreation would occur if a project increased the use of existing park facilities such that physical impacts occurred if a project included construction or expansion of park facilities leading to physical impacts. Adoption of Part 1 would not create additional demand for parks or recreational facilities, but would have a positive impact on existing recreational opportunities such as fishing and swimming.

Transportation / Circulation

Significant impacts to transportation and traffic would occur if a project caused a substantial increase in traffic in relation to existing traffic load/capacity of the existing street

system, exceeded established level of service standards, resulted in change in air traffic patterns, lead to increases in road-related hazards, resulted in inadequate emergency access or parking. Adoption of Part 1 would not create additional vehicle or air traffic, or alter traffic patterns. Remediation of contaminated sediments may temporarily alter vessel traffic that would require approval from port authorities, Harbor Master and U.S. Coast Guard. However these impacts would be mitigated under CEQA specifically for each project.

Utilities and Service Systems

Significant impacts to utilities and service systems would occur if a project exceeded wastewater treatment standards, required construction of new water or wastewater treatment facilities or new or expanded storm water drainage facilities, or a project's water needs exceeded existing resources or entitlements. Significant impacts would also occur if a project was not served by a landfill with sufficient capacity or the project failed to comply with federal, state, or local regulations for solid waste. Although Part 1 does not mandate the construction of wastewater treatment facilities, failure to meet the objectives could potentially result in additional controls and treatment to reduce the discharge of pollutants into waterbodies. As stated previously, it is unlikely that treatment plants that comply with the CWA, the Water Code , the toxic pollutant criteria in the CTR, the implementation provisions in the SIP, and basin plans will cause exceedances of the proposed SQOs and Part 1.

Discharge reductions can be accomplished through (1) treatment process optimization (measures facilities can implement to modify or adjust the operating efficiency of the existing wastewater treatment process – such measures usually involve engineering analysis of the existing treatment process to identify adjustments to enhance pollutant removal or reduce chemical additional); (2) waste minimization/pollution prevention costs (conducting a facility waste minimization or pollution prevention study); (3) pretreatment (conducting study of sources and reducing inflow from indirect discharges); or (4) new or additional treatment systems. For stormwater, implementation of BMPs can also be applied to *reduce* pollutants, rather than treatment of storm water to *remove* pollutants. Because of the nature of storm water discharges, the Water Boards have not typically established numeric effluent limitations for toxic pollutants in storm water permits. The limitations contained in storm water permits are typically narrative and include the requirement to implement the appropriate control practices and/or BMPs. BMPs can range from good housekeeping to structural controls.

6.11 Mandatory Findings of Significance

The results of this analysis demonstrate that Part 1 if adopted could potentially result in reasonably foreseeable adverse environmental impacts.. There are reasonably foreseeable mitigation measures identified above, and those required by federal, state, and local laws and regulations, that the lead agency responsible for the project level environmental review can and should adopt. These mitigation measures should mitigate any potential adverse impacts at the project level to less than-significant levels.

7. CWC SECTION 13241 AND ANTIDEGRADATION

The State Water Board must analyze the factors described in section 13241 of the Water Code when establishing water quality objectives. Chapter 5.6 requires that the State Water Board adopt SQOs "pursuant to the procedures established by [Division 7] for adopting or amending water quality control plans." (Wat. Code §13393(b).) While the State Water Board is not statutorily required to comply with the substantive requirements for adoption of water quality objectives, when adopting SQOs, the State Water Board has, nevertheless, considered the section 13241 factors. In addition, the State Water Board must ensure that its actions are consistent with Resolution No. 68-16, the state's antidegradation policy.

7.1 Past, Present, and Probable Future Beneficial Uses of Water

The proposed SQOs address:

1. Benthic communities exposed directly to pollutants in sediment.
2. Human health exposed indirectly through fish and shellfish tissue.

As a result these objectives will protect sediment quality for all the beneficial uses that focus on these specific receptors and the associated exposure pathways. The proposed SQOs and interpretive tools will compliment and support the Water Boards' existing water quality control plans and policies, and provide a better means to ensure that beneficial uses are protected.

7.2 Environmental Characteristics of the Hydrographic Unit Under Consideration, Including the Quality of Water Thereto

The indicators proposed to interpret the narrative objective protecting benthic communities were developed based upon the specific physical, environmental biological characteristics of these waters. Unlike many of the numeric criteria in the CTR or used in the development of national sediment quality guidelines, very little data collected from outside the state was used in the development and validation of each indicator. For this reason, all the indicators proposed in Part 1 exhibit better performance in general than indicators developed from national studies, and, as a result, better protect the beneficial uses in waters of the State.

The implementation language proposed in Part 1 provides direction on how the SQOs shall be implemented within the regions, however within Part 1 each Regional Water Board retains the authority and flexibility to apply the SQOs in the appropriate regulatory program. Part 1 does not describe how a particular site should be corrected or remediated. Selection of corrective action can be addressed only after many site-specific factors are considered such as:

- The hydrodynamics and flow regime in the area of concern
- The specific pollutant that is causing the degradation or impairment
- The receptors at risk due to the presence of the pollutants at the levels observed within the area of concern.
- The aerial extent
- Presence of existing sources or legacy releases
- Types of controls in place and feasibility of additional controls.

7.3 Water Quality Conditions that Could Reasonably Be Achieved Through the Coordinated Control of All the Factors Which Affect Water Quality in the Area

As described in Section 1, wastes have been discharged into bays and estuaries either directly as point sources, indirectly as runoff, or accidentally through releases and spills for many years. In addition, many contaminants readily attach to the sediments and are carried down rivers and creeks contributing to the contaminant loading. Once these sediments reach the bays and estuaries, poor flushing and low current speeds allow the sediments and contaminants to settle before reaching the open ocean.

The State and Regional Water Boards are required to ensure that all discharges, regardless of type, comply with all water quality control plans and policies. If the SQOs are adopted into a permit as receiving water limits, the discharge must meet the limits or, if the limits are not being met due to the discharge of toxic pollutants, determine the causative pollutant. If the discharger is contributing to the accumulation of the pollutant causing the degradation, the permittee would be required under existing authority to control the pollutant to the extent practical through BMPs or additional treatment. The same approach would occur if multiple discharges are contributing to the accumulation of the pollutant. For additional control measures see Controls under economic considerations

7.4 Economic Considerations.

The Water Boards must consider economic factors in establishing water quality objectives. Generally, this analysis entails consideration of whether the objectives and alternatives are currently being attained, the methods available to achieve compliance, and the costs of those methods. In addition, the Water Boards must consider economic factors under Public Resources Code §21159 when adopting rules that establish performance standards or treatment requirements.

For the proposed SQOs, the available compliance methods and costs depend on the types of sources that may be affected by the SQOs, which could include a variety of point and nonpoint sources. In order to assess the economic impacts of the proposed objectives and Part 1, DWQ staff consulted with Scientific Applications International Corporation (SAIC). More details of the economic considerations given here may be found in the report "*Economic Considerations of Sediment Quality Plan for Enclosed Bays in California*" (SAIC 2007).

Incremental Impact of Part 1

The incremental economic impacts of Part 1 include the cost of activities above and beyond those that would be necessary in the absence of Part 1 under baseline conditions, as well as the cost savings associated with actions that will no longer need to occur. Baseline conditions include current objectives and policies regulating activities and pollutant discharges that affect sediment quality (e.g., narrative Basin Plan objectives, CTR criteria, and other policies), existing monitoring programs, ongoing cleanup and remediation activities, and planned or anticipated cleanup and remediation actions that have not yet been completed [e.g., TMDL development and implementation schedules].

Under Part 1, Regional Water Boards would list sediment as exceeding the SQOs if multiple lines of evidence (with sufficient data) indicate impairment. This requirement for additional evidence of impairment could potentially reduce the number of water bodies that would be incorrectly listed as impaired for toxic substances. Potential costs or cost savings

associated with implementing the SQOs depend on the relative stringency of the objectives. Table 7.1 indicates the different incremental impacts that could occur under Part 1.

Table 7.1. Incremental Impacts Associated with Part 1

Assessment Under Existing Objective	Assessment Under Proposed SQOs	
	No Sediment Impairment	Sediment Impairment
No Sediment Impairment	• No change in sediment quality. • Potential incremental assessment costs.	• Sediment quality improvement. • Potential incremental assessment and control costs.
Sediment Impairment	• Sediment quality remains the same as now, which may be lower than under implementation of baseline narrative objective. • Potential incremental assessment costs, but will avoid unnecessary control costs.	• Change in sediment quality if better information leads to a change in control strategies. • Potential incremental assessment costs; potential incremental costs or cost-savings depending on differences between control strategies.

Under Part 1, compliance with the proposed aquatic life objective for estuaries would be based on comparing coupled biological effects and chemistry data to reference site conditions. Due to a lack of existing coupled data and known reference sites, an analysis of potential incremental impacts is not possible at this time. The State Water Board will adopt a final direct effects objective for estuaries under Phase II. Thus, it is likely that any control actions identified for compliance with the interim objective would not be implemented until it could be shown that those actions would also be required for compliance with final objective.

Compliance with the proposed human health objective under Part 1 would be based on a human health risk assessment that utilizes OEHHA policies for fish consumption as well as other fish tissue threshold values. In the absence of Part 1, waters will continue to be listed as impaired based on exceedances of fish tissue advisory levels or criteria. Because these same levels and criteria will be used under Part 1 to determine compliance with the objective there would be no incremental impacts associated with the interim human health SQO.

For the proposed aquatic life objective, the Southern California Coastal Water Research Program (SCCWRP) used the assessment matrices in Part 1 to determine compliance at sites for which available sediment monitoring data includes all three of the required sample types (toxicity, chemical exposure, and benthos community). To estimate incremental impacts of Part 1, these results can be compared to existing assessments [i.e., 303(d) listings] for the pollutants of concern in sediment, fish tissue, or the water column. This data is insufficient to determine compliance for all bays. However, for those for which data is available, the results indicate both potential incremental impairments and reduced listings, depending on the water body.

Monitoring and Assessment

The comparison of available assessment data and existing impairments indicates that there is insufficient data to assess compliance with the proposed SQOs for a number of bays, as well as estuaries. In addition, for those waters with sediments that exceed the proposed SQOs, Part 1 indicates that further investigation into stressor identification is necessary (SWRCB, 2006). Thus, the incremental impacts of Part 1 include monitoring and stressor identification costs. Although data for some parameters may not be needed at each sampling site or for each bay, potential per sample costs may range from $3,940 to $5,810 as shown in Table 7-2.

Table 7.2. Potential Sampling Costs under the Plan

Parameter	Cost per sample
Metals suite	$175 – $225
Total Mercury	$65 – $135
PAH suite	$400
Chlorinated pesticides	$200 – $575[a]
PCB congeners (not coplanar)	$200 – $575[a]
Sediment toxicity (acute lethal)	$800
Sediment toxicity (sublethal)	$800 – $1,400
Benthic survey	$800 – $1,200[b]
Sediment collection on boat	$500[c]
Total cost per sample	$3,940 – $5,810

Source: Chemistry cost estimates obtained from price lists used for southern California and San Francisco Bay regional monitoring programs; sediment toxicity and benthic survey costs obtained from southern California regional monitoring program and development of the Plan; sediment collection estimate from SCCWRP (2007).

a. High estimate represents low detection limit analyses.

b. High estimate represents difficult to sort samples, such as 0.5 mm mesh screen samples in San Francisco Bay.

c. Includes the cost of the boat, crew, and any activities associated with preparing the samples for transport to the analysis laboratory (e.g., compositing and subsampling and screening of benthic samples to remove excess sediment).

The number of stations needed to assess bay sediment quality will vary based on site-specific factors. Based on between 5 and 30 samples per bay, depending on area, statewide monitoring costs to assess those bays for which existing data are insufficient (a total of 131 samples representing 20,000 acres) may range from $516,000 to $762,000. . These estimated costs by water body are presented in Table 7.3. Costs associated with confirmatory monitoring for segments with only possibly impacted sites (no clearly or likely impacted sites) would be $8,000 to $12,000. A more detailed description of the assumptions and basis used to develop these costs are described in the report by SAIC (2007).

There are potentially eight bay segments not currently on the 303(d) list for sediment toxicity related impairments for which MLOE data indicate impairment under the Plan. If stressor identification and possible TMDL development activities are needed for those segments and would not be pursued in the future under existing objectives (for three of these segments, MLOE indicate sediment toxicity, and the Regional Board identified sediment cleanup and remediation necessary under the BPTCP), incremental cost could be approximately $8 million. There are also three segments listed for sediment related impairments under the baseline for which MLOE data indicate no impairment under the Plan. Assuming that no stressor identification or TMDL development would be needed for these segments under Part 1, there could be a potential cost savings of $3 million. Thus, the net incremental cost associated with assessment activities could be approximately $5 million (or lower if such costs would be incurred in the absence of the Plan for any of the 3 sites that exhibit sediment toxicity and for which cleanup and remediation actions are necessary).

For estuaries, the State Water Board is collecting data as part of the Phase II effort to develop appropriate tools and thresholds for implementing the SQO. These data can also be used to assess compliance with the final SQO. Thus, additional monitoring may be necessary for those waters not currently being sampled as part of this effort. However, costs of these monitoring efforts cannot be estimated until the data collection effort is complete.

Table 7.3. Potential Incremental Sediment Quality Monitoring Costs

Water Body	Size (Acres)	Number of Samples	Total Monitoring Costs (Low)[1]	Total Monitoring Costs (High)[2]
Region 1				
Crescent City Harbor	374	5	$19,700	$29,100
Bodega Bay	822	12	$47,300	$67,700
Region 2				
Drakes Estero Bay	12,780	30	$118,200	$174,300
San Francisco Bay, Richardson Bay	2,439	12	$47,300	$67,700
Half Moon Bay	355	5	$19,700	$29,100
Region 3				
Moss Landing Harbor	79	5	$19,700	$29,100
Monterey Harbor	76	5	$19,700	$29,100
Santa Barbara Harbor	266	5	$19,700	$29,100
Region 4				
Ventura Harbor	179	5	$19,700	$29,100
Port Hueneme Harbor	65	5	$19,700	$29,100
King Harbor	105	5	$19,700	$29,100
Los Angeles Harbor Consolidated Slip	36	5	$19,700	$29,100
Los Angeles Harbor – Cabrillo Beach	156	5	$19,700	$29,100
Region 8				
Bolsa Bay	116	5	$19,700	$29,100
Region 9				
Mission Bay	2,032	12	$47,300	$67,700
San Diego Bay, Shoreline, at Marriott Marina	32	5	$19,700	$29,100
San Diego Bay, Shoreline, Chula Vista Marina	49	5	$19,700	$29,100
Total	19,961	131	$516,200	$761,700

Detail may not add to total due to rounding.
1. Equals the number of samples times the low estimate of cost per sample ($3,940).
2. Equals the number of samples times the high estimate of cost per sample ($5,810).

Controls

For waters that Regional Water Boards identify as being impaired under the proposed Part 1, remediation actions and/or source controls will be needed to bring them into compliance. Many bays and estuaries are already listed for sediment impairments and, therefore, would require controls under baseline conditions. When the baseline controls are identical to the ones that would be implemented under Part 1, there is no incremental cost or cost savings associated with Part 1. When the baseline controls differ, there is potential for either incremental costs or cost-savings associated with the Plan.

Because strategies to meet current narrative objectives at many impaired sites are still in the planning stages and the overall effects of implementation strategies are unknown, estimates of incremental costs would be highly speculative. For incremental sediment remediation and/or cleanup activities to be required under Part 1, monitoring data would have to indicate biological impacts under the proposed SQOs in areas that would not be designated for clean up under

existing objectives. However, it is likely that most sites with sediment conditions that would require cleanup and remediation under Part 1 would also exceed current objectives. To the extent that results differ, it is possible that the additional assessment activities under Part 1 could lead to cleanup strategies that are more cost effective compared to baseline activities. In addition, based on the implementation plans for existing TMDLs, Regional Water Boards are likely to pursue source controls for ongoing sources and only require remediation activities for historical pollutants with no known, ongoing sources.

For an increased source control cost associated with additional pollution controls under the proposed Part 1, the concentration of toxic pollutants in discharges would have to meet levels that are more stringent than what is needed to achieve compliance with existing objectives (e.g., since they could have to control based on the narrative sediment objectives or the CTR). Incremental costs for controls may also result from the identification of additional chemical stressors that are not included in the CTR or Basin Plans. Since many practices that may be employed under existing TMDLs are applicable for controlling the mobilization of pollutants in general, this situation is also difficult to estimate. For example, the TMDL for pesticides and PCBs in the Calleguas Creek watershed indicates that the BMPs needed to achieve the nutrient and toxicity TMDLs for the watershed would likely reduce pesticides and PCBs to necessary levels as well (LARWQCB, 2005).

Thus, without being able to identify the particular pollutants causing biological effects, and the development of discharge concentrations needed to achieve the proposed objectives, the needed cleanups and/or controls to achieve those concentrations are difficult to estimate. Review of existing impairments and TMDL actions for the various bays suggests that incremental impacts may be unlikely. If there are incremental impacts as a result of the Part 1, controls are likely to focus on storm water sources, marinas, and wetlands. However, some level of control for these sources would occur under the implementation plans for existing TMDLs.

For any situation in which these sources are specifically required to control toxic pollutants to levels that are lower than what would be necessary in the absence of Part 1, potential means of compliance for storm water sources include increased or additional nonstructural BMPs (e.g., institutional, education, or pollution prevention practices designed to limit generation of runoff or reduce the pollutants load of runoff); and structural controls (e.g., engineered and constructed systems designed to provide water quantity or quality control). For marinas and boating activities, potential means of compliance may include use of less toxic paint on boats; performing all boat maintenance activities above the waterline or in a lined channel to prevent debris from entering the water; removing boats from the water and clean in a specified location equipped to trap debris and collect wastewater; prohibiting hull scraping or any process that removes paint from the boat hull from being conducted in the water; and developing a collection system for toxic materials at harbors. Wetlands controls may include aeration, channelization, revegetation, sediment removal, levees, or a combination of these practices.

For estuaries, Regional Water Boards need additional data to identify the sources that may need an incremental level of control.

7.5 The Need for Developing Housing Within the Region

The adoption of Part 1 is not expected to increase the need for housing in the areas surrounding enclosed bays and estuaries of California. Part 1 applies to the protection of subtidal sediments in surface waters.

7.6 THE NEED TO DEVELOP AND USE RECYCLED WATER

The adoption of Part 1 is not expected to increase the need to develop and use recycled water.

7.7 ANTIDEGRADATION

In 1986, the State Water Board adopted Resolution No. 68-16, entitled "Statement of Policy with Respect to Maintaining High Quality of Waters in California." The policy expresses the State Water Board's intent that the quality of existing high quality waters be maintained to the maximum extent possible. Lowering of water quality is allowed only if the lowering is consistent with the maximum benefit to the people of the state, will not unreasonably affect present and anticipated beneficial uses of waters, and will not result in water quality less than that prescribed in applicable policies. Resolution No. 68-16 has been interpreted to incorporate the provisions of the federal antidegradation policy as well, where the federal policy applies.

The federal policy, in 40 C.F.R. §131.12, establishes three tiers of water quality protection and, like Resolution No. 68-16, allows a lowering of water quality for high quality waters only if certain conditions are met. The state and federal antidegradation policies must be considered for a variety of actions, including water quality standards actions.

The State Water Board does not anticipate any lowering of water quality as a result of the adoption of Part I. For the first time, the state will have scientifically-defensible sediment quality objectives for bays and estuaries. These objectives can be consistently applied across the state to assess sediment quality, regulate waste discharges that can impact sediment quality and provide the basis for appropriate remediation activities where sediments are impaired. Adoption of the SQOs, rather than lowering water quality, should result in water quality improvements.

Currently, Regional Water Boards implement a variety of narrative objectives to address sediment quality. The objectives, in general, do not explicitly address sediment quality. The proposed SQOs, on the other hand, are specific to sediments, were developed with data from California waters, have undergone rigorous scientific review, and are intended to protect sediment quality. The proposed SQOs are likely to be more protective, vis-à-vis sediment quality, than current standards.

8. GLOSSARY

ACUTE TOXICITY: Short-term lethal response of an organism to a pollutant.

BEST MANAGEMENT PRACTICES (BMPs): Methods, measures, or practices designed and selected to reduce or eliminate the discharge of pollutants to surface waters from point and nonpoint source discharges including storm water.

BMPs include structural and non-structural controls, and operation and maintenance procedures, which can be applied before, during, and/or after pollution producing activities.

BENTHIC: Living on or in bottom of the ocean, bays, and estuaries, or in the streambed.

BINOMDIST: An Excel® function that can be used to calculate the cumulative binomial distribution.

BINOMIAL DISTRIBUTION: Mathematical distribution that describes the probabilities associated with the possible number of times particular outcomes will occur in series of observations (i.e., samples). Each observation may have only one of two possible results (e.g., standard exceeded or standard not exceeded).

BIOACCUMULATION: A process in which an organism's body burden of a contaminant exceeds that in its surrounding environment as a result of chemical uptake through all routes of chemical exposure; dietary and dermal absorption and transport across the respiratory surface.

BIOACCUMULATION FACTOR (BAF): The ratio of contaminant concentration in biota to contaminant concentration in some other matrix. In this report, unless specified otherwise, the term "bioaccumulation factor" refers to wet weight concentration in fish or invertebrate tissue divided by dry weight concentration in sediment.

BIOAVAILABILITY: The fraction of a chemical pollutant or contaminant that can be absorbed by an organism through gills or other membranes, potentially causing an adverse physiological or toxicological response. Bioavailability is dependent on the chemical form of the pollutant in the media, the physical and biogeochemical processes within the media, the route and duration of exposure, and the organism's age, metabolism, size and sensitivity.

BIOTA-SEDIMENT ACCUMULATION FACTOR (BSAF): This is the bioaccumulation factor for tissue vs. sediment, normalized for lipid and organic carbon. BSAF = (tissue contaminant concentration in wet wt. * sediment % organic carbon) / (sediment contaminant concentration in dry wt. * tissue % lipid).

BIOASSESSMENT: Assessment of biological community information along with measures of the physical/habitat quality to determine, in the case of water quality, the integrity of a water body of interest.

BTAG: Biological Technical Assistance Group, a multi-agency group of State and federal ecological and human health risk assessors supported by U.S. EPA responsible for providing technical assistance for Site remediation and mitigation.

CHEMICALS OF CONCERN (COCS): Pollutants that occur in environmental media at levels that pose a risk to ecological receptors or human health.

CONTAMINATION: An impairment of the quality of the waters of the State by waste to a degree that creates a hazard to the public health through poisoning or through the spread of disease. "Contamination" includes any equivalent effect resulting from the disposal of waste whether or not waters of the State are affected (CWC section 13050(k)).

CHRONIC TOXICITY: Sublethal response of an organism to repeated, long-term exposure to a chemical substance. Typical observed endpoints include growth expressed as length and weight.

CALIFORNIA TOXICS RULE (CTR): Numerical water quality criteria established by U.S. EPA for priority toxic pollutants for California's inland surface waters, enclosed bays, and estuaries.

DEGRADATION OF SEDIMENT QUALITY: Sediment toxicity and changes in benthic community attributes as a result of exposure to toxic pollutants in bedded surficial sediments. Unacceptable risk to human health and wildlife as a result of bioaccumulation from pollutants in bedded surficial sediments that are transported up the aquatic food chain.

DEMERSAL: Organisms that prefer to spend the majority of their time on or near the bottom of a water body.

DIEL: Measurements pertain to measurements taken over a 24-hour period of time.

DREDGED MATERIAL: Any material excavated or dredged from the navigable waters of the United States, including material otherwise referred to as "spoil."

EFFECTS RANGE-MEDIAN (ERM)/EFFECTS RANGE-LOW (ERL): Sediment quality guidelines based on a biological effects empirical approach. These values represent chemical concentration ranges that are rarely (i.e., below the ERL), sometimes (i.e., between ERL and ERM), and usually (i.e., above the ERM) associated with toxicity for marine and estuarine sediments. Ranges are defined by the tenth percentile and fiftieth percentile of the distribution of contaminant concentrations associated with adverse biological effects.

EFFECT SIZE: Maximum magnitude of exceedance frequency that is tolerated.

ENCLOSED BAYS: Indentations along the coast that enclose an area of oceanic water within distinct headlands or harbor works. Enclosed bays include all bays where the narrowest distance between headlands or outermost harbor works is less than 75 percent of the greatest dimension of the enclosed portion of the bay. This definition includes, but is not limited to: Humboldt Bay, Bodega Harbor, Tomales Bay, Drakes Estero, San Francisco Bay, Morro Bay, Los Angeles Harbor, Upper and Lower Newport Bay, Mission Bay, and San Diego Bay.

ENDPOINT: A measured response of a receptor to a stressor. An endpoint can be measured in a toxicity test or in a field survey.

EQUILIBRIUM PARTITIONING APPROACH: Approach used to relate the dry-weight sediment concentration of a particular chemical that causes an adverse biological effect to the equivalent free chemical concentration in pore water and to that concentration sorbed to sediment organic carbon or bound to sulfide. Based on the theory that the partitioning of a nonionic organic chemical between organic carbon and pore water and the partitioning of a divalent metal between the solid and solution phases are at equilibrium.

EQUILIBRIUM PARTITIONING SEDIMENT GUIDELINES: Sediment quality guidelines derived using the EqP approach. When used in conjunction with appropriately protective water only exposure concentration, a resulting guideline represents the sediment contaminant concentration that protects benthic organisms from the effects of that contaminant.

ESTUARIES AND COASTAL LAGOONS: Waters at the mouths of streams that serve as mixing zones for fresh and ocean waters during a major portion of the year. Mouths of streams that are temporarily separated from the ocean by sandbars shall be considered as estuaries. Estuarine waters will generally be considered to extend from a bay or the open ocean to the

upstream limit of tidal action but may be considered to extend seaward if significant mixing of fresh and salt water occurs in the open coastal waters. The waters described by this definition include, but are not limited to, the Sacramento-San Joaquin Delta as defined by Section 12220 of the California Water Code, Suisun Bay, Carquinez Strait downstream to Carquinez Bridge, and appropriate areas of the Smith, Klamath, Mad, Eel, Noyo, and Russian Rivers.

EUHALINE: Waters ranging in salinity from 25–32 practical salinity units (psu).

INDIRECT EFFECTS: Adverse effects to humans and wildlife as a result of consuming prey items exposed to polluted sediments.

INFAUNA: Organisms that live within sediment or substrate.

INLAND SURFACE WATERS: All surface waters of the State that do not include the ocean, enclosed bays, or estuaries.

LOAD ALLOCATION (LA): The portion of a receiving water's total maximum daily load that is allocated to one of its nonpoint sources of pollution or to natural background sources.

MIXING ZONE: Limited zone within a receiving water that is allocated for mixing with a wastewater discharge where water quality criteria can be exceeded without causing adverse effects to the overall water body.

MAXIMUM CONTAMINANT LEVEL (MCL): The maximum permissible level of a contaminant in water delivered to any user of a public water system.

MAXIMUM TISSUE RESIDUE LEVEL (MTRL): Tissue values developed from human health water quality objectives in the 1997 California Ocean Plan and from the California Toxic Rule as established in the Policy for Implementation of Toxics Standards for Inland Surface Waters, Enclosed Bays, and Estuaries of California. MTRLs are used as alert levels or guidelines indicating water bodies with potential human health concerns and are an assessment tool and not compliance or enforcement criteria. The MTRLs are calculated by multiplying human health water quality objectives by the bioconcentration factor for each substance.

MESOHALINE: Waters ranging in salinity from 5 to 18 psu.

NATIONAL ACADEMY OF SCIENCE TISSUE GUIDELINES: Guidelines established for the protection of predators. Values are suggested for residues in whole fish (wet weight) for DDT (including DDD and DDE), aldrin, dieldrin, endrin, heptachlor (including heptachlor epoxide), chlordane, lindane, benzene hexachloride, toxaphene, and endosulfan either singularly or in combination.

NATIONAL TOXICS RULE: Numerical water quality criteria established by U.S. EPA for priority toxic pollutants for 12 states and two Territories who failed to comply with the section 303(c)(2)(B) of the Clean Water Act.

NONPOINT SOURCE POLLUTION: Sources are diffused and do not have a single point of origin or are not introduced into a receiving stream from a specific outlet. The commonly used categories for nonpoint sources are agriculture, forestry, mining, construction, land disposal, and salt intrusion.

NULL HYPOTHESIS: Statement used in statistical testing that has been put forward either because it is believed to be true or because it is to be used as a basis for argument, but has not been proved.

OBJECTIONABLE BOTTOM DEPOSITS: An accumulation of materials or substances on or near the bottom of a water body which creates conditions that adversely impact aquatic life, human health, beneficial uses, or aesthetics. These conditions include, but are not limited to, the accumulation of pollutants in the sediments and other conditions that result in harm to benthic organisms, production of food chain organisms, or fish egg development. The presence of such deposits shall be determined by Regional Water Board(s) on a case-by-case basis.

OCEAN WATERS: Territorial marine waters of the State as defined by California law to the extent these waters are outside of enclosed bays, estuaries, and coastal lagoons. Discharges to ocean waters are regulated in accordance with the State Water Board's California Ocean Plan.

PELAGIC: Organisms living in the water column.

PERSISTENT POLLUTANTS: Substances for which degradation or decomposition in the environment is nonexistent or very slow.

POLLUTANT: Defined in section 502(6) of the CLEAN WATER ACT as "dredged spoil, solid waste, incinerator residue, filter backwash, sewage, garbage, sewage sludge, munitions, chemical wastes, biological materials, radioactive materials, heat, wrecked or discarded equipment, rock, sand, cellar dirt and industrial, municipal, and agricultural waste discharged into water."

POLLUTANT MINIMIZATION: Waste minimization and pollution prevention actions that include, but are not limited to, product substitution, waste stream recycling, alternative waste management methods, and education of the public and businesses.

POLLUTION: Defined in section 502(19) of the CLEAN WATER ACT as the "the man-made or man-induced alteration of the chemical, physical, biological, and radiological integrity of water." *Pollution* is also defined in CWC section 13050(1) as an alternation of the quality of the waters of the State by waste to a degree that unreasonably affects either the waters for beneficial uses or the facilities that serve these beneficial uses.

POLLUTION PREVENTION: Any action that causes a net reduction in the use or generation of a hazardous substance or other pollutant that is discharged into water and includes, but is not limited to, input change, operational improvement, production process change, and product reformulation (as defined in Water Code Section 13263.3). Pollution prevention does not include actions that merely shift a pollutant in wastewater from one environmental medium to another environmental medium, unless clear environmental benefits of such an approach are identified to the satisfaction of the State Water Board or the Regional Water Boards.

POLYHALINE: Waters ranging in salinity from 18–25 psu.

PROBABLE EFFECT CONCENTRATION (PEC): Empirically derived freshwater sediment quality guidelines (SQG) that rely on the correlation between the chemical concentration in field collected sediments and observed biological effects. PECs are based on geometric means of various SQG approaches (with matching chemical and toxicity field data) to predict toxicity for freshwater sediment on a regional and national basis.

PROBABLE EFFECTS LEVEL (PELS)/THRESHOLD EFFECTS LEVELS (TEL): Empirically derived sediment quality guidelines based on a biological effects empirical approach similar to ERMs/ERLs. A generalized approach used to develop effects-based guidelines for the state of Florida and others. The lower of the two guidelines for each chemical (i.e., the TEL) is assumed to represent the concentration below which toxic effects rarely occur. In the range of

concentrations between the two guidelines, effects occasionally occur. Toxic effects usually or frequently occurs at concentrations above the upper guideline value (i.e., the PEL). Ranges are defined by specific percentiles of both the distribution of contaminant concentrations associated with adverse biological effects and the "no effects" distribution.

RANK CORRELATION: The association between paired values of two variables that have been replaced by their ranks within their respective samples (e.g., chemical measurements and response in a toxicity test).

REFERENCE CONDITION: The characteristics of water body segments least impaired by human activities. As such, reference conditions can be used to describe attainable biological or habitat conditions for water body segments with common watershed/catchment characteristics within defined geographical regions.

SIMULTANEOUSLY EXTRACTED METALS (SEM): Metal concentrations that are extracted during the same analysis in which the acid-volatile sulfide (AVS) content of the sediment is determined.

STATISTICAL SIGNIFICANCE: When it can be demonstrated that the probability of obtaining a difference by chance only is relatively low.

TOXIC POLLUTANT: As used in this staff report toxic pollutants refers to priority pollutants AS USED

TOXICITY IDENTIFICATION EVALUATION (TIE): Techniques used to identify the unexplained cause(s) of toxic events. TIE involves selectively removing classes of chemicals through a series of sample manipulations, effectively reducing complex mixtures of chemicals in natural waters to simple components for analysis. Following each manipulation the toxicity of the sample is assessed to see whether the toxicant class removed was responsible for the toxicity.

TOXICITY REDUCTION EVALUATION (TRE): Study conducted in a step-wise process designed to identify the causative agents of effluent or ambient toxicity, isolate the sources of toxicity, evaluate the effectiveness of toxicity control options, and then confirm the reduction in toxicity. The first steps of the TRE consist of the collection of data relevant to the toxicity, including additional toxicity testing, and an evaluation of facility operations and maintenance practices, and best management practices. A Toxicity Identification Evaluation (TIE) may be required as part of the TRE, if appropriate. (A TIE is a set of procedures to identify the specific chemical(s) responsible for toxicity. These procedures are performed in three phases [characterization, identification, and confirmation] using aquatic organism toxicity tests.)

WASTE: As used in this document, waste includes a discharger's total discharge, of whatever origin, i.e., gross, not net, discharge.

WATER QUALITY-LIMITED SEGMENT: Any segment of a water body where it is known that water quality does not meet applicable water quality standards, and/or is not expected to meet applicable water quality standards, even after application of technology-based effluent limitations required by CLEAN WATER ACT sections 301(d) or 306.

Technical Report 522

ACKNOWLEDGMENTS

The authors would like to thank SCCWRP staff members Darrin Greenstein, Doris Vidal, and Becky Schaffner for their assistance in the preparation of this document. The United States Environmental Protection Agency (USEPA) Office of Research and Development provided funding for several of the data collections that supplied much of the basis for this report under the Environmental Monitoring and Assessment Program (EMAP) and National Coastal Assessment. Walter Nelson and Terry Fleming provided coordination with the USEPA. The authors would also like to thank those who contributed to data collections in the 1998 and 2003 Bight studies and Tony Olsen of the USEPA for assistance with data analyses. Lastly, the authors thank Michael Connor, Bruce Thompson, and Sarah Lowe of the San Francisco Estuary Institute for their contributions to data quality assurance and results interpretation, especially in the San Francisco Bay Region.

This study was funded in part by agreements with the State Water Resources Control Board (SWRCB) Sediment Quality Objectives (SQO) Program 01-274-250-0 and Surface Water Ambient Monitoring Program (SWAMP) Special Study 06-420-250-0.

EXECUTIVE SUMMARY

Sediment quality in California bays and estuaries was evaluated using a multiple lines of evidence (MLOE) assessment framework. This framework has been proposed for adoption as part of the sediment quality objectives (SQOs) portion of California's water quality control plan for bays and estuaries. Chemistry, toxicity, and benthic community data, each representing an independent line of evidence (LOE) regarding sediment quality, from six surveys conducted over eight years were analyzed. The analysis consisted of three parts: 1) determining sediment condition at each sampling station (site) using the assessment framework; 2) establishing a single integrated data set with known spatial attributes from the combined data of each survey; and 3) analyzing the integrated data set using spatial statistics to determine the percentage of area corresponding to each sediment condition category.

The assessment framework was used to classify 381 sites into one of the following six condition categories:

- **Unimpacted.** Confident that contamination is not causing significantly adverse impacts to aquatic life in the sediment.
- **Likely Unimpacted.** Contamination is not expected to cause adverse impacts to aquatic life in the sediment, but some disagreement among LOEs reduces certainty that the site is unimpacted.
- **Possibly Impacted.** Contamination at the site may be causing adverse impacts to aquatic life in the sediment, but the level of impact is either small or is uncertain because of disagreement among LOEs.
- **Likely Impacted.** Evidence of contaminant-related impacts to aquatic life in the sediment is persuasive, in spite of some disagreement among LOEs.
- **Clearly Impacted.** Sediment contamination at the site is causing clear and severe adverse impacts to aquatic life in the sediment.
- **Inconclusive.** Disagreement among LOEs suggests that either data are suspect or additional information is needed for classification.

Two levels of assessment were conducted. The first level used a combined data set from all surveys and evaluated statewide conditions. At the second level, spatial assessments were conducted independently for three regions within the state in order to investigate patterns related to differences in size of embayments, land use, and hydrological characteristics. The regions were: North, consisting of multiple small coastal embayments north of Point Conception to the Oregon border; South, which included multiple small coastal embayments south of Point Conception to the US-Mexico border; and the San Francisco Bay and its contiguous marine embayment areas (SFB).

Approximately 83% of the 1295 km^2 of California marine embayments included in the analysis were classified as having some degree of impact related to sediment contamination. Most of the area was classified as Possibly Impacted and less than 1% of the area was classified as Clearly

Impacted (Figure 4; Table 3). The statewide analysis results were dominated by the conditions present in SFB, which represented nearly 80% of the embayment area.

Large variations in sediment condition were present among the three geographic regions. The North region had the best sediment conditions, with 58% of the area classified as Unimpacted and no sites classified as Clearly Impacted (Figure 5; Table 4). Somewhat poorer sediment quality was observed in the South, with 43% of the area classified as Unimpacted and 2% classified as Clearly Impacted. A different distribution of sediment condition categories was present in San Francisco Bay; no sites were classified as Unimpacted and the proportion of area classified as Possibly Impacted (77%) was more than three times greater than that measured in the other regions.

The regional differences in sediment quality identified through the assessment framework were evaluated by analysis of the underlying LOEs (Chemistry, Toxicity, and Benthic Community) to examine various levels of response within each site's sediment. Sediment chemistry was least impacted in the North and most impacted in the South. The incidence of biological effects (toxicity or benthic community disturbance) was greatest in SFB and appeared to account for the comparatively high percent area classified as Possibly Impacted or Likely Impacted.

The large percentage of Possibly Impacted area within SFB suggests that sediment contaminants are more widespread and less concentrated in this region, possibly due to contaminant dilution and redistribution as a result of greater rainfall, high runoff inputs from urban and agricultural sources, and tidal mixing. There is also evidence that the relationship between sediment contamination and toxicity in SFB differs from that observed in other regions. As the causes of toxicity in California embayments have not been identified, the reason for this apparent difference in toxicity response cannot be determined. Unmeasured contaminants, such as current use pesticides, may be influencing these relationships. It is also possible that contaminant bioavailability differs between regions or that different contaminants are causing toxicity in each area.

The results of this study's integrated analysis using the assessment framework are consistent with previous studies of sediment quality in California bays and estuaries. However, use of the framework and combined survey data produced a more comprehensive and robust assessment of statewide sediment quality than has been achieved previously. Moreover, this study's assessment of sediment conditions on both statewide and regional scales can be used as a benchmark for future studies.

TABLE OF CONTENTS

INTRODUCTION

Sediment quality has an important influence on the overall condition of a water body. Sediments act as a reservoir for contaminants that can be transferred to the water column through physical disturbance, diffusion, and biological activities. Also, sediments are a primary source of contaminant exposure for sediment-dwelling organisms and animals that feed on the bottom, such as crabs and flatfishes. This exposure can produce adverse impacts on benthic communities and can also lead to indirect effects on wildlife and human health due to the accumulation of contaminants from the food chain.

Historically, sediment quality assessment has been an important feature of many California monitoring programs. It was a major focus in the Bay Protection and Toxic Cleanup Program (BPTCP; Anderson *et al.* 1997), the California Environmental Mapping and Assessment Program (EMAP; USEPA 2005), the San Francisco Regional Monitoring Program (SFEI 2005), and the Southern California Bight Regional Monitoring Program (SCCWRP 2003, 2007). Although numerous sediment quality surveys have recently been conducted, like the ones cited above, these studies focused on areas and used methods for data interpretation different from those used in this study, thereby preventing the integration of such data for analysis and inclusion in a statewide assessment of sediment conditions in California's embayments (bays and estuaries). Comprehensive sediment quality information is needed for California's 305(b) and 303(d) programs to establish priorities for water quality programs at the State and Regional Boards. The present study, under the auspices of the State Water Ambient Monitoring Program (SWAMP), is intended to provide this assessment.

Sediment is a complex matrix of components and forms. Consequently, evaluating contaminant impacts on beneficial uses based on a single line of evidence is problematic. For example, bulk measures of chemical concentration fail to differentiate between the fraction of a contaminant that is tightly bound to sediment and that which is biologically available. Multiple mechanisms of contaminant exposure, including uptake of chemicals from interstitial water, sediment ingestion, and bioaccumulation through the food web further complicate interpretation of sediment chemistry data.

For these reasons, sediment quality assessment often involves simultaneously evaluating multiple lines of evidence (MLOE) that measure both contaminant exposure and effects on organisms: an approach commonly known as the sediment quality triad (Long and Chapman 1985). Lines of evidence (LOEs), such as sediment chemistry, toxicity, and benthic community condition are often used. Virtually all of the ambient sediment quality monitoring programs in this country rely on more than one line of evidence (USEPA 1998, Crane *et al.* 2000, MacDonald and Ingersoll 2002, USEPA 2004). Such programs include the two largest nationwide estuarine monitoring programs: the United States Environmental Protection Agency (USEPA) EMAP and the National Oceanic and Atmospheric Administration (NOAA) National Status and Trends Program, as well numerous regional monitoring programs. The California State Water Board BPTCP also relied primarily on MLOE to assess sediment quality in bays and estuaries throughout the state (Anderson *et al.* 1997, Fairey *et al.* 1998, Phillips *et al.* 1998, Anderson *et al.* 2001, Hunt *et al.* 2001).

Staff at the State Water Resources Control Board (SWRCB) has proposed draft sediment quality objectives (SQOs) that use an assessment framework based on an MLOE approach to evaluate sediment quality in embayments (SWRCB 2007). If adopted, these SQOs will become the regulatory standard against which ambient sediment quality is measured, influence management and regulatory decisions, and serve as the basis for evaluating water body impairment (e.g., 303(d) listings) with regard to sediment quality.

Previous statewide assessments of sediment condition in California have been limited in terms of data integration and interpretation. Results from a 1999 EMAP survey were used to describe the statewide extent of sediment contamination, toxicity, and benthic community characteristics, but these separate LOEs were not integrated to assess overall sediment condition (USEPA 2005). Recent 305(b) reports of California sediment quality have included data from multiple studies, but again the condition assessment was limited by a lack of integration of LOEs and the use of variable data interpretation approaches among studies (SWRCB 2006, USEPA 2004).

This report represents the first application of the proposed assessment framework on a statewide basis to evaluate sediment quality in California's marine and estuarine embayments. The focus of this analysis is on the direct effects of contamination on aquatic life due to sediment contact or ingestion, rather than effects on humans or wildlife due to indirect exposure through the consumption of fish and shellfish. For this assessment, data from recent EMAP, SWAMP, and southern California Bight surveys were combined and evaluated using a common set of assessment indicators within an assessment framework.

Two levels of assessment were conducted (Figure 1). The first level evaluated statewide conditions. The purpose of this level was to determine the percentages of the State's embayments with various levels of impact from sediment contamination. At the second level, spatial assessments were conducted independently for three regions within the state in order to investigate patterns related to differences in size of embayments, land use, and hydrological characteristics. The northern region (North) included multiple small coastal embayments north of Point Conception to the Oregon border. The North embayments were characterized by low population density, where agricultural use is important and freshwater inputs are relatively high. The southern region (South) included multiple small coastal embayments south of Point Conception to the US-Mexico border. These southern embayments were often surrounded by high population density, extensive commercial/industrial use, and low freshwater inputs. The third assessment region was the San Francisco Bay and its contiguous marine embayment areas (SFB). The hydrology of the SFB is different from the North and South in that runoff into SFB is nearly continuous, tidal mixing is strong, and agricultural and industrial uses are relatively high.

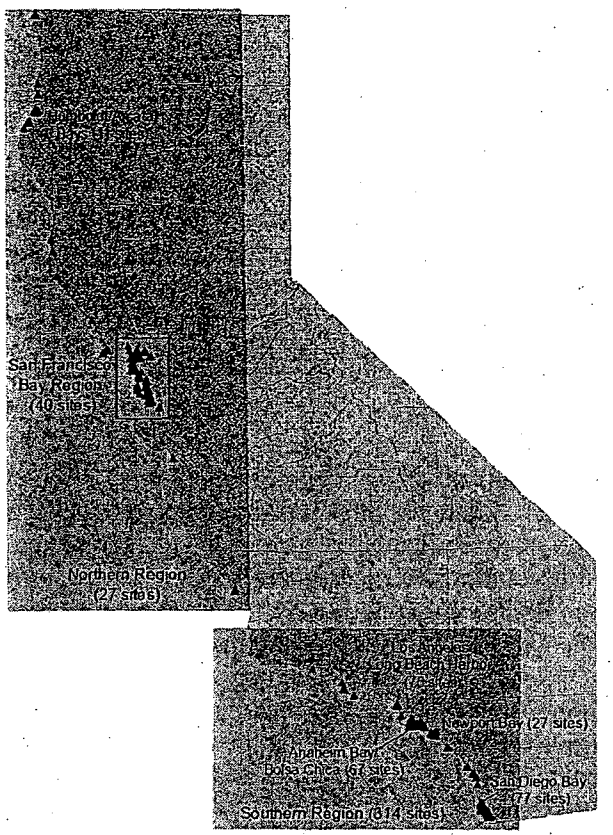

Figure 1. Distribution of sampling sites for the statewide assessment. The shaded boxes indicate the three regional assessment areas.

METHODS

The proposed assessment framework for California's SQOs (SWRCB 2007) was applied to data from multiple random stratified surveys conducted throughout the state to evaluate the sediment quality of marine embayments. The analysis consisted of three parts: 1) determining sediment condition at each sampling station (site) using MLOE response classifications or attributes; 2) establishing a single statewide data set with known spatial attributes based on the integrated data for all stations within each survey; and 3) analyzing the integrated data set using spatial statistics to determine the percentage of area corresponding to each sediment condition category. Spatial analyses were conducted for the state as a whole and regionally for northern California (North), the San Francisco Bay (SFB), and southern California (South).

Data

The statewide and regional estimates of sediment condition were based on data collected from six stratified random surveys with probability-based designs, conducted over eight years (Table 1). Probability-based designs were selected because the area represented by each site was known, allowing sampling results to be expressed as the percent area affected. In addition, each survey met the following criteria: (i) samples were collected within 10 years of the current analysis, (ii) site locations were subtidal areas within bays and estuaries, (iii) corresponding data for sediment chemistry, toxicity, and benthic macrofauna were available, and (iv) sampling and analysis methods were comparable to those specified in the proposed SQO assessment framework. Several recent regional surveys did not meet these criteria and were not used in this study for reasons that included lack of a probability-based design (e.g., San Francisco Bay Regional Monitoring Program) and lack of sediment toxicity data or comparable toxicity/benthic macrofauna measurement methods (e.g., selected Western EMAP (WEMAP) surveys).

Sample collection for each survey was conducted in the summer and used comparable methods; however, the surveys encompassed different years and geographic regions. Two WEMAP surveys examined embayments along the entire California coast in 1999 and 2005, while one survey was limited to San Francisco Bay (2000). Three surveys included only southern California embayments: two examined multiple embayments along the entire southern coast (1998, 2003), while the third was an intensive study of only Huntington Harbor and Anaheim Bay (2001). These surveys followed the USEPA's Generalized Random Tessellation Stratified (GRTS) design with the intent of balancing samples spatially while allowing for intensification in certain areas of interest (http://www.epa.gov/nheerl/arm/designpages/design&analysis.htm).

Table 1. Probability-based surveys and number of sites per region for each survey.

Survey	Year	Area (km^2)	Number of Sites		
			North	SFB	South
Southern California Bight Regional Monitoring Program	1998	122	0	0	113
	2003	135	0	0	102
WEMAP	1999	139	19	0	24
	2000	1020	0	40	0
	2005	139	8	0	15
Huntington Harbor and Anaheim Bay Survey	2001	1.4	0	0	60
Total			27	40	314

Determination of Sediment Condition

Three lines of evidence: sediment chemistry, toxicity, and benthic macrofaunal community condition (benthos) were evaluated at each site. The indices and thresholds described in the draft SQO policy for California were then used to assign sediment assessments to one of four response-level categories relevant to respective LOEs. Details of the specific measures used for each LOE are provided in SWRCB (2007). The LOE responses were then integrated using the assessment framework to determine the level of impact, if any, with respect to sediment contamination for each site. A summary of each LOE and the integration process is provided below.

Lines of Evidence

Chemistry. A combination of two sediment chemistry indices was used to determine the magnitude of chemical exposure at each site: the California Logistic Regression Model (CA LRM) and the Chemical Score Indicator (CSI). The CA LRM was developed using a logistic regression modeling approach that estimates the probability of acute toxicity in sediments based on the chemical concentration (Field *et al.* 2002, USEPA 2005) calibrated using California data (Bay *et al.* 2007a). The CSI was developed using California data and is based on the association of chemical concentration with benthic community disturbance (Ritter *et al.* 2007). Calculation of the CSI differed from Ritter *et al.* (2007) by not including data for cadmium in order to maintain consistency with the SWRCB draft policy. Index-specific thresholds were then applied and resulting CA LRM and CSI exposure categories were averaged to determine an overall response for the chemistry LOE. The response-level categories used to define chemical exposure assessments were:

- **Minimal Exposure** - Sediment-associated contamination may be present, but exposure is unlikely to result in effects.
- **Low Exposure** - Small increase in contaminant exposure that may be associated with increased effects, but magnitude or frequency of occurrence of biological impacts is low.
- **Moderate Exposure** - Clear evidence of sediment contaminant exposure at concentrations that are likely to result in biological effects.
- **High Exposure** - Contaminant exposure is highly likely to result in substantial biological effects.

Toxicity. The 10-day amphipod survival test using *Eohaustorius estuarius* was used to determine the magnitude of sediment toxicity at each site (USEPA 1994). Thresholds based on percentage survival and statistical significance were applied to assign test results to one of the following response-level categories used to define toxicity assessments (Bay *et al.* 2007b):

- **Nontoxic** - Response not substantially different from that in uncontaminated control sediments.
- **Low Toxicity** - A low magnitude response that differs from control survival, but is within the variability typical for that test and thus may not be a reproducible effect.
- **Moderate Toxicity** - High confidence that a statistically significant toxic effect is present.
- **High Toxicity** - High confidence that a toxic effect is present and the magnitude of response includes the strongest effects observed for the test.

Benthos. A combination of up to four benthic community condition indices was used to determine the magnitude of disturbance to the benthos at each site. The indices include approaches based on community metrics and abundance of individual species. The benthic indices used include:

Benthic Response Index (BRI), which was originally developed for the southern California mainland shelf and extended into California's bays and estuaries (Smith *et al.* 2001, 2003). The BRI is the abundance-weighted average pollution tolerance score of organisms occurring in a sample.

Index of Benthic Biotic Integrity (IBI), which was developed for freshwater streams and adapted for California's bays and estuaries (Thompson and Lowe 2004). The IBI identifies community measures that have values outside a reference range.

Relative Benthic Index (RBI), which was originally developed for California's Bay Protection and Toxic Cleanup Program (Hunt *et al.* 2001). The RBI is the weighted sum of: (i) several community metrics, (ii) the abundances of three positive indicator species, and (iii) the presence of two negative indicator species.

River Invertebrate Prediction and Classification System (RIVPACS), which was originally developed for British freshwater streams (Wright *et al.* 1993, Van Sickle *et al.* 2006) and

adapted for California's bays and estuaries. The RIVPACS index calculates the number of reference taxa present in the test sample and compares it to the number expected to be present in a reference sample from the same habitat.

Not all indices were used in each region, due to the lack of calibration for some habitats. All four indices were used for most stations in the South (except that RIVPACS data were not available for the Huntington Harbor and Anaheim Bay survey) and portions of SFB. The RBI and IBI were used to evaluate the remainder of the SFB sites. The RBI was used to evaluate all of the North sites.

Thresholds specific to regional assemblages were applied to the results in order to classify each index result according to the level of disturbance. The resulting disturbance categories were then combined to provide an overall benthos LOE category. The four response-level categories used to define benthic condition assessments were:

- **Reference** - A community composition equivalent to a "least affected" or "unaffected" site.
- **Low Disturbance** - A community that shows some indication of stress, but could be within measurement error of unaffected condition.
- **Moderate Disturbance** - Confident that the community shows evidence of physical, chemical, natural, or anthropogenic stress.
- **High Disturbance** - Changes in the benthos are substantial enough to limit community function.

Integration of LOE Response Levels

The response-level categories within each of the three LOEs resulted in 64 possible combinations of outcomes (Appendix A). Each combination was associated with one of six final site condition classes. This was accomplished in a two-step process (Figure 2). Individual LOEs were first combined to form two intermediate classifications describing (i) the severity of biological effects and (ii) the potential for chemically mediated biological effects. These intermediate classifications were then integrated to determine the final MLOE assessment of site condition.

The benthos and toxicity LOEs were integrated to determine the severity of biological effects category for the site: Unaffected, Low Effect, Moderate Effect, or High Effect. The benthos LOE was given greater weight for determining this classification, as the benthic community is the resource to be protected. Moreover, the severity of effects classification reflects disturbance to the benthic community due to a variety of causes and is not intended to differentiate between effects that are due to chemical contaminants, physical disturbance of the habitat, or organic enrichment.

The potential for chemically mediated effects was determined using the toxicity and chemistry LOE categories data. These data were integrated to assign samples into one of four classifications describing the potential that the observed biological effects were caused by chemical contaminants: Minimal Potential, Low Potential, Moderate Potential, or High

Potential. The chemistry LOE was given slightly greater weight in determining this classification. The toxicity LOE was included in this classification because sediment toxicity is a measure of the bioavailability of sediment contaminants and also indicates whether unmeasured chemicals are present at levels of potential biological concern. The relationship of each LOE category to the intermediate response classifications is shown in Appendix A.

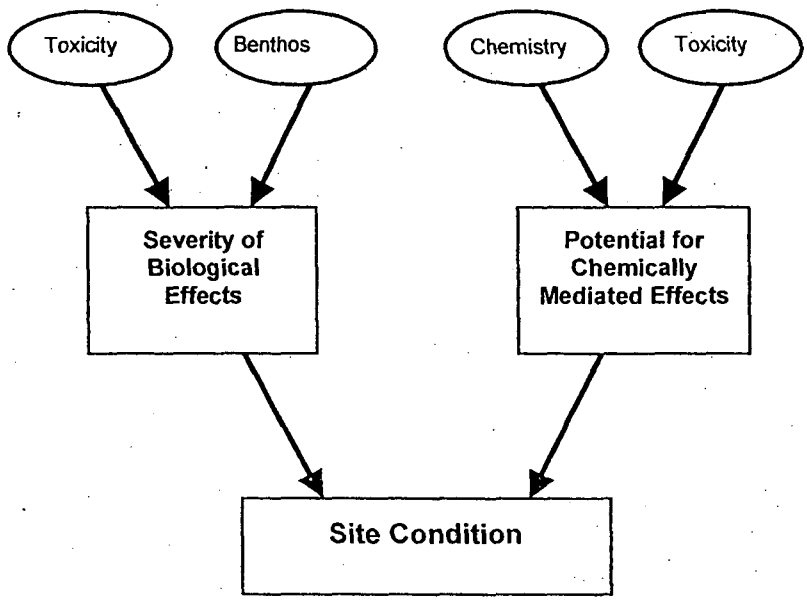

Figure 2. MLOE integration for site assessment.

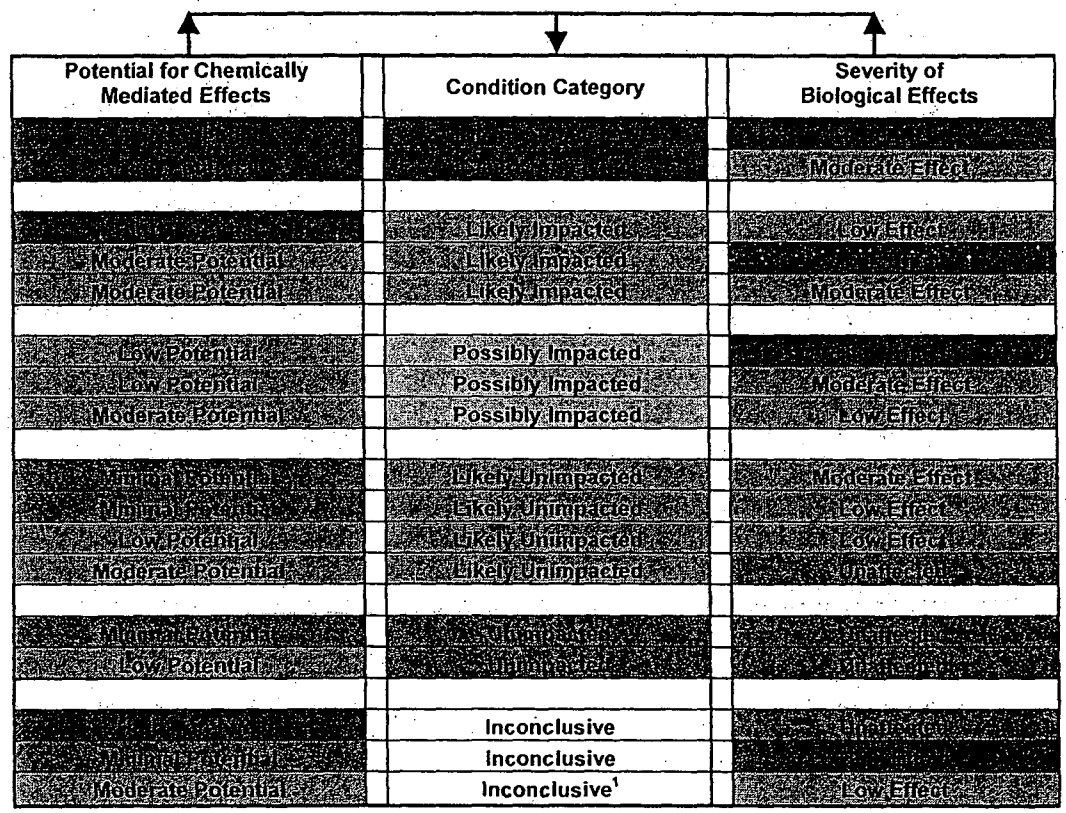
The final MLOE site condition categories (Table 2; Appendix A) were based on the severity level of biological effects and the potential for chemically mediated effects. Six assessment classes were developed to describe the contaminant impact in terms of level of certainty and magnitude:

- **Unimpacted.** Confident that chemical contamination is not causing significantly adverse impacts to aquatic life in the sediment.
- **Likely Unimpacted.** Chemical contamination is not expected to cause adverse impacts to aquatic life in the sediment, but some disagreement among the LOEs reduces certainty that the site is Unimpacted.
- **Possibly Impacted.** Chemical contamination at the site may be causing adverse impacts to aquatic life in the sediment, but the level of impacts is uncertain because of disagreement between LOEs.
- **Likely Impacted.** Evidence of contaminant-related impacts to aquatic life in the site sediment is persuasive, in spite of possible disagreement among LOEs.
- **Clearly Impacted.** Sediment chemical contamination at the site is causing clear and significantly adverse impacts to aquatic life in the sediment.

- **Inconclusive.** Disagreement among the LOEs suggests that either data are suspect or additional information is needed for classification.

Two central concepts were incorporated in the determination of the impact categories: (i) both exposure and effect must be present in order to classify a site as impacted and (ii) a greater magnitude of effect or exposure results in a more severe impact assessment category.

Table 2. Relationship of intermediate LOE classifications to final MLOE site condition categories. Arrows indicate the sequence of classification. The site condition assessment resulting from each possible LOE combination is shown in Appendix A.



[1] Inconclusive category results when High toxicity, Minimal chemical exposure, and a Reference benthic community are present.

Determination of Percent Area of California Embayments for Each Site Condition Category

The random stratified sampling design for each of the six surveys considered in this study consisted of three main components used for tesselation: a sampling frame, stratification, and polygons. The sampling frame represented the boundaries of the survey. Some surveys included strata (e.g., ports, marinas), while no stratification was used in others. Different polygons (subregions within a stratum) were used to constrain sample point distribution or control sample density. Consequently, the area weights (proportional to the number of sites within a stratum) of individual sample points varied greatly between surveys.

In order to conduct a statewide assessment that was spatially representative, the survey designs were combined to produce a common sampling frame and level of stratification. Three strata (regions) were established: North, SFB, and South. Within each region, the polygons representing survey-specific sampling frames and different sample densities were compared for each survey and a single set of polygons were drawn that included all of the combined area sampled. New area weights were calculated for the sites within each region by dividing the area of each final polygon by the number of sites within the area. Figure 3 provides an example of combining survey data points and sampling polygons for Newport Bay in the South region.

Two years of survey data were combined for the North: WEMAP 1999 and WEMAP 2005. No stratification was used for the data from the 2005 survey. As a result, we used the polygons from the 1999 survey and recalculated area weights based on the number of samples from both surveys falling within these polygons. For San Francisco Bay, there was only one survey, WEMAP 2000, therefore no adjustment of polygons or area weights were needed.

In the South, combining the data and calculating new area weights were more complex, as five surveys were integrated. Polygons that overlapped among surveys were split into subpolygons that reflected disjoint areas. New area weights were calculated by dividing the area of each subpolygon by the number of samples that fell into that subpolygon, regardless of survey.

Estimates of the percent area representing various sediment condition classifications were calculated using the new area weights. The proportion of each region representing each MLOE condition category was calculated as the sum of the area weights of the samples that fell into that category divided by the sum of the area weights for all samples within the region. This proportion was then converted to a percentage. The area (km^2) represented by this percentage was calculated by multiplying the proportion by the total area of the region. Confidence intervals for these estimates were computed using the local variance estimator option in the EPA analysis tools (Stevens and Olsen 2003, http://www.epa.gov/nheerl/arm/designpages/design&analysis.htm).

Statewide estimates of condition were calculated in the same manner used for the regional estimates. The area weights of sites having the same MLOE sediment condition classification in all regions were summed and then divided by the sum of the area weights in all regions. This calculation was repeated for each MLOE site condition category. The statewide area corresponding to each an MLOE condition category was calculated by multiplying the proportion by the total area of the three regions.

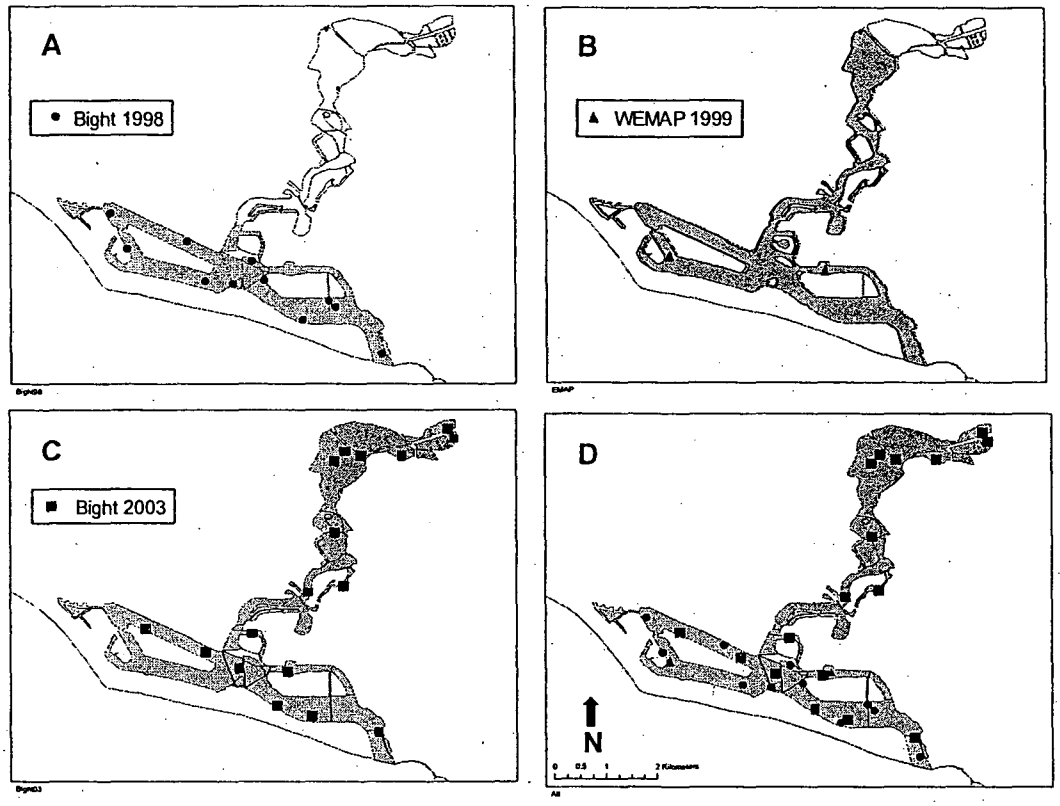


Figure 3. Combination of data from multiple surveys (illustrated for Newport Bay). Sampling polygon and data points for Southern California Bight Regional Monitoring Program 1998 survey restricted to lower bay (A). Sampling polygon and data points for WEMAP 1999 survey (B). Southern California Bight Regional Monitoring Program 2003 sample points associated with two separate polygons representing different sampling intensities (C). Combined data from all surveys associated with two polygons representing entire area sampled (D).

RESULTS

Statewide Assessment of Sediment Quality

Approximately 83% of the 1295 km^2 of California marine embayments included in the analysis was classified as having some degree of impact related to sediment contamination. Most of the area was classified as Possibly Impacted, the most uncertain classification, and less than 1% of the area was classified as Clearly Impacted, the most severe impact category (Figure 4; Table 3). The statewide analysis results were dominated by the conditions present in SFB, which represented nearly 80% of the embayment area.

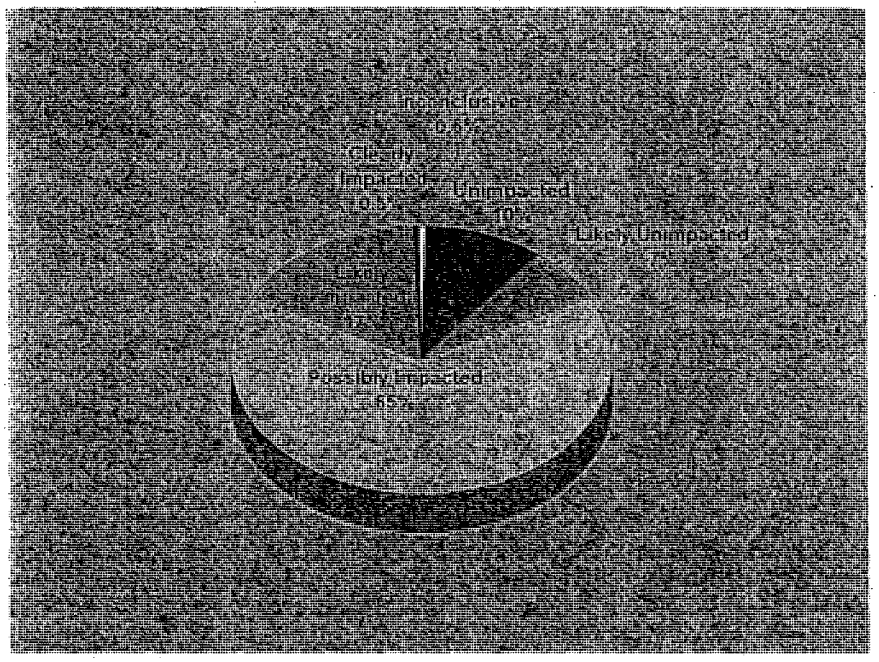

Figure 4. Percent area of California embayments for each sediment condition category as classified by the MLOE assessment framework.

Table 3. Statewide embayment sediment quality condition based on MLOE assessment. Further details on confidence limits and areas represented by each condition classification can be found in Appendix B.

Condition Category	Number of Sites	Percent Area	0.95 Confidence Limits
Unimpacted	131	10%	8 – 12%
Likely Unimpacted	57	7%	2 – 12%
Possibly Impacted	111	65%	55 – 76%
Likely Impacted	51	17%	7 – 26%
Clearly Impacted	25	0.5%	0 – 1%
Inconclusive	6	0.6%	0 – 1%
Total	381	100%	

Regional Assessment of Sediment Quality

Large variations in sediment condition were present among the three geographic regions. The North region had the best sediment condition, with 58% of the area classified as Unimpacted and no sites in the Clearly Impacted category (Figure 5; Table 4). Somewhat poorer sediment quality was observed in the South, with 43% of the area classified as Unimpacted and 2% classified as Clearly Impacted. A different distribution of sediment condition categories was present in San Francisco Bay; no stations were classified as Unimpacted and the proportion of area assigned to the Possibly Impacted category (77%) was more than three times greater than that measured in the other regions. The uncertainty in condition estimates varied among regions as a function of sample size. The estimates were most precise for the South, with 95th percentile confidence intervals of about 10%; confidence intervals for SFB and the North were usually two to three times greater (Table 4).

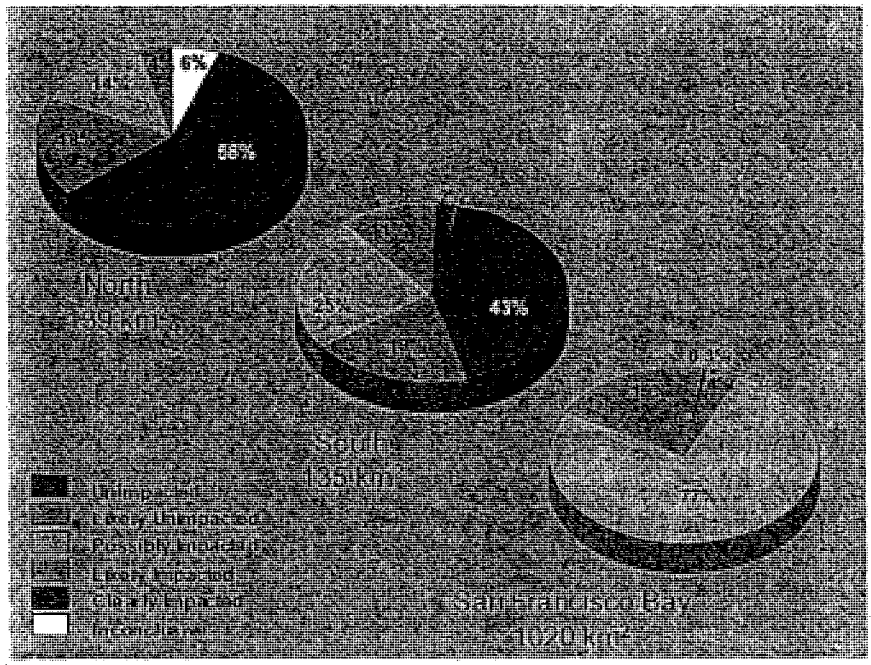

Figure 5. Percent area of sediment quality classification for regional MLOE assessments.

Table 4. Regional embayment sediment quality condition based on MLOE assessment. Further details on confidence limits and areas represented by each condition classification can be found in Appendix B.

Condition Category	Number of Sites	Percent Area	0.95 Confidence Limits
North			
Unimpacted	9	58%	37 – 80%
Likely Unimpacted	9	18%	1 – 34%
Possibly Impacted	4	14%	0 – 29%
Likely Impacted	2	4%	0 – 9%
Clearly Impacted	0	0%	-
Inconclusive	3	6%	0 – 12%
Total	27	100%	
SFB			
Unimpacted	0	0%	-
Likely Unimpacted	2	4%	0 – 10%
Possibly Impacted	28	77%	64 – 89%
Likely Impacted	9	19%	7 – 31%
Clearly Impacted	1	0.3%	0 – 1%
Inconclusive	0	0%	-
Total	40	100%	
South			
Unimpacted	122	43%	36 – 49%
Likely Unimpacted	46	19%	13 – 25%
Possibly Impacted	79	25%	19 – 30%
Likely Impacted	40	11%	7 – 15%
Clearly Impacted	24	2%	1 – 3%
Inconclusive	3	0.3%	0 – 0.6%
Total	314	100%	

Sediment Condition in Individual Embayments

A total of 381 sites were assessed in this study. Eight embayments contained 84% of the data and had sufficient numbers of sites to examine spatial patterns of condition within them (Figure 6; LOE combinations that resulted in the designated impact condition at each site are presented in Appendix C). Patterns of sediment condition could not be described for many of the small embayments because only one or two sites were located within them.

Two major spatial patterns of site condition were evident among the selected embayments. First, there was a greater proportion of Likely Impacted and Clearly Impacted sites in inner harbor and marina areas (e.g., Los Angeles and Huntington Harbors). Second, the more impacted sites tended to be located near the perimeters of the embayments where ports or commercial areas are situated (e.g., San Francisco and San Diego Bays).

Locations having the greatest severity of impacts (Clearly and Likely Impacted) were Huntington Harbor (a marina) and inner Los Angeles Harbor including Dominguez Channel. Sediment conditions were better at the deeper locations in Outer Los Angeles and Long Beach Harbors and outer Anaheim Bay, presumably due to increased distance from sources and better circulation. Similar trends were observed in the deeper waters of mid- and northern San Diego Bay, and Alamitos Bay. Typical of the North, most of the sites in Humboldt Bay were classified as Unimpacted or Likely Unimpacted (Figure 6).

Sites having Likely Impacted and Possibly Impacted sediment quality were most prevalent in Newport Bay and San Francisco Bay (Figure 6). Each of these embayments had over 80% of sites classified as either Likely Impacted or Possibly Impacted.

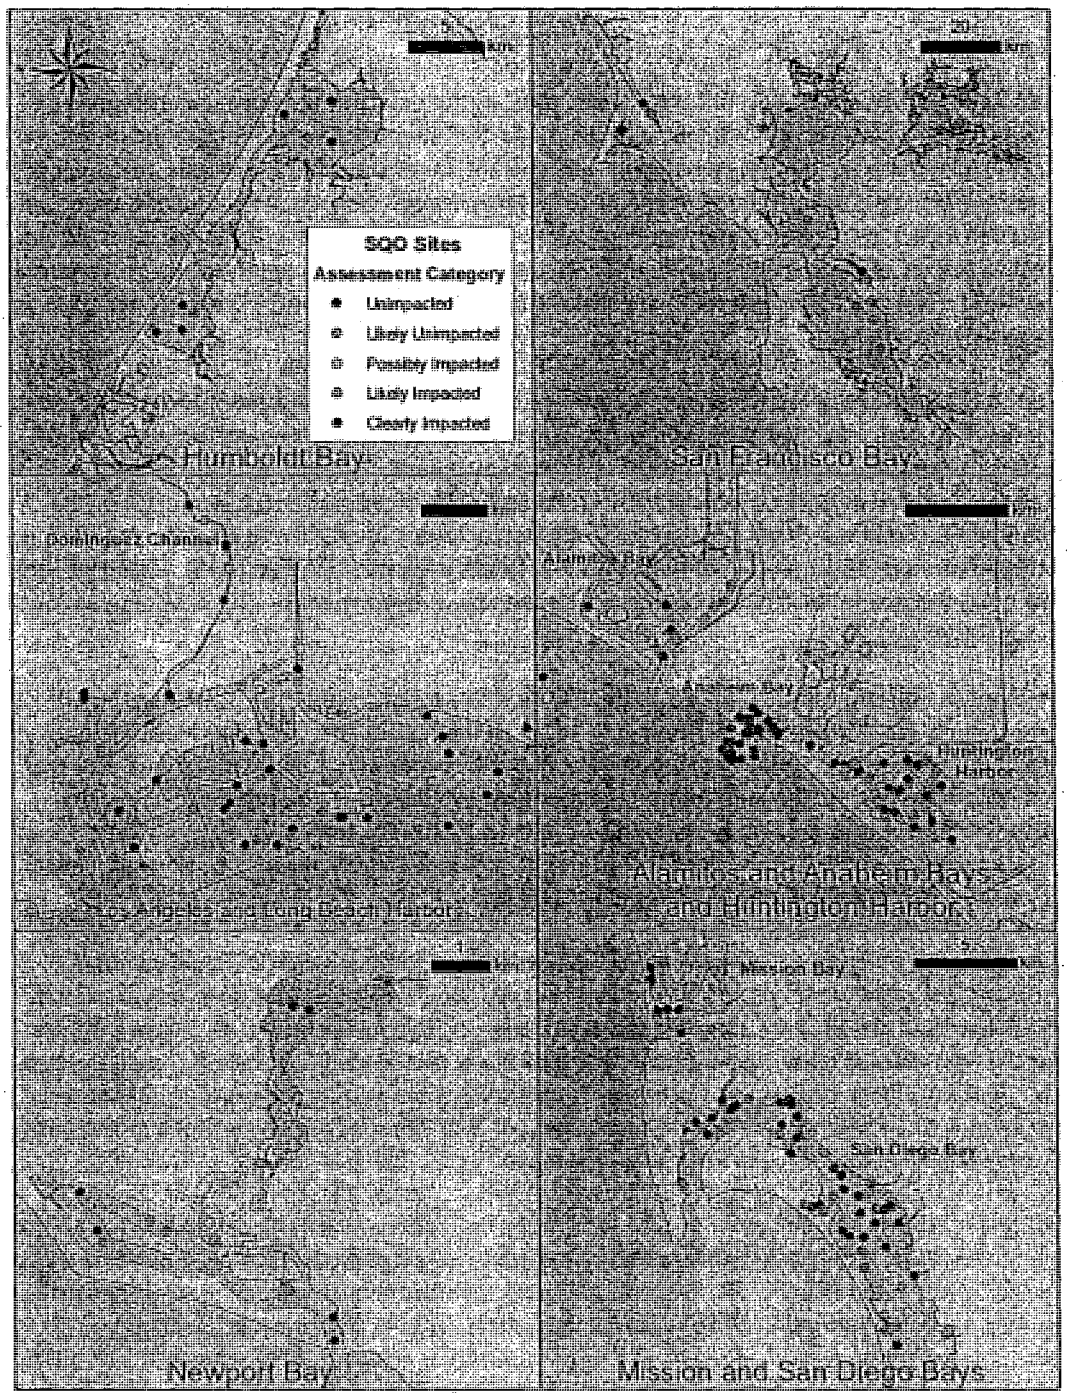

Figure 6. Sediment quality in selected California embayments. Further details for each site in these embayments are shown in Appendix C.

DISCUSSION

Sediment quality was found to be highly variable among California's marine and estuarine embayments. The SFB region had seven and one-half times the area of either the North or the South regions. As a result, the statewide assessment of condition in California embayments was dominated by the condition of SFB. A more representative view of the status of California's bays and estuaries was obtained from the regional analyses (Figure 5; Table 4), which found northern embayments to be the least impacted, and southern embayments to be less impacted than SFB. However, in contrast to the North and South, most of the SFB region was assessed as Possibly Impacted.

This study used an integrated analysis based on a novel MLOE assessment framework, resulting in a more spatially and temporally comprehensive and standardized analysis than previous studies of sediment quality in California bays and estuaries. Nevertheless, the results of this study are consistent with prior analyses. An assessment of coastal condition in 1999 (that included the WEMAP 1999 data used in the present study) found low levels of metal and organic contamination in embayments in the North and South regions (USEPA 2005). The 1999 survey also measured a similar extent of sediment toxicity to *E. estuarius* (19 - 24% of the area) as the present assessment.

The high prevalence in the South of sediment with Possibly, Likely, or Clearly Impacted conditions is consistent with previous studies by BPTCP. The BPTCP surveys also found a high frequency of sediment toxicity to amphipods, benthic community degradation, and elevated contaminant concentrations in multiple Southern embayments, including San Diego Bay, Newport Bay, Huntington Harbor, and Los Angeles Harbor (Fairey *et al.* 1998, Phillips *et al.* 1998, Anderson *et al.* 2001). The BPTCP program had different objectives, however, and focused on identifying the most highly impacted sites.

The widespread toxicity reported for SFB has been documented in BPTCP and regional monitoring studies since the 1980s (Anderson *et al.* 2007). While the spatial extent of toxicity calculated from the SFB data analyzed in this study appears to be somewhat larger than that found in the other studies, certain locations in SFB are consistently toxic to *E. estuarius* and other species. Prior studies have also observed benthic community degradation and reduced populations of localized clam species in portions of San Francisco Bay, with the greatest impacts associated with shallow water locations (Thompson *et al.* 2007).

SFB had a greater percentage of area in the Likely Impacted and Possibly Impacted condition than in the South where a greater portion of the area was classified in the most extreme category of Clearly Impacted (Figure 5). Whereas southern California is an area of greater industrial, commercial, and population concentration, the pattern in SFB suggests that sediment contaminants are more widespread and less concentrated, possibly due to contaminant dilution and redistribution as a result of greater rainfall, runoff, and tidal mixing.

Relationships Among LOEs

Because SFB sediment quality was so different from that in the North or South, further analyses and regional comparisons were conducted to investigate the results. The regional differences in sediment quality identified by the MLOE assessment were evaluated by analysis of the underlying lines of evidence (Chemistry, Toxicity, and Benthic Community). The percentage of area classified as having Moderate or High effects (i.e., affected) for each LOE were calculated for each region (Table 5). Sediment chemistry showed the lowest level of response in the North (1%) and greater impacts in the South and SFB. The North also had a low percentage of area with elevated toxicity (Table 5); however, a moderately high percentage of the area was classified as having affected benthos. This combination of results suggests that the benthos in the North might be affected by physical disturbance or noncontaminant stressors or that our indices are less well calibrated in this region.

The greater proportion of area with Possibly Impacted or Likely Impacted designations in SFB (Figure 5) was reflective of large percentages of this region's total area having either affected benthos or toxicity (Table 5; Appendix C). With lower percentages of areas of the South in the affected categories for benthos and toxicity (relative to SFB) and a moderate percentage affected for chemistry, the MLOE assessment framework seemed consistent in classifying most of the South as Unimpacted or Likely Unimpacted, although to a lesser degree than in the North (Figure 5). Thus, the patterns of individual LOE responses found in each region were consistent with the regional percentage area results.

Table 5. Percent of area affected for each LOE. Area 'Affected' = sum of percent area classified as moderate and high response categories.

	Percent Area Affected Per LOE		
Region	Benthos	Toxicity	Chemistry
North	27	17	1
SFB	34	85	20
South	23	28	40

There appeared to be a different relationship between chemistry and toxicity for the South and SFB. San Francisco Bay had high incidences of affected benthos and toxicity relative to the South, yet the extent of chemical contamination was lower in general (Table 5). The difference in this relationship is evident when the magnitude of toxicity (percent mortality) in a sample is compared to the magnitude of contamination between the regions (Figure 7). San Francisco Bay sediments tend to produce a greater toxic response than southern California sediments at similar levels of contamination (as represented by the CA LRM Pmax value). As the causes of toxicity in the South and San Francisco Bay were not identified in this study, the reason for this apparent difference in toxicity response cannot be determined. Unmeasured contaminants, such as current use pesticides, may be influencing these relationships. Prior studies in San Francisco Bay have

shown a correlation between biological impacts and sediment contamination in general, but a specific chemical cause for the majority of the effects has yet to be identified (Thompson *et al.* 2007). It is also possible that regional differences in contaminant bioavailability or contamination patterns are affecting the relationship between chemistry and toxicity.

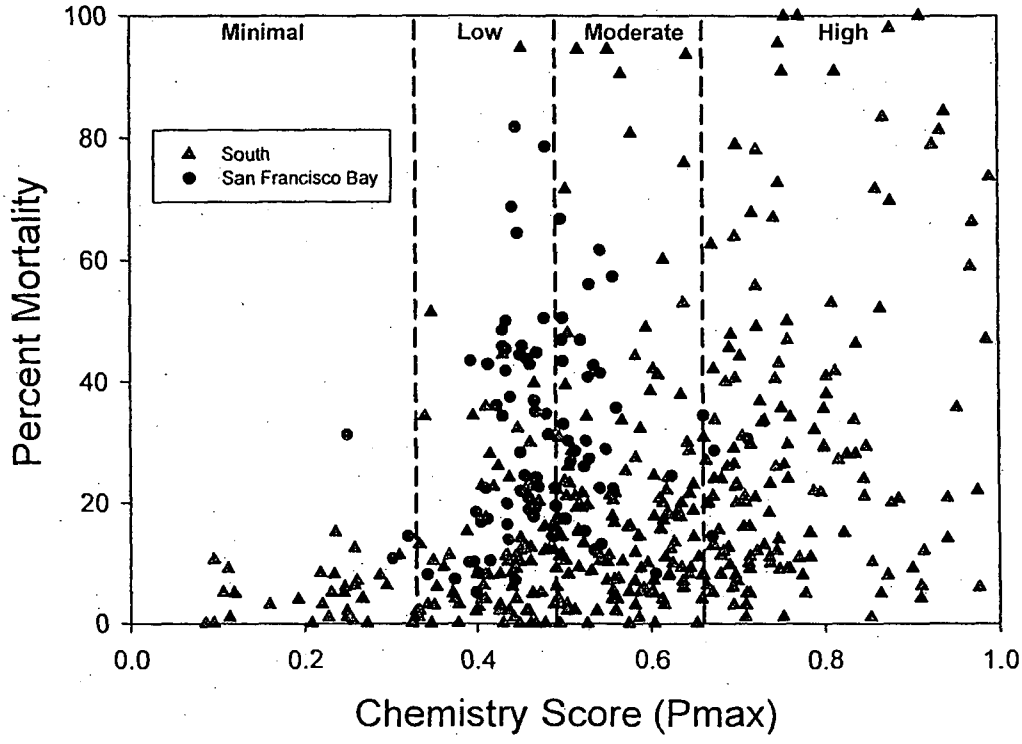

Figure 7. Toxicity:chemistry relationships in the South and SFB regions. The chemistry score is the CA LRM maximum probability of toxicity; dashed lines indicate the probability thresholds for the four response-level categories of chemical exposure.

Sources of Uncertainty

This assessment utilized a new approach and there are several sources of uncertainty in the results. First, the indices used to classify benthic community condition varied among regions due to a lack of habitat-specific calibration data for some of the indices. Four indices were used in the South, whereas only one index (RBI) was available for the North. Four benthic indices were also used in central SFB, but only the RBI and IBI were available for use in interpreting data from San Pablo Bay and the south Bay. All available indices were used wherever possible, as analyses have shown that the use of multiple indices gives a more accurate assessment of benthic community condition (Ranasinghe *et al.* 2007). To test the effect of using various combinations of benthic indices on the classifications, the analyses were repeated using only the RBI to classify benthic community condition in each region. While the percent of area classified as having affected benthos was increased when only the RBI was used, the effect on the overall sediment condition assessment was minor (Table 6).

The high abundance of nonindigenous species in SFB is another source of uncertainty in the benthic community evaluation. The effect of nonindigenous species on the assessments is expected to be small, since these species were included in the calibration of SFB benthic indices and prior analyses of southern California data indicate they do not confound the benthic index results. However, a detailed study to investigate the influence of nonindigenous species on the performance of the SFB benthic indices has not been conducted.

Table 6. Variability among regional area estimates based on benthic indices applied.

Region	Benthic Indices Applied	Benthos (% Moderate or High Disturbance)	MLOE (% Possibly, Likely, or Clearly Impacted)
North	All	27	18
North	RBI only	27	18
SFB	All	34	96
SFB	RBI only	85	100
South	All	23	38
South	RBI only	36	40

Another source of uncertainty is the limited number of sites available to characterize sediment quality in the North and SFB. In the present study, only 40 sites from a single survey were used in the SFB assessment, and only 27 sites were available to represent the North. Consequently, individual sites in the North and SFB had much greater area weights and a greater influence on the results than did individual sites in the South. This resulted in larger confidence intervals for the North and SFB area assessments (Table 4; Appendix B). However, even with these large intervals, statistically significant differences were observed between regions for some sediment condition categories.

A final source of uncertainty is related to the toxicity assessment. The results are based on only a single test of sediment toxicity: the 10-day amphipod survival test. While this is a widely used measure of sediment quality, the use of multiple tests is recommended for sediment quality assessment (Burton, Jr. *et al.* 1996, Greenstein *et al.* In press); the SQO assessment framework is intended to be used with at least two tests. The impact of using a single test in this assessment is unknown, but a greater proportion of the samples might have been identified as toxic if additional tests, especially those that measure sublethal effects, had been used.

Conclusions and Recommendations

The integration of multiple surveys and use of a standardized assessment framework provided a more comprehensive and robust assessment of California embayment sediment quality than has been achieved previously. This assessment yielded results that were consistent with expectations based on earlier studies, thus increasing confidence in the overall accuracy of the sediment condition assessments.

The SQO assessment approach used in this study provides a highly comparable and reproducible measure of sediment condition throughout the State. This approach identified regional differences is sediment condition and potentially different relationships between chemistry and toxicity that can only be detected by a statewide survey. Consequently, this evaluation of sediment condition at both statewide and regional scales can be used as a guide for prioritizing further research and management actions, as well as establishing a benchmark for future assessments.

Future statewide and regional assessments can be improved in several ways. The precision and confidence in the assessment can be improved by sampling more sites in SFB and North using methods that are compatible with the MLOE assessment framework. Future studies should also include multiple toxicity tests and benthic indices in order to provide greater confidence in the measurement of these lines of evidence. The environmental significance of sediments classified as Possibly Impacted is uncertain, as this category may indicate a minor level of contaminant effect, or substantial disagreement among the LOEs. Stressor identification studies, such as toxicity identification evaluations, are needed at Possibly Impacted sites to determine whether sediment quality at these sites is adversely impacted by contaminants.

Subject:	OAL file no. SWRCB_2008-0229-07 sediment quality

Chris, I left a message for you this morning as to how things are going, but maybe you're out today.

A couple of other questions came up from our rulemaking file review committee. Two were just questions on the plan and one was a request for some additional information in response to one of the comments as long as I had asked about those other 14.

In terms of the plan, on page 08602 (page 8 of the plan), the committee wondered what the standard will be for approval of the "other methods" approved for use by the boards? In other words, if there are some standards already in mind, those should be stated in the plan, or the plan should simply explain why that approval process needs to be case by case.

On page 08614 (page 20 of the plan), what does the phrase "or other waters of significant national importance" refer to?

The other response to comment (and I'll find the page in the record in the morning) was just the one in which the use of the narrative as opposed to numeric object was challenged and being responded to and you mentioned that when numeric criteria are infeasible, the Water Code and Clean Water Act authorize the use of narratives. Could you provide the Water Code and Clean Water Act cites for that?

Thank you.

Please let me know how things are going. We have a due date of 4/14.

CAROL NYGARD DROBNY

In terms of responses, I identified 12 where the response was only that Staff Disagrees, but the comment wasn't lacking in specifics or merely rhetorical. Could you flesh out the responses to those 12 somewhat please? They are on the following pages: 08717 (30), 08718 (228), 08719 (231), 08719 (557), 08727 (23), 08737 (257), 08739 (262), 08747 (20), 08777 (298), 08800 (366), 08805 (381), and 08805 (384).

On page 08725 (241), the comment contains a specific question [Does this mean that significant differences for any two lines of evidence could drive an impairment designation?] and a specific recommendation [We recommend that benthic community data must be one of the two lines of evidence suggesting adverse effects before an impairment designation is assigned.]. The response is not really responsive. Could you flesh out that response?

On page 08803 (375), the comment is that monitoring may be as infrequent as once in five years and that such infrequent monitoring will allow degradation. The response is that the language describing maximum frequency has been deleted. There is nothing in the response explaining/justifying the minimum frequency monitoring which the commenter raised. Could you flesh out that response?

Please call or reply if you have any questions.

Dale Mentink, Office of Administrative Law, 323-6817.

EVALUATION OF METHODS FOR MEASURING SEDIMENT TOXICITY IN CALIFORNIA BAYS AND ESTUARIES

Technical Report 503

FOREWARD

The State Water Resources Control Board (SWRCB) initiated a program in 2003 to develop sediment quality objectives (SQOs) for chemical contaminants in California bays and estuaries. The SQOs will include narrative descriptions of the condition to be protected and the associated analytical methods needed to determine whether the condition has been attained. The Southern California Coastal Water Research Project, in partnership with other state and federal agencies, conducted a series of technical studies in order to provide a sound scientific foundation for the selection of methods and the development of a data interpretation framework for use in the SQO program. This report presents the results of an evaluation of sediment toxicity test methods for use in the assessment of the direct effects of sediment contamination. Other reports will describe studies related to the assessment of benthic macrofaunal community condition, sediment contamination, assessment of indirect effects from consumption of contaminated seafood by humans and wildlife, and the integration of all of these data to assess overall sediment quality. Copies of this and related reports are available for download at www.sccwrp.org and www.waterboards.ca.gov.

This study was funded in part by agreement 01-274-250-0 with the State Water Resources Control Board.

ACKNOWLEDGMENTS

The authors would like to thank Art Barnett and Stephen Weisberg for their assistance in the preparation of this document. We would like to thank J. Daniel Farrar, David Moore, Bryn Phillips, and Michele Redmond for providing data that was used in the evaluation and calculation of thresholds.

Many thanks are due to the members of the Scientific Steering Committee (Todd Bridges, Rob Burgess, Tom Gries, Peter Landrum, Ed Long, and Bob Van Dolah) for their advice during all phases of this project. Finally, the authors wish to thank members of the Sediment Quality Advisory Committee and Agency Coordination Committee for their input during this study.

EXECUTIVE SUMMARY

Toxicity tests have been widely used to assess sediment quality in a variety of research, monitoring, and regulatory programs. While many programs use a combination of test methods and follow standardized protocols, there is variation between programs in the selection of test methods or in the way that the data are interpreted. This is problematic when incorporating sediment toxicity into a regulatory program with broad applicability, such as the sediment quality objectives program under development in California. Multiple factors such as test feasibility, relevance to program/policy objectives, data comparability, cost, and sensitivity must be considered, yet this information is frequently not available. In addition, a consistent method of toxicity data interpretation is needed so that station assessments conducted in one region are comparable to the results from other locations or times.

The current study had two objectives: to evaluate a variety of acute and sublethal toxicity tests in order to identify methods that were best suited for use in a statewide regulatory program, and to develop a system to classify the toxicity test results into a series of categories of effect. A list of candidate test methods was developed based on a literature review and consultation with other scientists. The candidate test methods list included acute test methods with four amphipod species. Six sublethal methods were also evaluated: a copepod life cycle test, amphipod growth, polychaete growth, clam growth, oyster cell stress, and mussel or sea urchin embryo development.

Data on the feasibility, sensitivity, variability, and cost of each candidate method were compiled from the literature and from two sets of laboratory experiments. The first set of experiments compared the relative sensitivity of each of the candidate test methods for detecting toxicity in a set of 15 sediment samples from various California embayments. A wide range of responsiveness to the samples was observed. The copepod life cycle and polychaete growth tests showed the greatest responses to the sediment samples. Some of the sublethal tests identified a smaller total number of stations as toxic than the standard amphipod survival test(s), yet each of the sublethal tests detected toxicity in some samples that were classified as nontoxic by the amphipod survival test. This suggests that sublethal tests and acute tests are complementary rather than redundant and can provide different sensitivity responses.

Experiments were also conducted to evaluate the interlaboratory variability of the clam growth and embryo development test methods when applied to both field and laboratory-spiked sediments. The interlaboratory variability of these tests was greater than reported for some amphipod survival tests, but was within the range of variability for other sublethal test methods.

The data were compiled into a matrix of test characteristics and scored based on relative performance of each test. The acute and sublethal methods were evaluated separately.

The following five tests were identified as best suited for use in a California statewide sediment quality assessment program.

Species	Taxonomic Group	Matrix	Duration (days)	Endpoint(s)
Acute				
Eohaustorius estuarius *Leptocheirus plumulosus* *Rhepoxynius abronius*	Amphipod	Whole sediment	10	Survival
Sublethal				
Neanthes arenaceodentata	Polychaete	Whole sediment	28	Growth
Mytilus galloprovincialis	Bivalve	Sediment-water interface	2	Embryo development

The use of multiple toxicity tests to assess sediment quality is suggested, as none of the test methods ranked consistently highest with respect to sensitivity or reliability. The use of a diversity of test methods provides two key advantages: it reduces the influence of spurious results from a test and it also increases the overall sensitivity of the testing program by using species with different patterns of contaminant sensitivity.

A data analysis framework was developed for the highest rated test methods. This framework was based on an ordinal scoring system consisting of four categories of effect.

- **Nontoxic:** Response not substantially different from that expected in sediments that are uncontaminated and have optimum characteristics for the test species
- **Low toxicity:** A response that is of relatively low magnitude; the response may not be greater than test variability
- **Moderate toxicity:** High confidence that a statistically significant effect is present
- **High toxicity:** Highest confidence that a toxic effect is present and the magnitude of response is among the strongest effects observed for the test

Three response thresholds (low, moderate, and high) were developed for use in assigning one of the above response categories to each test result.

Species	Low (%)	Moderate (% Control)	High (% Control)
Eohaustorius estuarius	90	82	59
Rhepoxynius abronius	90	83	70
Leptocheirus plumulosus	90	78	56
Neanthes arenaceodentata	90[1]	68	46
Mytilus galloprovincialis	80	77	42

[1] % of control growth.

Several data limitations were encountered in the course of this study that either reduced the ability of a test method to meet the minimum evaluation criteria or complicated the calculation of the classification thresholds. Research is needed to improve the feasibility

of some of the candidate test methods. Additional data are also needed to refine the thresholds for the *Leptocheirus plumulosus* and *Neanthes arenaceodentata* tests.

LIST OF TABLES

INTRODUCTION

Toxicity tests are an integral part of the sediment quality triad used in many monitoring and assessment programs (Long and Chapman 1985). These tests provide information on the potential for adverse biological effects from contaminants and are recognized as a key component of the ecological risk assessment process (USEPA 1998) and programs to evaluate the suitability of dredged material for ocean disposal (USEPA 1991, PSWQA 1995). Sediment toxicity tests have also been widely used in monitoring and assessment programs to evaluate sediment quality within coastal bays and estuaries (Fairey *et al.* 1998) and at regional and national scales (Long 2000, USEPA 2004).

A wide variety of methods have been used to measure sediment toxicity (Lamberson *et al.* 1992). Many studies use a suite of tests that includes both acute (short-term survival) and sublethal methods. Much of the acute testing has employed amphipod survival methods using standard protocols established by the U.S. Environmental Protection Agency (USEPA 1994). The use of these standard protocols provides a measure of biological effects that can be compared among regions statewide and nationwide; such comparisons are not always possible using other measures of biological effects. The types of sublethal toxicity tests used in assessment studies is more variable, with methods including growth and reproduction tests of whole sediment, pore water, water or solvent extracts of the sediment (Ringwood *et al.* 1996, Bay *et al.* 1998, Long *et al.* 1999, Long *et al.* 2005). There is little consistency among programs in the types of the sublethal tests used; selection is often performed on a site-specific basis and is based on factors such as availability of test organisms, expected sensitivity, cost, local interests, and availability of collaborators. Consequently, only a few sublethal methods have been used commonly; they include the amphipod *Leptocheirus plumulosus* 28-day growth and reproduction test (USEPA 2001), a 20-day polychaete growth test using *Neanthes arenaceodentata* (PSWQA 1995), pore water or elutriate tests using echinoderm or bivalve gametes or embryos (PSWQA 1995, ASTM 2002a, Carr and Nipper 2003), and a sediment-water interface (SWI) test using sea urchin or mussel embryos (Anderson *et al.* 1996).

Information on the comparative sensitivity of sediment toxicity tests is an important factor to consider in test selection, yet only limited data are available. Most comparative studies include just a few species and sometimes provide conflicting results (Table 1). The differences in species, test methods, sample type, and relative sensitivity of the test methods complicate the integration of the results of these studies for use in selecting methods for use in other studies. Additional comparative studies that use a consistent study design applied to each test are needed to help evaluate the relative sensitivity of the toxicity tests of interest.

The selection of sediment toxicity test methods requires a consideration of many factors in addition to sensitivity, depending upon the study's objectives and design. Much variability in method selection is found among research studies conducted on a small scale, as the emphasis is often on selecting methods to address site-specific scientific questions, method development, or building upon previous work by an investigator. Additional factors must be considered when selecting test methods for use in large-scale monitoring or regulatory programs. For example, the methods must be feasible for use by many different laboratories and at different times of the year, and have a wide tolerance of habitat variables such as sediment grain size and salinity.

Toxicity test method selection for these types of programs must consider factors such as test feasibility, relevance to program/policy objectives, data comparability, and cost, in addition to sensitivity. The sediment quality objectives (SQO) program under development by the State of California provides an example of the many factors to be considered when sediment toxicity tests are used in a regulatory context. The California SQO program is based on the sediment quality triad and will be applied to bays and estuaries throughout the state (SWRCB 2006). The selection of toxicity test methods for a statewide regulatory program must be sensitive to environmental contamination at levels that are ecologically relevant, standardized to ensure consistent application, and feasible for application in a variety of situations. The test methods should also be ecologically relevant, meaning that the choice of species and test conditions results in a test that responds to environmental contamination on a scale that is useful for describing potential impacts on California species. In addition, a consistent and relatively simple method of toxicity data interpretation is needed so that station assessments conducted in one region are comparable to the results from other locations or times. Past comparisons of sediment toxicity test methods have not addressed many of these issues or were limited to a small subset of test methods that do not fully address the needs of a statewide regulatory program.

The current study had two principal objectives. The first objective was to evaluate a variety of acute and sublethal toxicity tests in order to identify methods that were best suited for use in a statewide regulatory program. To address this objective, a candidate list of potential tests was identified and evaluated with respect to feasibility, performance, and cost. The second objective was to develop a consistent and comparable system to classify the toxicity test results into a series of categories of effect. The approach to address this second objective included developing a conceptual data analysis framework and identifying a series of test-specific response thresholds that incorporated the magnitude and uncertainty in the test response.

EVALUATION OF ACUTE AND SUBLETHAL TESTS

Approach

A set of candidate acute and sublethal test methods was selected for evaluation. Methods were selected that had a direct sediment exposure, appeared to be technically feasible and had data available that indicated sensitivity to contaminated sediments. The test methods and species included those that have been recommended for use in other regulatory programs in California (USEPA and Engineers 1998) or were documented in standard procedures developed by government or scientific agencies (e.g., EPA or ASTM). Priority was given to methods using species resident in California and species representative of important infaunal groups. In order to increase the diversity of life histories and biological endpoints evaluated, additional candidate methods were selected based on a review of the scientific literature and from recommendations by other scientists familiar with sediment toxicity testing. This process led to the identification of six candidate sublethal methods for evaluation (Table 2). Four amphipod species recommended by the USEPA for testing acute sediment toxicity were also included in the list (USEPA 2001).

Each test was evaluated based on a set of characteristics relating to test feasibility, performance and cost. The list of characteristics was established to include parameters used in previous test comparisons (Long *et al.* 1990, Lamberson *et al.* 1992) and was refined using input from an external scientific review committee. The following characteristics were evaluated:

- **Organism availability.** This category relates to both abundance of suppliers of the animals and any seasonal aspect of either their availability or sensitivity. Ideally, test organisms should be available from multiple suppliers on a year-round basis with no seasonal variation in test sensitivity. Information for this parameter came from contacting suppliers or from experience in using the organisms.

- **Method description.** This category describes whether a standardized protocol for a given test has been established. Methods that are termed as "standard" have a protocol that has received the rigorous testing necessary to be published as an EPA or ASTM method and is the preferred level of method description. These methods have control acceptability criteria and quality assurance standards for parameters such as water quality associated with them.

- **Technical difficulty.** An important consideration is the ease for laboratories to successfully conduct the test. If a method is difficult to perform, laboratories may have to perform multiple tests just to obtain acceptable results. The difficulty was rated based on ability to obtain acceptable controls (i.e., relative number of test failures), the necessity of special techniques or equipment, and complexity of the exposure system. The information for this parameter was based on a combination of personal experience of the authors and comments from others who routinely perform the tests.

- **Concordance of results.** For evaluating the degree of concordance, the effects on the sublethal methods were compared to those of the acute methods tested simultaneously. For the sublethal methods, there was an expectation that if a site were strongly, acutely

toxic to a test organism, then an effect would also be seen for the sublethal test. Conversely, if a site were considered to be in "reference condition" then there would be an expectation that no toxicity would be found for any of the test methods. The information for this parameter was taken from published reports in which both an amphipod species and at least one of the sublethal tests had been applied on the same samples. To evaluate concordance, the acute amphipod test was used as the ground truth, so no acute amphipod data appear in Table 3.

- **Relative sensitivity.** This category describes the relative response of the acute and sublethal tests by observing the relative frequency that the test identifies a sample as being toxic, compared to a benchmark test. Sensitivity in the context of this study refers to the range in response obtained using a specific test method, not the inherent sensitivity of a species to individual chemicals. Many factors related to the specifics of the test, such as duration, temperature, and life stage can affect the response and apparent sensitivity of a toxicity test. Test sensitivity was evaluated relative to the acute amphipod test species most commonly used in California, *Eohaustorius estuarius*. This species has a substantial history of use in California for both monitoring and assessment studies. The logic behind this assessment was that if a test method was usually less sensitive than the most commonly used test, then its value in providing additional information would be limited. Information for this characteristic was gathered from published reports where the benchmark test was conducted alongside at least one of the sublethal methods. For many of the methods, no data was available, so a study was conducted to help fill this information gap (Appendix A).

- **Reproducibility among laboratories.** This category describes the relative amount of variability in the results that is observed when multiple laboratories test the same sample. The information was mostly obtained from literature reports on round-robin tests. In the case of the *Mercenaria mercenaria* growth test and the SWI test using mussel embryos, round-robin testing was conducted to add information that was missing from the literature (Appendix B).

- **Reproducibility within laboratories.** This category describes the relative amount of variability in the results when an individual lab tests the same sample multiple times. The information was obtained mostly from reference toxicant exposures.

- **Precision.** The relative precision of response describes the between-replicate variability of the methods. Information for this parameter was obtained from published reports and journal articles.

- **Documentation of confounding factors.** Most toxicity tests are sensitive to some type of non-contaminant effect (e.g., grain size) that can have a confounding effect on test results. Knowledge of which factors can affect a test and the range where effects occur is needed for study design and data interpretation. Information for this parameter was gathered from test protocols or from values published in the literature.

- **Cost.** Cost is a limiting factor in many sediment assessment studies. The use of sensitive tests that are also relatively inexpensive will enable a larger number of stations to be evaluated, thus improving spatial resolution and overall confidence in the results. The unit cost of each test was evaluated relative to the standard 10-day amphipod survival test. The first source of information for this parameter was from the costs associated with the tests that were commissioned as part of this study. Secondarily, biological consulting firms in California provided costs for tests that they currently perform. For the tests that were new to California, the firms were asked to estimate what they would charge to conduct them.

The characteristics were summarized into narrative categories that reflected the relative level of attainment for each of the candidate tests (e.g., poor, fair, good). The acute and sublethal test methods were treated separately during this process due to differences in the characteristics evaluated.

A scoring system was then applied to integrate the category level information in order to produce an overall evaluation and ranking of each test. Test selection was based on consideration of both test feasibility and relative performance/cost. The three feasibility characteristics (organism availability, method description, and technical difficulty) were evaluated using a binary (yes/no) scoring system. These characteristics were deemed to be so important that the test was classified as not feasible if minimum criteria were not met. For organism availability, at least one commercial source of animals must currently be available to purchase animals ready to use for testing. For method description, there must be a published document available that has a complete description of the method, including test acceptability criteria. The technical difficulty criterion was that there was a reasonable expectation that a laboratory experienced in performing other toxicity tests could follow the protocol and successfully conduct the method without receiving additional outside training. For each of these characteristics, the method was assigned a "+" if the criterion was met and a "-" if it was not.

The remaining performance and cost characteristics were evaluated using a weighted scoring system based on the narrative categories. A weighting factor was established for each category based on our assessment of the relative importance of each category. The comparative sensitivity category was assigned the highest weight: a factor of 4. The high weight given to this category was based on the assumption that high sensitivity to contaminants was the most desirable trait for a sediment toxicity test method. The "relative precision of response" category was deemed to be the least important and was assigned a weighting factor of 1. All of the remaining categories were considered to be of intermediate importance and were assigned a weighting factor of 2.

A numeric value was assigned for each of the performance and cost characteristics. The values for each category ranged from 0 to 3 and corresponded to the narrative categories assigned based on the data review. A value of zero was assigned when no data were available for a characteristic. Each individual value was multiplied by its respective weighting factor to produce a score for the characteristic. The scores were then summed to obtain final score for each candidate test method.

Table 2. List of candidate sediment toxicity tests, the citations containing testing protocols and whether quality assurance and test acceptability criteria have been established.

Species	Taxonomic Group	Duration (days)	Matrix	Endpoint(s)	Literature Level	Citations	QA Criteria[1]	State/National Program Use[2]
Ampelisca abdita *Eohaustorius estuarius* *Rhepoxynius abronius* *Leptocheirus plumulosus*	Amphipod	10	Whole sediment	Survival	Well established	(USEPA 1994, ASTM 1996)	Yes	EMAP NOAA USACE WA, RMP

[3]The same species and endpoint is used in dredged material evaluations, but the duration and aspects of the test method differ

Results

Acute Test Method Evaluation

The four acute amphipod test species were similar in regards to the test feasibility characteristics of organism availability, method description, and technical difficulty (Table 3). Each of the species is available from commercial suppliers, test methods have been standardized, and the level of difficulty is generally low. All of the amphipod species were scored as having met the feasibility criteria (Table 4).

E. estuarius received the highest overall score for the performance and cost characteristics (Table 4). *E. estuarius* has an extensive history of use in toxicity testing studies on California sediments (Anderson *et al.* 1997, Bay *et al.* 2000, Bay and Brown 2003, Bay *et al.* 2005). The method has been shown to have good reproducibility between laboratories (Bay *et al.* 2003).

A slightly lower total score was obtained for *L. plumulosus* (Table 4), which was due to lower reproducibility within and among laboratories. *L. plumulosus* received a lower rating compared to *E. estuarius* and *Rhepoxynius abronius* regarding documentation of confounding factors due to a lack of information on sensitivity to hydrogen sulfide, which was available for *E. estuarius* and *R. abronius*. The high ranking for relative sensitivity compared to *E. estuarius* was based on limited data from a single study and may not represent overall trends. The *L. plumulosus* 10-day test has been conducted in California on a very limited basis. However, it has long been used in other parts of the country, especially on the Gulf coast for monitoring and assessment studies. In studies using diluted, contaminated field sediments or spiked sediments, it has been shown that *L. plumulosus* has a sensitivity similar to the other species (Schlekat *et al.* 1995, Boese *et al.* 1997, DeWitt *et al.* 1997). One of the most attractive attributes of *L. plumulosus* is that it is easily cultured in the laboratory and available year round from commercial suppliers who have them in culture.

The *R. abronius* 10-day test was ranked similarly to the other acute methods, except for a low score for relative sensitivity compared to *E. estuarius*. The relative sensitivity score was based on limited data for split samples from a single study and may not represent overall trends. *R. abronius* has been previously used in California sediment toxicity programs (Long *et al.* 1990, Anderson *et al.* 1998, Anderson *et al.* 2001). These studies found the *R. abronius* method to have equal or better sensitivity to contaminated sediments as compared to other methods tested simultaneously. An interlaboratory comparison exercise using this method found good agreement amongst the testing laboratories (Mearns *et al.* 1986). However, test organism availability has recently been a problem with *R. abronius*. Laboratories have had recent difficulty in locating a supplier of *R. abronius*. The only available source of animals is in Washington, which requires an export permit prior to receipt of the animals. These factors may interfere with the ability to conduct this amphipod test in a timely manner. Sediments with a silt-clay content of ≥80% have also been shown to be an adverse confounding factor for *R. abronius* (DeWitt *et al.* 1988). Care should be taken when planning a survey that sediment grain size will not be an issue and that an animal source is readily available.

The Ampelisca abdita 10-day test was assigned the lowest total score among the four acute test species. The low score was driven by a lack of sensitivity compared to *E. estuarius* and a lower reproducibility among laboratories (Table 3). Specifically, in tests of California sediments where *A. abdita* has been tested simultaneously with *E. estuarius* or *R. abronius* it has consistently been found to be less sensitive (Figures 1 and 2). Very few data are available to make direct comparisons between *E. estuarius* and *R. abronius*, but toxicity in southern California sediments has been detected at a similar frequency using either of these species. The lower apparent sensitivity of *A. abdita* may be due to the fact that this species does not burrow in sediment, but lives in a tube-like structure and does not ingest sediment.

A. abdita also received a lower rating regarding documentation of confounding factors due to a lack of information on sensitivity to hydrogen sulfide. In addition, it is difficult to obtain *A. abdita* during the winter months and if they are available, they are of a size that is smaller than desired for use in testing (Table 3). The *A. abdita* test was also rated as being more difficult to conduct than other 10-day amphipod survival tests, based on the experiences of several California laboratories in having a higher test failure rate when using *A. abdita*, compared other amphipod species (Table 3). These difficulties are not due to intrinsic problems with the test organism, but are likely due to problems in obtaining *A. abdita* from suppliers within California. *A. abdita* is widely used as an indicator of sediment toxicity in many monitoring programs and the data have been used to characterize sediment quality on a national scale (Long 2000, USEPA 2004). Laboratories outside of California have had a high rate of success in conducting tests with *A. abdita* and technical difficulties reported in California do not preclude the use of the test in other regions.

Table 3. Characteristics of candidate sediment toxicity test methods. Not applicable for test (NA).

Sublethal Test Method Evaluation

The candidate sublethal tests were more variable in regards to feasibility, performance, and cost than the acute methods (Table 3). Three of the sublethal test methods had substantial limitations in regard to method documentation, organism availability, or technical difficulty that resulted in an overall rating of not feasible for use in a statewide assessment program at this time (Table 4). These methods were the bivalve *M. mercenaria* growth test, the copepod *Amphiascus tenuiremus* life cycle test, and the lysosomal destabilization test using the oyster *Crassostrea virginica*.

The *M. mercenaria* growth test received the highest total performance and cost score of any of the methods, based on average to slightly above ratings in all of the categories (Tables 2 and 3). However, there is not a single, cohesive document that completely details the protocol and there are no published test acceptability criteria. The test is economical (Table 5) and is not technically difficult to perform. The method exhibited fair reproducibility between laboratories in a round-robin study (Appendix B). In a previous study in the EMAP Carolinian Province, the clam test found no toxicity in reference areas, but did well at identifying areas that were clearly degraded as being toxic; it did better in both these regards than did the *A. abdita* 10-day test (Hyland *et al.* 1998). However, in testing on California sediments the clam test proved to be less sensitive than the *E. estuarius* 10-day test and was one of the least sensitive tests overall (Appendix A). In the Carolinian Province it was found that the *M. mercenaria* test was the best of the toxicity tests conducted at predicting expected bioeffects (Van Dolah *et al.* 1999).

The life cycle test with the copepod *Amphiascus* was by far the most sensitive of the sublethal methods compared to amphipod acute tests (Table 4, Appendix A). This method was also shown to very sensitive compared to an amphipod acute test in a previous study in Florida (Long *et al.* 1999). Nevertheless, the *Amphiascus* test did not pass two of the feasibility criteria. There is no established commercial supplier of the test animals. Only one laboratory in the country maintains a culture of the animals that can be used by other laboratories to start their own cultures. The necessity to culture the animals in individual laboratories leads to the second feasibility limitation, which is technical difficulty. In order to conduct this toxicity test, a laboratory must maintain a copepod culture, and cultures of three algal species used to feed the copepods. In addition, the protocol requires specialized exposure containers and a finely-controlled seawater flow through system. The *Amphiascus* life cycle test is also approximately three times more expensive than other tests (Table 5) and has received no interlaboratory testing to document reproducibility.

Table 5. Per sample cost of performing sediment toxicity tests. Prices are based on quotes from a minimum of three laboratories.

Test	Low Quote ($)	High Quote ($)
Amphipod Acute		
Ampelisca abdita	600	800
Eohaustorius estuarius	600	800
Leptocheirus plumulosus	600	800
Rhepoxynius abronius	600	800
L. plumulosus 28-day Growth and Reproduction	1,375	1,800
Neanthes arenaceodentata 28-day Growth	800	1,400
Sediment-water Interface Embryo Development		
Strongylocentrotus purpuratus	550	1,100
Mytilus galloprovincialis	700	1,200
Mercenaria mercenaria Survival and Growth	600	750
Crassostrea virginica Lysosomal Stability	400	1,500
Amphiascus tenuiremus Life Cycle	2,200	2,800

The oyster lysosomal destabilization test had the lowest total score of any of the test methods (Table 4). Besides the low ranking, this test method does not have a complete protocol that is published (Table 2). In preliminary tests of the procedure, we also found the endpoint determination to be very difficult to discern without significant training from someone very experienced in the procedure, leading to the acceptability failure for technical difficulty. Further, this method has had very limited testing with individual chemicals and until this project, had not been used in field studies along side other test methods. In the testing conducted to date, the oyster lysosomal destabilization test has not been demonstrated to be particularly sensitive compared to acute amphipod tests (Appendix A).

The remaining three sublethal test methods, the *N. arenaceodentata* 28-day growth test, the SWI test with either *M. galloprovincialis* or *Strongylocentrotus purpuratus*, and the *L. plumulosus* 28-day growth and reproduction test, met all of the feasibility criteria. The ranking scores of these tests covered a fairly narrow range of 27 to 33 (Table 4).

The *N. arenaceodentata* growth test received the highest ranking of the remaining sublethal tests (Table 4). It is fairly well established with an ASTM method, although the method documentation is currently under revision to reflect some changes in the procedure. It has been used in multiple field studies and individual chemical exposures to spiked sediments (Dillon *et al.* 1993, Green *et al.* 1999, Lotufo *et al.* 2000, Lotufo *et al.* 2001b, Moore *et al.* 2003, Kennedy *et al.* 2004). The *N. arenaceodentata* 28-day test has also been the subject of considerable refinement efforts considering animal age, test duration and food ration (Bridges and Farrar 1997, Bridges *et al.* 1997). For the methods comparison study using California sediments, the *N. arenaceodentata* test was the second most sensitive test (Appendix A). In that study, the *N. arenaceodentata* test either agreed with the *E. estuarius* test or identified stations as toxic that the *E. estuarius* did not; there were no stations that were found to be toxic by *E. estuarius*, but not *N. arenaceodentata*. When compared to the *L. plumulosus* 10-day results, the *N. arenaceodentata* test was about equal in its ability to detect toxicity, and was second only to the copepod test in sensitivity. While the *N. arenaceodentata* test is one of the more expensive to conduct (Table 5) it has relatively high sensitivity, reliability, and technical feasibility.

The SWI test using mussel embryos received a lower total score than the *N. arenaceodentata* test (Table 4). The SWI test using either developing sea urchin or mussel embryos is an established test method that has been used by multiple laboratories to assess California sediments. The exposure protocol for this procedure is published in a well respected compendium of toxicity test methods (Table 2) and the embryo testing methods are based on standard EPA procedures (USEPA 1995). The protocol has previously been successfully employed in multiple studies within California (Hunt *et al.* 2001, Bay *et al.* 2004, Brown and Bay 2005). The cost of conducting the test is relatively low and the mussels are available in spawning condition year round from multiple suppliers. The test protocol also addresses an important pathway of toxicant effects: exposure of water column organisms to chemicals released from contaminated sediments. The relative sensitivity of this protocol compared to amphipod acute tests is uncertain since the results of side-by-side testing have been mixed. The SWI tests were classified as having relatively low precision (Table 3). This low score reflects increased variability among replicates due to the SWI test design, where the replicates often represent discrete sediment core samples as opposed to replicates of a homogenized sample. Between replicate precision of mussel or sea urchin embryo tests in water only tests is much higher than the SWI results.

The SWI test has been used in the past with both sea urchin and mussel embryos; however, review of the data available for the sea urchin method led to a lower score than for the mussels (Table 4). This low score was due to low interlaboratory reproducibility. Greater technical difficulty is associated with conducting the SWI test with sea urchins. One issue is that sea urchins have a short spawning season in the field and it is cumbersome to extend the spawning season by maintaining the animals in the laboratory. Second, laboratories have reported greater difficulty in recovering the sea urchin embryos at the end of the exposure period. This may be due to a more delicate structure of the sea urchin embryos, which may cause them to stick to the exposure chamber. The reduced embryo recovery success may produce higher between replicate variability for the sea urchins, which may account for the lower sensitivity and reproducibility scores. Compared to sea urchins, *M. galloprovincialis* embryos provide advantages of being available year round in spawning condition and having an endpoint that is easier to measure with precision.

The *L. plumulosus* 28-day test received a relatively high total score that was only two points below the *N. arenaceodentata* test method. This test is both well established and documented (USEPA 2001). The method has been used in multiple field studies and individual chemical exposures to spiked sediments (DeWitt *et al.* 1997, McGee *et al.* 1999, Lotufo *et al.* 2001a, McGee *et al.* 2004). The *L. plumulosus* 28-day test was the third most sensitive of the sublethal methods tested using California sediments (Appendix A). However, there were several California stations where the acute amphipod tests detected toxicity and *L. plumulosus* 28-day did not. Also during this testing, the *L. plumulosus* 28-test experienced a test failure and there were questions regarding the reliability of the reproduction data (Appendix A). Inconsistent reliability of the *L. plumulosus* 28-day test reproductive endpoint has also been reported in another study (Kennedy *et al.* 2004). In a study of sediments in Chesapeake Bay, it was found that the 28-day test did not provide more information regarding toxicity than the 10-day test with the same species and that the 10-day test data had a better correlation with changes in the benthic

community (McGee *et al.* 2004). The *L. plumulosus* 28-day test is the second most expensive test to perform (Table 5).

Discussion

The evaluation of the candidate acute and sublethal tests identified five methods that had the best overall combination of technical feasibility and relatively high performance. These methods include three acute amphipod and two sublethal test methods (Table 6). Each of these methods is well suited for use in a California statewide sediment quality assessment program where feasibility, sensitivity, reliability, and cost are all important factors.

Table 6. Sediment toxicity test methods with the highest overall ranking with respect to the evaluation characteristics.

Species	Taxonomic Group	Matrix	Duration (days)	Endpoint(s)
Acute				
Eohaustorius estuarius *Leptocheirus plumulosus* *Rhepoxynius abronius*	Amphipod	Whole sediment	10	Survival
Sublethal				
Neanthes arenaceodentata	Polychaete	Whole sediment	28	Growth, survival
Mytilus galloprovincialis	Bivalve	Sediment-water interface	2	Embryo development

The two sublethal tests in Table 6 provide important features not present in the suite of amphipod acute tests that are most commonly used to assess sediment quality. The use of a polychaete worm in the *N. arenaceodentata* test provides greater taxonomic diversity among the test organisms and is representative of one the most abundant taxonomic groups comprising the benthic community. The SWI test also represents a different taxon that is also a dominant member of most benthic macrofaunal communities, and the use of an early life-stage may provide enhanced sensitivity to different contaminants. The incorporation a SWI exposure in the *M. galloprovincialis* test also provides a means to evaluate the significance of sediment contaminant impacts on organisms residing in the water column, and thus increases the chance that the testing program will detect toxicity that is present under a diversity of conditions.

Only one of several sediment toxicity methods using the polychaete *N. arenaceodentata* was evaluated in this study. The two methods that are the most established are a 20-day growth test used in the Pacific Northwest (PSWQA 1995), California and many other regions for dredged material characterization, and a 28-day test (ASTM 2002b) that has been optimized to achieve a more sensitive growth endpoint (Bridges *et al.* 1997). The 20-day method has been successfully used in the state of Washington for over 15 years. However, some researchers have found it to be less sensitive than amphipod survival tests (Anderson *et al.* 1998, Pinza *et al.* 2002). In side-by-side testing, one study found the 28-day test to be more sensitive than the 20-day method (Gardiner and Niewolny 1998). Based on the results of these studies, it was decided to focus the evaluation on the 28-day method.

The *L. plumulosus* 28-day test is also a feasible test that had a relatively high total score and could be used in a statewide assessment program. This method was judged to have lower overall suitability because the test is fairly costly to perform, provides no increase in taxonomic diversity, and an uncertain increase in sensitivity relative to the acute amphipod methods already in widespread use.

This study was restricted to toxicity tests where whole sediment samples were included in the exposure. Tests on sediment pore water or elutriate samples were not considered for evaluation because of technical limitations in the methods and a greater uncertainty in the relationship between the test exposure and sediment contaminant concentrations. Pore water tests are a widely used method for testing sediment toxicity (Carr and Nipper 2003), but it is often difficult to collect enough sample for testing. There are other issues associated with pore water toxicity tests that make these methods problematic for use as an initial test of sediment toxicity, including potential changes in metal toxicity due to oxidation, change in sample pH, sorption of contaminants to test chambers, confounding effects of ammonia toxicity, and elimination of sediment ingestion as a route of uptake (Chapman *et al.* 2002, Ho *et al.* 2002). While many of these issues may also be associated with whole sediment tests, they are magnified with the use of pore water.

While elutriate tests are used in several assessment programs, the relationship of the results to direct sediment exposure is not clear. Elutriate tests were developed for testing the effects of the resususpension of the dredged sediment on water column toxicity, not the toxicity of bedded sediment. The proportions of sediment and water and the method of agitation used to prepare the elutriate are operationally defined and the relationship of the resulting exposure experienced by a test organism to that from a whole sediment exposure is unknown. The State of Washington uses a modified elutriate toxicity test method that includes the whole sediment after mixing with the water and tests bivalve or echinoderm larvae (PSWQA 1995, ASTM 2002a). These methods have been used successfully in Washington for over a decade. The Puget Sound method was not included in the present study because of concerns that the organism's response to the whole sediment in the test chamber would be confounded by the presence of the elutriate.

The *A. abdita, M. mercenaria,* and *A. tenuiremus*, tests showed good potential as tests that might be feasible for statewide application in the future. For now, more work needs to be performed on issues regarding animal availability, method development, relative sensitivity, and interlaboratory variation to make these protocols viable choices. Although the oyster lysosome test scored poorly in our ratings, the endpoint represents an important indicator of cellular stress that is responsive to toxicant exposure. The applicability of this method to assess sediment toxicity would be improved through the use of an organism with a greater direct exposure to the sediment, such as a crustacean, polychaete or deposit-feeding bivalve.

The use of multiple toxicity tests is needed to provide a complete and confident evaluation of sediment toxicity. None of the methods identified in Table 6 has been shown to be consistently the most sensitive or reliable test. This situation is to be expected, since there are species-specific variations in contaminant sensitivity and mode of exposure among the test organisms, and many different combinations of chemical type and magnitude may produce sediment toxicity. The use of multiple tests provides two key advantages. First, this approach provides a more reliable assessment of toxicity by reducing the chance that a spurious result in any one test will determine the toxicity classification. The influence of potentially confounding factors such as sediment grain size and organic carbon content are still not entirely known for many tests. Confidence in the results is increased when the results of multiple toxicity tests are similar. Second, the use of multiple test methods increases the sensitivity of the testing program by using

a variety of species, response endpoints, and exposure methods. This combination reduces the chance of a false negative (failure to detect sediment toxicity) due to species-specific variations in contaminant sensitivity or mode of exposure. Multiple toxicity tests were used in NOAA's National Status and Trends Program (Long *et al.* 1996) and are currently used in Washington's Puget Sound Ambient Monitoring Program (Long *et al.* 2005).

TOXICITY RESPONSE THRESHOLDS

Approach

An ordinal scoring system consisting of four categories of response was developed for each of the toxicity tests listed in Table 6. The use of multiple categories, as opposed to a simple binary approach (nontoxic/toxic) retains more information about the toxicity response and thus provides greater potential resolution when combining the toxicity data with other lines of evidence in a sediment quality triad approach. Each category was based on a narrative description of condition that incorporated both the degree of confidence that a toxic effect was present and the magnitude of mean response to the sample.

- **Nontoxic:** Response not substantially different from that expected in sediments that are uncontaminated and have optimum characteristics for the test species
- **Low Toxicity:** A response that is of relatively low magnitude; the response may not be greater than test variability
- **Moderate Toxicity:** High confidence that a statistically significant effect is present
- **High Toxicity:** Highest confidence that a toxic effect is present and the magnitude of response is among the strongest effects observed for the test

This four-category system is an adaptation of the three-category system that is often used to classify sediment toxicity (Long *et al.* 2000), where the test response is classified as nontoxic, marginal, or toxic. The nontoxic and marginal categories correspond to the nontoxic and low toxicity categories of the scoring system used here. The toxic category used in many studies usually represents a reliably statistically significant response that encompasses a wide range of effect (e.g., 20 to 100% mortality) and thus provides little discrimination among the majority of the toxic samples. Two categories of response, moderate and high, were established to represent these toxic samples in order to provide the ability to distinguish severe effects from more moderate responses.

A conceptual approach was developed to relate each of the above categories to a series of numeric thresholds and statistical criteria (Figure 3). This approach relies on the comparison of the test result (e.g., % survival) to Low, Moderate, and High thresholds, corresponding to the upper bound of the response range for the Low Toxicity, Moderate Toxicity, and High Toxicity categories. The thresholds were developed using test-specific characteristics, such as test variability (minimum significant difference (MSD)) and distribution of the toxicity response data. A statistical criterion was also used in the classification scheme (Figure 3). Samples qualifying for the Low or Moderate categories based on test response magnitude were classified into the next lower category if the response was not significantly difference relative to the control (t test, $p \leq 0.05$). A statistical significance criterion was not applied to the highest toxicity category because the derivation of the high toxicity threshold already incorporated a high degree of statistical confidence.

The methodology used to derive the numeric thresholds is described in the following sections.

Low Threshold

The threshold separating the Nontoxic and Low categories was defined as the lowest acceptable control response value for the given test, as established in the test protocols. The response value is defined as the mean value for the endpoint for a given test method (i.e., survival, growth). Any test sample having a response value that is greater (e.g., greater survival) than or equal to the low threshold will be classified as nontoxic, regardless of whether a statistical difference from the control is present. A test response that is less (e.g., lower survival) than the low threshold will be classified as low, moderate, or high, depending on the magnitude of response and statistical significance (Figure 3).

This threshold was based on the rationale that any response that fell within the range expected of animals exposed to optimum sediment conditions (i.e., controls) should indicate a nontoxic condition in the test sample. The control acceptability criteria were obtained from the appropriate protocol for each test method.

Moderate Threshold

The intent of the Moderate Threshold is to distinguish between samples producing a small response of uncertain significance and larger responses representing a reliably significant difference relative to the control. This threshold was based on the Minimum Significant Difference (MSD), which was specific to each test method. The MSD represents the minimum difference between the control and sample mean response that is necessary to be statistically different at $p \leq 0.05$ level. The moderate threshold was equal to the 90th percentile of the MSDs for a given toxicity test method. This approach for calculating a toxicity threshold has been used by other researchers (Phillips *et al.* 2001). Use of the 90th percentile results in a threshold with a high degree of confidence that the sample is different from the nontoxic condition.

The MSD values were calculated using a dataset of replicate control and sample data that were compiled from the SQO database and from laboratories outside of California. Details of this calculation can be found in Phillips *et al.* (2001). An MSD was calculated for each combination of a control and a sample using the following equation:

$$MSD = t_{critical} (s_1^2/n_1 + s_2^2/n_2)^{-½}$$

where $t_{critical}$ = t value from the standard statistical table ($\alpha = 0.05$); s_1^2, s_2^2 = variances for control and field sample; and n_1, n_2 = numbers replicates. All of the MSD values in the dataset for each toxicity test method were then sorted in rank order. The 90th percentile value of this set of data was then calculated (MSD_{90}). The MSD_{90} values were calculated using all available data for each toxicity test method. Finally, the moderate threshold value was calculated by subtracting the MSD_{90} from 100% in order to produce a value that could be compared to the control-adjusted test response value.

Sample response values (i.e., survival or growth) between the low and moderate thresholds are classified as Low Toxicity if they are significantly different from the control response (Figure 3). Sample response values that are less than the moderate threshold and are significantly different from the control are categorized as moderately toxic.

High Threshold

The narrative intent of the High Threshold is to identify samples producing a severe and highly significant effect from those samples producing lesser effects. No precedent for this threshold was available from the literature, so this threshold was based on a combination of test variability and response distribution that corresponded to the category definition.

The 99th percentile MSD value was used to link the high threshold to test variability. A sample having a response that falls below this limit (e.g., lower survival) would be expected to be significantly different from the control 99% of the time. This value therefore represents a response that is associated with a very high level of confidence of statistical significance. The 99th percentile MSD for the high threshold was calculated using the same data and methodology described for the calculation of the MSD_{90} for the moderate threshold.

The response distribution component of the high threshold was based on the distribution of toxic samples from California. For purposes of this calculation, toxic samples were defined as samples having a mean response that was significantly different from the control response. The toxic samples were ranked in descending order based on the control-adjusted mean survival. The response magnitude component of the high threshold corresponded to the 75th percentile of the data. The value obtained from this calculation represents the response associated with the most strongly affected 25% of the toxic samples found in California. It was required that data for this calculation be from stations within California in order to obtain a response value that was relevant to the characteristics of sediments in California.

Both the variability and data distribution response values represented important, but partial, aspects of the High Threshold. Therefore, the mean of the two values was used as the High Threshold. Response values (i.e., survival or growth) below the high threshold are classified as high toxicity regardless of whether they are significantly different from the control response or not (Figure 3).

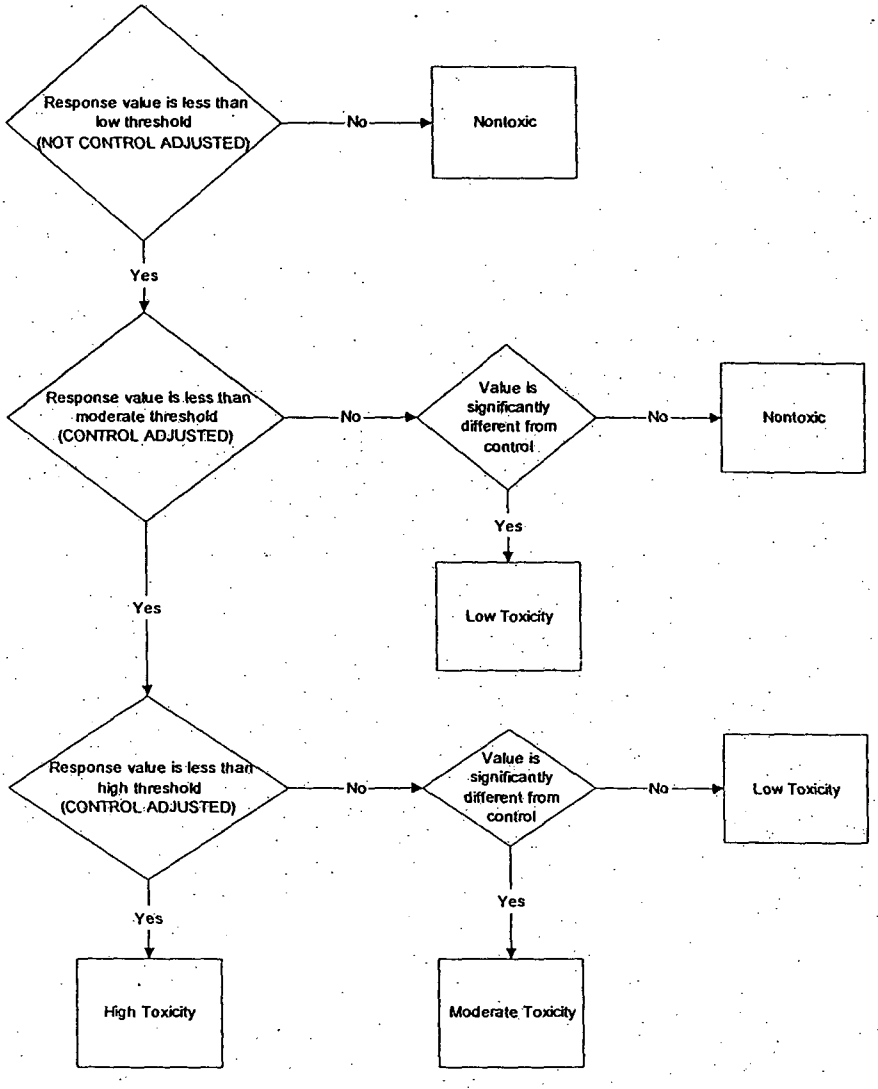

Figure 3. Conceptual approach for assigning the category of toxic effect from exposure response data. The test response value is expressed as survival, embryo development or growth.

Results

Low Threshold

For the amphipod acute survival tests the threshold is 90% survival (USEPA 1994). For the *N. arenaceodentata* growth endpoint, the threshold is 90% of the mean control growth, according to the revised ASTM protocol that is in preparation (J. D. Farrar, personal communication). For the SWI test using *M. galloprovincialis* embryos, the low threshold is 80% normal-alive (not control adjusted). The control criterion for the *M. galloprovincialis* test was established by the Marine Pollution Studies Laboratory, Granite Canyon (B. Phillips, personal communication).

Moderate Threshold

The moderate threshold for the *E. estuarius* 10-day survival test was calculated using data from the California Sediment Quality Objectives database, which included 876 MSD values. The 90th percentile of the MSD values was 18%, which corresponds to a control adjusted survival of 82% (Figure 4).

The *R. abronius* 10-day acute test threshold was also calculated using data from the California database. The dataset included 264 data points (Figure 5). The calculated control adjusted survival threshold for *R. abronius* was 83%, very similar to the *E. estuarius* value.

The threshold for the *L. plumulosus* 10-day survival test was calculated using data from tests on sediment from throughout the U.S. The data were provided by multiple laboratories. Few of the 199 samples in the data set were from stations located in California. The calculated control adjusted survival threshold for the *L. plumulosus* acute test was 78% (Figure 6).

Like the *L. plumulosus* 10-day value, the threshold of the *N. arenaceodentata* growth test was calculated from tests of samples from throughout the United States, with few California stations included. There were less data available for this test method; the calculation was based on 92 data points. The threshold value for the *N. arenaceodentata* growth endpoint was 68% of the mean weight of the control animals (Figure 7).

The threshold for the SWI test with *M. galloprovincialis* embryos was calculated using data from the statewide SQO database. The threshold value of 77% was calculated from 118 MSD values (Figure 8).

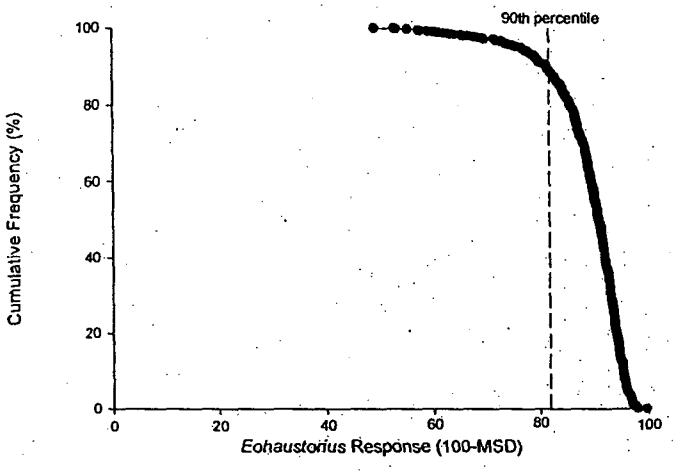

Figure 4. Cumulative frequency of *Eohaustorius estuarius* response (100-MSD) values expressed as a percentage of control survival. The 90th percentile value is the moderate response threshold. Sample size = 876.

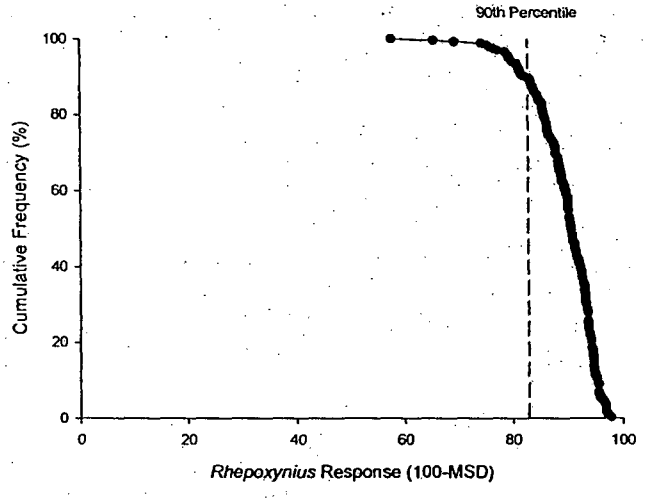

Figure 5. Cumulative frequency of *Rhepoxynius abronius* response (100-MSD) values expressed as a percentage of control survival. The 90th percentile value is the moderate response threshold. Sample size = 264.

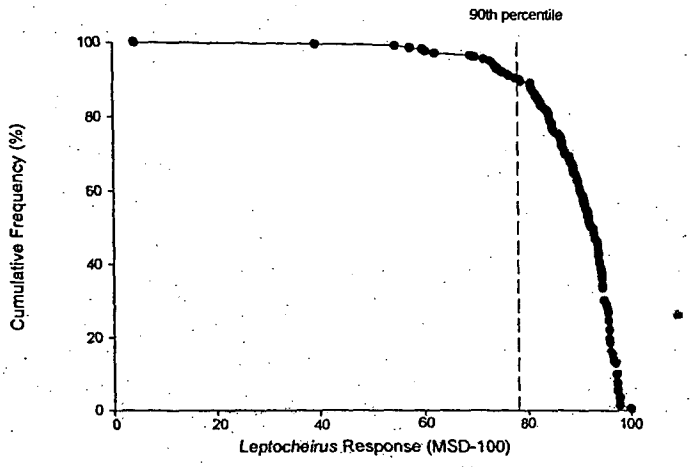

Figure 6. Cumulative frequency of *Leptocheirus plumulosus* response (100-MSD) values expressed as a percentage of control survival. The 90th percentile value is the moderate response threshold. Sample size = 199.

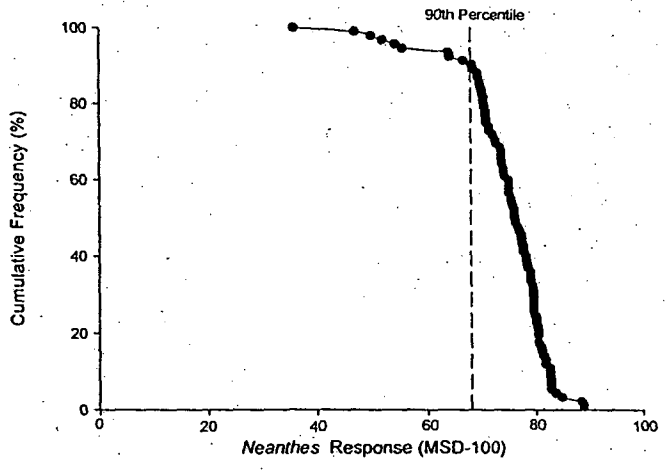

Figure 7. Cumulative frequency of *Neanthes arenaceodentata* growth response (100-MSD) values expressed as a percentage of control growth. The 90th percentile value is the moderate response threshold. Sample size = 92.

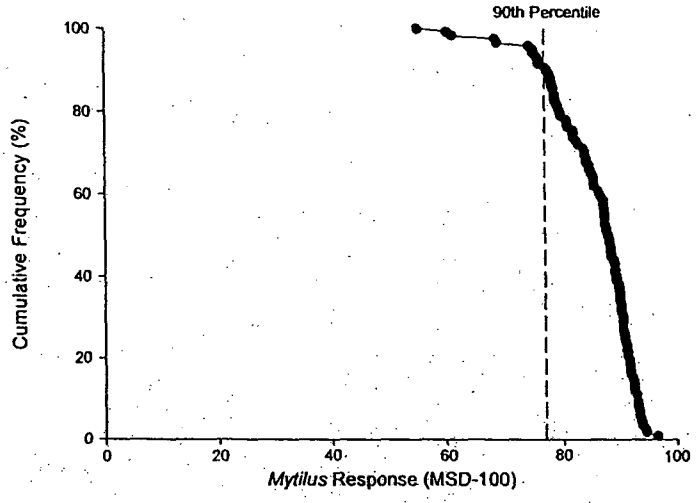

Figure 8. Cumulative frequency of *Mytilus galloprovincialis* sediment-water interface normal-alive response (100-MSD) values expressed as a percentage of response. The 90th percentile value is the moderate response threshold. Sample size = 118.

High Threshold

The species-specific MSD_{99} values were calculated using the same data described for the moderate threshold (Figures 4 through 8). The MSD_{99} values (expressed as the control normalized response) ranged from 46% for *N. arenaceodentata* to 73% for *R. abronius* (Table 7).

The 75th percentile of the toxic *E. estuarius* samples corresponded to a control-adjusted survival of 57% (Figure 9). The 75th percentile value for *R. abronius* was 66% (Figure 10). The data distribution of the toxic *M. galloprovincialis* samples from California produced the lowest 75th percentile value: 24%. This relatively low value may have been related to the small number of toxic samples available for analysis (Figure 11). The toxic data distribution approach could not be used for the *L. plumulosus* and *N. arenaceodentata* tests since most of the samples in the dataset were from outside of California. For *L. plumulosus*, the 75th percentile value of 57% from the *E. estuarius* dataset was substituted for the threshold calculation.

Calculation of the mean of the MSD_{99} and 75th percentile values produced high threshold values ranging from 42% for *Mytilus* to 70% for *R. abronius* (Table 7). This threshold was more variable than the Moderate or Low thresholds, which had ranges of 14% and 10% respectively.

The calculated toxicity test thresholds are summarized in Table 8. For application of the moderate and high thresholds, the data from each exposure must first be normalized to the control response ((sample÷control) x 100). The low threshold is evaluated using the raw data (not normalized), except for the *N. arenaceodentata* 28-day growth endpoint. Normalized data are used for the low, moderate, and *N. arenaceodentata* thresholds because these thresholds are defined relative to the control response, which can vary among tests.

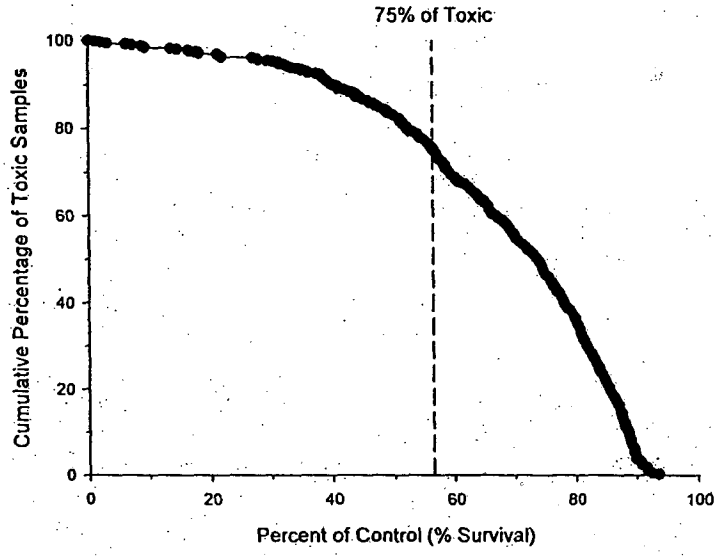

Figure 9. Cumulative frequency distribution plot of *Eohaustorius estuarius* survival data used for 75th percentile of toxic stations calculations. Sample size = 333.

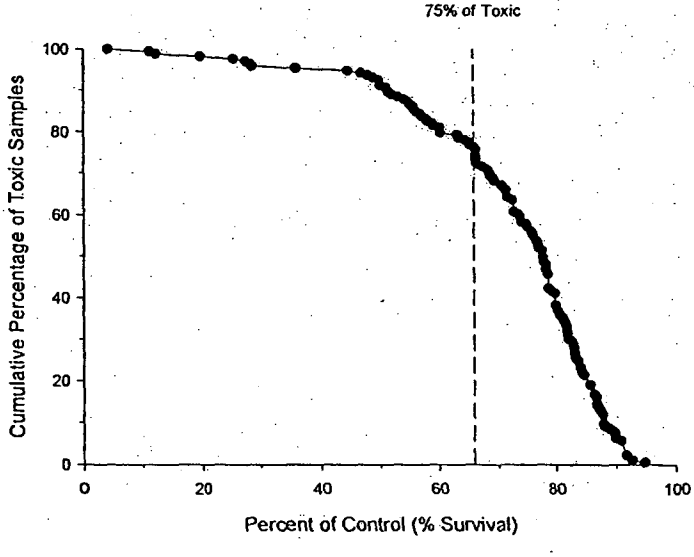

Figure 10. Cumulative frequency distribution plot of *Rhepoxynius abronius* survival data used for 75th percentile of toxic stations calculations. Sample size = 114.

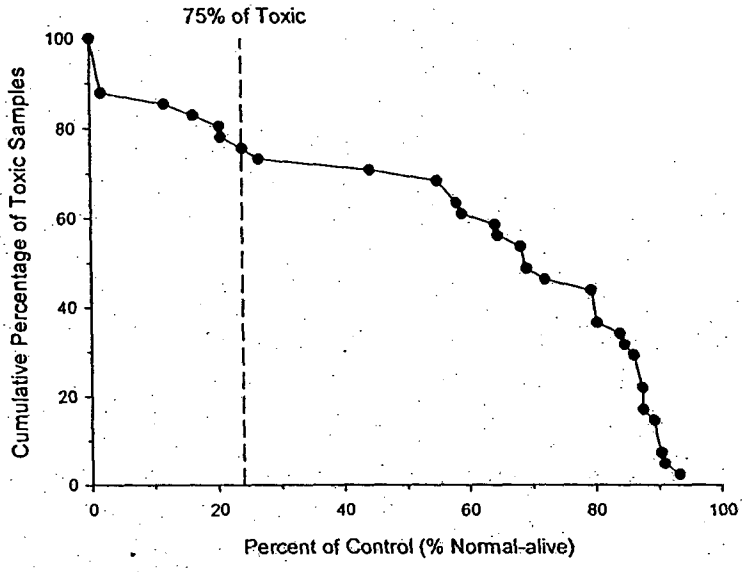

Figure 11. Cumulative frequency distribution plot of sediment-water interface method *Mytilus galloprovincialis* embryo percent normal-alive data used for threshold calculations. Sample size = 28.

Table 7. Data used in calculation of high threshold values for acute and sublethal sediment toxicity test methods. The high threshold is the mean of the two response values shown in the table.

Species	99th MSD	75th of Toxic	High Threshold
Eohaustorius estuarius	61	57	59
Rhepoxynius abronius	73	66	70
Leptocheirus plumulosus	54	57[1]	56
Neanthes arenaceodentata	46	-[2]	46
Mytilus galloprovincialis	60	24	42

[1] No California data available, so *E. estuarius* data was used for this calculation
[2]No California data available

Table 8. Toxicity threshold values for the proposed sediment toxicity test methods.

Species	Low (% Control)	Moderate (% Control)	High (% Control)
Eohaustorius estuarius	90	82	59
Rhepoxynius abronius	90	83	70
L. plumulosus	90	78	56
Neanthes arenaceodentata	90[1]	68	46
Mytilus galloprovincialis	80	77	42

[1] % of control growth.

Discussion

The thresholds derived in this study represent a unique combination of established and new approaches to achieve the goal of being able to classify sediment toxicity into multiple clearly delineated categories. By incorporating both magnitude of response and statistical uncertainty, these categories represent the two factors that are essential to describing a toxicity test response.

Thresholds based on minimum significant difference (MSD_{90}) values have been used by others to establish a threshold representing a test response associated with moderate to strong toxicity (Phillips *et al.* 2001, Field *et al.* 2002). Control acceptability criteria are also frequently used to characterize test responses. This study represents the first known application of the MSD_{99} and 75th percentile of toxic samples for classifying samples in a high toxicity category.

The thresholds developed for this study are similar to comparable thresholds calculated by others. The calculated value of 82% for the *E. estuarius* test is within the range of thresholds of 83% calculated for the Bight'03 regional monitoring project in southern California (Bay *et al.* 2005) and 75% for data from the California Bay Protection and Toxic Cleanup Program (Phillips *et al.* 2001). The moderate threshold of 77% for the SWI test with *M. galloprovincialis* is similar to the MSD value of 80% reported by Phillips *et al.* (2001) for a larger dataset for *M. galloprovincialis* that included pore water and water column data.

The *M. galloprovincialis* SWI test low and moderate thresholds appear to represent a very narrow range of response (Table 8). This response window is not as small as it first seems because the low and moderate thresholds are expressed differently. The low threshold value is not control adjusted while the moderate threshold is adjusted. The average control value for *M. galloprovincialis* SWI tests in the statewide database is 85% normal-alive. Therefore, the control-adjusted value of 77% for the moderate threshold represents a noncontrol-adjusted value of 65% (77% x 85% = 65%), representing a response window of about 15% for the low toxicity category.

Little data from California stations was available to calculate the MSD for the *L. plumulosus* and *N. arenaceodentata* test methods. This is of little concern since the MSD is a measurement of the inherent variability of the test method and should not be affected to a great extent by sample source. However, as more data becomes available the MSD should be recalculated to provide a more confident value. The thresholds for the SWI test with *M. galloprovincialis* should also be recalculated when more data become available, since the number of data points was limited in comparison to the *E. estuarius* and *R. abronius* datasets.

The greatest amount of uncertainty is associated with the high threshold values. The approach used to calculate these values is new so there is no basis of comparison to help identify spurious values. In addition, this threshold is based on the analysis of extreme portions of data distributions (99th and 75th percentiles), which are more sensitive to data quantity and may be more variable. Confidence in the high threshold values would be improved by the availability of more data collected on samples from within California. For the calculation of the 75th percentile of toxic stations, it is vital that the data is generated using California samples so that future comparison of samples from within the State will be evaluated in the correct context.

Currently, there is a very limited amount of California data for the *L. plumulosus* 10-day and *N. arenaceodentata* growth tests.

RESEARCH NEEDS

The analyses described in this report were used to select a suite of test methods for use in sediment toxicity testing. These represent a minimum suite of test methods that had the best available combination of feasibility and performance. Several data limitations were encountered in the course of this study that either restricted the suite of suitable test methods or complicated the calculation of the classification thresholds. The following research activities are needed to improve the use of toxicity tests for evaluating sediment quality:

- **Refine thresholds for the *L. plumulosus* and *N. arenaceodentata* tests as new data become available.** Limited data were available to calculate the toxicity thresholds for these species. More toxicity data from California samples are needed to refine calculation of the 75th percentile of toxic stations, which would improve confidence in the calculation of the high toxicity threshold values.

- **Evaluate additional sublethal test methods for inclusion in the suite of recommended test methods.** A wider variety of sublethal test methods that are feasible and sensitive should be available. Use of a wider variety of toxicity tests would help ensure that the toxicity information addresses variations in routes of exposure and sensitivity to sediment contaminants among the sediment-dwelling organisms. Some of the methods evaluated in the current study showed promise for future use, but were lacking in protocol development, had little field testing, and had not been compared in sensitivity to more established methods. Research is needed to fully document these tests and develop quality assurance criteria, such as required pH, salinity and temperature ranges. Research should be conducted to field test any additional methods side by side with the methods already evaluated in this document in order to evaluate relative sensitivity and produce the data needed for threshold development.

ABSTRACT

Sublethal test methods are being used with increasing frequency to measure sediment toxicity, but little is known about the relative sensitivity of these tests compared to the more commonly used acute tests. A study was conducted to compare the sensitivity of several acute and sublethal toxicity methods, and investigate their correlations with sediment chemistry and benthic community condition. Six sublethal methods (amphipod, *Leptocheirus plumulosus* 28-day survival, growth and reproduction; polychaete, *Neanthes arenaceodentata* 28-day survival and growth; benthic copepod, *Amphiascus tenuiremis*, 14-day life cycle; seed clam, *Mercenaria mercenaria* 7-day growth; oyster, *Crassostrea virginica* lysosome destabilization; and sediment-water interface (SWI) testing with embryos of the mussel *Mytilus galloprovincialis*) and two acute methods (10-day amphipod survival with *Eohaustorius estuarius* and *Leptocheirus plumulosus*) were used to test split samples of sediment from stations in southern California and San Francisco Bay. The most sensitive sublethal test, and most sensitive overall, was the life cycle test with the copepod, *Amphiascus*. The *L. plumulosus* 10-day survival test was the most sensitive of the acute tests. The sublethal tests were not, in general, more sensitive to the sediments than the acute tests. Of the sublethal tests only the *A. tenuiremus* endpoints and polychaete growth correlated with sediment chemistry. There was poor correspondence between the toxicity endpoints and indicators of benthic community condition. Differences in test characteristics such as mode of exposure, species-specific contaminant sensitivity, changes in contaminant bioavailability, and the influence of noncontaminant stressors on the benthos may have been responsible for the variations in response among the tests and low correspondence with benthic community condition. The influence of these factors cannot be easily predicted and underscores the need to use multiple toxicity methods in combination with other lines of evidence to provide an accurate and confident assessment of sediment toxicity.

ACKNOWLEDGMENTS

The authors would like to the field crews and analytical laboratories participating in the Southern California Bight 2003 Regional Survey and Sarah Lowe (San Francisco Estuary Institute) for their assistance in sample collection and analysis. We also wish thank J. Ananda Ranasinghe and Bruce Thompson for providing analysis of the benthic community data for this study.

INTRODUCTION

Acute sediment toxicity testing has been routinely conducted as part of monitoring and assessment programs, such as the USEPA's Environmental Monitoring and Assessment Program (Strobel *et al.* 1995). The toxicity tests are usually conducted on whole sediments using amphipod 10-day survival tests in accordance with standard protocols (USEPA 1994). Sublethal testing has been conducted on a much more limited basis, but there is increased interest in using sublethal methods due to the assumption that they are more sensitive to contaminated sediments than the acute methods (Adams *et al.* 2005). Sublethal methods include embryo development tests and other tests with various life stages of animals having endpoints such as growth and reproduction in addition to survival. A wide variety of sublethal methods have been described (Lamberson *et al.* 1992), but only a few such methods have been used commonly; they include the amphipod *Leptocheirus plumulosus* 28-day growth and reproduction test (USEPA 2001), a 20-day polychaete growth test using *Neanthes arenaceodentata* (PSWQA 1995), pore water testing using echinoderm gametes or embryos (Carr and Nipper 2003) and a SWI test using sea urchin or mussel embryos (Anderson *et al.* 1996). Additional promising sublethal tests that have been developed recently and include the measurement of copepod reproduction (Chandler and Green 1996), juvenile clam growth (Ringwood and Keppler 1998), and oyster biomarker responses (Ringwood *et al.* 1998).

Because sublethal toxicity methods have been used less commonly, there are questions regarding whether these test methods are practical, reproducible, and more sensitive than the acute methods already in use (Anderson *et al.* 1998, Pinza *et al.* 2002). Few studies have been conducted that were designed specifically to compare the relative attributes of various sublethal tests. Studies conducted to date have only compared two or three methods together (DeWitt *et al.* 1997, Anderson *et al.* 1998, Green *et al.* 1999), or have focused more on sublethal elutriate or pore water tests rather than whole sediment tests (Long *et al.* 1990). Important factors to consider in the selection and interpretation of toxicity tests include the degree of exposure to whole sediment, the relative sensitivity to sediment contaminants, and the level of concordance with benthic community impacts. Information on these factors is extremely limited for many sublethal tests.

This study was designed to investigate relative performance of several acute and sublethal test methods with whole sediments. Three specific points were examined. First, the relative sensitivity of the toxicity test methods was compared. Sensitivity was defined as the relative ability of a test method to detect toxicity in a sample. Sensitivity comparisons were made both between acute and sublethal methods and among the sublethal methods. Secondly, the relationship between sediment chemical concentrations and toxicity of each method was examined. Finally, this study investigated the relationship between changes in benthic community condition and toxicity.

METHODS

Six candidate whole sediment sublethal methods were selected (Table 1). These methods appeared to be technically feasible and had data available that indicated some level of sensitivity to contaminated sediments. Methods were first selected that had established, published methods by a government or scientific agency (e.g., USEPA methods, ASTM methods). Additional methods were selected from the scientific literature and from recommendations by toxicologists with experience in sediment quality assessment. Acute amphipod testing was also conducted for comparison with sublethal methods using two species, *E. estuarius* and *L. plumulosus*.

Table 1. Characteristics of the sublethal sediment toxicity methods included in the comparison study. Duration given in days.

Species	Taxon	Test endpoint(s)	Duration
Mytilus galloprovincialis	mussel	sediment-water interface, embryo development	2
Mercenaria mercenaria	clam	growth	7
Crassostrea virginica	oyster	lysosomal destabilization	4
Leptocheirus plumulosus	amphipod	growth, reproduction, survival*	28
Neanthes arenaceodentata	polychaete	growth, survival*	28
Amphiascus tenuiremis	benthic copepod	reproduction, survival*	14

* Secondary endpoint

The sediment samples that were tested were collected as part of two regional monitoring surveys, Southern California Bight 2003 Regional Monitoring Program (Figure 1) and the San Francisco Estuary Institute Regional Monitoring Program (RMP; Figure 2). The stations represented a wide range of expected contamination levels and habitat types with the aim being to target stations expected to have a low to moderate level of acute toxicity. Stations expected to have a high degree of acute toxicity were not included in the study because they would be less effective in eliciting different sublethal responses among the tests. The stations from southern California were selected to include a range of geographical location, proximity to sources of contamination, and expected sediment grain size. The RMP sites have been monitored for about 10 years and were chosen based on their wide geographic distribution and a range of acute toxicity to amphipods.

Tests on split samples were conducted by laboratories with extensive experience using the various tests. The *L. plumulosus* and *N. arenaceodentata* testing was conducted at the Army Corps of Engineers, Research and Development Center, Environmental Laboratory in Vicksburg, MS. The *A. tenuiremis* assays were performed at the University of South Carolina in Columbia, SC. The *M. mercenaria* growth test and *C. virginica* lysosomal destabilization procedures were done at the South Carolina Department of Natural Resources, Marine Resources Research Institute in Charleston, SC. The SWI testing was conducted at the University of California, Davis, Marine Pollution Studies Laboratory in Carmel, CA. Ten-day *E. estuarius* acute survival tests were performed on sediment from each station. These acute tests were performed by multiple laboratories, as part of the regional monitoring efforts. The laboratories that performed the *E. estuarius* tests on southern California stations participated in intercalibration procedures, which showed

reasonable agreement between laboratories (Bay *et al.* 2005). The laboratory testing the San Francisco Bay stations did not participate in this intercalibration. A summary of the characteristics of all of these test methods can be found in Bay *et al.* (2007). Samples were also analyzed for organic and metals chemistry, total organic carbon (TOC), grain size and benthic infauna.

Sediments were collected in July through August 2003. A Van Veen grab was used to collect whole sediment from the surface (top 2 cm) and subcores. Surface sediment was obtained from multiple grabs at each site, composited, transferred to plastic containers, and stored at 5°C. Sediment-water interface subcores were also collected from the Van Veen grab by inserting a polycarbonate core tube into the sediment to a depth of 5 cm and capping the bottom and top of the tube. All sediment samples were transported to Southern California Coastal Water Research Project (SCCWRP) within 24 hours of collection. The core samples were then transported with ice packs to the testing laboratory within 24 hours. Core samples from the San Francisco Bay stations were transported directly to the testing laboratory.

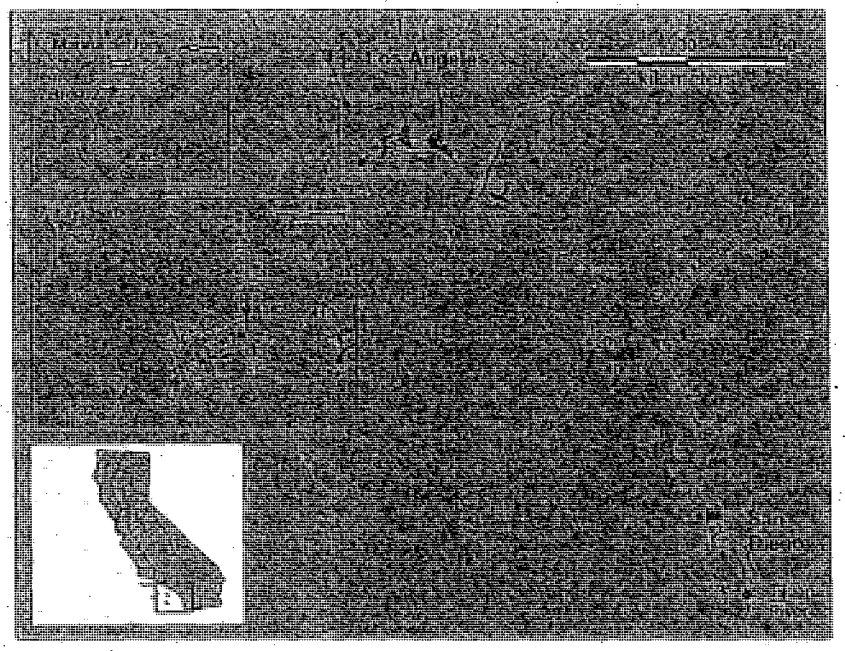

Figure 1. Location of southern California stations used for the sediment toxicity methods comparison study.

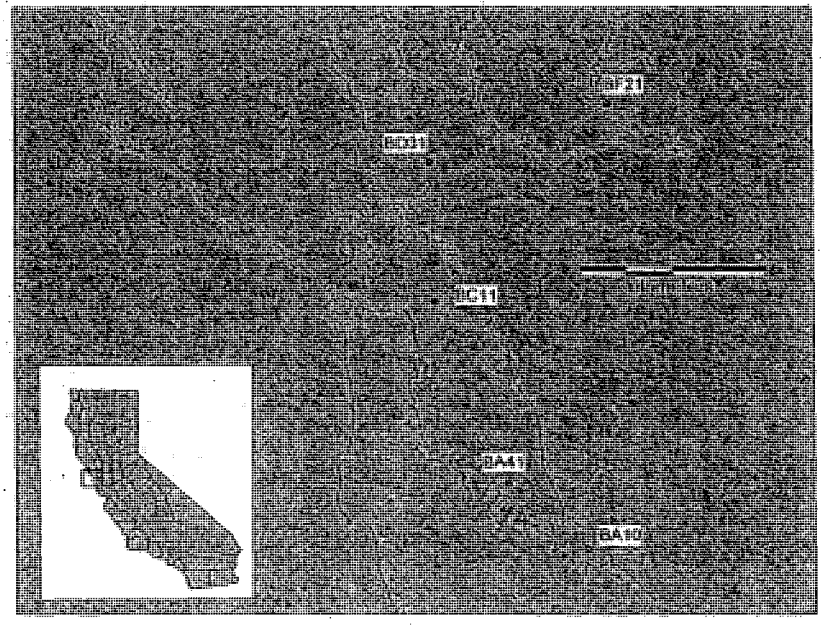

Figure 2. Location of San Francisco Bay stations used for the sediment toxicity methods comparison study.

The subcores were shipped to the testing laboratory within 48 hours of collection and the SWI tests were initiated within 10 days of collection (Table 2). The whole sediment samples were shipped to the testing labs in two batches, one with six of the southern California stations, the other with the remaining four southern California and all five San Francisco stations. Before shipment of each batch, all of the sediment from each station was placed in a large polycarbonate bowl and homogenized with a polycarbonate spoon. Samples for each laboratory were then aliquoted into polyethylene containers and shipped overnight with sufficient quantities of ice packs to maintain temperature at 5°C. Holding time between collection and testing of the composites varied from 6 to 116 days (Table 2).

Toxicity Testing

Eohaustorius estuarius 10-day survival

Ten day survival tests with *E. estuarius* were conducted using standard USEPA testing procedures (1994). Sediment samples were pre-sieved through a 2-mm mesh screen and homogenized in the laboratory before testing. Sediment was placed in 1-L glass jars to a depth of 2 cm. The samples were aerated and allowed to equilibrate overnight before addition of 20 adult amphipods to each of five replicates. All of the laboratories obtained the amphipods from Northwestern Aquatic Sciences (Yaquina Bay, OR). The exposures took place at 15°C, at a salinity of 20 g/kg with constant lighting. The animals were not fed and the water was not renewed during the exposures. At the end of the exposure, the sediment from each jar was sieved and the surviving animals were counted and recorded. Water quality measurements (dissolved oxygen, pH, salinity and overlying water ammonia) were determined at day 0 and prior to test termination.

Leptocheirus plumulosus 10-day survival

The experimental design followed guidelines set forth by the USEPA (1994). Sediment was added to each of 5 replicate 1-L beakers to obtain a 2 cm depth. Sediment was then overlain with 20 g/kg synthetic seawater. Temperature was maintained at 25°C with constant illumination and the beakers were aerated during the exposure. At day 0, 20 *L. plumulosus* (500- to 750-µm sieve size class) obtained from in-house cultures were gently transferred to each replicate beaker. The animals were not fed and the water was not renewed during the exposures. Water quality measurements (dissolved oxygen, pH, salinity and overlying water ammonia) were determined at day 0 and prior to test termination. On day 10, the sediment in each beaker was sieved and the surviving animals recovered. The number of surviving organisms was counted and recorded.

Leptocheirus plumulosus 28-day survival, growth and reproduction

The *L. plumulosus* 28-day experiments were conducted following the guidelines provided by the USEPA (2001). Due to conflicts in the laboratory schedule and a test failure, the samples for this test method were held for a much longer period than the other test methods (Table 2). Sediment was added to 5 replicate 1-L beakers to obtain the required depth of 2 cm. Sediment was then overlain with 20 g/kg synthetic seawater and gently aerated. Temperature was maintained at 25°C and the light cycle was set at 16:8 h light:dark. At day 0, *L. plumulosus* (250- to 600-µm sieve size class) were obtained from in-house cultures. Twenty animals were transferred to each replicate beaker. Water quality measurements (dissolved oxygen, pH, salinity and overlying water ammonia) were determined at day 0, prior to test termination and in one replicate per sediment three times per week. Water was changed in each beaker after water quality parameters were measured. Each beaker was provided with 20 mg of Tetramin® three times per week for the first two weeks and 40 mg per beaker the final two weeks of testing. On day 28, the sediment in each beaker was sieved and surviving animals were recovered. Surviving adults and neonates were counted and recorded. The surviving adults from each replicate were placed on a tared pan and dried at 60°C for 24 hours. The pans were then removed, allowed to cool and weighed to obtain total dry-weight for each replicate. The reproductive endpoint had an acceptability criteria failure in batch and an abnormal response in another. It was therefore decided that the reproductive data would not be used for analysis.

Neanthes arenaceodentata 28-day survival and growth

The 28-d *N. arenaceodentata* experiments were conducted following guidelines developed by the US Army ERDC (Bridges and Farrar 1997, Bridges *et al.* 1997). Sediment was added to 10 replicate 300 ml tall-form beakers to obtain the required depth of 2 cm. Sediment was then overlain with 30 g/kg synthetic seawater and gently aerated. Temperature was maintained at 20°C and light cycle was set at 12:12 hour light:dark. Organisms were obtained from Dr. Don Reish (California State University, Long Beach, CA). On day 0, one *N. arenaceodentata* (≤7 days old) was gently transferred to each replicate beaker. Water quality measurements (dissolved oxygen, pH, salinity and overlying water ammonia) were determined at day 0, prior to test termination, and in three replicates per sample weekly. Water was changed in each beaker once per week after water quality parameters were measured. Each beaker was provided 2 mg of

Tetramarin® once per week and 2 mg of Tetramarin® plus 2 mg of Alfalfa once per week. On day 28, the sediment contained in each beaker was sieved and surviving worms were recovered, counted and recorded. Surviving animals from each replicate were put on a pre-weighed pan and placed in a drying oven at 60°C for 24 hours. The pans were then removed, allowed to cool, and weighed to obtain the individual dry weight for each replicate/animal.

Amphiascus tenuiremis 14-day life cycle

Testing of the copepods followed the methods of Chandler and Green (1996). A sediment reference sample was collected from Oyster Landing at North Inlet, SC. Stations BA41, BC11, BRI2, 4085, 4202, 4262, were press-sieved through a 125 µm sieve in order to facilitate recovery of the animals at the conclusion of the exposure. A larger sieve size was used for some of the larger grained stations in order to obtain a sufficient volume of sediment for testing. Sediment samples 4008 and 4695 were screened with a 250 µm sieve while 4209 and 4130 were sieved through a 212 and 180 µm sieve, respectively. Sediment samples 4066 and 4142 were too sandy to pass a 250 µm sieve, and could not be tested with the copepod method. A total of ten stations were tested with *Amphiascus*. Teflon 50-ml Erlenmeyer flasks with mesh-covered outflow holes were filled with 0.45-µm filtered, aerated seawater. Press-sieved sediment samples were then packed into Teflon syringes and slowly extruded onto the bottoms of their respective chambers (4 replicates per sediment sample). Adult non-gravid female and adult male copepods (*Amphiascus tenuiremis*) were then counted into each quadruplicate test chamber (25/sex). Chambers were placed in an incubator at 20°C under continuous dripping flow for 14 days with a 12:12 hour light:dark cycle. Chambers were fed every third day a mixture of frozen algal stock (10^7 cells of 1:1:1 *Isochrysis galbana, Phaeodactylum tricornutum* and *Dunaliella tertiolecta*). Water quality parameters (dissolved oxygen, pH, and salinity) were measured every third day. Overlying water ammonia was measured once, at the end of each exposure period. At the end of 14 days of exposure, copepods were collected on a 63-µm sieve. Samples were checked/counted for dead bodies. Copepods were stained with Rose Bengal and preserved in 5% borate-buffered formalin. Non-gravid adult females, gravid adult females, adult males, copepodites, nauplii, and clutch sizes were enumerated under a Nikon SMZ-U stereo dissection microscope. Two endpoints of the *A. tenuiremus* test were calculated: the number of copepodites produced and the realized offspring production (output of new animals normalized to the number of females surviving at the end of the test).

Mercenaria mercenaria 7-day growth

The clam tests measured growth during a 7-day exposure to whole sediment (Ringwood and Keppler 1998, Keppler and Ringwood 2002). Sediment samples were pressed through a 500-µm sieve, homogenized, and 50-ml aliquots were placed into four replicate 250-ml beakers. The sediment was then overlain with clean 25 g/kg seawater. The replicates were gently aerated for the duration of the experiment, and the assays were conducted at room temperature (22 to 25°C) for 7 days with a 16:8 light cycle. Juvenile clams (*M. mercenaria*) used for all experiments were obtained from Atlantic Littleneck Clam Farm, Charleston, SC. Clams were sieved through two mesh sizes (1.0 mm and 1.2 mm) to ensure that the clams were of a similar size range. Twenty-five clams were used

for each replicate. Pre-assay wet weights of each clam group were taken for growth rate estimates, and to ensure that all replicate groups had similar initial weights. Replicate subsets of clams were also counted, wet weighed, dried overnight and reweighed to verify the wet:dry weight ratio used to estimate initial dry weights. Each replicate was fed on the first, third and sixth days of the assay (50:50 mix of *I. galbana* and *Chaetoceros gracilis*: 20 x 10^6 cells / replicate). The overlying water was not renewed during the exposure. At the end of the exposures, clams were sieved from the sediments and placed in fresh 25 g/kg seawater for approximately 2 hours to depurate. Dead clams were counted and removed, and percent mortalities were calculated. The surviving clams were counted and rinsed with distilled water to remove excess salts. Post-assay wet weights were determined, and clams were then dried for 48 hours (at 70°C). Each clam replicate was recounted and final dry weight per clam was determined. Initial dry weights were subtracted from the final dry weights, and the results were expressed as growth rates (µg/clam/day). Sediment pore water chemistry parameters (salinity, pH, and total ammonia – nitrogen [TAN]) were measured for each sediment sample prior to use in any assay. Overlying water quality was also measured.

Crassostrea virginica 4-day lysosomal destabilization

The lysosomal destabilization assay was conducted following the methods described in Ringwood et al. (1998). Sediment samples were homogenized and 100-ml aliquots were placed into three replicate 1L beakers. The sediment was topped with clean 25 g/kg seawater. The beakers were allowed to settle for 2 hours, and then 3 clean-scrubbed oysters were gently added to each replicate. Oysters (5.3 $\pm$0.7 cm) used for laboratory sediment exposures were collected from control sites and acclimated to laboratory conditions for at least 24 hours prior to the start of the experiment. The replicates were gently aerated for the duration of the experiment, and the assays were conducted at room temperature (22 to 25°C) for 4 days with a 16:8 light cycle. Each replicate was fed on the first and third days of the assay (algal paste mixed into filtered sea water, 70 x 10^6 cells / replicate). The overlying water was not renewed during the exposure. Water quality parameters for both the pore and overlying waters were measured in the same way as for the *M. mercenaria* testing. Digestive gland tissue from the exposed oysters was diced and treated with trypsin to produce a cell suspension. A cell suspension aliquot was mixed with an equal aliquot of neutral red (NR) solution, placed on a microscope slide and examined under a light microscope to evaluate NR retention by digestive gland cells containing lysosomes. At least 50 cells were scored as stable (NR retention in the lysosomes) or destabilized (NR leaking into the cytoplasm), and the data were expressed as the percentage of cells with destabilized lysosomes per oyster.

Mytilus galloprovincialis 2-day embryo development at the sediment-water interface

Exposure procedures followed those detailed by Anderson *et al.* (1996). One day prior to the start of the test, 300 ml of clean seawater (1-µm filtered, approximately 34 g/kg) was added over the sediment to each of five replicate core tubes. Samples were then aerated overnight to equilibrate. On test day 0, water quality samples were collected from the core tubes and tubes containing a 25-µm screen were placed on the sediment surface. The screen was approximately 1 cm above the sediment. Mussel embryos were unavailable to test stations 4008, 4209, and 4695, so sea urchin embryos were used

instead. Embryos were prepared following USEPA protocols (USEPA 1995) and added to the screen tubes. Mussels were exposed for 48 hours and sea urchins for 96 hours. Exposures were carried out at 15°C with gentle aeration. Water quality parameters of dissolved oxygen, total ammonia, pH, and salinity were measured at the beginning and end of the exposure period. Temperature was measured continuously. The exposures were terminated by removing the screen tube, rinsing the embryos into a vial, and adding formalin to fix and preserve embryos. The samples were then examined microscopically for normal embryo development. Data were expressed as percentage normal-alive. This endpoint is calculated by dividing the number of normal embryos by initial number of embryos inoculated into the chambers.

Chemical Analysis

Sediment samples were analyzed for a suite of parameters that included metals, organics, grain size and TOC. Analyses were conducted by a variety of laboratories participating in the regional monitoring programs and used standardized EPA recommended methods (Bight'03 Coastal Ecology Committee 2003, SFEI 2005). The laboratories had achieved acceptable comparability during pre-project intercalibration exercises and the data were subjected to rigorous post survey review. Quality assurance samples were included in each sample batch and included method blanks, duplicates, matrix spikes, and a certified reference material. Sediment particle size was measured by light-scattering technology using either a Coulter LS230 or a Horiba LA900 instrument. The sediment samples analyzed for all metal analytes except mercury were digested in strong acid according to the procedures described in EPA Method 3050B. Metals were quantified using either inductively coupled plasma mass spectrometry, inductively coupled plasma emission spectroscopy, flame atomic absorption, or graphite furnace atomic absorption. Mercury was analyzed using cold vapor atomic absorption spectroscopy. Samples for organic chemistry analysis were solvent extracted using accelerated solvent extraction, sohxlet, or roller table. The extracts obtained were subjected to each laboratory's own clean-up procedures and were analyzed by gas chromatographic method (e.g., dual-column GC-ECD or GC-MS in the selected ion monitoring mode).

Benthic Community Analysis

A separate grab sample was taken for benthic community analysis at all the stations. The contents of the grab were washed through a 1.0-mm screen and all of the retained animals identified to species or the lowest possible taxon. Different benthic indices were used to assess community status for the San Francisco Bay and southern California stations because of habitat differences between the two regions that affected species composition. The benthic community condition of the southern California stations was assessed using the Benthic Response Index (BRI; Ranasinghe *et al.* 2003). The BRI is the abundance-weighted average pollution tolerance score of organisms occurring in a sample. The Index of Biotic Integrity (IBI) was used to determine benthic community condition for the San Francisco Bay stations (Thompson and Lowe 2004). The IBI uses a multimetric index to discriminate between impacted and reference areas.

Data Analysis

Toxicity data were control normalized ((station value/control) x 100) to facilitate comparisons among the test methods. Statistical significance was tested using Student's t-test ($p \leq 0.05$) assuming unequal variance (Zar 1999). For sublethal methods having more than one endpoint, if either or both endpoints were significantly different from control, the station was designated as toxic.

The mean ERM quotient (ERMq; Long *et al.* 1998) was calculated for each station to integrate a subset of the analyzed chemicals into a value that is predictive of toxic effects. The ERM for DDT was not used in calculations because it has been found to be unreliable (Long *et al.* 1995). Relationships between sediment chemistry parameters or benthic community condition and toxicity response were analyzed using a non-parametric Spearman's rank correlation.

RESULTS

The experimental batches for all toxicity data that is presented passed test control acceptability criteria, except for one SWI batch with *M. galloprovincialis*. That batch contained the only sample with a significant toxic response for the SWI test and had a low control normal-alive percentage. Because the difference between the control and sample response was very large, we have chosen to include the data.

There were two quality assurance issues with the *L. plumulosus* 28-day test. First, there was a test failure based on insufficient reproduction in the controls. When the test was repeated, the controls reproduced sufficiently, but all of the other samples had greatly less reproduction than the controls. This situation had never been encountered by the testing laboratory and led to our decision to not use the reproduction data for analysis. The second issue with this test was the very long holding time of the sediments before testing began compared to the other methods (Table 2). The effects of this prolonged holding time are unknown. The data are presented for the purposes of comparison, but may have differed had the holding times been identical between methods.

Water quality measurements made during testing indicated that the values were within acceptable range for the majority of sample/test combinations. For the *M. mercenaria* test, station 4130 exhibited elevated pore water ammonia (37.5 mg/L total ammonia-nitrogen). While the tolerance of *M. mercenaria* to ammonia is not known, there is correlative evidence that the ammonia level in the sample may have been the cause of toxicity. For the SWI test, station BC11 had an overlying water ammonia concentration of 0.145 mg/L un-ionized ammonia, which is very near the EC50 (approximately 0.17 mg/L, unpublished data).

Comparisons Among Sublethal Tests

There was a wide range in the percentage of stations that each of the sublethal methods identified as toxic (Figure 3). The highest percentage was for the copepod, *Amphiascus* that found 9 out of the 10 stations tested to be toxic, followed by *N. arenaceodentata* with 8 out of 15 stations. The proportion of stations identified as toxic was much lower for the remaining test methods, with the lowest percentage for the SWI testing which identified 1 out of 15 stations as toxic.

Comparisons Between Acute Tests

The *E. estuarius* method was the less sensitive of the two amphipod acute protocols, identifying 4 out of 15 stations as toxic (Figure 4). Overall the *E. estuarius* method was near the mid-point in sensitivity relative to the sublethal tests. The *L. plumulosus* 10-day method identified 9 out of the 15 sites as toxic and was more sensitive than all but one of the sublethal methods.

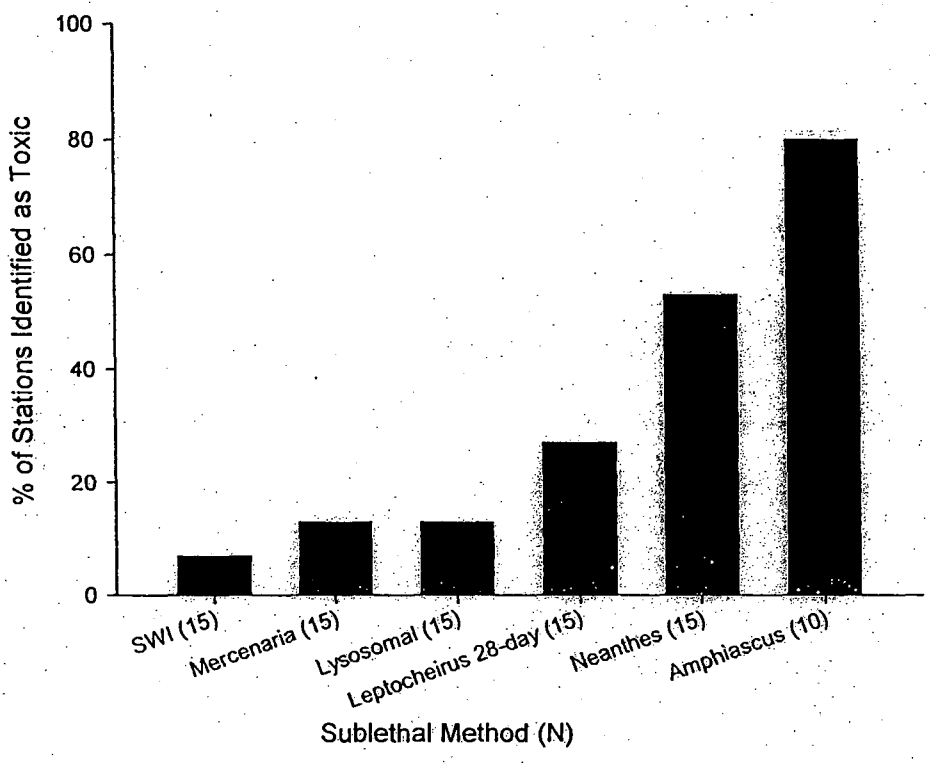

Figure 3. Percentage of stations that each sublethal method identified as being toxic. Number of samples tested is in parentheses. *Leptocheirus plumulosus* (*Leptocheirus*), Sediment-water Interface (SWI), *Mercenaria mercenaria* (*Mercenaria*), *Crassostrea virginica* (Lysosomal), *Neanthes arenaceodentata* (*Neanthes*), and *Amphiascus tenuiremus* (*Amphiascus*).

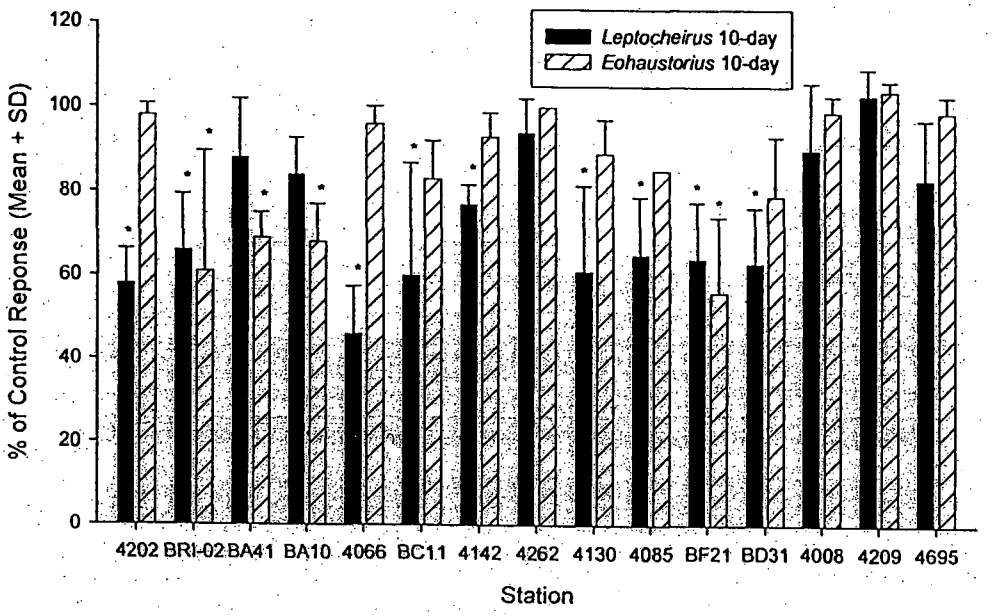

Figure 4. Results of *Eohaustorius estuarius* (*Eohaustorius*) 10-dayand *Leptocheirus plumulosus* (*Leptocheirus*) 10-day survival tests conducted as part of the Bight'03 and RMP regional monitoring programs. Stations marked with * are significantly different from control values (p <0.05) and less than 80% of the control response.

Comparisons Between Sublethal and Acute Tests

The *N. arenaceodentata* and *Amphiascus* tests detected toxicity at stations where *E. estuarius* did not at 27% and 70% of the stations, respectively; while in no cases did *E. estuarius* demonstrate toxicity where either of these two tests did not (Table 3). Alternatively, the *E. estuarius* test identified a higher percentage of stations as toxic than did the SWI, *M. mercenaria* and *C. virginica* tests. The *E. estuarius* test identified toxicity in 27% of the samples that the other tests classified as nontoxic.

Table 3. Comparative ability of acute and sublethal sediment toxicity test methods to detect toxicity in stations from southern California and San Francisco Bay. Numeric values are expressed as percentage of stations tested. The station order is based on a combined ranking of chemical contamination and benthic community health, with the most contaminated/impacted stations listed first. *Eohaustorius estuarius* (*Eohaustorius*), *Leptocheirus plumulosus* (*Lepto*), Sediment-water Interface (SWI), *Merceneria mercenaria* (*Mercenaria*), *Crassostrea virginica* (Lysosome), *Neanthes arenaceodentata* (*Neanthes*), and *Amphiascus tenuiremus* (*Amphiascus*).

Y = Station identified as toxic
N = Station not identified as toxic
– = Station or comparison not tested

The *L. plumulosus* 10-day test found a higher percentage of toxic stations than all of the sublethal methods except for the *Amphiascus* test (Table 3). The *Amphiascus* test found four stations (40%) to be toxic that were not identified by the *L. plumulosus* acute test. There was concordance between the *L. plumulosus* 10-day test and the *Amphiascus* test for the remaining stations with both finding five stations to be toxic and one not. The *N. arenaceodentata* test found four stations to be toxic that were not identified by the *L. plumulosus* acute test. However, there were five stations that were toxic in the *L. plumulosus* acute test, but were not toxic in the *N. arenaceodentata* test. For the *M. mercenaria, C. virginica, L. plumulosus* 28-day and SWI tests there was a high percentage of stations (40% or more) that the *L. plumulosus* acute test found to be toxic that the sublethal methods did not.

Combining the data from either a lethal and sublethal test or two lethal tests provided more information regarding toxicity than conducting just one test of either kind. The greatest sensitivities (most toxic stations detected) were found with the combinations of *L. plumulosus* 10-day and *N. arenaceodentata* or *Amphiascus* methods (Table 3). Nearly as sensitive was the combination of the two acute tests (see Figure 4 where 11 out of fifteen stations were identified as toxic by one or both tests).

Chemistry

Sediment physical parameters were very wide ranging with grain sizes that were nearly 100% fines (silt + clay) to 100% sand (Table 4). TOC values ranged from 0.02% to 2.9%.

Sediment contaminant concentrations also were variable among stations (Table 4). Three stations had elevated chemistry compared to the other stations. Station 4202, on the Palos Verdes shelf, had a very high concentration of total DDTs. Station BRI-02, in Marina Del Rey, had low concentrations of organic contaminants, but substantial concentrations of copper, lead and zinc. Station 4085 contained intermediate concentrations of several metals and organics. Based on the mean ERMq calculations, all of the stations tested fell into what would be considered the low to moderate range of contaminant concentrations with all mean quotients less than 0.7 (Table 4). Five samples had mean ERMq values below 0.1, a level not expected to be toxic. The mean quotients for the remaining stations fell between 0.11 and 1.0, a range that has been found to be toxic in about half of the cases (Long *et al.* 1998).

Eohaustorius estuarius survival, both *Amphiascus* endpoints and *N. arenaceodentata* growth had significant Spearman correlations with sediment chemistry (Table 5). Correlations with various metals were present, but none with organics. All of the significant correlations were negative, indicating that as the concentration increased the endpoint decreased (e.g., decreased survival or growth). All the toxicity test methods that correlated with chemistry also had significant correlations with sediment grain size. The chemical constituents that correlated with toxicity also correlated with the grain size parameters.

Benthic Community

A range of benthic community condition was present among the stations. Most stations were classified as being in reference condition (8/15) or having an intermediate level of disturbance (5/15 stations at Level 2 or 3). Two stations (4066 and 4142) had Level 4 designations (Table 6), which indicated severe effects to the benthic community. The variations in benthic community condition did not correspond with the sediment contamination gradient. The average mean ERMq of all stations in each benthic condition category was lowest for the Level 4 stations and highest for the Level 2 stations (Table 6).

There was little correspondence between changes in benthic community condition and toxicity for most of the test methods. *L. plumulosus* 10-day survival was the only test that consistently detected toxicity at the Level 4 stations (Table 6). Most of the stations that did show toxicity were in the Reference or Level 2 categories for benthic community condition. Four of the test methods (*E. estuarius*, *L. plumulosus* 10-day and 28-day and *Amphiascus*) showed an increased incidence of toxicity among all impacted stations (Levels 2 through 4 combined) compared to stations classified as having a reference benthic condition. Correlations of BRI values for the southern California stations showed that only the *L. plumulosus* 10-day test method had a significant correlation with benthic community condition (Table 6). The correlation coefficients were negative for all but the *C. virginica* lysosome method, indicating that as the BRI value increased the toxicity endpoint value decreased (i.e., survival or growth decreased).

Table 6. Incidence of toxicity within benthic index categories and Spearman's Rank Correlation values for toxicity test endpoints. Boxed values are statistically significant ($p \leq 0.05$).

Ranking of Stations to Reflect Sediment Condition

Since most of the stations in this study had not been previously sampled, there was not a known gradient of expected sediment condition. To put the data into this context, the stations were ranked by a combination of chemical contamination and benthic community health. To achieve this the stations were ranked by their mean ERMq values (Table 4). The stations were also ranked similarly by the benthic community analysis results (Table 6). These two rankings were then summed and the stations re-ranked to get the combined effect. The data presented in Figure 5 have the stations with the lowest rankings (highest chemistry and most degraded benthos) on the left and highest rankings on the right. Station 4202 had the highest concentrations of the most chemical constituents and showed a toxic response to two of the sublethal test endpoints. It ranked as having the worst sediment condition of all the stations even without the high value of DDT taken into consideration. Station BRI-2 with high concentrations of three metals and with a Level 2 benthic designation ranked as the second worst. Station 4085 with moderate levels of several chemicals ranked in the middle. Although stations 4066 and 4142 had Level 4 benthic designations, they fell in the middle of the ranks because their chemical concentrations were lower.

DISCUSSION

The sensitivity of the toxicity methods were variable within the two broad categories of tests evaluated, indicating that general classifications of tests as either acute or sublethal do not reliably indicate their relative sensitivity. For example, the most sensitive test in this study was the sublethal *Amphiascus* life cycle method, but the acute *L. plumulosus* survival test was more sensitive that any of the other sublethal tests compared. This variation in sensitivity between acute and sublethal tests is consistent with other studies, suggesting that the relative sensitivity of acute and sublethal tests to whole sediment samples varies according to the combination of tests and sample types evaluated. Comparative studies using the *L. plumulosus* 28-day test have shown that the sublethal endpoints from this test are not consistently more sensitive than acute amphipod tests to field and spiked sediments (DeWitt *et al.* 1997). Another study found that the acute *A. abdita* test was more sensitive than the *L. plumulosus* 28-day test, which was more sensitive than the *N. arenaceodentata* 28-day test (Kennedy *et al.* 2004). In contrast to the results of the present study, the *M. mercenaria* test was found to be more sensitive than the acute *A. abdita* survival test when sediment samples from the Carolinian Province were tested (Ringwood *et al.* 1996).

Our finding that *Amphiascus* was the most sensitive method overall is consistent with other studies indicating the high sensitivity of this life cycle test. Tests using sediments from Biscayne Bay in Florida by Long *et al.* (Long *et al.* 1999) found a greater incidence of toxicity with the *Amphiascus* life cycle method (73%) than with the *A. abdita* 10-day survival test (7%). The high sensitivity, chronic exposure and multiple endpoints that are characteristic of this test are desirable qualities, however, more investigation is needed to determine whether the high level of response of the test to southern California samples having low contaminant concentrations and reference benthic community condition reflect chemical toxicity or the effects of potentially confounding factors such as ammonia or organic carbon.

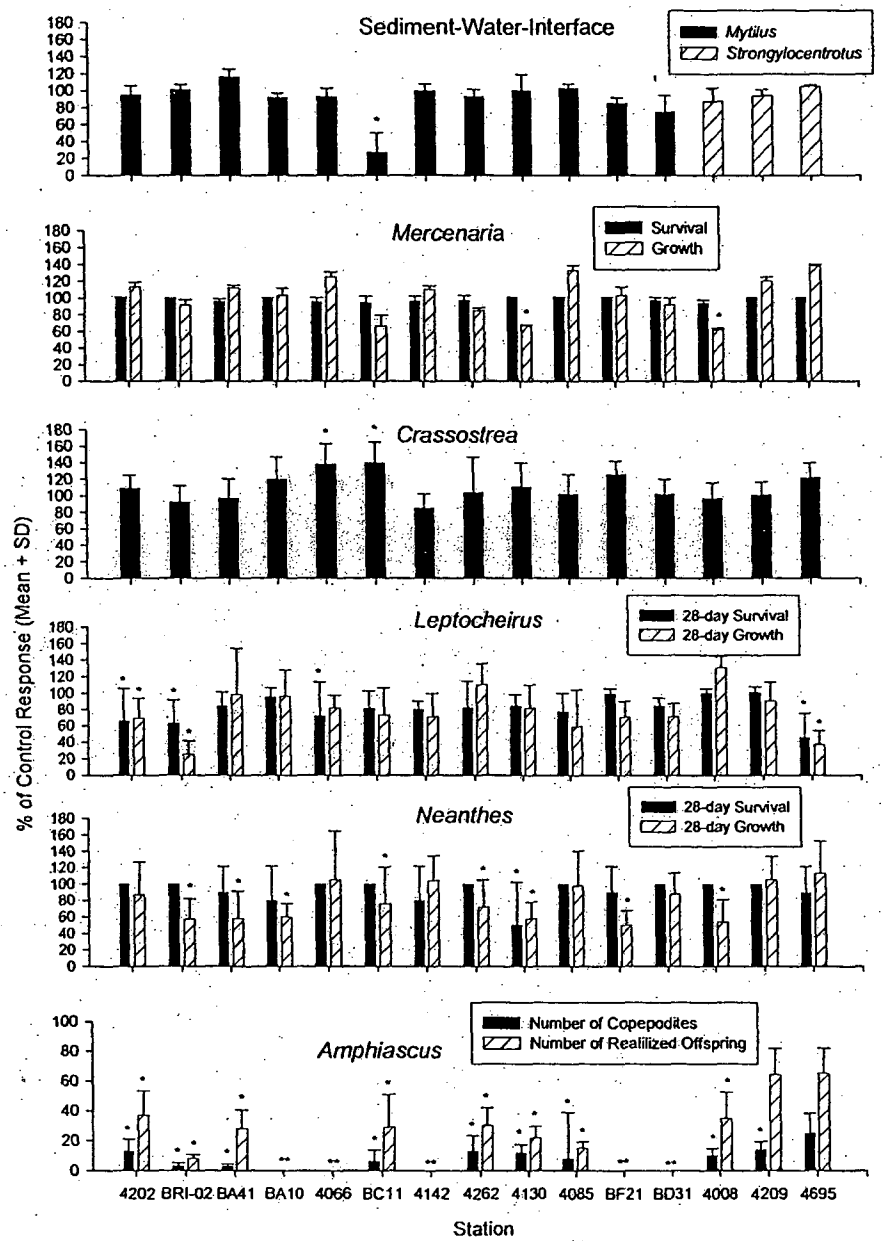

Figure 5. Results of sublethal test methods conducted on samples from southern California and San Francisco Bay. Stations marked with * are significantly different from control values ($p < 0.05$). Stations with ** indicate that the station was not tested using that method. *Eohaustorius estuarius* (*Eohaustorius*), *Leptocheirus plumulosus* (*Leptocheirus*), *Merceneria mercenaria* (*Mercenaria*), *Crassostrea virginica* (Crassostrea), *Neanthes arenaceodentata* (*Neanthes*), *Mytilus galloprovincialis* (*Mytilus*), *Strongylocentrotus pupuratus* (*Strongylocentrotus*) and *Amphiascus tenuiremus* (*Amphiascus*).

Several factors may have accounted for the variation in sensitivity among methods observed in this study, including: mode of exposure, species-specific sensitivity to contaminants, and the influence of confounding factors. The mode of exposure varied greatly among tests and those tests with the longest exposure duration and most direct contact with the sediment (i.e., *Amphiascus* and *N. arenaceodentata*) tended to be most sensitive. For the SWI method, which was least sensitive, the organisms are in the water column directly above the sediment, and are exposed for a relatively short period of time to only those contaminants diffusing into the overlying water. These differences in exposure method and sample response can be used to advantage to investigate the mode of contaminant exposure or identify the cause of toxicity.

Differences in contaminant sensitivity among test methods have been documented for some of the test species and may have influenced the results of this study. Several studies have been conducted that compared the *L. plumulosus* 10-day and 28-day tests and the *N. arenaceodentata* 28-day test to various chemicals and found varying patterns of response. The *N. arenaceodentata* test was more sensitive than *L. plumulosus* to sediments contaminated with metals or the explosive TNT, both of these sublethal tests were more sensitive than the acute *L. plumulosus* test to PCBs, yet the *L. plumulosus* acute method was more sensitive to PAH contaminated sediments than *N. arenaceodentata* (Farrar *et al.* 2005, Green *et al.* 1999). Comparisons among acute tests using *A. abdita*, *E. estuarius* and *R. abronius* showed that *E. estuarius* was the most sensitive to DDT, while *A. abdita* and *R. abronius* were more sensitive to cadmium (Weston 1996). Sediment contaminant mixtures varied among the stations in the present study, with differences of up to two orders of magnitude in metals, PCB, and PAH concentrations, and up to three orders of magnitude in DDT. These differences may have contributed to the variation in response among the test methods.

Variations in holding time or sediment handling that occurred among the laboratories are potential confounding factors that may have altered the toxicity of the samples through changes in bioavailability or chemical composition. The nature and magnitude of such effects was not determined in this study, but an analysis of the data indicates that the patterns of relative sensitivity observed among the test methods were independent of holding time. For example, holding times were shortest and similar for the SWI and *Amphiascus* methods, yet these two tests had very different patterns of response to the samples (Table 7). The patterns of relative response among the tests were also similar for the two batches of whole sediment tested (e.g., *Amphiascus* most sensitive, *M. mercenaria* and *C. virginica* usually least sensitive), indicating that variations in holding time or sediment handling among the tests and batches were not major confounding factors.

The most responsive of the acute and sublethal toxicity tests showed a general correspondence with the gradient of sediment condition described by a combination of the chemistry and benthic community data. The *Amphiascus* and *N. arenaceodentata* tests reflected the expected pattern of decreasing toxicity with improving sediment condition (Figure 5), as did both of the acute tests (Figure 4). These relationships were inconsistent for stations having intermediate rankings of sediment conditions, indicating

substantial uncertainty in the relationships among the different indicators of sediment quality. In addition to the sources of variability mentioned previously for the toxicity tests, measures of sediment chemistry and benthic community condition also have inherent uncertainty and sources of error that may have accounted for the inconsistent relationships.

Significant correlations with chemistry concentrations were found in the present study for the *E. estuarius* survival, *Amphiascus* reproduction and *N. arenaceodentata* growth tests. Similar relationships have also been documented in many other studies for a variety of test organisms and form the basis for empirical sediment quality guidelines (Long *et al.* 1995, Fairey *et al.* 2001). There were also significant correlations with grain size for each test. The chemistry values also correlated with grain size and many of the chemical constituents also correlated with one another. These intercorrelations make determining whether toxicity is associated with chemistry or the confounding factor of grain size a difficult matter. Grain size is not known to be a confounding factor for *E. estuarius* (USEPA 1994). Grain size should not have been an issue for *Amphiascus* since all samples were sieved to remove large particles and optimize the sediments for the animals. *Neanthes arenaceodentata* have been tested in grain sizes ranging from 5 to 100% sand with no effects on either survival or growth (Dillon *et al.* 1993). These factors indicate that there is a likelihood of an association between sediment contamination and toxicity for these three methods in the current study, rather than a grain size effect.

The lack of correlations with sediment chemistry for some of the test methods may have several causes. There was little observed toxicity for many of the tests making the detection of correlations difficult. In addition, no measure of bioavailability of chemical constituents was made for the sediments, adding uncertainty regarding the actual chemical dose received by the test animals. Sediment chemistry analyses do not quantify all possible toxicants, so it is possible that unmeasured chemical constituents or interactions between compounds may have caused the observed toxicity. Another potential source of uncertainty is toxicity from confounding factors such as ammonia or sulfides. While the sensitivity of some of the test methods to these factors is poorly known, water quality data from the tests showed that dissolved ammonia concentrations were low and below concentrations of concern for most of the samples, indicating that these factors did not have a significant influence on the results.

A strong relationship between the toxicity results and benthic community condition was not found in this study, suggesting that these indicators were responding to different aspects of sediment quality. Other studies have reported similar results. Analyses of Chesapeake Bay sediment toxicity using the *L. plumulosus* 10-day and 28-day tests found a similar lack of correspondence with benthic community response (McGee *et al.* 2004). A statistically significant correlation between *E. estuarius* mortality and benthic community impact was found for southern California embayment sediments, but the relationship accounted for only 10% of the variation in community condition (Ranasinghe *et al.* 2003). Toxicity tests differ from the *in situ* benthic environment in many aspects, such as the exposure duration, species type, and laboratory handling of the

sediment. These factors can affect contaminant bioavailability or the sensitivity of the response and may have accounted for the relatively high frequency of toxicity detected in samples containing an unimpacted benthic community. It is not possible for toxicity tests to perfectly replicate environmental exposure conditions and provide a substitute for assessment of biological effects on resident organisms; these tests are intended to provide a measure of potential contaminant effects that is complementary to chemical and biological measures.

The effects of noncontaminant factors on the benthic community analyses may have also influenced the correlation analyses with toxicity. Changes in benthic community condition did not correspond with increasing contamination levels, as represented by the mean ERMq (Table 6). This finding contrasts with studies in other regions of the United States that have shown an increase in the incidence of degraded benthos within the mean ERMq range present among the southern California samples (Hyland *et al.* 2003). It is possible that variations in noncontaminant factors related to the diversity of habitats and sediment types included in this study may have influenced the benthic community results and confounded the ability of to discern impacts due to toxicity.

This study and others have shown marked differences in sensitivity among toxicity tests that cannot be easily predicted on the basis of biological endpoint and mode of exposure. This diversity presents both a challenge and opportunity for sediment toxicity evaluation. The challenge lies in selecting the most appropriate tests for use in a particular study. Variations in relative sensitivity related to contaminant type and uncertainties in the interpretation of chemistry and benthic community data suggest that the use of just a single test method, selected on the basis of high sensitivity to a subset of samples, is unlikely to provide a complete or confident assessment of toxicity. Data from multiple toxicity tests that represent a diversity of species, endpoints, and exposure modes, in addition to sediment chemistry and benthic community analyses, are needed to assess sediment quality to the level of confidence needed to support management decisions (Chapman and Anderson 2005). The use of a diverse suite of toxicity tests also provides an opportunity to improve our understanding of the causes of sediment toxicity, as differences in the patterns or symptoms of response between tests can be used to help identify the case of toxicity (USEPA 1993).

APPENDIX B

Interlaboratory Comparison of Sublethal Sediment Toxicity Test Methods Using *Mercenaria mercenaria* and *Mytilus galloprovincialis*

Steven Bay, Diana Young and Darrin Greenstein

Southern California Coastal Water Research Project, Westminster, CA

INTRODUCTION

Many sediment quality monitoring and assessment programs use a combination of acute amphipod survival and sublethal sediment toxicity test methods. The acute amphipod methods are usually conducted using standard protocols for a small number of species (USEPA 1994) and several studies have been conducted that document important aspects of the tests such as relative sensitivity and interlaboratory variability. A greater diversity of sublethal sediment toxicity test methods have been applied in various studies (Lamberson *et al.* 1992), yet few studies have been conducted that compare the relative performance of these methods.

A significant data gap for some sublethal toxicity tests is information on interlaboratory variability. An understanding of the amount of variation associated with conducting the test in different laboratories is needed to assist in decisions regarding the selection of test methods for use in a study and for determining the significance of various ranges in the organism's response to the test samples. Interlaboratory variability data are not available for two sublethal methods that are promising candidates for use in regional monitoring programs: the seven-day growth test using the seed clam, *Mercenaria mercenaria* (Ringwood and Keppler 1998), and the two-day sediment-water interface (SWI) test using embryos of the mussel *Mytilus galloprovincialis* (Anderson *et al.*, 1996). Interlaboratory variability for these two test methods is needed to support the evaluation of these methods for use in sediment testing programs.

The objective of this study was to measure the interlaboratory variability associated with the seed clam and mussel embryo sediment toxicity tests. Interlaboratory comparison tests were conducted with both test methods using field and spiked sediments.

METHODS

Concurrent sediment toxicity tests were conducted by two laboratories for the mussel embryo test and by three laboratories for the seed clam test. Two types of samples were tested in each set of experiments: dilutions a contaminated field sediment and several concentrations of sediment spiked with nonylphenol. In both cases, one of the participating laboratories was the originator of the test method. For both test methods, each laboratory also conducted reference toxicant exposures to demonstrate laboratory comparability. Additionally, range finding tests were conducted to determine the proper concentrations of the spiked and diluted samples.

Field

The sediment used for spiking with nonylphenol and for dilution of contaminated field sediment was collected by Orange County Sanitation District near their reference site 18. This station is located offshore and has low levels of chemical contamination and a moderate grain size (~50% sand). The contaminated field sediment was from Consolidated Slip (CS) in Los Angeles Harbor and had been in storage since collection in October 2002. Consolidated Slip has a long history of contamination from industrial sources with very high levels of PAHs, DDT and metals and very fine grain size. Both the sediment from CS and Orange County (OC) were stored in plastic containers at 5 °C.

Test Sediment Preparation

Stock solutions of 4-n-nonylphenol (Alfa Aesar) in acetone were placed into 2 L glass jars and the carrier was allowed to volatilize on a Wheaton roller apparatus (Distworth *et al.*, 1990). After volatilization, OC sediment was added to the containers in amounts in amounts corresponding to nominal nonylphenol concentrations of 0.1-1000 mg/kg and rolled for the first 24 hours of the seven-day equilibration time. Sediment was stored at 5°C in amber glass jars for the remainder of the equilibration period. Chemical verification of the final sediment concentrations was not preformed.

The CS dilutions were made as 10, 25, and 50 percent wet weight:wet weight CS sediment diluted with OC sediment. Mixing was accomplished with a polycarbonate spoon in a large polycarbonate bowl. A control sample consisting of 100% OC sediment was also tested. Aliquots of the mixtures were placed into separate containers for each laboratory. The samples were then stored in plastic containers at 4°C and allowed to equilibrate for seven days, before being used in the interlaboratory experiments.

Mussel Embryo Development Test

The University of California Davis Marine Pollution Studies Laboratory (MPSL) and Southern California Coastal Water Research Project (SCCWRP) conducted the laboratory intercalibration for the sediment-water interface (SWI) mussel embryo development test. The mussels (*M. galloprovincialis*), obtained from Carlsbad Aquafarms in Carlsbad, CA, were acclimated in 32 g/kg seawater at 15°C overnight. The procedure for the mussel development test and the exposure procedures followed methods described in Appendix A. To simulate a core sample, the core tubes were filled with 5 cm of the sediment samples, with five replicate tubes per treatment. Seawater was

added over the sediments, aeration was added and the system was allowed to equilibrate overnight.

Both laboratories also performed a 48-hour water only reference toxicant experiment with copper. A stock solution of $CuCl_2$ was provided by SCCWRP. Each laboratory prepared dilutions of the stock to achieve concentrations of 4.5, 6.5, 9.5, 13.9, 20.4, and 30.0 µg/L copper plus a water only seawater control. Four replicates of each concentration were tested.

At the end of the experiment all normal and abnormal embryos were counted. The %Normal-Alive endpoint was calculated by dividing the number of normal embryos in each vial by the mean initial embryo count and then multiplying by 100.

Juvenile Clam Growth Test

Three laboratories participated in the seed clam (*M. mercenaria*) interlaboratory calibration experiment: South Carolina Marine Resources Research Institute (MRRI), SCCWRP, and Weston Solutions (Carlsbad, CA). Exposure methods followed those described in Appendix A. The clams were fed the algae *Isochrysis galbana* during all exposures. For the interlaboratory experiment all laboratories used live *I. galbana* cultures. However, during the range finding tests, a concentrated *I. galbana* solution obtained from Reed Mariculture was used for feeding after proper dilution.

All laboratories performed a water only 7-day reference toxicant test exposure to copper with the same feeding regime as for the sediment experiment. The reference toxicant experiment used a 10,000 µg/L stock solution of $CuCl_2$ provided by SCCWRP. Dilutions were prepared at each of the laboratories to achieve concentrations of 6.25, 12.5, 25, 50, and 100 µg/L copper.

Although OC sediment was used as a control, it had never been previously tested using the juvenile clams. Therefore, a second control was included that has historically been used as a reference for this clam test, to ensure reasonable control response. MRRI provided this reference sediment (coded LTH), which was sandy sediment from a clean site in South Carolina.

Data analysis

Data for all tests were adjusted to control response within each laboratory. For the SWI test, the data was adjusted to the water only control value from the reference toxicant test. For the *M. mercenaria* test, the data was adjusted to the response in the LTH sample. Significant differences between controls and treatments were calculated by t-tests assuming unequal variance ($p \leq 0.05$). Differences between laboratories were calculated with either t-tests (SWI) assuming unequal variance or ANOVAs (*M. mercenaria*) followed by Tukey's multiple comparison test. EC50s for reference toxicant exposure for the mussel embryos were calculated using probit analysis. For the clam reference toxicant exposure, the IC50 (the inhibition concentration where a 50% reduction in growth is predicted to occur) was calculated using the EPA ICP program.

RESULTS

Mussel Embryo Development

Range Finding

For the SWI mussel embryo development test, range finding experiments using nonylphenol and CS samples were completed at SCCWRP. An initial selected series of 10, 100, and 1000 mg/L nonylphenol produced a dose response with 87% of control normal-alive embryos in the 10mg/L nonylphenol, 80% in the 100 mg/L nonylphenol, and 21% in the 1000 mg/L nonylphenol sample. Because this was a suitable dose-response, these concentrations were selected for use in the intercalibration exercise.

The CS dilutions were tested at 5, 10, and 25% of CS sediment. The percent of control normal-alive embryos at 5 and 10% CS was 99%, and at 25% CS was 79%. In order to increase the range of response, the percentage of CS in the samples was increased to 10, 25 and 50% for the intercalibration exercise.

Interlaboratory Calibration

MPSL results showed a significant difference between all three concentrations of the nonylphenol spiked sediments and the non-spiked OC control station. MPSL obtained a good dose response, with each concentration showing substantially more toxicity than the previous one and severe toxicity at 1000 mg/L nonylphenol, with no normally developed embryos (Figure 1). SCCWRP found only the 1000 mg/L nonylphenol sample significantly different from the control with 0% of the embryos developed normally (Figure 1). SCCWRP found development in the other two nonylphenol concentrations was similar to the OC sediment.

MPSL found the highest two concentrations of the CS sediment to be significantly different from the OC station. However, the toxicity in the dilution series of 10, 25, and 50% CS was of moderate degree with 77, 70, and 57% normal-alive relative to the control, respectively (Figure 2). SCCWRP did not find a dose response for CS dilution sediments and did not find any of the dilutions to be significantly different from the OC station. The two higher concentrations of CS had normal development only slight less than that found in the water only controls.

There was little agreement between the two laboratories' results. Of the seven samples tested only two, OC and 10% CS, were not significantly different between the laboratories. The five other samples were significantly different from each other, and in all cases the MPSL %normal-alive results were lower than those of SCCWRP.

Reference Toxicant

The EC50s for the two laboratories were comparable with MPSL being 6.8 µg/L copper (upper and lower 95% confidence limits were 6.5 and 6.9) and SCCWRP 7.6 µg/L copper (lower and upper 95% confidence limits were 7.2 and 8.0). The dose-response plots of the copper exposure were remarkably similar between the two laboratories (Figure 3).

Juvenile Clam Growth

Range Finding

Range finding tests were conducted at SCCWRP to select the concentrations for nonylphenol and the CS dilution samples in the interlaboratory exposures. Two experiments were needed to find concentrations of nonylphenol and CS that showed a dose response. In the first range finding experiment, the three nonylphenol concentrations (10, 100, and 1000) mg/L showed a very similar strong response, each producing growth between 25 to 30 % of control response. Both the CS dilutions tested, 0.5 and 2.0%, had no effect, with growth very similar to the control.

Adjustments were made for the second range finding experiment, decreasing the concentration of nonylphenol by a factor of ten and increasing the concentration of CS in the samples to 5, 10, and 25%. For the second nonylphenol experiment, there was a range of response from 10 to 40% of control growth among the three treatments and these concentrations were selected for use in the intercalibration experiment. In the CS dilution series a strong response in the 25% CS was still not present, therefore concentrations of 10, 25, and 50% CS were tested in the interlaboratory comparison.

Interlaboratory Calibration

None of the laboratories found a significant difference between any of the nonylphenol concentrations and the OC sediment. However, two of the laboratories found that the OC sediment had significantly less growth than the LTH sediment (Figure 4). Therefore, further comparisons were made between all nonylphenol treatments and the LTH sediment (Figure 4). MRRI found a significant difference between all the nonylphenol concentrations and the LTH sample. SCCWRP found a significant difference between the 0.1 and 1.0 mg/kg concentrations and the LTH sample. Weston found no significant difference between any of the nonylphenol samples and the LTH sample.

SCCWRP and Weston found no significant difference in clam growth between LTH and any of the three CS (10, 25, and 50%) dilutions. MRRI found only the 10% CS dilution to be significantly different with 74% of control growth (Figure 5). For all of the laboratories, the growth in the highest two concentrations was similar to or greater than what was observed in the LTH sediment.

The above comparisons detailed whether samples were significantly different from control values, which was deemed a reflection of whether a sample was toxic or not. Another method of comparison is to examine the differences in the growth values themselves between laboratories. For this analysis, the control adjusted means were compared using ANOVAs. There was only one sample (1.0 mg/L nonylphenol) where there was not statistical agreement between the laboratories for clam growth. However, the statistical agreement may be more due to between replicate variability rather than close agreement of the mean growth data from each laboratory. MRRI, SCCWRP and Weston had mean coefficients of variation of 26.6, 35.4, and 42.9, respectively (Table 1). While the mean coefficients of variation were not very different, the differences within individual samples were quite high in many cases. The variation is a little higher than for

the SWI tests where SCCWRP and MPSL had coefficients of variation of about 17 and 36 respectively.

Reference Toxicant

There was a large range of IC50s between MRRI, SCCWRP, and Weston, with 50.2 (95% CI = 43.1 and 58.3), 29.9 (95% CI = 11.8 and 37.5), and 13.5 (95% CI = 10.7 and 19.0) µg/L copper, respectively. All of the laboratories showed decreasing growth with increasing copper concentration (Figure 6). The values above were compared to previous data from Keppler and Ringwood (2002), of the MRRI laboratory. They published an IC50 for copper of 37.6 µg/L from five separate exposures. The IC50 data from MRRI, SCCWRP, and Weston were within one standard deviation of the mean of the five values from the published exposures. Therefore it was concluded that the three laboratories did not differ in reference toxicant outcomes.

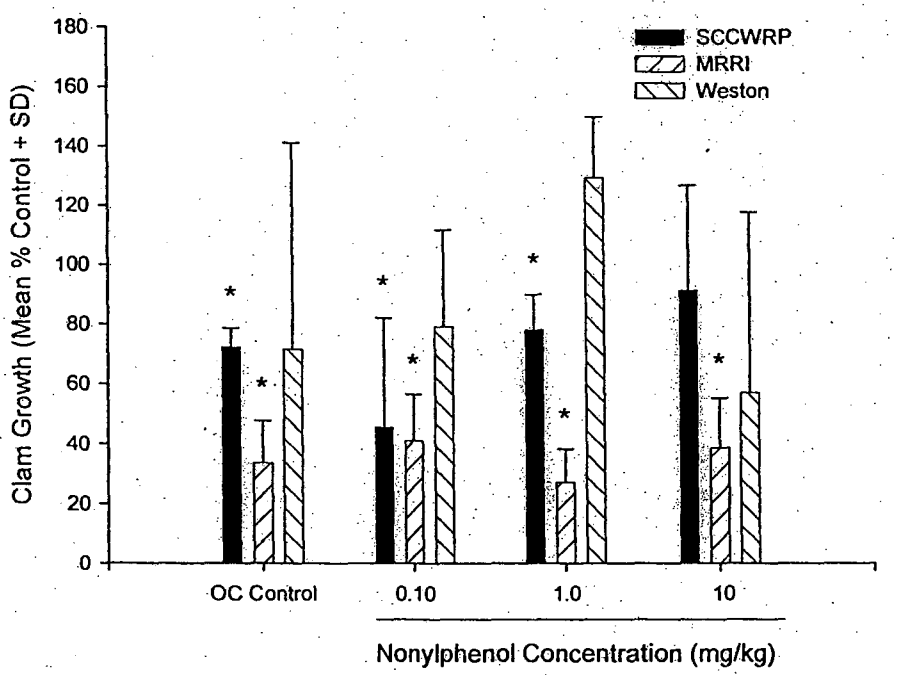

Figure 4. LTH sediment control adjusted juvenile clam 7-day growth test responses to nonylphenol from MRRI, SCCWRP, and Weston. * indicates values significantly different from LTH sediment. Marine Pollution Studies Laboratory (MPSL), Marine Resources Research Institute (MRRI), Weston Solutions (Weston), and Southern California Coastal Water Research Project (SCCWRP).

Table 1. Coefficients of variation for Marine Resources Research Institute (MRRI), Weston Solutions (Weston), and Southern California Coastal Water Research Project (SCCWRP) results for the *Mercenaria mercenaria* 7-day growth endpoint.

	Laboratory		
Sample	MRRI	SCCWRP	Weston
LTH	12.8	6.7	13.9
OC	41.8	8.7	97.2
0.1 mg/L nonylphenol	37.8	80.2	41.3
1.0 mg/L nonylphenol	40.1	15.0	15.8
10.0 mg/L nonylphenol	42.8	38.9	106.5
10% CS	14.5	73.8	27.2
25% CS	5.2	36.1	32.5
50% CS	17.9	23.5	8.6
Mean	26.6	35.4	42.9

DISCUSSION

An important attribute of any toxicity test is that the results are comparable between laboratories using the method. There must be confidence that similar results can be achieved when any given test is used by a reputable laboratory. In the current study comparisons were made for the SWI test using mussel embryos and the *M. mercenaria* test. For each intercalibration, the results of a laboratory highly experienced in the use of the method was compared to laboratories with much less experience.

The SWI test has been used previously by a number of laboratories for field studies. However, no previous intercalibration testing has been conducted. For this study, only two laboratories performed the intercalibration. All but two of the samples tested had a significant difference between the laboratories. In all of the cases where there was a difference, the more experienced laboratory had more sensitive results. No other clear explanation for the differences between the laboratories is apparent. Possible explanations are differences in toxic exposure due to differences in sample handling, differences in interpretation of the microscopic endpoint and differences in animal sensitivity. Given the simplicity of the endpoint determination and the similarity in the EC50 values of the reference toxicant between the laboratories, the last two reasons seem unlikely. While there was no previous interlaboratory testing for the SWI test, there is interlaboratory data for the *M. galloprovincialis* embryo test in aqueous solutions. In that testing, it was found that coefficient of variation between five laboratories was 23.6% for cadmium and 14.4% for lyophilized pulp mill effluent (U.S. EPA 1995). The coefficient of variation from the copper reference toxicant exposure in the current study was 7.9%, which compares favorably with the previous study.

For the *M. mercenaria* test, there was no significant difference in growth among the laboratories for most of the sediment samples. However, the less experienced laboratories encountered a higher degree of between replicate variability than the experienced laboratory. This variability may in part explain the lack of a significant difference among the laboratories. With more familiarity with the procedures, the between replicate variability should decrease, as should the degree of difference in mean growth.

Examining various aspects of the results can help to make an overall assessment of the degree of variability between laboratories in this study. For the SWI testing, the agreement between the laboratories for the nonylphenol spikes was judged to be fair, with one laboratory finding significant toxic response for all three concentrations, while the other found only one. However, both laboratories agreed that there was complete mortality at the highest concentration. There was poor agreement for the CS dilutions with one laboratory finding toxicity in two dilutions and the other finding no toxicity in any. Finally, both laboratories had very good agreement on the reference toxic exposure. Given this mixture of results the overall assessment is that the interlaboratory agreement was assessed as fair.

The *M. mercenaria* results can be judged for interlaboratory agreement using the same method. For the nonylphenol spiked sediments, there was good agreement between two of the laboratories, but poor agreement with the third. For the CS dilutions, there was decent agreement among all three laboratories, however there was very little toxicity associated with the samples. While there was a fairly wide spread in the IC50 data for the reference toxic, data fell within range of variability observed during previous testing. As for the SWI test, it was judged that the overall degree of interlaboratory variability for the *M. mercenaria* test was a rating of fair.

EXTERNAL MEMORANDUM

TO:	California Regional Water Quality Control Board, Los Angeles Region, U.S. Environmental Protection Agency, Region 9
FROM:	D. Frederick Bodishbaugh, Ph.D., and Charles Menzie, Ph.D.
CC:	Paul Singarella
DATE:	February 18, 2011
SUBJECT:	Potential for Misuse of California Sediment Quality Objectives in the TMDL Process for Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters

This memorandum addresses the potential use of Sediment Quality Objectives (SQO Part 1) as part of the TMDL process. We refer to these as the *direct effects SQOs* when they apply to benthic invertebrates living within the sediments and *indirect effects SQOs* when they refer to sediment concentrations associated with specific fish tissue levels. We argue here and elsewhere that working backwards from sediments to derive TMDLs introduces substantial uncertainties into the process. We also argue that the SQOs themselves do not translate into reliable TMDLs even presuming sediment should be the driver for TMDL development. Nevertheless, the SQO process represents the approach that the state has developed for such assessments. The TMDL development has not relied on this process and instead defaults to the type of screening-level approach that the California presumably recognized was unreliable for management purposes. The SQO approach was meant to be the more reliable scientific policy alternative to the potential for misuse of screening levels. We refer to Dominguez Channel and Greater Los Angeles and Long Beach Harbor Waters as "The System." With respect to this aspect of the TMDL process we make the following points:

- The State of California has developed a step-by-step SQO plan for assessment of sediments. Although discussed with respect to the TMDL process, direct effects SQOs have not been developed and therefore have not been applied to The System.
- Direct effects SQOs are designed to yield information on the degree to which contaminants in sediments impact benthic invertebrates and the degree of confidence regarding contaminant-related impact. Direct effects SQOs do not provide numeric standards, and they cannot be used to establish single chemical effects on benthic organisms. Therefore direct effects SQOs are to

be used as "narrative" standards, in addition to the numeric standards derived through other means. For systems such as ports and harbors that have many different types of contaminants in sediments, the direct effects SQOs in of themselves do not provide a basis for developing contaminant-specific TMDLs.

- The proposed use of direct effect SQOs to develop TMDL standards is not consistent with the SQO assessment procedure, as described by State Board guidance. The proposal oversimplifies interpretation of the SQO station scores, and fails to consider many of the complexities inherent in the use of multiple line of evidence (MLOE) methods to assess potential impacts of sediment chemicals on benthic communities. Most importantly, the proposed use of SQOs makes no provision for establishment of causality between any observed biological effects and specific chemicals or stressors. State Board guidance on implementation of SQOs to support development of response actions is ignored.

- While the indirect effects SQOs process has not been completed for California, sediment target levels are developed for The System for indirect (bioaccumulation) effects intended to be protective of human health. These values are derived using a BAF-based approach that incorrectly infers causation between particular sediment levels and fish tissue levels.

- The uncertainties associated with deriving direct and indirect effects sediment concentrations are not considered in the development of TMDLs. Thus, risk managers are given a false impression about relationships between effects, target levels, and loadings. There is considerable uncertainty throughout the TMDL development process. As a result, the environmental and health benefits of actions designed to meet TMDLs are very uncertain. Explicit consideration of uncertainties would provide risk managers and affected parties with critical information now absent, regarding potential benefits and environmental/health costs of alternative TMDLs and actions.

- A risk zone approach for sediments would provide a means of incorporating uncertainty into the TMDL process and of evaluating benefits and costs of alternative TMDLs and associated actions.

Use Of SQOs In The TMDL Process

The State of California has developed a step-by-step SQO plan for assessment of sediments. This approach involved a stakeholder process and considerable scientific review. This approach is designed to provide a more scientifically reliable basis for assessing impairment that the historical screening-level approach that involves comparisons of sediment concentrations to benchmarks such as the Effects-Range Low (ER-L). The considerable effort invested in developing an alternative approach to screening-levels, underscores the uncertainty and unreliability associated with relying on screening levels for management purposes. But, despite

the recognition of this uncertainty and the availability of an approach that California developed as a more reliable alternative, the TMDL process for The System remains a screening-level assessment inasmuch as it uses ER-Ls as the targets for TMDLs (see Table 3-7 of the TMDL report and associated rationale given in the report). The Staff Report in support of the TMDL[1] makes reference to the use of Sediment Quality Objectives (SQOs) as part of the TMDL process. Specifically, the report discusses the potential application of The California Water Quality Control Board has set a State policy, *The State Water Quality Control Plan for Enclosed Bays and Estuaries – Part 1 Sediment Quality* (SQO Part 1)[2]. SQO Part 1 relates to direct toxic effects on benthic invertebrates, the animals that reside within or on the sediments. While the Staff Report makes reference to the Sediment Quality Plan – Part 2 – Indirect Effects (pp 96-97 of report), the report notes that these SQOs are still in development and, therefore, are not utilized to develop TMDLs at this time. However, the report does make use of a Biota Sediment Accumulation Factor (BAF) to derive sediment target levels for bioaccumulative compounds such as PCBs and DDT that are associated with a health-based tissue target level in fish (Table 3-8 on p 52 of report). We discuss this BAF-based indirect effects approach later in this memorandum.

Limitations and Uncertainties on the Use of Direct Effects SQOs for TMDLs

The draft TMDL approach describes the use of Part 1 SQOs in Sections 3.2.1 and 6.4 of the staff report. The major limitation on their use is that the direct effects SQOs do not provide numeric standards, and they cannot be used to establish single chemical effects on benthic organisms for systems that have many different types of contaminants and differential exposures for these contaminants. Therefore SQOs are intended to be "narrative" standards.

The narrative standards are applied on a station by station basis and include sixteen exposure effects combinations and six resultant station classifications that reflect degree of effects and degrees of confidence that the effect is associated with the presence of contaminants (Table 1).

Table 1. Station classification system for California Part 1 direct effects SQOs (Table 11 from SQO Part 1).

		Severity of Effect			
		Unaffected	Low Effect	Moderate Effect	High Effect
Potential For Chemically-Mediated Effects	Minimal Potential	Unimpacted	Likely Unimpacted	Likely Unimpacted	Inconclusive
	Low Potential	Unimpacted	Likely Unimpacted	Possibly Impacted	Possibly Impacted
	Moderate Potential	Likely Unimpacted	Possibly Impacted or Inconclusive[1]	Likely Impacted	Likely Impacted
	High Potential	Inconclusive	Likely Impacted	Clearly Impacted	Clearly Impacted

[1] Inconclusive category when chemistry is classified as minimal exposure, benthic response is classified as reference, and toxicity response is classified as high.

Source: Available at http://www.swrcb.ca.gov/water_issues/programs/bptcp/docs/sediment/sed_qlty_part1.pdf

Consistent with the Part 1 SQO document, the TMDL report for The System identifies protective conditions that meet the narrative objective for direct effects to include two of the six categories: "Unimpacted" and "Likely Unimpacted" (p. 20 of the report) and these are presented as goals for the TMDL (p. 46 of report). These are the two lowest of the 6 possible Multiple Line Of Evidence (MLOE) station score categories. However, The TMDL report does not include a discussion of a third category that also may be deemed protective according to the Part 1 SQO document[3]:

> *The Water Board shall designate the category **Possibly Impacted** as meeting the protective condition if the studies identified in Section VII.F demonstrate that the combination of effects and exposure measures are not responding to toxic pollutants in sediments and that other factors are causing these responses within a specific reach segment or water body. In this situation, the Water Board will consider only the Categories **Likely Impacted** and **Clearly Impacted** as degraded when making a determination on receiving water limits and impaired water bodies described in Section VII.*

This caveat indicates that there is uncertainty regarding the classification of contaminant-related effects on sediment dwelling organisms. And, as we describe later, the degree of effect and confidence regarding their attribution to contaminants (i.e., unimpacted to clearly impacted) provides one basis for defining risk zones and the appropriateness of various degrees of intervention or controls to attain goals.

The System is an urban harbor that is regularly disturbed by a variety of physical and chemical stressors. Navigational dredging is carried out in areas that have silted in and these areas would

[3] Part 1 SQO document p. 11.

be favored depositional areas (sediment traps). The U.S. Environmental Protection Agency recognizes the importance of considering the nature of a water body when attempting to achieve sediment management goals such as those contemplated in the TMDL report. These considerations are described in the Agency's Sediment Management Guidance[4]. This guidance is germane to the TMDL because dredging of sediments is being contemplated as an action to meet goals; that type of action is essentially a sediment remediation. With respect to sediment management, Section 2.5 of the guidance discusses watershed considerations. The essential point of this section is to understand the nature of the water body and current and future uses. The guidance recognizes that there are differences among water bodies and these differences are important to consider when evaluating the appropriateness of various remedial alternatives. The specific introductory language in this section of the Agency guidance is:

> *A unique aspect of contaminated sediment sites is their relationship within the overall watershed, or drainage area, in which they are located. Within the watershed there often is a spectrum of issues that the project manager may need to consider. Foremost among them at many sites is to work with the state to ensure that fish consumption advisories are in place and well publicized. In addition, project managers should understand the role of the contaminated water body in the watershed, including the habitat or flood control functions it may serve, the presence of non-site-related contaminant sources in the watershed, and current and reasonably anticipated or desired future uses of the water body and surrounding land.*

A large and operational urban port is a very different type of environment for benthic invertebrates than is an undisturbed coastal embayment. This difference is a factor that should be considered for assessment and risk management. In light of this difference, the TMDL report is very restrictive with respect to evidence for judging effects on benthic invertebrates. This is reflected in the target individual lines of evidence station scores specified for the biological Lines of Evidence (LOEs). The report identifies that the benthic community should resemble either "reference" or "low disturbance" (p. 47). These are the lowest two of four possible benthic LOE categories. The target toxicity LOE score is "nontoxic" (p. 49). This is the lowest of four possible toxicity LOE categories. Considering the uncertainty associated with factors influencing benthic invertebrates in a large operating urban harbor, it may be more appropriate to consider a range of biological states and/or degrees of toxicity. This would allow for a valid consideration of a range of goals and associated range of interventions. We discuss this later with respect to establishing risk zones. We also observe that the SQO chemistry LOE does not appear to factor into the proposed TMDL standards, though it must be calculated in order to assess the MLOE station score.

The stated objectives may not be realistic or attainable for a harbor system and if those objectives are not met the TMDL target defaults to a numeric ER-L, a very restrictive value for

[4] U.S. EPA. 2005. Contaminated sediment remediation guidance for hazardous waste sites. EPA-540-R-05-012. U.S. Environmental Protection Agency, Washington, DC.

which the limitations are discussed elsewhere. The TMDL report states that the proposed numeric TMDL objectives are expected to attain the narrative objectives (p. 88):

> *Attainment of the narrative sediment quality objective may occur either through demonstrating the water body has achieved the desired qualitative condition [clearly unimpacted or likely unimpacted] or the quantitative condition; i.e., if the ambient sediment chemistry levels within a waterbody are equal to or below the sediment quality values.* (p.90).

> *Compliance with the TMDL shall be determined through water, sediment, and fish tissue monitoring and comparison with the TMDL waste load and load allocations and numeric targets. Compliance with the sediment TMDL for metals and PAH compounds shall be based on achieving the loads and waste load allocations or, alternatively, demonstrating attainment of the SQO Part 1 through the triad/multiple lines of evidence approach outlined therein.* (p.116).

Inconsistencies Between the Use of SQOs as TMDL Standards and SQO Guidance

Direct effect SQOs are not in any way analogous to sediment quality values or concentration benchmarks that are associated, even theoretically, with a chemical adverse effect threshold. Rather, the SQO method establishes a framework for assessing potential impacts of sediment chemicals on benthic communities, through the use of Triad data (synoptic measurement of sediment chemistry, toxicity, and benthic community condition). In and of themselves, the MLOE station scores generated by the SQO assessment paradigm do not establish causality between observed biological effects and any given sediment chemical. They cannot therefore be used to identify "safe" chemical levels, or to establish cleanup triggers or target levels for contaminants. Part 1 SQOs were never intended to be used as a standalone cleanup indicator, but rather as a tool to identify sediments for which a sediment management strategy may be needed. With respect to appropriate use of Part 1 SQOs to establish a management strategy for specific pollutants, the method document states the following: [5]

> *In order to demonstrate an exceedance of the proposed SQO, a toxic pollutant or pollutants must be identified. Additional studies would be required to identify the specific cause.*

The guidance goes on to describe and discuss toxicity identification evaluation methods. This process requires additional evaluation of site-specific information and significant application of professional judgment. Steps required include an evaluation of confidence in the SQO assessment, consideration of the magnitude of exceedances, and stressor identification. None of these essential steps has been incorporated into the proposed TMDL narrative standards based on Part 1 SQOs. The Part 1 SQO method document further states that bioavailability of

[5] Part 1 SQO document p. 119.

measured contaminants must be considered in the development of potential response actions, including TMDL development:[6]

> *If stressor identification is performed and a stressor is identified, a logical application would be the development of biologically relevant guidelines that could be applied to support TMDL development or remediation goals. Guideline development would account for site and receptor specific factors that control bioavailability. Adopting sediment quality guidelines to fulfill this role does not account for these factors.*

In summary, the TMDL's proposed use of Part 1 SQO MLOE station scores as strict indicators of a need for dredging fails to incorporate any of the required implementation considerations, and is inconsistent with the intended use of the SQOs, as promulgated by The Board and described in State guidance.

Uncertainty Associated with TMDL Target Sediment Concentration for Indirect Effects

Sediment target concentrations are developed in the TMDL process for bioaccumulative compounds such as PCBs and DDT. We use the TMDL process for DDT to illustrate the uncertainties in this approach. The TMDL document derives a DDT sediment target level of 1.9 µg/g for protection of human health based on a fish tissue concentration of 21 µg/g. There are two areas of uncertainty with regard to this derivation. First, there is an implication of proportional causation between the sediment DDT levels and fish tissues. In other words, the TMDL document presumes that a sediment concentration of 1.9 µg/g will cause a fish tissue level of 21 µg/g. This reflects a presumed Biota to Sediment Accumulation Factor (BAF) of 11 (21 divided by 1.9). Second, the TMDL presumes that a fish tissue concentration of 21 µg/g is the only value that should be considered by risk managers for TMDL development.

The presumed causal relationship between fish tissues and sediments is attributed to a report by SFEI (2007)[7]. This report considers two case studies – Newport Bay and San Francisco Bay. The TMDL document appears to rely mainly on the case study for Newport Bay but both case studies are important to consider with respect to judging the uncertainty in the process. The SFEI report does a good job at identifying the uncertainties associated with the derivation process. However, none of these uncertainties are discussed or carried into the TMDL draft. Examples of uncertainties highlighted in the SFEI report that are especially relevant for the development of TMDLs include:

- Because of limited data for Newport Bay, it is not possible to develop meaningful spatially explicit statistical models of tissue vs. sediment

[6] Part 1 SQO document p. 121

[7] Greenfield, B. K., A. R. Melwani, J. J. Oram, and S. M. Bay. 2007. Indicator development and framework for assessing indirect effects of sediment contaminants. SFEI Contribution #524. San Francisco Estuary Institute, Oakland, CA

chemistry relationships. Several fish species have relatively wide average estimates for DDT. In particular, standard errors of the mean are wide for diamond turbot, spotted sand bass, California corbina, arrow goby, and pacific staghorn sculpin. Generally, the standard error of the mean estimates for these species is larger than the standard error taking the combined average of all fillet samples, all whole body samples, or all samples.

- Newport Bay differs from many estuaries in having a significant proportion of primary production due to benthic algae. Simulation results indicated consistently higher predicted contaminant concentrations for benthic algae, than for phytoplankton. Although substantial efforts were made to develop model parameters appropriate for benthic algae, local data are lacking.

- For Newport Bay, there was uncertainty associated with several technical policy decision and technical parts of the analyses. These were associated with various scenarios that incorporated variable assumptions. (These scenarios were not described in the TMDL document.) The following aspects introduce moderate to high uncertainty to the analyses: risk assessment assumptions and averaging method (arithmetic vs. geometric) substantially influenced sediment thresholds. Changing to geometric averaging methods (Scenario G), increasing allowable cancer risk tenfold (Scenario E), and switching to subsistence fisher consumption rates (Scenario D) each caused an order of magnitude or greater difference in sediment thresholds for DDTs. These changes often resulted in a different categorization of the majority of sediments. For example, when allowable increased cancer risk was switched from one-in-one hundred thousand to one-in-ten thousand (Scenario E), the percent of sediment samples exceeding the high human health threshold for DDTs changed from 63% to 0%.

- For humans, Scenarios D and E caused the greatest effects on outcome. These scenarios changed standard risk assessment parameters. Scenario D changed assumptions regarding the definition of the target population to protect and Scenario E changed the acceptable level of increased carcinogenic risk. Both of these parameters are strongly influenced by policy decisions, which often vary among water bodies based on agency judgments. These findings support the need for substantial efforts to engage stakeholders in framework application, to adequately resolve these policy issues.

The TMDL document indicates in Table 3-8 that the BAF for DDT in The System is ~11. However, this particular value is not identified in either of the case studies included in SFEI (2007) and the TMDL document does not describe how it selected a BAF of ~11. The BAF values associated with the case studies are variable but the “average” BAF for both case studies is less than 11. For Newport Bay, a sediment concentration of 1.9 µg/g is associated with a “low tissue threshold” of 9.8 µg/g in fish; this is an apparent BAF of 5 (see Table 4-19 in SFEI, 2007). For human resident prey only, the apparent BAF for Newport Harbor is ~1.8 (see Table

4-19 in SFEI, 2007). The apparent BAFs for San Francisco Bay (around 5 on average) are similarly lower than the one used in the TMDL document. Therefore, even presuming that the sediments were the cause of DDT in fish tissues, the selection of the BAF for The System inflates the sediment contribution relative to that for the case studies on which the TMDL process relies.

The TMDL document also fails to communicate the uncertainty described in SFEI (2007) concerning the contribution of sediments to tissue levels. Although the TMDL document assumes a proportional relationship between sediment concentrations and fish tissue levels, the modeling results included in SFEI (2007) would argue that there is not such a one-to-one correspondence. Instead the SFEI (2007) report states on p. 145 that:

> *The case studies also revealed a number of technical uncertainties and data limitations. Mechanistic model simulations indicated that a significant portion of biota exposure to DDTs stemmed from dissolved and particulate compounds in the water column. In general, modeled BAFs were highly sensitive to water column concentrations, highlighting the potential uncertainty regarding the ultimate source of pollutants. Although it is likely that a large portion of the water column concentrations were linked to direct sediment resuspension, direct loading from the watershed and upstream rivers should also be considered.*

The larger contribution of water column concentrations to fish tissue levels for DDT-related compounds is shown in the following figure for Newport Bay (Figure 1). This indicates that the assumption of one-to-one causal relationship between fish tissues and sediments is incorrect and that use of a BAF as a tool for back-calculation of sediment target levels is flawed. As the figure shows, water exposures are the most important source of tissue levels. These would include dissolved and particular DDT-related compounds in the water column. The figure shows that sediments vary in contribution from 0% to 10% for the Jack Smelt up to ~25% for white croaker. While sediments may be a contributor to the water column, the modeling results indicate that it is incorrect to presume a proportional relationship between fish tissue concentrations and sediment concentrations for DDT-related compounds. Furthermore, applying an apparent BAF that presumes a 100% contribution of sediments will result in target levels that likely is low by a factor of four or more. The TMDL development process for The System is not based on the nature of the system or on what is currently known about the relationships among exposures and fish tissue levels. Those exposures vary spatially (exposure within The System v external to the system) and with respect to media and the nature of loads (water v sediment; in-place contaminants v external loads). Thus, the calculations are not based on reality. As such, they are unreliable for management pourposes.

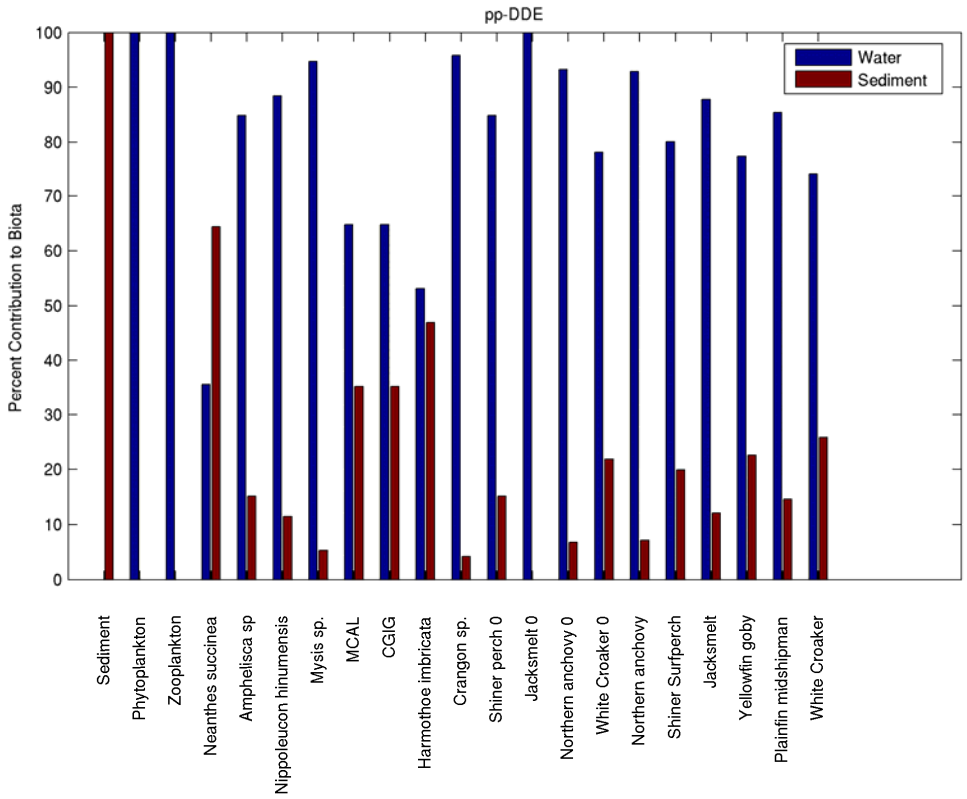

Figure 1. Relative contribution of sediments and water to fish tissue levels in Newport Bay (presentation by Ben Greenfield of SFEI to the Santa Ana Water Control Board).

The second source of uncertainty involves selecting and presenting single values to represent protective levels for human health. The TMDL document utilizes a fish tissue level of 21 µg/g wet weight for DDT. This value is associated with an upper bound estimate for a one-in-one million risk of cancer. However, risk managers in California and elsewhere have relied upon other values to make informed management decisions. Typically, a risk manager will weigh relative risks and benefits of actions. But when one value is put forward as the only target, as it has in the case of the TMDL document, the opportunity to make informed management decisions is greatly limited. A few examples illustrate the arbitrary aspects of putting forward one particular value – 21 µg/g. The most obvious contrast is the OEHHA screening value for DDT in fish tissues, 100 µg/g, which is ~ five times higher than the value used to derive TMDL target levels. This screening value is used for the TMDL development for Newport Bay. And, there are many other values that could have been selected as described in the SFEI (2007) report. Rather than limit the risk manager to a single value for a single risk level, it is more common to discuss a range of values. For example, the one-in-one hundred thousand lifetime incremental risk tissue concentration would be 10 times higher, i.e., 210 µg/g. A range in target

levels with associated risk information would provide the risk manager with insight and opportunity to identify meaningful interventions and controls for protecting human health.

Uncertainties in Deriving Target Levels and TMDLs Have Not Been Considered

The TMDL document does not consider uncertainties in the various components of the assessment or in the derivation of TMDLs. To a large extent the TMDL document deals with uncertainty by selecting bounding values such as ER-Ls for direct effects and the presumption that contaminants in sediments are the only contributor to contaminants in fish for indirect effects. While such an approach may be useful as a screening analysis, it suffers greatly when it is used as a basis for making major engineering judgments. The actions associated with these judgments carry with them potentially significant health, safety, environmental, and economic costs that the TMDL document does not acknowledge. Because the TMDL document does not share information on uncertainty and is essentially constructed as a screening-level analysis, it places the risk manager in a box. There is no reasonable range of risks and associated confidence upon which to compare the efficacy and appropriateness of interventions. Instead, TMDLs are presented with high precision (e.g., multiple decimal places) implying that there is an in-depth understanding on the part of the technical analysts that prepared the staff report. That in-depth understanding is missing from the report.

Information is available for conveying uncertainty to the risk manager. For example, instead of selecting bounding estimates, the TMDL document could discuss the range of possible target levels with attendant degrees of confidence. Some of these target levels may already be met or could be met in a short period of time while others might require some additional control. However, because the TMDL document is silent on uncertainty, the risk manager has not been provided with an opportunity to review and consider such information. Instead, the TMDL document leads only to engineering solutions that are substantially invasive and may carry unaddressed health and environmental costs.

"Risk Zones" for Sediments Provide a Means for Incorporating Uncertainty

The concept of risk zones is evolving as a way of considering alternative remedial strategies that take into account that there are variable degrees of risk and also confidence about risks. Therefore, risk zones provide a way to incorporate uncertainties in an explicit way. These can be established for direct and indirect (bioaccumulative) effects or risks. For example, each of the targets for DDT has an associated range that captures degree of effects or risks and attendant uncertainty. Therefore, rather than selecting only the bounding (typically lowest) value, the target could be expressed as a range or as several values. With respect to the Part 1 direct effects SQOs, these too could include the full range. This approach avoids the binary (risk v no risk) approach associated with the selection of a single TMDL target concentration.

The ranges in target levels can then be used to develop isopatch maps of sediments that reflect the regions associated with the intervals of target concentrations for contaminants or direct effects levels. That provides the risk manager with a visual representation of surface areas of

The System for which a variety of management approaches can be contemplated. Such an approach does not nullify or undermine the TMDL development process and is entirely consistent with the history of water management in California. This is certainly evidenced by the six classification categories currently used for the Part 1 direct effects SQOs and with the water, fish, and sediment target levels associated with various human health risk levels.

Professional Profiles

D. Frederick Bodishbaugh

- Ph.D., Aquatic Toxicology, Duke University, 1995
- B.S., Chemical Engineering, University of Tulsa (*cum laude*), 1985

Dr. Rick Bodishbaugh is a Managing Ecotoxicologist in Exponent's EcoSciences practice. He has 19 years of diverse experience in aquatic toxicology research, chemical and site assessment, ecological risk assessment (ERA) in aquatic and terrestrial systems, and natural resource damage assessment (NRDA). His specific areas of technical expertise include fish and wildlife toxicity assessment, resource/habitat equivalency analysis (REA/HEA), bioavailability of chemical contaminants in aquatic and terrestrial ecosystems, and chemical structure-activity relationships. Dr. Bodishbaugh is experienced in evaluating the effects of contaminated soil, groundwater, surface water, and sediments on ecological receptors. He has conducted assessments of chemical risk at dozens of sites for energy, petrochemical, pulp and paper, manufacturing, and mining industry clients. He is intimately familiar with federal, regional, and various state guidance and standards or practice for ERA under common regulatory frameworks. He is also experienced in evaluating and interpreting field bioaccumulation and laboratory toxicity bioassay data for use in assessing ecological risk. He is well versed in the environmental toxicology and assessment of metals and persistent organic pollutants, especially PCBs and PAHs.

Charles A. Menzie

- Ph.D., Biology, City University of New York, 1978
- M.A., Biology, City College of New York, 1974
- B.S. Biology, Manhattan College, 1971

Dr. Menzie is a Principal Scientist and Director of Exponent's EcoSciences practice. His primary area of expertise is the environmental fate and effects of physical, biological, and chemical stressors. He has investigated a broad range of contaminants, including solvents (TEC, PCE, TCA, and others), persistent chlorinated compounds such as DDT and PCBs, hydrocarbons, cyanides, and metals. Dr. Menzie is recognized as one of the leaders in the field of risk assessment and was awarded the Risk Practitioner Award by the Society for Risk Analysis. He has served on the Councils of SRA and the Society of Environmental Toxicology and Chemistry. Dr. Menzie has participated in numerous national and regional scientific panels and advisory groups and has led many scientific peer reviews for industry and for government.

He has taken the lead in developing guidance documents for industry and government and has focused on methods that are workable and acceptable to a broad range of parties. He has developed and applied a formal causal-analysis methodology for assessing causation in cases of environmental impairment and contributions of chemical contamination.

Incidence of Adverse Biological Effects Within Ranges of Chemical Concentrations in Marine and Estuarine Sediments[1]

ABSTRACT / Matching biological and chemical data were compiled from numerous modeling, laboratory, and field studies performed in marine and estuarine sediments. Using these data, two guideline values (an effects range-low and an effects range-median) were determined for nine trace metals, total PCBs, two pesticides, 13 polynuclear aromatic hydrocarbons (PAHs), and three classes of PAHs. The two values defined concentration ranges that were: (1) rarely, (2) occasionally, or (3) frequently associated with adverse effects. The values generally agreed within a factor of 3 or less with those developed with the same methods applied to other data and to those developed with other effects-based methods. The incidence of adverse effects was quantified within each of the three concentration ranges as the number of cases in which effects were observed divided by the total number of observations. The incidence of effects increased markedly with increasing concentrations of all of the individual PAHs, the three classes of PAHs, and most of the trace metals. Relatively poor relationships were observed between the incidence of effects and the concentrations of mercury, nickel, total PCB, total DDT and p,p'-DDE. Based upon this evaluation, the approach provided reliable guidelines for use in sediment quality assessments. This method is being used as a basis for developing National sediment quality guidelines for Canada and informal, sediment quality guidelines for Florida.

Chemical analyses indicate that coastal sediments in some areas of North America are contaminated (Bolton and others 1985, O'Connor 1991, US NOAA 1991, Wells and Rolston 1991, Goyette and Boyd 1989). However, data on the mixtures and concentrations of contaminants in sediments, alone, do not provide an effective basis for estimating the potential for adverse effects to living resources. Moreover, interpretive tools are needed to relate ambient sediment chemistry data to the potential for adverse biological effects. A variety of biological measures (including toxicity and/or bioaccumulation tests) can be performed to determine the biological significance of sediment-associated contaminants (Burton 1992). Furthermore, numerical, effects-based, sediment quality guidelines can be used as screening tools to evaluate sediment chemistry data and to identify and prioritize potential problem areas (Di Toro and others 1991, Persaud 1992, MacDonald 1993, Long and Morgan 1990, Smith and MacDonald 1992, US EPA 1989a, 1992a). In this respect, effects-based guidelines can be used to help identify those areas in which the potential for biological effects is greatest.

KEY WORDS: Sediment quality guidelines; Ecological risk assessment; Contaminants; Biological effects; Marine; Estuarine

[1]The methods and guidelines presented in this report do not necessarily represent the policy of the National Oceanic and Atmospheric Administration, Environment Canada, or Florida Department of Environmental Protection.

*Author to whom correspondence should be addressed.

A variety of biological effects-based approaches to the development of sediment quality guidelines have been reviewed by many investigators (US EPA 1989a, 1992a, Adams and others 1992, Chapman 1989, MacDonald and others 1992). These approaches can be grouped into three categories: equilibrium-partitioning modeling, laboratory bioassays, and field studies. Each approach has particular strengths and weaknesses and each defines guidelines in different ways. Thus far, there is no general agreement as to which approach will provide the most reliable, flexible, and credible guidelines for evaluating sediment quality. However, sediment quality guidelines derived from the combination of the results of multiple methods have been recommended for a broad range of applications (Adams and others 1992, US EPA 1989b, Lorenzato and others 1991).

Using data available from all the major approaches to the development of effects-based criteria, Long and Morgan (1990) prepared informal guidelines for use by the National Oceanic and Atmospheric Administration (NOAA). Subsequently, the data base with which these values were prepared was updated and expanded and the approach was refined (MacDonald 1993, Smith and MacDonald 1992). In both the NOAA (Long and Morgan 1990) and Florida (MacDonald 1993) studies, two guideline values were developed for each chemical. These values defined three ranges in chemical concentrations that were anticipated to be: (1) rarely, (2) occasionally, or (3) frequently associated with effects. The identification of ranges in chemical concentrations has been recommended in the development of sediment quality criteria (US EPA 1992b).

The objectives of the present study are: (1) to present updated guideline values based upon the expanded data base, (2) to quantify the percent incidence of adverse biological effects associated with the guidelines, and (3) to compare the guidelines with those developed with other data or methods. In this paper we determined the percent incidence of effects as a measure of the "accuracy" of the guidelines.

Methods

The methods used in this study have been described in detail (Long and Morgan 1990, MacDonald 1993, Smith and MacDonald 1992, Long 1992) and will be only summarized here. Sediment chemistry and biological effects data from numerous reports were assembled to support the derivation of the guidelines. The data base used by Long and Morgan (1990) was refined by excluding data from freshwater studies and including data from additional sites, biological test end points, and contaminants (MacDonald 1993, Smith and MacDonald 1992). Briefly, the approach involved three steps: (1) assemble, evaluate, and collate all available information in which measures of adverse biological effects and chemical concentrations in sediments were reported; (2) identify the ranges in chemical concentrations that were rarely, occasionally, or frequently associated with effects; and (3) determine the incidence of biological effects within each of the ranges in concentrations for each chemical as an estimate of guideline accuracy.

Development of a Biological Effects Database for Sediments

A biological effects database for sediments (BEDS) was developed to compile and integrate chemical and biological data from numerous studies conducted throughout North America. Nearly 350 publications were reviewed and screened for possible inclusion in the BEDS. Data from equilibrium-partitioning modeling, laboratory spiked-sediment bioassays, and field studies of sediment toxicity and benthic community composition were critically evaluated. Only matching, synoptically collected biological and chemical data from marine and estuarine studies were included in the database. Data were excluded if the methods were not clearly described. Data were excluded if sediments were frozen before toxicity tests were initiated or if toxicity of controls was higher than commonly acceptable. If there was less than a tenfold difference in the concentrations of all contaminants among sampling stations, all data from that particular field study were excluded. The tenfold criterion was selected to ensure that data were included in the BEDS only from studies in which significant contaminant gradients were reported. Furthermore, data were excluded if the chemical analytical procedures were inappropriate for determining total concentrations in bulk sediments; for example, trace metals data were excluded if strong acid digestions were not used. The majority of the data sets that were excluded were those in which either no biological data or no chemical data were reported. A total of 89 reports met all the screening criteria and were included in the BEDS. The screening criteria and their use were described previously (MacDonald 1993, Smith and MacDonald 1992). The potential limitations of using data "encountered" from many different studies have been described (Long 1992).

The data entered into the BEDS were expressed on a dry weight basis. Only a minority of the reports included measures of factors that are thought to influ-

ence bioavailability (e.g., grain size, total organic carbon, acid-volatile sulfides). Sediment quality guidelines derived from the equilibrium-partitioning approach (US EPA 1988) were converted from units of organic carbon to units of dry weight, assuming a total organic carbon (TOC) concentration of 1.0%. These conversions were based upon a TOC concentration of 1.0% since the overall mean TOC concentration in the BEDS was 1.2%. Data from spiked-sediment bioassays were incorporated directly into the BEDS.

Guideline values derived using the apparent effects threshold (AET approach, Barrick and others 1988) and national screening level concentration (SLC approach, Neff and others 1986) were entered into the BEDS as reported. AET and SLC values represent large amounts of data compiled from multiple surveys. Therefore, extremely high and extremely low concentrations in some parts of study areas used to produce these values may be ameliorated by highs and lows in other regions, resulting in intermediate concentrations. Raw data from other individual field surveys that passed the initial screening steps were evaluated in "co-occurrence analyses" with either of two methods (Long 1992). If the statistical significance of the data was reported, then the mean chemical concentrations in the statistical groups (i.e., toxic and nontoxic) were compared. If no such statistical evaluations were reported, the frequency distributions of the biological data were examined, and mean concentrations in subjectively determined groups of samples were compared (e.g., most toxic versus least toxic). The extreme high and low concentrations reported in individual studies, generally performed over relatively small spatial scales, were not masked by merging data from other studies.

To maximize the broad applicability of the guidelines, a wide variety of measures of adverse biological effects was included in the BEDS. The kinds of adverse effects included: (1) measures of altered benthic communities (depressed species richness or total abundance), significantly or relatively elevated sediment toxicity, or histopathological disorders in demersal fish observed in field studies; (2) EC_{50} or LC_{50} concentrations determined in laboratory bioassays of sediments spiked with single compounds or elements; and (3) toxicity predicted by equilibrium-partitioning models. All of the measures of effects were treated as if equivalent. However, by screening prospective data sets and including only those biological data that were in concordance with chemical gradients, the prevalence of data from relatively insensitive measures of effects was minimized.

Each entry was assigned an "effects/no-effects" descriptor. An entry was assigned an "effects" descriptor (identified with an asterisk in the data tables) if: (1) an adverse biological effect, such as acute toxicity, was reported; and (2) concordance was apparent between the observed biological response and the measured chemical concentration.

The documentation supporting each BEDS record included the citation, the type of test or biological effect observed or predicted, the approach that was used, the study area, the test duration (if applicable and reported), the species tested or the benthic community considered, the total organic carbon (TOC) and acid-volatile sulfide (AVS) concentrations (if reported), and the chemical concentration.

In our co-occurrence analyses of field-collected data entered into BEDS, an effects descriptor was assigned to data entries in which adverse biological effects were observed in association with at least a two-fold elevation in the chemical concentration above reference concentrations. Either "no gradient," "small gradient," or "no concordance" descriptors were assigned when no differences between stations were reported in the concentration of the chemical of concern, when mean chemical concentrations differed by less than a factor of two between the groups of samples, or when there was no concordance between the severity of the effect and the chemical concentration, respectively. In these cases, we assumed that other factors (whether measured or not) were more important in the etiology of the observed effect than the concentration of the contaminant considered. Finally, a "no effects" descriptor was applied to biological data from background, reference, or control conditions.

Collectively, the effects data sets from the modeling, laboratory, and field studies were assigned an asterisk in the ascending tables and used to derive the guidelines. All of the effects data were given equal weight in the guidelines derivation. Collectively, data assigned no gradient, small gradient, no concordance, and no effects descriptors were regarded as the no-effects data set.

Derivation of Sediment Quality Guidelines

For each chemical, the data from BEDS were retrieved and arranged in ascending order of concentration in a tabular format. These ascending data tables, as reported by Long and Morgan (1990) and updated by MacDonald (1993) and Smith and MacDonald (1992), summarized the available information for each chemical or chemical group that was considered.

Table 1. Summary of available data on effects of sediment-associated acenaphthene (ppb) in coastal sediments

Concentration (±SD)	Area	Analysis type[a]	Test duration[b]	End point measured[c]

306 ± 604	Commencement Bay, WA	COA	48 h	Highly toxic (44.5 ± 19% abnormality)

The distributions of the effects data were determined using percentiles (Byrkit 1975). Two values were derived for each chemical or chemical group. The lower 10th percentile of the effects data for each chemical was identified and referred to as the effects range-low (ERL). The median, or 50th percentile, of the effects data was identified and referred to as the effects range-median (ERM). Percentiles of aquatic toxicity data were used by Klapow and Lewis (1979) to calculate marine water quality standards; the authors noted that this approach tended to minimize the influence of single (potentially outlier) data points on the development of guidelines. Environment Canada and Florida Department of Environmental Protection used a slight modification to this method, the rationale for which has been documented (MacDonald 1993, Smith and MacDonald 1992).

Determination of Percent Incidence of Adverse Biological Effects

The two guideline values, ERL and ERM, delineate three concentration ranges for a particular chemical. The concentrations below the ERL value represent a minimal-effects range; a range intended to estimate conditions in which effects would be rarely observed. Concentrations equal to and above the ERL, but be-

(Continued)

low the ERM, represent a possible-effects range within which effects would occasionally occur. Finally, the concentrations equivalent to and above the ERM value represent a probable-effects range within which effects would frequently occur. The incidence of adverse effects within each range was quantified by dividing the number of effects entries by the total number of entries and expressed as a percent. The ERL and ERM values were derived with only the effects data set, whereas the calculations of the percent incidence of effects within each concentration range were based upon both the effects and no-effects data sets.

An evaluation of the reliability of any proposed guidelines is essential to determine their applicability in sediment quality assessments. In this study, the reliability of the guidelines for each chemical was considered to be relatively high when: (1) they agreed closely (within factors of 3.0 or less) with those developed with other methods and/or with guidelines developed with the same methods applied to different data; (2) the incidence of effects was low (<25%) in the minimal-effects ranges; (3) the incidence of effects increased consistently and markedly in concordance with increasing chemical concentrations; and

[a]Analysis type: COA = co-occurrence analysis; AETA = apparent effects threshold approach; EqPA = equilibrium partitioning approach; SQO = sediment quality objective; SQG = sediment quality guideline; SSBA = spiked sediment bioassay approach; SLCA = screening level criteria approach.

[b]Test duration: d = day; h = hour; m = minute.

[c]End point measured: AET = apparent effects threshold; PSDDA = Puget Sound dredge disposal analysis; LC_{50} = lethal concentration to 50% of the tested organisms; SRUs = species richness units; SDUs = species diversity units.

[d]Life stage: ADT = adult; LAR = larval; JUV = juvenile.

[e]Effects/No effects: NE = no effect; NC = no concordance; SG = small gradient; NG = no gradient; * = effects data used to calculate ERL and ERM values.

[f]1, Malins and others, 1985; 2, Tay and others, 1990; 3, Anderson and others, 1988; 4, Long and Morgan, 1990; 5, Becker and others, 1990; 6, Swain and Nijman, 1991; 7, Tetra-Tech, 1985; 8, US Army Corps of Engineers, 1988; 9, Swartz, and others, 1989; 10, Washington Department of Ecology, 1989; 11, McLeay and others, 1991; 12, Alden and Butt, 1987; 13, Winn and others, 1989; 14, Beller and others, 1986; 15, PTI, Inc., 1988; 16, CH2M-Hill, Inc., 1989; 17, Bolton, 1985.

(4) the incidence of effects was very high (>75%) in the probable-effects ranges. The reliability of the guidelines that failed to meet these evaluation criteria was considered to be lower.

Results

ERL and ERM values were derived for 28 substances: nine trace metals, total PCBs, 13 individual polynuclear aromatic hydrocarbons (PAHs), three classes of PAHs (total low molecular weight, total high molecular weight, and total PAH), and two pesticides (p,p'-DDE and total DDT). The data available for acenaphthene and phenanthrene are shown in Tables 1 and 2, respectively, to illustrate the format and content of the ascending tables with which the guidelines were derived. Space limitations preclude inclusion of equivalent tables for all of the substances.

Adverse effects measured in association with acenaphthene included high amphipod mortality in sediment toxicity tests, low species richness in benthic communities, high prevalence of liver lesions in demersal fish, and chronic toxicity predicted by an equilibrium-partitioning model (Table 1). No data from spiked-sediment bioassays were available. As an example of the kinds of data analyses that were performed for entry into the BEDS, matching sediment chemistry and amphipod mortality data from Commencement Bay (Washington) were evaluated in a co-occurrence analysis. The average concentration of acenaphthene was 85.9 ppb in the samples that were the least toxic to amphipods (12.5 ± 4.5% mortality). This data entry was assigned a no-effects (ne) descriptor. In samples that were moderately toxic (26 ± 5.2% mortality), the average concentration of acenaphthene was 127 ppb. The ratio of 127 ppb to 85.9 ppb was less than 2.0, therefore, the moderately toxic data entry was assigned a small-gradient descriptor. The average acenaphthene concentration associated with highly toxic samples (78.5 ± 19.5% mortality) was 654 ppb, a factor 7.6-fold higher than the average concentration in the least toxic samples. It was assigned an asterisk and used in the calculation of the ERL and ERM values. A total of 30 data entries for acenaphthene were assigned effects designators. No biological effects were reported over the range of 1–8.8 ppb acenaphthene. The lower 10th percentile value of the effects data (the ERL) was 16 ppb and the median value (ERM) was 500 ppb. The percent incidence of adverse effects within the minimal-effects, possible-effects, and probable-effects ranges were 20%, 32%, and 84%, respectively.

Phenanthrene data were available from equilibrium-partitioning studies, spiked sediment bioassays, and numerous field surveys performed in many different areas (Table 2). A total of 51 data entries were assigned effects designators in the phenanthrene database. Adverse effects were not observed in asso-

[a]Number of data entries within each concentration range in which biological effects were observed divided by the total number of entries within each range.

ciation with phenanthrene concentrations of <5 ppb to 66 ppb. The ERL value for phenanthrene was 240 ppb and the ERM value was 1500 ppb. The percent incidence of adverse effects within the minimal-effects, possible-effects, and probable-effects ranges were 18%, 46%, and 90%, respectively.

The incidence of adverse effects increased with increasing concentrations of all trace metals, except nickel (Table 3). The incidence of effects was 10% or less in the minimal-effects ranges and 11%–47% in the possible-effects ranges from all of the trace metals. The incidence of adverse effects exceeded 75% in the probable-effects ranges for chromium, copper, lead, and silver but was only 42.3% and 16.9% for mercury and nickel, respectively. However, the incidence of effects in the probable-effects range for chromium was greatly influenced and exaggerated by data from multiple tests conducted in only two field surveys.

The incidence of adverse effects consistently and markedly increased with increasing concentrations of all organic compounds, except p,p'-DDE and total DDT (Table 4). The incidence of effects ranged from 5.0% to 27.3% in the minimal-effects ranges for organic compounds and was 25% or less for all but one of the compounds—fluorene. Within the possible-effects ranges, the incidence of effects ranged from 18% to 75%. The incidence of effects ranged from 50% to 100% in the probable-effects ranges and equaled or exceeded 75% for all but four compounds. The incidence of effects in the probable-effects range for total PCBs was relatively low (51%).

Discussion

Guidelines Accuracy

Among the trace metals, the most accurate guidelines appeared to be those for copper, lead, and silver; the incidence of effects were very low (<10%) in the minimal-effects ranges, increased steadily through the possible-effects and probable-effects ranges, and were very high (>83%) in the probable-effects ranges. Among the organic compounds, the guidelines appeared to be highly accurate for all of the classes of PAHs and most of the individual PAHs. Except for fluorene, the incidence of effects was 25% or less at concentrations below the respective ERL values. Except for dibenzo(a,h)anthracene, p,p'-DDE, total DDT, and total PCBs, the incidence of effects was 75% or greater at concentrations that exceeded the respective ERMs. At concentrations in the probable-effects ranges, the incidence of adverse effects was 100% for acenaphthylene, 2-methyl naphthalene, and low-molecular-weight PAHs and 90% or greater for chromium, lead, silver, benz(a)anthracene, and fluoranthene.

The accuracy of the guidelines for some substances appeared to be relatively low. For example, the incidences of effects associated with nickel were 1.9%, 16.7%, and 16.9%, respectively, in the three concentration ranges. The incidence of effects did not increase appreciably with increasing concentrations of nickel and were very low in all three ranges. The incidence of effects in the probable-effects ranges for mercury and total PCBs were relatively low (42.3% and 51.0%, respectively). Furthermore, the incidence of effects did not increase consistently and markedly with increasing concentrations of p,p'-DDE, and total DDT. The p,p'-DDE and total DDT databases may have been unduly influenced by relatively low equilibrium-partitioning values, which were based upon chronic marine water quality criteria intended to protect against bioaccumulation in marine fish and birds, not toxicity to benthic organisms. The incidence of effects in the probable-effects range for chromium

Table 4. ERL and ERM guideline values for organic compounds (ppb, dry wt) and percent incidence of biological effects in concentration ranges defined by the two values

Chemical	Guidelines		Percent (ratios) incidence of effects[a]

[a]Number of data entries within each concentration range in which biological effects were observed divided by the total number of entries within each range.

ostensibly appeared to be very high but was unduly exaggerated by data from multiple tests performed in only two studies.

Comparisons with Other Guidelines

Agreement within a factor of 3 or less among guidelines developed with different methods has been recommended by a panel of experts as an indication of good precision (Lorenzato and others 1991). In the following discussion, the comparisons of guidelines were conducted by determining the ratios between them, i.e., the larger of the two values was divided by the smaller value.

The ERL and ERM values reported in Tables 3 and 4 were based upon a considerable expansion and revision of the database used by Long and Morgan (1990). The quantities of data used to derive the present values exceeded those used previously by factors of 1.4 to 2.6. About 30%–50% of the data used in the present analysis came from the database used previously. Furthermore, the considerable amounts of freshwater data in the previous database were deleted in the present analysis. Of the 25 ERL values derived in the two analyses, seven remained unchanged, nine decreased, and nine increased. The ratios between the two sets of ERL values ranged from 1.0 to 9.4 (average of 1.88, N = 25). The ERL values for only two substances changed by factors greater than 3.0×: arsenic (decreased by 4.2×); and acenaphthene (decreased by 9.4×). The ratios between the two sets of ERM values ranged from 1.0 to 7.6 (average of 1.63, N = 25). The average ratios between the two sets of ERM values was 1.2 for the individual PAHs and 1.5 for the trace metals; seven remained unchanged, seven decreased, and eight increased. Only one ERM value changed by a factor greater than 3.0: total DDT (decreased by 7.6×). The ERL and ERM values for p,p'-DDE increased by factors of 1.1 and 1.8, respectively. The ERL value for total PAHs remained unchanged and the ERM value increased by a factor of 1.3. The results of these comparisons indicate that the guidelines are relatively insensitive to changes in the database, once the minimum data requirements have been satisfied.

The national sediment quality criteria proposed by the US Environmental Protection Agency for fluoranthene, acenaphthene, and phenanthrene in salt water are based upon equilibrium-partitioning models (US EPA 1993a–c). The proposed mean criterion for fluoranthene is 300 μg/g organic carbon (with 95% confidence limits of 140 and 640 μg/goc). For acenaphthene the mean criterion is 240 μg/goc (with 95% confidence limits of 110 and 500 μg/goc). For phenanthrene the mean criterion is 240 μg/goc (with 95% confidence limits of 110 and 510 μg/goc). Assuming a TOC concentration of 1%, these criteria

values are equivalent to 3000 (1400–6400) ppb dry weight for fluoranthene; 2400 (1100–5000) ppb dry weight for acenaphthene; and 2400 (1100–5100) ppb dry weight for phenanthrene. The mean criteria exceeded the ERM values of 500 ppb for acenaphthene and 1500 ppb for phenanthrene by factors of 4.8, and 1.6, respectively. The criterion for fluoranthene was lower than the ERM by a factor of 1.7. The criteria expressed in units of dry weight would increase with increasing TOC concentrations.

The ERL and ERM values generally agreed within factors of two to three with freshwater effects-based criteria issued by Ontario (Persaud and others 1992). Lowest effect levels and severe effect levels were reported, based upon a screening level concentration (SLC) approach applied to matching benthic community and sediment chemistry data. The ratios between the present ERL values and the lowest effect levels for Ontario ranged from 1.25 to 3.1 (average of 1.7) for eight trace metals (As, Cd, Cr, Cu, Pb, Hg, Ni, Zn). The ratios between the present ERM values and the severe effect levels for Ontario ranged from 1.0 to 3.4 (average of 2.0) for the same eight trace metals. Of the 16 comparisons, the ERL/ERM values were lower than the respective values for Ontario in six cases and higher in ten cases.

Among all of these comparisons, most of the guidelines agreed within the recommended factor of 3.0 or less. In the worse case, two values (previous and present ERL values for acenaphthene) differed by a factor of 9.4.

Merits of the Approach

This approach attempts to identify the concentrations of toxicants that are rarely associated with adverse biological effects and those usually associated with effects, based upon data from many studies. The advantages of this approach are that guidelines can be developed quickly with existing information and that they are based upon data gathered from many different studies. An underlying assumption of the approach is that, if enough data are accumulated, a pattern of increasing incidence of biological effects should emerge with increasing contaminant concentrations.

Data from all available sources were considered in this study, including those from equilibrium-partitioning models, spiked sediment bioassays, and numerous field surveys. The modeling and bioassay methods differ considerably from those used in the field studies, since they generally are performed with single chemicals as if they were acting alone. The field studies invariably involve complex mixtures of contaminants, acting synergistically, additively, or antagonistically. Whereas the modeling studies and spiked sediment bioassays can be used to establish cause–effect relationships for single chemicals, the data from field studies cannot establish such relationships. However, the data from field studies of complex mixtures reflect real-world, natural conditions in ambient sediments. We believe that the most meaningful assessment tools are those that are based upon evidence from and agreement among all three of these methods. If data compiled from different study areas with different pollution histories and physical–chemical properties converge upon ranges of contaminant concentrations that are usually associated with effects, then guidelines derived from those studies should be broadly applicable to many other areas and situations. Therefore, in this report, the data from numerous studies were used to identify the concentrations of individual chemicals that were rarely, occasionally, and usually associated with effects.

The biological data compiled for derivation of the guidelines included a variety of different taxonomic groups and toxicological end points. The sensitivities of the taxa to toxicants may have differed considerably, and, therefore, contributed to variability in the data base. However, we believe that the inclusion of data from multiple taxa ensures the broad applicability of the guidelines and the protection of a diversity of organisms.

The bioavailability of sediment-associated contaminants is controlled to a large degree by certain physical–chemical properties of the sediments. For example, high acid-volatile sulfide (AVS) concentrations appear to reduce the bioavailability of cadmium, and, possibly, other trace metals in sediments (Di Toro and others 1990). Similarly, the influence of increasing TOC concentrations in reducing the bioavailability of many nonionic organic compounds has been demonstrated in modeling and laboratory studies (Di Toro and others 1991, Swartz and others 1990, Pavlou and others 1987). Significant differences in toxicity can occur at similar toxicant concentrations over relatively small ranges in TOC and/or AVS concentrations (Adams and others 1992). It has been argued that sediment quality criteria are indefensible if they do not account for factors that control bioavailability (Di Toro and others 1991). The data evaluated in the present analysis were not normalized to either TOC or AVS concentrations, since only a small minority of the reports that were encountered included results for these parameters. Nevertheless, the present evaluation indicates that the guidelines derived using the approach reported herein are accurate for most

chemicals and agree reasonably well with other guidelines. Therefore, they are likely to be reliable tools in sediment quality assessments.

While factors that are thought to control bioavailability were not considered explicity, surely they were operative in the tests of field-collected sediments and influenced the bioavailability of all of the potential toxicants. However, the data that were encountered indicated that TOC concentrations usually ranged from 1% to 3% in most study areas. In contrast, the concentrations of some chemicals differed by several orders of magnitude among the same samples. These observations suggest that, over these large concentration gradients, the relatively small differences in TOC and/or AVS concentrations may have been relatively unimportant in controlling toxicity or, otherwise, were masked in the data analyses.

Since the data bases used to develop the present guidelines included data from many field studies, the guidelines may tend to be more protective than those based upon only single-chemical approaches. The cumulative (e.g., synergistic) effects of mixtures of toxicants in ambient sediments, including those not quantified may tend to drive the apparent effective concentrations of individual toxicants downward (i.e., toward lower concentrations).

Conclusions

Based upon an evaluation of existing data, three ranges in chemical concentrations were determined for 28 chemicals or chemical classes. These ranges were defined by two guideline values: the lower 10th percentile (ERL) and the 50th percentile (ERM) of the effects data distribution. The incidence of biological effects was quantified for each of these ranges as an estimate of the accuracy of the guidelines. The incidence of effects usually was less than 25% at concentrations below the ERL values. For most chemicals, the incidence of effects increased markedly as the concentrations increased. Furthermore, the incidences of effects often were greater than 75% (occasionally 100%) at concentrations that exceeded the ERM values. However, for a few chemicals (especially mercury, nickel, total PCBs, total DDT, and p,p'-DDE) there were relatively weak relationships between their concentrations and the incidence of effects. The guideline values reported herein generally agreed within factors of 3× or less with guidelines derived earlier using the same methods applied to a different data base and with guidelines developed with other methods. The numerical guidelines should be used as informal screening tools in environmental assessments. They are not intended to preclude the use of toxicity tests or other measures of biological effects. The guidelines should be accompanied by the information on the incidence of effects. The percent incidence data may prove useful in estimating the probability of observing similar adverse effects within the defined concentration ranges of particular contaminants.

Abstract—The U.S. Environmental Protection Agency (EPA) Environmental Monitoring and Assessment Program–Estuaries and the National Oceanic and Atmospheric Administration Bioeffects Surveys provide large data sets with which to test proposed relationships between sediment chemistry and toxicity. We conclude that guidelines based on bulk chemistry can provide useful triggers for further analysis but should not be used alone as indicators of toxicity. The sediment quality criteria for nonionic organic compounds proposed by the EPA are exceeded in so few samples that they may be of limited practical value. Toxicity was present in many cases when acid-volatile sulfide (AVS) concentrations exceeded the sum of concentrations of sulfide-insoluble metals. However, there is no way to test whether that toxicity was due to those trace elements. The AVS criterion is much more sensitive to AVS concentration than to trace metal contamination.

Keywords—Sediment Equilibrium partitioning Acid-volatile sulfide Cooccurrence Measured toxicity

INTRODUCTION

Adams et al. [1] reviewed the three main approaches used in the United States to estimate biological effects of contaminated sediment based on chemical data alone. The cooccurrence [2] method is representative of those that use bulk chemical concentrations. The equilibrium partitioning method for neutral organics [3] assumes that pore water is in equilibrium with sediment and that, to be nontoxic, pore water must meet water quality standards. The method based on acid-volatile sulfide (AVS) concentration [4] applies to metals with insoluble sulfides and assumes that as long as AVS is in excess, those metals are unavailable and not toxic. A recent U.S. Environmental Protection Agency draft report [5] describes application of all of these chemical-based methods to categorize sediments into tiers on the basis of their potential for causing adverse biological effects.

Theoretical reasons exist for doubting that any of these chemical-based guidelines reflect sediment toxicity. For example, the equilibrium assumption at the foundation of equilibrium partitioning may not be valid, the presence of AVS should mean a lack of oxygen and obvious toxic conditions, and the cooccurrence methods assume that bulk concentrations represent biological availability of chemicals. Such considerations aside, however, we have a large data set with which to empirically test the applicability of these methods. The EPA Environmental Monitoring and Assessment Program—Estuaries (EMAP–E) [6–9] and the National Oceanic and Atmospheric Administration (NOAA) National Status and Trends Bioeffects Surveys [10–13] provide a 1,508-sample data set containing measurements of both chemical concentrations and toxicity.

The EMAP–E program was designed to randomly sample estuaries within entire biogeographical provinces of the United States. For example, a random grid of hexagonal cells was overlain on a map of the United States, and samples were taken from the cells. We have annual data for 1990–1993 from sampling in the Virginian Province (Chesapeake Bay, VA, to Cape Cod, MA), for 1991–1994 in the Louisianian Province (Gulf of Mexico except south of Tampa Bay, FL), and for 1993 in the Carolinian Province (Cape Henry, VA, to St. Lucie Inlet, FL). Because the samples were selected with a probability-based method, there was no tendency or bias for them to be from particularly contaminated areas near harbors, industrial waterways, or urban centers. Sediment samples from the NOAA Bioeffects Surveys, on the other hand, are from intensive sampling in urban waterways. In general, therefore, they have higher concentrations of contaminants than the EMAP–E samples. Taken together, these data allow us to evaluate how well the three chemical-based methods predict sediment toxicity.

METHODS

All data and methods have been previously reported [6–14]. Chemical analyses for trace elements were based on hydrofluoric acid extractions and are total metal analyses [6–8,14]. Acid-volatile sulfide was measured by the method of Di Toro et al. [4]. Amphipod (*Ampelisca abdita*) survival bioassays [6–13] were all 10-d exposures to whole sediment. The other bioassays used different endpoints and different components of sediment. Microtox® bioassays of sediments from Boston Harbor, Long Island Sound, the Hudson–Raritan Es-

Pyrene	670	2,600

[a] Effects range–low (ER–L) values are bulk sediment concentrations (dry weight) below which sediment is unlikely to be toxic.
[b] Effects range–median (ER–M) values are concentrations above which toxicity is probable.
[c] Dichlorodiphenyldichloroethylene (*p,p′*-DDE) is part of the total dichlorodiphenyltrichloroethane (DDT) and individual polycyclic aromatic hydrocarbon (PAH) compounds are part of the total PAH, low-molecular-weight (LMW) PAH (2- and 3-ring compounds), and high-molecular-weight (HMW) PAH (more than 3-ring compounds). However, double and triple counting is of no consequence when we are interested in knowing only whether there is at least one exceedance of ER–L or ER–M. PCB = polychlorinated biphenyl.

tuary, and Tampa Bay [10–13] all began with dichloromethane extracts of homogenized sediment. Subsequently, the solvent was replaced with ethanol and bioluminescence of the bacterium *Photobacterium phosphoreum* measured in the standard Microtox diluent. Sea urchin fertilization and embryo development assays of sediments from Boston Harbor [13] and Tampa Bay [11] were conducted with gametes of *Arbacia punctulata* exposed to pore water that was pressure-extracted from whole sediment. Bivalve survival and development tests with sediments from Long Island Sound [10] and the Hudson–Raritan Estuary [12] began with embryos of the clam *Mulinia lateralis* exposed to elutriates (i.e., seawater extracts) of homogenized sediment.

Our procedure for this report was simply to categorize the data according to the different criteria and guidelines and to observe how closely predicted responses conformed to measured toxicity. The amphipod survival toxicity test is common to all data sets and serves as our primary measure of toxicity.

RESULTS

Cooccurrence

It has been suggested [2] that sediment toxicity is unlikely when bulk concentrations in sediment of all chemicals listed in Table 1 are below the effects range–low (ER–L) value. Conversely, toxicity is probable when any chemical concentration exceeds an effects range–median (ER–M) value. We have chemical data on 1,508 samples along with the results of 10-d exposures of amphipods (*A. abdita*) to whole sediment. Sediments are considered toxic if fewer than 80% of the amphipods, relative to controls, survive the exposure [6–8,15]. Table 2 lists numbers of samples in various categories relative to ER–L and ER–M exceedances and the numbers that were toxic. Of the 481 samples without an ER–L exceedance, only 5% were toxic. This is in agreement with the prediction. On the other hand, of the 239 samples that had at least one concentration greater than an ER–M, only 38% were actually toxic. While the cooccurrence of ER–M exceedances with amphipod toxicity is less than ''probable,'' exceedances may identify samples for further examination.

Equilibrium partitioning

Five sediment quality criteria (SQC) for nonionic organic compounds based on assuming equilibrium between sediment

Table 2. Total numbers of samples per data set, number of effects range–low (ER–L) nonexceedances, number of ER–L nonexceedances that were toxic to amphipods, number with at least one effects range–median (ER–M) exceedance, number with at least one ER–M exceedance that were toxic, and total number that were toxic (<80% survival after 10 d)

Data set[a]	Total samples	Total samples with all <ER–L	Toxic samples with all <ER–L	Total samples with at least 1 >ER–M	Toxic samples with at least 1 >ER–M	Total toxic samples (%)
EMAPV	537	211	12	82	25	59 [11]

HRE	38	20	18	16	11	—	—
TB	61	10	—	—	—	52	—

[a] The various tests (see text) in addition to that for amphipod survival are based on Microtox® (bacterial luminescence), bivalve (*Mulinia lateralis*) embryo survival and development, and sea urchin (*Arbacia punctulata*) gamete fertilization and embryo development.
[b] Sample deemed toxic if response is statistically different and <80% of control.
[c] See footnote a in Table 2 for definitions of abbreviations.

and interstitial water and requiring that interstitial water meet surface water quality criteria have been proposed [3]. The chemicals endrin, dieldrin, acenaphthalene, fluoranthene, and phenanthrene exceed criteria when their concentrations (on a per total organic carbon [TOC] basis) exceed 0.76, 20, 230, 300, and 240 μg/g TOC, respectively. Among the 1,179 EMAP–E samples, only nine exceeded at least one of those criteria, and only two of the nine were toxic. Among the 236 samples from the Bioeffects Surveys, three from the Hudson–Raritan Estuary exceeded at least one of those criteria, and all were toxic.

Swartz et al. [16] introduced a variation on this approach for polycyclic aromatic hydrocarbons (PAHs). Their method first assumes equilibrium to calculate the interstitial water concentration of each PAH compound, that concentration is converted to a toxic unit by dividing by the 10-d median lethal concentration (LC50) for the compound, then the individual toxic units are summed to a total that indicates a high probability of toxicity if it exceeds 1.0. Using the equilibrium coefficients and LC50 concentrations for the 13 PAH compounds in the report by Swartz et al. [16], we calculated toxicity units for the data in hand. The results were about the same as for the original application of equilibrium partitioning, that is, fewer than 10 samples had 1 or more total toxic units, and about half of those were not toxic to amphipods.

Acid-volatile sulfide

Di Toro et al. [4] proposed that if the simultaneously extracted metals (SEM)/AVS ratio is less than 1, there will be no toxic effect from Cd, Cu, Hg, Ni, Pb, or Zn. The SEM and AVS values are the concentrations of those metals and sulfide, respectively, extracted from sediment with 1 N hydrochloric acid. Toxicity may still be present but would be attributed to other elements, to organic chemicals, or to other stressors. Conversely, nothing about toxicity is to be implied when the SEM/AVS ratio is greater than 1.

Among the Virginian and Louisianian EMAP–E samples are 978 with measured AVS concentrations. Only 544 of those also had measured SEM concentrations, but we can substitute the summed concentration of the six metals extracted for total elemental concentrations. This sum, called TotM, exceeds SEM; so, wherever TotM/AVS was less than 1, SEM/AVS must also have been less than 1. In 355 cases TotM/AVS was greater than 1. Nothing is predicted in these cases. In the 623 cases where TotM/AVS was less than 1, 48 (8%) were toxic. However, the existence of toxicity does not conflict with prediction. The method only predicts that such toxicity could not have been due to any of the six sulfide-insoluble metals. We have no way of knowing whether or not it was.

Among the 978 samples, the median concentrations for AVS and TotM were 2.47 and 1.62 μM/g (dry weight), respectively. Among the 355 where the ratio exceeded 1, the corresponding medians were 0.45 and 1.70 μM/g. The fact that median concentrations of metals are almost the same in both cases illustrates that the method is sensitive to AVS but not to metal contamination.

Among the Bioeffects Survey data sets, there were 272 samples with AVS and SEM data (letting SEM equal TotM for Tampa Bay). The AVS criterion applies in the 252 cases where SEM/AVS was less than 1, yet toxicity was observed in 72 (29%) of them. Again, the toxicity may have been due to characteristics other than concentrations of sulfide-insoluble metals.

Other biological tests

If other biological tests were used to assess toxicity, there would be more cases where ER–M exceedances coincide with a toxic response. The Bioeffects Surveys included other tests, and it is evident that more instances of toxicity were found when other tests were conducted in conjunction with the amphipod test (Table 3). If a toxic response in any test is sufficient to categorize a sample as toxic, it is more likely that an ER–M exceedance will cooccur with toxicity. As seen in Table 4, 91% of the samples with an ER–M exceedance were toxic by at least one biological test. However, of the 183 samples with only an ER–L exceedance, 156 (85%) were toxic. Moreover, five of the nine (55%) samples without even an ER–L exceedance were toxic. What has happened by including all biological tests is that even a random sample now has an 84% chance of being toxic. In effect, any connection between bulk chemistry or any sediment characteristic and toxicity has been overwhelmed.

DISCUSSION AND CONCLUSIONS

An SQC based on equilibrium partitioning was exceeded in only 12 cases among the 1,508 samples. Only six of those were toxic, but the paucity of extremely contaminated samples probably disallowed a rigorous test of the SQC. As a practical matter, the SQCs would be exceeded so rarely that they would have limited application.

When the SEM/AVS ratio is less than 1 there should be no toxicity due to sulfide-insoluble metal concentrations. In the data we examined, toxicity was observed in 120 cases where the SEM/AVS ratio was less than 1, but that may have been due to sediment characteristics other than sulfide-insoluble metals. The AVS criterion did not apply in the 30% of the samples where AVS was exceeded by the metal concentrations. These were usually not cases where metal concentrations were

Table 4. Same as Table 2 but with toxicity from any test deemed sufficient to put sample into the toxic category

[b] ER–L = effects range–low.
[c] ER–M = effects range–median.

high but where AVS was low. In effect, the SEM/AVS criterion is sensitive to AVS and not to sediment contamination with trace metals.

The cooccurrence method is, by definition, sensitive only to concentrations of trace elements and organic compounds. This advantage is also a failing because it does not acknowledge that noncontaminant characteristics of sediment can mitigate toxicity. Thus, while there were many samples with ER–M exceedances, fewer than 40% of those were toxic to amphipods.

Among the three methods, the cooccurrence method is empirically the most useful because it applies to both organic and inorganic contaminants, it predicts toxicity (not its absence), and it can be applied within concentration ranges that occur in less than extremely contaminated areas. The lack of even an ER–L exceedance does mean that toxic effects are unlikely, but ER–M exceedances should only be taken to indicate that further analysis is in order. They should never be taken, by themselves, to mean that sediment is exerting a toxic effect upon the environment or that there would be any benefit to decreasing its chemical content.

A call to further analysis based on chemical data means that bioassays should be done, but as more types of tests are done, the likelihood of a toxic response increases. So, one toxic response accompanied by no response in other tests should not signal a need for action with regard to mitigating sediment. As pointed out by Adams et al. [1], one needs to consider the spatial scale of the sediment in question and, when that is large, also examine the community living in and on the sediment. Even these considerations can be insufficient because indigenous community alteration can be due to excess organic matter, not chemical contaminants, and because considerations of scale are somewhat subjective.

In the end, many aspects of the sediment come into consideration. Chemical data are important, as are bioassay data, but decisions on sediment management cannot be prescribed. They need to be based on judgement.

RE: **The Effects Range-Low (ERL) Value for Numeric Target of Water Body-Pollutant Combinations in Marine Sediments of the Dominguez Channel Estuary and Greater Los Angeles and Long Beach Waters**

SUMMARY

The Regional Board's intended use of the effects range-low (ERL) sediment quality guideline (SQG) as the basis for total daily maximum loads in the Los Angeles and Long Beach Harbor marine and estuarine waters is not scientifically defensible. The limitations noted by the original authors of the ERL and others concluded that:

- ERLs should be used only as an informal screening tool and should not preclude gathering additional information such as adverse sediment effects and toxicity testing;

- The relationship between concentrations of nickel, mercury, total PCBs, and total DDT and adverse effects is at most, weak and therefore, the Regional Board's use of the ERL will not result in expected gains in sediment quality; and,

- The presence of unmeasured or unknown contaminants will lead to large uncertainties in sediment toxicity, thereby substantially limiting the usefulness of the ERL as a sediment target.

The principal conclusions of this report are as follows:

- Use of the ERLs to set sediment targets for the Harbor Waters TMDL is inappropriate because data used to develop the ERLs has not been made available by the ERL authors, so it is presumed that the Regional Board does not possess those data and has not reviewed them. Also, it is not known whether the ERLs are based on data relevant to the nine water bodies that are the subject of the draft TMDL, or whether the author's underlying database (which is not publicly available) contains any data from these water bodies. Under these circumstances, it would be inappropriate to base a regulatory decision on the ERLs, and neither I nor anyone else who is interested in this TMDL can independently verify or reproduce the ERLs.

- The ERLs are not intended or designed for the use to which the draft TMDL intends. The authors of the ERLs and federal agencies caution against the use of the ERLs for anything other than an informal screening tool to help rank and prioritize different sediment sites. The ELRs are not recommended by the authors to be used for making remedial decisions with regard to contaminated sediments, as is being done in the draft TMDL. In fact, over many years of experience at various contaminated sediment sites around the country, I have never once seen the ERLs used to establish sediment remedial or cleanup levels as is the Regional Board has proposed. This unprecedented use of ERLs is not warranted and invalid.

- An independent statistical evaluation of other sediment screening values prepared by McDonald, one of the authors of the ERLs, has demonstrated a very weak, and almost random, relationship between DDT on the one hand, and impacts to the benthic ecosystem, on the other. In fact, the authors of the ERLs acknowledged that their ERLs provide a poor relationship between the concentration of DDT in contaminated sediment and any toxic effects to benthic biota that might be from the DDT. In short, the ERLs are not a reliable or useful measure of the potential for DDT to adversely impact the benthic ecosystem, and no reasonable scientist would rely on them for this purpose.

- What is known about the ERLs is that they ascribe toxicity to DDT and other compounds based on pulling data from published studies where the authors of those underlying studies do not ascribe the reported toxicity to DDT or these other compounds. In some cases, the authors of the underlying studies specifically state that DDT is not the cause of the observed toxicity. In other instances, the authors of the underlying studies ascribe the toxicity to the presence of compounds or conditions other than DDT. In this regard, the use by the ERLs of data from such studies to build a threshold for DDT is inappropriate and not technically justified.

INTRODUCTION

The California Regional Water Quality Board, Los Angeles Region (Regional Board) and U.S. Environmental Protection Agency (USEPA) have developed total daily maximum loads (TMDLs) for water body-pollutant combinations to help achieve water quality standards in the Dominguez Channel Estuary and the Greater Los Angeles and Long Beach Harbor waters (Regional Board and USEPA 2010). These areas addressed by the TMDLs are associated with the greater Los Angeles and Long Beach Harbor marine and estuarine waters. In its problem statement, the Regional Board stated that one or more environmental media (i.e., water, sediments or tissues) were contaminated by one or more of the following constituents: cadmium, copper, mercury, lead, zinc, chlordane, dieldrin, DDT, polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs). This report primarily uses DDT as an example. For sediments in these areas, the Regional Board identified a total of 8 metals and organic chemical pollutant impairments for the Dominquez Channel and Greater Los Angeles and Long Beach Harbor waters, and 15 for the Consolidated Slip; DDT is included in both areas. It is noteworthy that the freshwater portion of the Dominquez Channel also contains pollutant impairments but does not include DDT; therefore, this area is not considered further in this report.

The Regional Board established numeric sediment targets for these metals and organics based on effects range-low (ERL) sediment quality guidelines developed by Long *et al.* (1995). The purpose of this report is to assess whether these ERL values for the identified water body-pollutants are scientifically defensible based on the limitations identified by numerous authors who have reported on their use and on how values are to be interpreted.

SEDIMENT QUALITY GUIDELINES (SQGS)

Numerous federal and state agencies have developed or adopted sediment quality guidelines (SQGs) to provide informal, non-regulatory chemical benchmarks for evaluating risks to sediment dwelling organisms (Long *et al.* 1995; Long and MacDonald 1998; National Oceanic and Atmospheric Administration [NOAA] 1999; among others). In one set of guidelines, the ERL and the effects range-median (ERM) were developed for helping interpret sediment sample data obtained under the National Status and Trends Program of NOAA (Long and Morgan 1990; Long *et al.* 1995). A biological effects database for sediments (BEDS) was developed by these investigators from numerous studies that were conducted throughout North America. However, these data did not include information for the Los Angeles or Long Beach Harbor marine and estuarine waters. These data included synoptically collected biological effects and chemical data from sediments; other conditions to which the data were subjected are described by Long *et al*. (1995). The BEDS database is not publically available and therefore, the derived ERL and ERM values cannot be independently reproduced and are not transparent. Another set of marine SQGs called the threshold effects level (TEL) and probable effects level (PEL) were developed

for the State of Florida (MacDonald *et al*. 1996). Values of the two sets of SQGs (ERLs and ERMs, and TELs and PELs) are different, having been developed using different rules.

The ERL and ERM values were developed using paired chemical concentrations associated with only adverse biological effects, which included measures of altered benthic communities, sediment toxicity, histopathological disorders in dimersal fish, EC_{50} or LC_{50} concentrations from laboratory bioassays, and toxicity predicted by equilibrium partitioning models. All of these adverse effects were considered equivalent. The ERL and ERM values for 9 trace metals, 13 individual PAHs, 3 classes of PAHs, and 3 classes of chlorinated organic hydrocarbons are shown in Tables 1 and 2. The values are statistically based in that the 10^{th} percentile of the effects data was termed the ERL and the 50^{th} percentile (median) was termed the ERM. Very generally, the ERL value reflects sediment concentrations below which adverse effects were rarely observed. Alternatively, the ERM reflects sediment concentrations above which adverse effects frequently occurred. The TEL and PEL values were developed using both effects and no observed effects but have generally the same interpretations as the ERL and ERM values. The TEL and PEL values are not shown in this report and are mentioned only because they appear later in a procedure used for classifying sites.

Measures of reliability, recommended uses and limitations of the empirically derived in ERL and ERM values are presented in Long and MacDonald (1998) and NOAA (1999). The reliability and uses are reflected in Table 3, which also includes TEL and PEL values. This table represents how sites can be prioritized based on 1) mean values of ERM or PEL quotients, 2) the number of ERMs or PELs exceeded and 3) whether any ERLs or TELs are exceeded. Associated with each priority categorization are the probabilities of amphipod toxicity as reported by Long *et al*. (1998). Mean ERM quotients are determined using the data in Tables 1 and 2. For example, for *each* constituent listed in the tables, the concentration found in a sediment sample is divided by its associated ERM value. The quotients are then averaged for the sample. If multiple samples are collected for a site, then the grand average is determined. Based on the mean ERM quotient, the site can be classified into one of four categories that reflect increasing probabilities of toxicity. From Table 3, there are four priority categories from highest to lowest. The number of individual ERMs exceeded is also determined, which can lead to different toxicity probabilities in each of the four priority categories. The only use of the ERL values is to define the lowest priority category, which generally indicates that no further action is needed. Recall that if no ERLs are exceeded then the likelihood of toxicity was rare. The methods for determining mean PEL quotients are equivalent but use different PEL values.

LIMITATIONS OF SQGs

The ERM and ERL sediment quality guidelines were intended to provide informal and interpretive tools to aid in assessing contamination and the potential for toxicity. They are intended to be used to rank or prioritize chemicals of potential concern and to assess whether further investigation or management action is needed. These further investigations can include

but are not limited to planning of monitoring activities, designing whole-sediment or spiked sediment bioassays. Long *et al.* (1995) stated that "The numerical [ERL and ERM] guidelines should be used as informal screening tools in environmental assessments. They are not intended to preclude the use of toxicity tests or other measures of biological effects. The guidelines should be accompanied by the information on the incidences of effects." Long and MacDonald (1998) stated that "Data from investigations of hazardous waste sites can be compared to the SQGs to aid in ranking and prioritizing sites and to determine the need for further information to support management decisions."

However, there are several serious limitations to ERL values associated with mercury, nickel, total PCBs, total DDT, and ρ,ρ'-DDE. There is a very low correlation between toxic effects and the ERL values for these constituents such that the ecological thresholds for these compounds should be used cautiously. Long *et al.* (1995) stated that ". . . for a few chemicals (especially mercury, nickel, total PCBs, total DDT, and ρ,ρ'-DDE) there were relatively weak relationships between their concentrations and the incidence of effects." Hence, it is unlikely that the Regional Board's use of the ERL for total DDT would yield defensible results in terms of sediment quality objectives. Data reported by Fairy *et al.* (1996) and assessed by Geisy *et al.* (1998) were used to assess the relationship between total DDT and amphipod mortality in sediments from San Diego, CA harbor. This relationship is shown in Figure 1. The Pearson correlation between the plotted variables is -0.304 meaning that amphipod mortality (a measure of toxicity) *decreases* with *increasing* concentrations of total DDT. This relationship does not correspond at all with a dose-response that would be typical if total DDT were causing toxicity. It is noteworthy that the highest toxicity was found at concentrations of total DDT that were below the ERL value. This analysis provides further evidence that the Regional Boards intended use of the ERL as a sediment target is not defensible.

The low correlation means that even if the ERL for total DDT is exceeded, there is no reasonable confidence that the sample would in fact be toxic and therefore, no reason to use this value as a sediment quality target. The same limitations apply to the ERM values for mercury, nickel, total PCBs and total DDT. The likelihood that these ERMs accurately predict adverse (toxic) effects are much lower than for the other constituents shown in Tables 1 and 2. Regarding exceeding an ERM value, O'Conner *et al.* (1998) stated that "ERM exceedance should only be taken to indicate that further analysis is in order. They should never be taken, by themselves, to mean that sediment is exerting a toxic effect upon the environment or that there would be any benefit to decreasing its chemical content."

Chemicals in sediments largely occur as mixtures and, while the ERM or ERL value for a single constituent may be exceeded, the exceedance does not provide confidence that it is toxic to sediment organisms. In addition, there are no SQGs available for many toxic constituents. The ability of SQGs to predict toxicity of co-occurring constituents for which there are no SQG values is unknown. Di Toro (2008) further added that ERMs, ERLs, and other SQGs cannot ". . .

predict with more than a modest degree of certainty the outcome of a toxicity test on sediment from the field that is contaminated with many, and possibly unknown and unmeasured constituents." This situation is true in the Los Angeles and Long Beach Harbor marine and estuarine waters and reflects the co-occurrence of toxic chemicals in sediments. Di Toro's statement means that even if, for example, DDT exceeds the ERL value, it is not the cause of sediment toxicity (see Figure 1). Toxicity results from numerous, co-occurring chemicals many of which are not measured but which can act independently to produce adverse effects to sediment organisms. Given that only a modest degree of certainty is achievable with respect to toxicity, it is clear that exceeding an ERL cannot lead to the conclusion that DDT (or any other single chemical) is responsible for toxicity.

NOAA (1999) stated that "SQGs should be used with caution and common sense. There are no SQGs available for many substances that can be highly toxic in sediments. The abilities of the SQGs to correctly predict toxicity of co-varying substances for which there are no SQGs are unknown. The SQGs were derived in units of dry weight sediments; therefore, they do not account for the potential effects of geochemical factors in sediments that may influence contaminant bioavailability. The SQGs were not intended for use in predicting effects in wildlife or humans through bioaccumulation pathways. The SQGs were neither calculated nor intended as toxicological thresholds; therefore, there is no certainty that they will always correctly predict either non-toxicity or toxicity."

Furthermore, NOAA (1999) stated that "The SQGs are best applied when accompanied by measures of effect such as laboratory toxicity tests and/or benthic community analyses and/or bioaccumulation tests, which lead to the preparation of a weight of evidence. Furthermore, they are best applied in a comprehensive assessment framework involving the establishment of clear study objectives, a priori methods for data analyses, and well-understood decision points regarding the uses of the data."

USE OF ERL AS NUMERIC TARGET

The Regional Board's intended use of the ERL as a conservative numeric target of mercury, nickel, total PCBs and total DDT in marine sediments of the Dominquez Channel Estuary and the Greater Los Angeles and Long Beach Harbor waters is not defensible scientifically. Given the limitations stated above, it is quite likely that these ERLs do not accurately forecast sediment toxicity. Even exceeding the higher ERM value, which the Regional Board does not use, does not meet this accuracy criteria. Sediments in these two areas likely contain a mixture of toxic constituents that are not listed in the SQG tables and therefore, cannot be understood toxicologically.

The ERL, and in fact all SQGs, were originally developed as tools or benchmarks to aid in further understanding of adverse effects in sediments. It was never meant to be used in a regulatory manner as the Regional Board is intending as the basis for TMDL allocations. To

date, the ERMs or ERLs have not been promulgated and implemented for standards or criteria in the U.S. If used as the Regional Board intends, it likely will lead to unreasonable allocations and sediment remedial actions that will not have the effect of restoring sediment quality. Finally, the ERL (and the SQGs in general) do not provide a direct means of determining which constituents are causing toxicity in sediments.

The Regional Board has minimal data upon which to assign numeric targets for mercury, nickel, total PCBs and total DDT in sediments. At a minimum, these data should lead to further investigations of adverse effects including sediment toxicity that include:

- Field validation of the ERL for total DDT, PCBs and other chemicals
- Comprehensive and statistically designed whole-sediment toxicity testing
- Spiked bioassays using DDT, PCBs and other chemicals to assess toxicity in single chemical situations
- Laboratory-based bioaccumulation testing
- Initiation of Phase 1 and Phase 2 toxicity identification evaluations (TIEs) that will lead to better understanding of causation if toxicity is present

The statements above are a true and accurate statement of my analyses and opinions of this matter. If the agencies require further information on this matter or would like to speak with me directly, please let me know. I can be reached through Chuck Anthony at Latham and Watkins, LLP at 714-540-1235.

Table 1. Effect range-low (ERL) and effects range-high (ERM) sediment guideline values for trace metals (mg/kg sediment dry weight).

Metal	Effects Range-Low (ERL)	Effects Range-High (ERM)
Arsenic	8.2	70

TO: California Regional Water Quality Control Board, Los Angeles Region;
United States Environmental Protection Agency, Region 9
CC: Paul Singarella, Latham & Watkins, LLP
FROM: David Sunding, Director, The Brattle Group and Professor, College of Natural Resources, UC Berkeley

RE: Comments on the cost consideration of, "Dominguez Channel and Greater Los Angeles and Long Beach Harbor Water Toxic Pollutants Total Maximum Daily Loads Draft"

I appreciate the opportunity to submit this comment to the California Regional Water Quality Control Board, Los Angeles Region, in response to the Board's issuance of a draft TMDL for toxic pollutants in the Dominguez Channel and Greater Los Angeles and Long Beach Harbor waters. I am submitting these comments on behalf of Montrose Chemical Corporation of California.

My background and qualifications are listed on the curriculum vitae attached as an exhibit to this comment. I am a principal at The Brattle Group, a global firm providing consulting and expert testimony in economics, finance and regulation to corporations, law firms and governments. I am also the Thomas J. Graff Professor of Natural Resource Economics at UC Berkeley, where I am also the Co-Director of the Berkeley Water Center. Prior to joining the faculty at Berkeley, I served as senior economist at President Clinton's Council of Economic Advisers. I am currently a Visiting Professor in the Woods Institute of the Environment at Stanford University.

The staff of the Regional Board has not met its burden under Porter-Cologne and U.S. EPA guidance to consider economics in the development of the TMDL. The Staff Report does not attempt to gauge the significance of the TMDL in that it does not consider or even calculate the benefits of the action relative to current water quality levels. The Staff Report does not discuss benefits of the TMDL in relation to the costs of implementation, which is the only logical way to assess economic reasonableness. The plan for implementing the proposed regulation is not described in enough detail to permit an adequate calculation of costs. The report makes no mention of who will bear the costs of complying with the regulation, or of the regional economic implications of the action. The report does not acknowledge the potential employment impacts of the proposed TMDL, or the effect of the cleanup plan on competitiveness of California businesses.

The costs of the proposed regulation are not adequately described in the staff report. Available information demonstrates that the assertions of the Staff Report regarding the costs of compliance are misleading. For example, the report makes assertions about the costs of dredging based on two projects completed more than a decade ago. These assertions are not consistent with the actual costs of dredging at other locations in California. The report also mischaracterizes the actual costs of impounding and treating stormwater to the levels required by the TMDL. Using more realistic assumptions on the cost of dredging ($200/cy based on a sample of projects around California instead of the $60/cy used in the Staff Report), the present value of dredging over 11 million cubic yards to fulfill the requirements of the Sediment Quality Objective could total $2.2 billion in 2011 dollars, equivalent to an annual expenditure over 20 years of $150.2 million. The cost of dredging over 35 million cubic yards to meet the Effect Range Low requirements would total $6.9 billion, or an annual expenditure of $476.9 million.

The Regional Board staff made no attempt to evaluate the benefits of the proposed TMDL. There is no mention of the number of people participating in recreational fishing activities in the area of the TMDL, nor for any other type of recreational use (sailing, hiking, bird watching, etc.). There is no mention in the Staff Report of how any of these uses would be improved by the proposed action, if they would be affected at all. There is

no mention of the value to residents of Los Angeles County, or any other area of California, of the wildlife benefits achieved by the TMDL. This circumstance is in violation of the State requirement that major regulations are subject to a demonstration of economic value.

The proposed action is likely to result in an unacceptably high level of costs in relation to the actual benefits achieved. The staff report fails to demonstrate that the Regional Board considered alternatives to the proposed TMDL that would be less burdensome, or that it considered the relative cost effectiveness of alternative standards. This is inconsistent with basic principles of economic analysis of regulation, and in contradiction to established federal guidelines promulgated by the US Environmental Protection Agency and the Office of Management and Budget.

2. Failure to Consider Economics

Under the Porter-Cologne Water Quality Control Act, the State Water Resources Control Board has the ultimate authority over State water rights and water quality policy. Porter-Cologne also establishes that the nine Regional Water Quality Control Boards shall oversee water quality on a day-to-day basis at the local and regional level. The Regional Boards engage in a number of water quality functions in their respective regions. One of the most important is preparing and periodically updating Basin Plans. Each Basin Plan establishes beneficial uses of water designated for each water body to be protected; water quality objectives for both surface water and groundwater; and actions necessary to maintain these standards in order to control nonpoint and point sources of pollution to the State's waters.

Porter-Cologne requires that when determining water quality targets the Regional Boards shall consider the following factors: "the beneficial uses to be protected, the water quality objectives reasonably required for that purpose, other waste discharges, the need to prevent nuisance, and the provisions of Section 13241." Section 13241 in turn lists six "factors to be considered," including "economic considerations" and "water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area."

CEQA also requires the Regional Boards to consider economic impacts when establishing a performance standard. Discussing the application of CEQA to TMDLs, the State Board has acknowledged that "numeric targets and load allocations would probably fall into the category of performance standards." Thus, CEQA requires that the Regional Board should detail the likely methods and costs of compliance with the proposed TMDL.

In addition to these California requirements, the U.S. EPA has published guidelines for the preparation of TMDLs in California.[1] In particular, the EPA states that the State may consider a mix of allocation criteria (see Technical Support Document for Water Quality Based Permit Decisions (EPA, 1991) for more information). These criteria include technical and engineering feasibility, cost or relative cost, economic impacts/benefits, cost effectiveness and fairness/equity. Based on the Staff Report, there is no evidence that staff considered any of these factors in developing the TMDL.

It is worth noting that under federal law, economics can be considered in the basin planning process in designating potential beneficial uses. Specifically, the federal water quality standards regulations allow a state to dedesignate, to decide not to designate, or to establish a subcategory of a potential beneficial use on economic grounds. To rely on this basis, the state must demonstrate that attaining the use is infeasible
