Another point to consider in biomarker choice is temporality: is the biomarker an adequate indicator of exposure during critical developmental windows? NRC noted that cord-blood mercury tends to reflect exposure in the later stages of pregnancy, whereas hair mercury can be used to determine exposure at any point in pregnancy, given the appropriate sample. The NRC panel noted that for most assessment of hair mercury there will be significant uncertainty when attempting to relate a particular

hair level to a time-specific dose to the fetal brain. In addition, there is no information on differential effects of methylmercury at different periods of gestation; it is in no way certain when critical developmental windows occur. Considering the information (or lack thereof) on time of exposure offered by each biomarker, there is no compelling reason to consider one more appropriate than the other.

NRC provided a table (Table 6-1, NRC, 2000, p. 253) that compares test performance associated with mercury concentration as a function of either cord-blood or maternal hair measurement. This comparison suggests that the cord-blood measure explains more of the variability in more of the outcomes than does maternal hair mercury.

In selecting the exposure metric, the above factors were considered. Cord blood is the biomarker most closely linked (at least conceptually) to the target organ. Cord blood is the marker for which there are the most associated adverse effects in the Faroes study. Neither cord-blood nor maternal hair mercury (as generally measured) provides a clear advantage in assessing exposure during putative critical developmental windows. Maternal hair mercury is conceptually closer to maternal ingested dose than is the cord-blood compartment. However, sensitivity analyses indicate that the maternal hair:maternal blood ratio is a key contributor to variability in calculations of ingested dose (Stern,1997; Clewell et al., 1999). On balance, the best choice for exposure metric for RfD calculation is cord-blood mercury.

4.3.3 Choice of BMD

In applying a BMD approach to data that are continuous in effect, there are several interdependent steps as defined by Gaylor and Slikker (1992). The first is to fit a regression model that characterizes the mean of the set of outcome measurements as a function of dose; the assumption of a normal distribution is made. (Choice of model is described in Section 4.3.4). The second step is to define the cutoff for normal versus abnormal response. This cutoff point (x_0) is defined statistically. In the third step, the dose-specific probability of falling into the abnormal category is determined (P_0). One chooses a specific increase in the frequency of abnormal responses by comparison to background probability; this specific risk above background risk is the benchmark response, or BMR. The dose at which the BMR is reached is the BMD. In other words, the BMD is the dose that results in an increased probability of an abnormal test performance by a benchmark response; that is, from P_0 for an unexposed person to P_0 + BMR for a person exposed to the BMD. The last step is to calculate the BMDL or 95% lower limit on the BMD. Choices for P_0 and BMR are described below.

One could set P_0 based on clinical definitions of adverse response or other information. For example, long experience with birth weight in a population could prompt a choice of 2500 g as a cutoff for normal. Alternatively P_0 can be set as a fixed percentile of performance in the unexposed population. For a linear model and random error normally distributed with variance, this has the effect of setting P_0 at a specified number of standard deviations below the mean for the unexposed group. Generally the larger the P_0, the lower the BMD. For the analysis of the behavioral data, including the Faroe study, the NRC panel (NRC, 2000, p. 298) recommended that $P_0 = 0.05$: that is, that the cutoff for abnormal response be set at the lowest 5% (5^{th} percentile) of children. This means that the cutoff point (x_0) is defined by a probability of 5% in an unexposed population. It should be noted that specification of P_0 for the Faroese data (or the other human methylmercury studies) is somewhat problematic because there are no subjects with true zero exposure. The mean response rate at zero is not actually based on observed data but is extrapolated from the fitted model (Budtz-Jørgensen et al., 1999). Support for P_0 of 0.05 is found in Crump et al. (2000); the authors note that this choice is "suggested by the convention of considering 95% of the clinical responses in healthy individuals to define the normal range." EPA agrees that $P_0 = 0.05$ is a reasonable choice.

BMR is the benchmark response, the specific risk above background risk. In other risk assessments (mostly on quantal data) it has been set at 0.1, 0.05, or 0.01. In the MSRC, BMDs and BMDLs were calculated for BMRs of 0.1, 0.05, or 0.01. EPA chose to apply a BMR of 0.1 to the Iraqi data (MSRC volume V, pp. 6-27-6-28; U.S. EPA, 1997e). This was based on publications by Allen et al. (1994) that indicated that a 10% risk level roughly correlated with a NOAEL for developmental toxicity data from controlled animal studies. For a methylmercury RfD based on the Faroese data, NRC recommended that the BMR be set to 0.05, which would result in a doubling of the number of children with a response at the 5^{th} percentile of an unexposed population (NRC, 2000, pp. 283, 298).

The NRC panel felt that their choice of a P_0 of 0.05 and a BMR of 0.05 was justifiable in terms of being sufficiently protective of public health. The committee recognized, however, that the choice of P_0 and BMR is at the interface of science and policy and should be a science-informed policy judgment. EPA at this time has no established policy on an acceptable risk level for the effects reported in the Faroese children. EPA is in the process of publishing guidance on benchmark dose methodology and processes. Most of the experience that supports this guidance comes from assessment of toxicological

(animal) data. The guidance acknowledges that choices of model, and inputs such as P_0 and BMR, should be informed by a consideration of the type of data and the ancillary information on which the assessment is based. Our decision in the specific case of methylmercury is influenced by the public health conclusions that NRC articulated: the measured effects in the human studies are sentinels of adverse outcomes in children, related to their ability to learn and achieve success in educational settings. Thus, EPA accepts the NRC recommendation to set $P_0 = 0.05$ and BMR = 0.05 in this instance.

4.3.4 Choice of Model

A report prepared for EPA and subsequently published by Budtz-Jørgensen (1999) provided calculations of BMD and BMDL using square root and log transformations as well as calculations for K-power models. NRC used these results and similar calculations for the New Zealand and Seychelles studies to make some assessments of model suitability. They noted great variability in calculated BMDs and BMDLs as a function of model. This was so despite the inability of standard statistical assessments of model adequacy to distinguish between models. In response to NRC, Budtz-Jørgensen and colleagues provided some additional analyses. These were sensitivity analyses that repeated the regression models after omitting some of the highest observations (E. Budtz-Jørgensen, Copenhagen University, N. Keiding, Copenhagen University, and P. Grandjean, University of Southern Denmark, unpublished material, April 28, 2000, quoted in NRC, 2000, p. 293). Their results suggested that the influence of the extreme observations did not explain the model-to-model variability (NRC, 2000, p. 293).

NRC concluded that the most reliable and defensible results for the purpose of risk assessment are those based on the K-power model. (NRC, 2000, pp. 293-298). This model takes the following form, as presented in Budtz-Jørgensen et al. (2000):

$$\mu(d) = \beta \cdot d^K$$

where d is the child's mercury dose and K and β are parameters to be estimated. The K-power model was fit under the constraint that $K \geq 1$, so that supralinear models were ruled out. A power of 1 generally provided the best fit to the Faroese data (Budtz-Jørgensen et al., 2000). With K = 1, the above model is linear.

NRC observed that in situations where there are no internal controls (i.e., no unexposed individuals) and where the dose response is relatively flat, the data will often be fit equally well by

linear, square-root, and log models. The models can yield very different results for BMD calculations, however, because these calculations necessitate extrapolating to estimate the mean response at zero exposure level. Both the square-root and the log models take on a supralinear shape at low doses, leading to lower estimates of the BMD than do linear or K-power models. The mechanisms by which methylmercury exerts its neurotoxic effects in developing systems are speculative. However, no likely mode of action for methylmercury leads one to expect a supralinear dose-response at low dose. Thus, from a toxicological perspective, the K-power model has greater biological plausibility, because it allows for the dose-response to take on a sublinear form, if appropriate.

NRC pointed out that the model sensitivity for BMD from the Faroes data appears in conflict with the concept, put forward by Crump and others, that by estimating risks at moderate levels, such as 5% or 10%, the BMD should be relatively robust to model specification. Budtz-Jørgensen et al. (2000) responded that this model dependence is a consequence of the lack of true controls (subjects with zero exposure). The majority of exposures in the Faroes resulted in hair mercury concentrations exceeding 5 ppm (or 24 ppb cord blood). The interquartile range for hair mercury was 3 to 8 ppm (13 to 40 ppb for cord blood) (Grandjean et al., 1992). Models fit to the Faroese data are in effect capturing the shape of the dose-response in this middle range of exposure. The NRC report Figure 7-5, taken from Budtz-Jørgensen et al. (1999), shows dose-response curves fitted to hair mercury data for the linear, square-root, and log transformations. Budtz-Jørgensen et al. (2000) provided some information on model fit. They did not present goodness-of-fit statistics *per se*, but rather tested each model against an expanded model that included both the linear and logarithmic term. The authors observed that for $P_0 = 0.05$, and with cord blood as the exposure metric, the logarithmic transformation tended to show a better fit than the linear model for the following tests: CPT, BNT, and CVLT. There was no difference in fit for the Finger Tapping and Bender Gestalt test or for any of the five tests when maternal hair mercury was the biomarker. The NRC notes that variations in estimated BMDs are not explained by differences in how well the models fit the bulk of the data, but rather by what the models predict for the mean response for unexposed individuals.

In reaching its conclusion on model choice, NRC concluded that biologically based arguments were needed. The argument was as follows:

> One useful way to think of differences between the various models is that the linear model implicitly assumes an additive effect of Hg exposure, the log model assumes a multiplicative effect, and the square root lies somewhere in between. All three models fit essentially equally well to data that for the most part correspond to concentrations between 2 and 20 ppm in hair. However, the models differ fairly dramatically with regard to

how they extrapolate to values below those levels. The linear model would predict that the change in mean outcome as MeHg concentration goes from 0 to 10 ppm in hair should be the same as the change observed in the mean outcome as concentration increases from 10 to 20 ppm. In contrast, the log model would predict that the change in mean outcome associated with any doubling of MeHg concentration should be the same as the change observed in the mean outcome as concentration increases from 10 to 20 ppm. Thus, the log model would predict that the same magnitude change in outcome would be expected as the concentration goes from 1 to 2 ppm or from 4 to 8 ppm as that observed for the concentration going from 10 to 20 ppm—that is, the extrapolation down to zero exposure will predict a very steep slope at low doses. Given the relative absence of exposures at very low levels, a decision should be made on biological grounds regarding which model makes the most sense for risk assessment. The committee believes that an additive (linear) or perhaps sublinear model is the most justifiable from a biological perspective, thus ruling out square-root and log-transformed models. For MeHg, the committee believes that a good argument can be made for the use of a K-power model with K constrained to be greater than or equal to 1 (NRC, 2000 p. 297).

4.3.6 Selection of the Point of Departure for the RfD

Based on all considerations in the preceding sections, the following is selected as the basis for the RfD. Our choice is a benchmark approach using the results of the Faroese tests with significant associations with cord-blood mercury. As an example, the BNT results for the whole cohort are used. The K-power model ($K \geq 1$ to eliminate supralinearity) is the model choice, with $P_0 = 0.05$ and BMR = 0.05. Consistent with other uses of BMD, the 95% lower limit or BMDL is used as the point of departure for the RfD.

The result for the example calculation is a BMD of 85 ppb and a BMDL of 58 ppb; other BMDs and BMDLs are given in Table 4-8.

4.4 DOSE CONVERSION

The biomarker of choice for the Faroes data was cord blood and the BMDLs were presented in units of ppb mercury in cord blood. In order to calculate an RfD, it is necessary to convert this figure to an ingested daily amount that would result in exposure to the developing fetus at the BMDL level in terms of ppb mercury in blood. NRC (2000) offered advice on the use of these dose-conversion procedures.

4.4.1 PBPK Models Versus One-Compartment Model

In estimating the 1995 RfD, EPA used a one-compartment model. Since publication of the MSRC, there have been evaluations of the use of this model and the parameter inputs as well as the discussion of PBPK models for methylmercury. None of the existing models deal specifically with young children, nor are there data on methylmercury pharmacokinetics in children.

NRC briefly discussed the PBPK model published by Clewell et al. (1999). This model includes several fetal compartments that could be considered fetal submodels. NRC noted that this model is conceptually more accurate and flexible than the one-compartment model. The report also notes that the complexity of the model makes evaluation of it more problematic (NRC, 2000, p. 84). Moreover, given the state of the data on methylmercury exposure, it would be necessary to use default values for some model inputs. These factors add to the overall uncertainty in the use of this or any of the other available PBPK models for methylmercury. EPA has chosen to use the one-compartment model for dose conversion for this RfD. This model has shown reasonably good fit to data on mercury blood level changes in human subjects during and after consumption of methylmercury-contaminated fish (Ginsberg and Toal, 2000). It has been used by other public health agencies such as WHO and ATSDR (1999).

4.4.2 One-Compartment Model for Methylmercury

4.4.2.1 Description of Model

The model is described by the formula below:

$$d\ \mu g/day = \frac{c \times b \times V}{A \times f}$$

where

d = daily dietary intake (expressed as μg of methylmercury)
c = concentration in blood (expressed as μg/L)
b = elimination constant (expressed as $days^{-1}$)
V = volume of blood in the body (expressed as liters)
A = absorption factor (expressed as a unitless decimal fraction)
f = fraction of daily intake taken up by blood (unitless).

The following form of the equation expresses d in units of μg/kg body weight/day.

$$d = \frac{c \times b \times V}{A \times f \times bw}$$

where

bw = body weight (expressed in kg).

In this one-compartment model, all maternal compartments are compressed to one: namely, blood. It is assumed that the blood methylmercury concentration is at steady state. This assumption constitutes an area of uncertainty with the use of this model. One could either assume that the methylmercury concentrations of fetal blood and maternal blood are the same or adjust the cord-blood concentration to maternal levels using an empirically derived factor. There are some published indications that mercury in cord blood is higher than in maternal blood (for example, Dennis and Fehr, 1975: Pitkin et al., 1976; Kuhnert et al., 1981). Other publications show that there is no difference in concentration (for example, Fujita and Takabatake, 1977; Sikorski et al., 1989). EPA has chosen to assume that maternal blood mercury is at the same level as fetal or cord blood and acknowledges that this is an additional area of uncertainty in the dose conversion. This is discussed in Section 4.5.4.1.

4.4.2.2 Choice of Parameter Inputs—Distributions Versus Point Estimates

NRC presents an analysis of uncertainty and variability in the values to be used in the equation above (NRC, 2000, pp. 83-95). Although there are data from human studies that form the basis of the parameter estimates, it is clear that there is variability (and uncertainty) in these estimates. NRC notes that each of the model parameters is a random variable best described by a probability distribution. The ingested methylmercury concentration that leads to the benchmark cord-blood concentration is also a probability distribution determined by the combination of the distributions of the individual parameters. NRC cited two analyses of the variability and uncertainty in the ingested dose estimates based on the one-compartment model applied to maternal hair (Stern, 1997; Swartout and Rice, 2000) as well as similar analysis of a PBPK model (Clewell et al., 1999). Table 4-9 reproduces NRC's compilation of those analyses. In this table NRC also presented results of analyses that took maternal blood as the starting point, rather than maternal hair as was done in the published papers.

In 1995, EPA used central tendency estimates (or point estimates intended to reflect central tendency estimates) for all parameter inputs in the RfD dose conversion. Although this is a reasonable approach, it does not encompass the range of likely parameter values or the range of estimated ingestion values. The RfD is not intended to protect only the mid-part of a population, but the whole population including sensitive subgroups. Thus, if one chooses to use central tendency or point estimates in the dose

Table 4-9. Comparison of Results from Three Analyses of the Interindividual Variability in the Ingested Dose of MeHg Corresponding to a Given Maternal-Hair or Blood Hg Concentration

Study	Maternal medium	50th percentile[a] (μg/kg-d)	50th percentile/ 5th[b] percentile	50th percentile/ 1st percentile[c]
Stern (1997)	Hair	0.03-0.05[d]	1.8-2.4	2.3-3.3
		(mean = 0.04)	(mean = 2.1)	(mean = 2.7)
	Blood	0.01	1.5-2.2	1.7-3.0
			(mean = 1.8)	(mean = 2.4)
Swartout and Rice (2000)	Hair	0.08	2.2	Data not reported
	Blood[e]	0.02	2.1	2.8
Clewell et al. (1999)	Hair	0.08	1.5	1.8
	Blood[f]	0.07	1.4	1.7

[a]Predicted 50th percentile of the ingested dose of methylmercury that corresponds to 1 ppm Hg in hair or 1 ppb in blood.
[b]Ratio of 50th percentile of ingested dose of methylmercury that corresponds to 1 ppm Hg in hair or 1 ppb in blood to the 5th percentile.
[c]Ratio of 50th percentile of ingested dose of methylmercury that corresponds to 1 ppm Hg in hair or 1 ppb in blood to the 1st percentile.
[d]Range reflects minimum and maximum values among eight alternative analyses.
[e]Data from J. Swartout, U.S. Environmental Protection Agency, personal commun.; June 9, 2000.
[f]Data from H.J. Clewell, ICF Consulting, personal commun.; April 19, 2000.

conversion, it is necessary to include a UF in the final RfD calculation to ensure that pharmacokinetic variability is appropriately factored into the consideration of sensitive subgroups.

The choice of UF can be informed by the analyses of variability presented by NRC. In general, all three analyses found similar ranges of variability due to pharmacokinetic factors. The ratios of estimated ingested doses at the 50th percentile/99th percentile ranged from 1.7 to 3.3. If one considers only the estimates using maternal blood as the starting point, then the range for all three studies is 1.7 to 3.0. NRC noted that variability was higher when maternal hair, rather than blood mercury was the biomarker used. In 1997, EPA identified the hair-to-blood ratio as a major contributor to the variability (and thus uncertainty) in estimating the ingested dose and in the RfD based on it. This provides an additional rationale for use of the cord-blood-based BMD.

In determining the methylmercury RfD, EPA chooses to use point estimates, rather than distributions, in the dose conversion and to account for uncertainty by application of a numerical UF. This UF considers the probability distribution that relates biomarker concentration and ingested dose (see Section 4.5). This approach was recommended in the NRC report. NRC notes that use of parameter distributions and an ingested dose distribution (the "direct approach") does not eliminate uncertainty. In the direct approach, one would select an ingested dose corresponding to a BMD blood mercury concentration for the percentile of the population variability that is to be accounted for; that is, one would select the 95th or 99th (or some other suitable) percentile. The choice must be made among probability distributions predicted by analyses such as those done by Stern (1997) and Swartout and Rice (2000). NRC said that "the differences in the analyses are due to the use of different data sets for parameter estimates, and there is no clear basis for choosing one data set over another. Even when central-tendency estimates and uncertainty factors are used, the most appropriate value for each model parameter must be selected. Selection of different values for model parameters could underlie differences in the modeling results" (NRC, 2000, pp. 94-95).

EPA chooses to make explicit choices for each dose-conversion parameter and to deal with both the uncertainty and variability implicit in those choices by the application of a UF in the calculation of the RfD.

4.4.2.3 Choice of Parameter Inputs—Values for One-Compartment Model Terms

NRC recommended (NRC, 2000, p. 95), that in choices of point estimates EPA should consider the information and analyses in three publications: Stern (1997), Swartout and Rice (2000), and Clewell et al. (1999). All are recent contributions to the peer-reviewed literature. In addition, Swartout and Rice (2000) largely comprises analyses that received extensive scientific review as part of the MSRC (U.S. EPA, 1997e). EPA found little in Clewell et al. (1999) that could be used directly to make parameter estimates, but rather used data and analyses from the other two papers. The rationales for use of specific values for equation parameters follow.

Concentration in blood (c)

The concentration in blood is that corresponding to the BMDL (58 ppb in the example). As noted above, no numerical change is made to account for any potential differences between maternal blood mercury level and cord-blood concentration.

Fraction of mercury in diet that is absorbed (A)

After administration of radiolabeled methylmercuric nitrate in water to three healthy volunteers, uptake was reported to be >95% (Aberg et al., 1969). This value is supported by experiments in human volunteers conducted by Miettinen et al. (1971). These researchers incubated fish liver homogenate with radiolabeled methylmercury nitrate to produce methylmercury proteinate. The proteinate was then fed to fish for a week; the fish were killed, cooked, and fed to volunteers after confirmation of methylmercury concentration. The authors reported that the fraction of the administered dose not excreted in the feces within 3 to 4 days ranged from 91.2% to 97.0% with a mean of 94%. This fraction was assumed to be the amount absorbed; it probably includes some inorganic mercury formed from the ingested methylmercury and subsequently excreted. Stern (1997) noted that this method is most likely to result in an underestimate. It is generally felt that absorption of ingested methylmercury is high and not likely to vary a great deal. Use of an absorption factor of 0.95 as was done in the MSRC is reasonable.

Fraction of the absorbed dose that is found in the blood (f)

The MSRC notes that in 1995 EPA used data from Kershaw et al. (1980), Miettinen et al. (1971), and Sherlock et al. (1984) as the basis for the choice of a value of 0.05 (U.S. EPA, 1997e).

There are currently four published reports of the fraction of absorbed methylmercury dose distributed to blood volume in humans. Kershaw et al. (1980) reported an average fraction of 5.9% of absorbed dose in total blood volume, based on a study of five adult male subjects who ingested methylmercury-contaminated tuna. In a group of nine male and six female volunteers who had received ^{203}Hg-methylmercury in fish, approximately 10% of the total mercury body burden was present in 1 L of blood in the first few days after exposure; this dropped to approximately 5% over the first 100 days (Miettinen et al., 1971). In another study, an average value of 1.14% for the percentage of absorbed dose per kg of blood was derived from data on subjects who consumed a known amount of methylmercury in fish over a 3-month period (Sherlock et al., 1984). Average daily intake in the study ranged from 43 to 233 µg/day, and there was a dose-related effect on percentage of absorbed dose that ranged from 1.03% to 1.26% in 1 L of blood. Smith et al. (1994) administered radiolabeled methylmercury to seven subjects. The paper presented published modeled data rather than observations; the mean fraction of absorbed dose in blood was 7.7% (SD, 0.88%).

Stern (1997) noted that although the Smith et al. (1994) and Kershaw et al. (1980) data could be fit by a log-normal distribution, the data sets were too small for a reasonable determination of the

underlying distributions. Stern used the mean and standard deviation of those two data sets for average parameter values as inputs to the log-normal distribution; the average of the means is 0.067. Swartout and Rice (2000) used the observations published by Kershaw et al. (1980), Miettinen et al. (1971), and Sherlock et al. (1984) as adjusted for 5 L of blood as inputs with a log-triangular distribution. The median value was 5.9% or 0.059, close to the values of 0.05 used in the MSRC and by other groups (e.g., Berglund et al., 1971, and WHO, 1990).

ATSDR (1999) used a factor of 0.05. They noted that estimates of f for the 6 women from the study by Sherlock et al. (1984) had an average value of 0.048, as compared with the value of 0.059 for the 14 men in the same study. ATSDR offered the opinion that these data suggest f may be lower for women than men. Apparently the study by Miettinen et al. (1971) included six female volunteers (in addition to nine males), though ATSDR did not comment on whether these data similarly provided any indication that the fraction daily intake taken up by blood was lower for females. It is not likely that any of the female subjects were pregnant. Sherlock et al. (1984) published a negative correlation between f and body weight; thus, if this is generalizable, one would expect f to decrease (as V increases) throughout pregnancy.

EPA chooses to use the median value of 0.059 published by Swartout and Rice (2000) for f in the dose conversion.

Elimination constant (b)

Currently, five studies report clearance half-times for methylmercury from blood or hair: Miettinen et al. (1971), Kershaw et al. (1980), Al-Shahristani et al. (1974), Sherlock et al. (1984), and Smith et al. (1994). The clearance half-lives for blood in these reports are quite variable, ranging from 32 to 189 days. In the Al-Shahristani et al. (1974) study, 10% of the sample population had mercury half-lives of 110 to 120 days. Average mercury half-lives from the five publications are 45 to 70 days. The MSRC (U.S. EPA, 1997e) used an average elimination constant from four of the studies (data from Smith et al. [1994] were not used). The corresponding elimination constant of 0.014 was also noted to be the average of individual values reported for 20 volunteers ingesting from 42 to 233 µg mercury/day in fish for 3 months (Sherlock et al., 1982).

Swartout and Rice (2000) applied a log-triangular distribution to the data from the five extant studies. They note that the distribution is highly skewed and that the median is 53 days; the corresponding elimination constant is 0.013.

Stern (1997) discussed the variability in the data sets. His analysis of variance indicated significant differences among the sets, which were eliminated when the Al-Shahristani data were removed. The author observed that the half-lives reported by Al-Shahristani are larger than those observed in the other studies. Stern offers the opinion that this may be due to the relatively large size of the Al-Shahristani data set by comparison to the others. Stern says that an alternative explanation is that the Al-Shahristani data reflect a genetic polymorphism in the metabolism occurring with higher frequency in the Iraqi population, which was the subject of this study. In his analyses, Stern (1997) treated the Al-Shahristani data both separately and in combination with the data from the other four studies. He reports a mean elimination constant of 0.011 for Al-Shahristani data alone; the combined data set mean elimination constant is 0.014.

The decision to select point estimates for dose conversion parameters was done with the acknowledgment that some of the variability around these parameters would be truncated. This is being compensated for by the use of a pharmacokinetic uncertainty factor. Nevertheless, it does not seem prudent to select a point estimate, which is meant to be reflective of population central tendency, from one data set only. The two central tendency estimates of Swartout and Rice (2000) and Stern (1997) are very close in value (0.013 versus 0.014); the differences are presumably due to the application of different distribution types. The value of 0.014 is used for b in the dose conversion.

Volume of blood in the body (V)

In the MSRC (U.S. EPA, 1997e), blood volume was estimated, as there were no data from the study population (the 81 pregnant women exposed in the poisoning episode in Iraq). It was noted then that blood volume is 7% of body weight, as determined by various experimental methods. MSRC assumed an increase of 20% to 30% (to about 8.5% to 9%) during pregnancy on the basis of the publication by Best (1961). Specific data for the body weight of Iraqi women were not found. Assuming an average body weight of 58 kg and a blood volume increase of 9% during pregnancy, a blood volume of 5.22 L was derived and was rounded to 5 L for the dose conversion.

Stern (1997) cited three studies (Brown et al., 1962; Retzlaff et al., 1969; Huff and Feller, 1956) wherein correlation of body weight and blood volume were demonstrated. All studies were of U.S. women, presumably not pregnant at the time of the study. The mean blood volumes for each study were 3.58 L, 3.76 L, and 3.49 L, respectively; the mean of the combined data set is 3.61 L. If one assumes a 30% increase in blood volume with pregnancy, this would be 4.67 L.

In their analysis, Swartout and Rice (2000) used data from a cohort of 20 pregnant Nigerian women (Harrison, 1966). Whole-blood volumes in the third trimester ranged from 4 to 6 L; the mean and median were both 5 L. Although 5 L is somewhat higher than the blood volume estimated from three studies of U.S. women, it is a reasonable value to use for *V*.

Body weight (bw)

The MSRC found no data on body weight for the study population and used a default value of 60 kg (rounded from 58) for an adult female (U.S. EPA, 1997e). Swartout and Rice (2000) in their distributional analysis used the body weight data collected on the cohort of 20 pregnant Nigerian women (Harrison, 1966); this was the data set that they used for blood volume. Body weight during the third trimester of pregnancy ranged from 49.5 kg to 73.9 kg, with a geometric mean of 55 kg. Stern (1997) used the Third National Health and Nutritional Survey (NHANES III) data for women 18 to 40 years old (National Center for Health Statistics, 1995). The mean weight was 66.6 kg and the 50th percentile value was 62.8 kg. The EPA Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (U.S. EPA, 2000a) also cites NHANES III data; in the Agency document, women of childbearing age were considered to be between the ages of 15 and 44 years old. The median body weight in this group was 63.2 kg and the mean was 67.3 kg. EPA also cites the earlier analyses of Ershow and Canter (1989); they do not state the age range but give a median of 64.4 kg and a mean of 65.8 kg. The recommendation in the EPA Methodology was to use a body weight value of 67 kg for a pregnant woman on the basis of the relatively current data from NHANES III. This is the value used for body weight in the dose conversion.

4.4.2.4 Dose Conversion Using the One-Compartment Model

The parameter values are as follows:

c	=	concentration in blood (expressed as 58 μg/L)
b	=	elimination constant (expressed as 0.014 $days^{-1}$)
V	=	volume of blood in the body (expressed as 5 L)
A	=	absorption factor (expressed as 0.95, unitless decimal fraction)
f	=	fraction of daily intake taken up by blood (0.059, unitless)
bw	=	body weight (expressed as 67 kg)

$$d = \frac{c \times b \times V}{A \times f \times bw}$$

$$d = \frac{58\ \mu g/L \times 0.014\ days^{-1} \times 5L}{0.95 \times 0.059 \times 67\ kg}$$

$$d = 1.081\ \mu g/kg\text{-}day$$

rounded to 1.0 μg/kg/day. Other BMDLs expressed as ingested maternal dose can be found in Table 4-8.

4.5 CHOICE OF UNCERTAINTY FACTOR

4.5.1 Background

The RfD can be considered a threshold for a population at which it is unlikely that adverse effects will be observed. In estimating this level from either a NOAEL or a BMD, the risk assessor applies uncertainty factors; these are used to deal with both experimental and population variability and with lack of information that results in uncertainty in the risk estimate. For a discussion of uncertainty factors, refer to the Technical Support Document for Risk Assessment, Human Health Methodology for Ambient Water Quality Criteria (U.S. EPA, 2000g).

In the MSRC, EPA published qualitative discussions and quantitative analyses of uncertainty and variability in the RfD based on the Iraqi data (U.S. EPA, 1997e,g). Major sources of uncertainty identified were these: variability in susceptibility within the study cohort, variability in pharmacokinetic parameters for methylmercury (particularly biological half-life of methylmercury and the hair-to-blood ratio for mercury), response classification error, and lack of data on long term sequelae of *in utero* exposure. At that time a composite UF of 10 was applied to account for these factors and the EPA policy choice to use a UF in the absence of a two-generation reproductive bioassay.

NRC considered areas of uncertainty and variability relevant to the generation of an RfD based on data from the Faroes population and given the current state of the databases on both pharmacokinetics and effects of methylmercury. The panel concluded that not all sources of uncertainty or variability require addition of numerical UFs. NRC (NRC, 2000, p. 319) suggests that given the state of the human data on methylmercury, UFs be considered for two reasons:

- If the uncertainty could result in underestimation of the adverse effects of methylmercury exposure on human health.

- If there is reason to suspect that the U.S. population is more sensitive than the study populations to the adverse effects of methylmercury.

NRC's recommendation was that a UF of at least 10 be applied to a BMD calculated from the BNT results from the Faroe Islands study (NRC, 2000, pp. 321-322). EPA is in general agreement with NRC's conclusions and recommendations and considered them in the choice of the numerical UF. EPA's choice is to consider the RfD to be based on the group of Faroese neuropsychological measures associated with cord-blood mercury; the areas of uncertainty and variability are the same for the choice of one test result (e.g., BNT whole cohort) or the group of test results. Descriptions of areas of uncertainty and variability and choice of UF are in the following sections.

4.5.2 Toxicodynamics

Individual response to methylmercury can vary as a function of many factors: age, gender, genetic makeup, health status, nutritional influences (including interaction among dietary components), and general individual toxicodynamic variability. Individual sensitivity has been noted in the published human studies; NRC cited the example of members of the Iraqi population who seemed insensitive to high levels of mercury exposure. EPA believes there are insufficient data to conclude that the U.S. population is more or less sensitive than the reported human study populations. The U.S. population is extraordinarily diverse by any measures listed above, certainly by comparison to the Faroese population. The Faroese population is northern Caucasian, has been relatively isolated, and is thought to be descended from a small number of so-called founders who settled the islands many generations ago. In the heterogeneous U.S. population, it is entirely likely that there are individuals both more and less sensitive to methylmercury toxicity than the cohort studied in the Faroes. As the RfD must be calculated to include sensitive subpopulations, variability in response to mercury is a consideration. EPA believes there are insufficient data to support a quantitative analysis of this area of variability and uncertainty for methylmercury, but that toxicodynamic variability must be considered in the determination of the overall uncertainty factor.

4.5.3 Exposure Estimation as an Area of Uncertainty

Limitations in evaluation of exposure can be an additional source of uncertainty. As the RfD is based on a developmental outcome, there is particular concern for uncertainty in the linkage between time and intensity of exposure and critical periods of brain development. As noted before, cord-blood mercury generally reflects mercury exposure during late pregnancy and does not reflect temporal variability in exposure level. Use of any biomarker of methylmercury exposure can result in misclassification of exposure. Generally, exposure misclassification presents a bias to the null; that is, this source of error leads to decreased ability to detect a real effect. To the degree that there is exposure misclassification in the critical study, it would be expected to result in underestimation of the methylmercury effect. At this time there are not data to support a quantitative determination of this area of uncertainty.

4.5.4 Pharmacokinetic Variability

4.5.4.1 Cord:Maternal Blood Ratios

In its use of the one-compartment model for dose conversion, EPA chose to make no adjustment for potential differences between fetal and maternal blood mercury levels. Investigators have found that the placenta is not a barrier to the transfer of methylmercury from the mother to the developing fetus. Typically, there is a strong correlation between maternal blood mercury concentrations and fetal blood mercury concentrations, as shown by cord blood.

Review of the literature identified 21 studies that reported cord blood mercury and maternal blood mercury data (Amin-Zaki et al., 1974; Baglan et al., 1974; Dennis and Fehr, 1975; Pitkin et al., 1976; Kuhnert et al., 1981; Nishima et al., 1977; Lauwerys et al., 1978; Fujita and Takabatake, 1977; Kuntz et al., 1982; Tsuchiya et al., 1984; Truska et al., 1989; Sikiorski et al., 1989; Hansen et al., 1990; Soong et al., 1991; Soria et al., 1992; Ong et al., 1993; Akagi et al., 1997; Yang et al 1997; Ramirez et al., 2000; Bjerregaard and Hansen, 2000; Vahter et al., 2000). Twenty of the studies provided data in a format that could be compared with one another. The exception is Truska et al. (1989), whose published data were based on erythrocyte mercury concentrations without reported hematocrit values. Absence of these values precluded expressing mercury concentration on a μg/L or ppb whole-blood basis.

Data from 18 of the 20 studies (with a combined total of 2,676 maternal and 2,522 cord-blood samples) indicated that cord-blood mercury concentration exceeded maternal-blood mercury

concentration. Mean values ranged from a ratio of 1.04 (Fujita and Takabatake, 1977) to 2.63 (Amin-Zaki et al., 1974); the average of mean ratios was 1.55. Two studies reported cord:maternal blood ratios equal to or less than 1. Kuntz et al. (1982) (based on 57 maternal-cord blood pairs) and Sikorski et al. (1989) (based on 56 maternal-cord blood pairs) reported cord/maternal blood mercury concentration of 1.0 and 0.83, respectively.

Speciated mercury measurements were performed in 9 studies that included 550 maternal and 526 cord-blood samples. This permitted calculation of the ratios of cord blood methylmercury:maternal blood methylmercury that are presented in Table 4-10. In all nine studies, the mean values for methylmercury concentration was higher for cord blood than maternal blood. The number of subjects in these 9 studies ranged from 9 to 226 pregnant woman-fetal pairs. To deal with this variation in *n*, Table 4-10 reports both a simple average of mean ratios (cord methylmercury:maternal methylmercury = 1.68) and the mean ratio weighted by the number of subjects in the study (ratio =1.73).

Overall, these data indicate that cord-blood mercury is higher than maternal-blood mercury. The composite ratio from the studies reporting methylmercury concentrations indicates that the cord blood:maternal blood ratio is around 1.7. These values are ratios of means and do not reflect the full range of variability in the individual mother-fetal pairs. Vahter et al. (2000 reported the 5th and 95th percentiles of cord:maternal Hg to be 0.88 and 3.1. Individual data were available from Fujita and Takabatake (1997); ratios calculated from these data ranged from 0.78 to 4.36.

As indicated in Section 4.4.2.1, EPA chooses not to make a numerical adjustment between cord-blood and maternal-blood mercury. Such an adjustment factor would best be calculated after evaluation of data quality and variability within and between studies. EPA feels that this analysis would be an important contribution to reducing uncertainty in the RfD. At this time the relationship between cord blood and maternal-blood mercury is considered an area of uncertainty to be included in the determination of the UF.

Table 4-10. Ratio of Cord to Maternal Blood Methylmercury

Investigator	Number of Subjects	Ratio of Cord:Maternal Blood
Nishima et al., 1977	49 maternal, 49 fetal	2.17
Kuhnert et al., 1981	29 maternal, 29 fetal	1.34
Tsuchiya et al., 1984	226 maternal, 226 fetal	1.60
Hansen et al., 1990	37 maternal, 37 fetal	2.11
Soria et al., 1992	19 maternal, 19 fetal	1.08
Ong et al., 1993	29 maternal, 29 fetal	1.65
Akagi et al., 1997	21 maternal, 21 fetal	1.75
Yang et al., 1997	9 maternal controls, 9 fetal controls; 9 occupationally exposed mothers, 9 occupationally exposed fetuses.	1.67 - controls 1.39 - occupationally exposed
Vahter et al., 2000	112 maternal (gestation week 36), 98 fetal	1.92
Arithmetic mean of average ratios of cord:maternal methylmercury		1.68
Mean weighted by number of subjects for cord:maternal blood methylmercury		1.73

4.5.4.2 Other Areas of Pharmacokinetic Variability

There is no specific evidence of genetic polymorphisms that affect methylmercury metabolism or excretion. Human studies have established, however, that there is great variability in some of the factors affecting the delivery of ingested methylmercury to target organs. The MSRC sensitivity analysis and the publication by Swartout and Rice (2000) noted that the greatest variability resided in the hair:blood ratio (not a factor in the current dose conversion), the fraction of absorbed methylmercury found in blood (*f*), and the half-life of methylmercury in blood (the reciprocal, *b*, in the current dose conversion).

NRC presented an analysis of methods of ingested dose reconstruction from biomarker measurements. NRC noted that cord-blood mercury is closely linked kinetically to the fetal brain compartment but less closely linked to ingested dose. As described in Section 4.4.2 of this document, EPA chose a one-compartment model and measures of cord-blood mercury for back-calculation of the ingested dose of mercury. EPA also chose to use central tendency estimates for the parameters of the one-compartment model, rather than introduce an additional degree of uncertainty inherent in making choices of distribution shapes and the portion of the distribution that represents a sensitive population.

NRC presented analyses of uncertainty around dose-conversion estimates, which are summarized in Table 4-9 in Section 4.5.2.2. NRC discussed three independent analyses to characterize toxicokinetic variability in estimates of ingested dose corresponding to a BMD level in a particular biomarker, whether maternal hair or cord blood (NRC, 2000, pp. 91-95). These analyses were published by Stern (1997), Swartout and Rice (2000, after their work on EPA 1997), and Clewell et al. (1999). Each analysis used Monte Carlo simulation to combine probability distributions for each parameter of the model. For Stern (1997) and Swartout and Rice (2000), this was the one-compartment model shown in Section 4.4.2.1. Clewell et al. (1999) used a PBPK model with a fetal submodel. The analyses of the one-compartment model were done in a similar fashion; distributions for model parameters were determined from the published literature, and shapes of the distributions were set by the authors. Both analyses assumed correlations between some model parameters. Stern (1997) assumed that blood volume and body weight were correlated. Swartout and Rice (2000) made that assumption, as well as these correlations: hair-to-blood ratio and elimination rate constant, and fraction of absorbed dose in blood and body weight. The analysis based on the PBPK model also used parameter distribution values from the literature but included many more parameters than the one-compartment model (and more default distributions for model parameters).

The three published analyses all took maternal hair mercury as their starting point. NRC asked all three sets of authors to provide analyses of variability that used maternal blood as the starting point (as a surrogate for cord blood). These analyses were done by removing the hair:blood ratio from the model and running the Monte Carlo simulations.

Table 4-9 presents median estimates of ingested dose corresponding to 1 ppm maternal hair or 1 ppb maternal blood. Useful points of comparison are the ratios between the 50th percentile estimates and those at the end of the distribution (5th and 1st percentiles). Table 4-9 shows that using maternal blood as a starting point, the ratios of 50th percentile:1st percentile estimates ranges from 1.7 to 3.0. EPA's interpretation is that a factor of 3 will cover the toxicokinetic variability of 99% of the population. The uncertainty introduced by assuming cord-blood mercury is equivalent to maternal mercury provides additional justification for a toxicokinetic UF of 3. The choice of a factor of 3 is consistent with the standard EPA practice of a using a half-log to account for toxicokinetic variability.

4.5.5 Uncertainty in Choice of Critical Effect

Another critical area discussed by NRC is uncertainty around choice of a critical effect. NRC notes that developmental neurotoxicity is a sensitive indicator of methylmercury toxicity but that there is some

uncertainty as to the likelihood of other effects occurring at even lower levels of exposure. They cite indications of cardiovascular effects as well as neurotoxic effects uncovered later in life.

EPA agrees that there is a degree of uncertainty in our choice of critical effect; EPA believes this is not currently amenable to quantitative estimation but must be considered in the setting of the uncertainty factor. Summarized below are observations that support a concern that developmental neurotoxicity may not be the most sensitive indicator of methylmercury effects.

4.5.5.1 Cardiovascular Effects

There are some human data linking cardiovascular effects with exposure to elemental, inorganic, and organic forms of mercury. In addition, there are two recently published studies that show an association between low-level methylmercury exposure and cardiovascular effects. Sørensen et al. (1999) reported that in a study of 1,000 7-year-old Faroese children, diastolic and systolic blood pressures increased by 13.9 and 14.6 mm Hg, respectively, as the cord-blood mercury increased from 1 to 10 μg/L. They also reported a 47% decrease in heart rate variability (an indication of cardiac autonomic control) for the same increase in cord-blood mercury. Salonen et al. (1995) reported effects in adults from a study of 1,833 Finnish men. Over the 7-year observation period, men with hair mercury in the highest tertile (2 ppm or higher) had a 2.0 times greater risk of acute myocardial infarction than the rest of the study population.

As indicated by the Salonen (1995) study, the relatively subtle effects of methylmercury on cardiovascular indices can have public health implications. There is an analogous situation with lead exposure. Pirkle et al. (1985) reported on analyses of NHANES II data comparing the relationship between systolic and diastolic blood pressure to blood lead levels. They included in their model the 37% decrease in mean blood lead levels that was observed in white adult males between 1976 and 1980. Their calculation predicted a 4.7% decrease in the incidence of fatal and nonfatal myocardial infarction over 10 years, a 6.7% decrease in the incidence of fatal and nonfatal strokes over 10 years, and a 5.5% decrease in the incidence of death from all causes over 11.5 years.

4.5.5.2 Persistent and Delayed Neurotoxicity

Another area of concern is the onset or exacerbation of neurological deficits in aging populations exposed *in utero* or as children. There are indications of this in the followup studies of the Minamata population. These present evidence that neurological dysfunction among people who have been exposed

to methylmercury becomes more pronounced with aging. This heightened diminution of function is greater than that attributable to either age or methylmercury exposure alone. Specifically, Kinjo et al. (1993) surveyed 1,144 current patients with Minamata disease (MD) aged 40 or over and an equal number of neighbor controls matched by age and sex. MD patients have symptoms of sensory disturbance at a high prevalence rate (e.g., hypoesthesia of mouth, ~20% to 29% of subjects; hypoesthesia of limbs, ~66% to 90% of subjects; dysesthesia of limbs, ~83% to 93%; weakness, ~75% to 84%), but these problems did not systematically increase with age. However, the MD patients did show, as a function of age, increased difficulties in speaking, tremor, stumbling, and difficulties with buttoning, clothing, or hearing. Although such changes also occurred among controls, evaluation of odds ratios showed that the MD patients had higher prevalence rates than the controls for 18 separate problems including those specifically listed above. Also evaluated were "acts of daily living" (ADL) that included the abilities to independently eat, bathe, wash, dress, and use the toilet. Among subjects under age 60 there were no significant differences in ADL abilities between MD patients and controls. However, among patients aged 60 or greater there were significantly lower ADL abilities among MD patients than among age-matched controls. A conclusion of the Kinjo et al. study is that the prevalence of deficits was relatively greater in cases compared with controls as a function of increasing age. In other words, exposure to methylmercury three decades earlier accelerated the aging process in aged individuals relative to younger ones.

There has also been evaluation of the health status of people living in methylmercury-polluted areas who were not designated as MD patients. Later followup by Fukuda et al. (1999) evaluated 1,304 adults who lived in a methylmercury-polluted area near Minamata City in Kumamoto Prefecture in Japan (but were not designated MD patients) and 446 age-matched adults in a non-mercury-polluted area of Japan. All subjects were older than 40 years of age. A questionnaire survey evaluated 64 complaints that could be grouped as nonspecific, sensory, arthritic, and muscular. Complaints identified among male and female subjects that were significantly higher in methylmercury-contaminated areas included heart palpitation, dysesthesia, staggering when standing, resting and intention tremor in the hands, dizziness (especially when standing), low-tone tinnitus, low pain sensation in hands and legs, and (among women only) loss of touch sensations in hands and legs.

Animal studies lend support to the conclusion that methylmercury can have delayed effects that are uncovered with age. Spyker (1975) exposed mice during gestation and lactation to methylmercury. Offspring noted to be normal at birth developed deficits in exploratory behavior and swimming ability at 1 month; neuromuscular and immune effects were noted as the animals reached 1 year of age. Rice (1989a) exposed monkeys to 50 μg/kg/day methylmercury for the first 7 years of life. The animals were

observed with motor incoordination only when they reached the age of 14; subsequent testing showed effects on somatosensory functioning (Rice and Gilbert, 1995). Rice (1998) also exposed monkeys *in utero* and for the first 4 years. Exposure to 10 to 50 μg/kg/day was observed to result in decreased auditory function compared with controls when the animals were tested at 11 and 19 years. The deficit at 19 years was relatively greater than at 11 years, providing evidence for an interaction of aging and methylmercury exposure on auditory impairment. Rats exposed to methylmercury *in utero* through 16 days of age exhibited a decline in performance in a task that required a substantial motor output at an earlier age than did control rats; high-dose rats exhibited a decline in performance at about 500 days of age compared with 950 days for controls (Newland and Rasmussen, 2000), with no differences between groups in survival time. All of these observations are consistent with a hypothesis that early life or *in utero* exposure to methylmercury can have adverse long-term sequelae that may not be detected in childhood.

4.5.5.3 Reproductive Effects

EPA has a concern for potential reproductive effects of methylmercury. There are no studies of reproductive deficits in humans exposed to low-dose methylmercury. Bakir et al. (1973) did comment on the low number of pregnant women in the Iraqi population exposed to methylmercury in treated grain. They noted that among the 6,350 cases admitted to the hospital for toxicity, they would have expected 150 pregnancies; only 31 were reported. There are no two-generation reproductive assays for methylmercury. Shorter term studies in rodents and guinea pigs have reported effects including low sperm counts, testicular tubule atrophy, reduced litter size, decreased fetal survival, resorptions, and fetal malformations (Khera, 1973; Lee and Han, 1995; Hughes and Annau, 1976; Fuyuta et al., 1978, 1979; Hirano et al., 1986; Mitsumori et al., 1990; Inouye and Kajiwara, 1988). Burbacher et al. (1988) reported decreased conception rates, early abortions, and stillbirths in *Macaca fascicularis* monkeys treated with methylmercury hydroxide; the NOAEL for this study was 0.05 mg/kg/day. In a study of male *Macaca fascicularis* (Mohamed et al., 1987), a LOAEL for sperm abnormalities was 0.05 mg/kg/day.

The MSRC did an evaluation of the potential for methylmercury to be a germ-cell mutagen. Methylmercury is clastogenic but does not appear to cause point mutations. Methylmercury is widely distributed in the body, crossing both blood–brain and placental barriers in humans. Data indicate that methylmercury administered intraperitoneally. reaches germ cells and may produce adverse effects. When Suter (1975) mated female mice to treated males, he observed a slight reduction in both numbers of implantations and viable embryos; this was true for one mouse strain but not for another tested at the

same time. When Syrian hamsters were treated intraperitoneally with methylmercury, aneuploidy but not chromosomal aberrations was seen in oocytes (Mailhes, 1983). Sex-linked recessive lethal mutations were increased in *Drosophila melanogaster* given dietary methylmercury (Ramel, 1972). Watanabe et al. (1982) noted some decrease in ovulation in hamsters treated subcutaneously with methylmercury, further indication that methylmercury is distributed to female gonadal tissue. Studies have reported increased incidence of chromosome aberrations (Skerfving et al., 1970, 1974) or sister chromatid exchange (Wulf et al., 1986) in lymphocytes of humans ingesting mercury-contaminated fish or meat. Chromosome aberrations have been reported in cats treated in vivo and in cultured human lymphocytes in vitro. Evidence of DNA damage has been shown in a number of in vitro systems. The MSRC (U.S. EPA 1997e) concluded that because there are data for mammalian germ-cell chromosome aberrations and limited data from a heritable mutation study, methylmercury is placed in a group of high concern for potential human germ-cell mutagenicity. The only factor keeping methylmercury from the highest level of concern is lack of positive results in a heritable mutation assay.

In summary, there is increasing weight of evidence for effects other than neurodevelopmental that may be associated with low-dose methylmercury exposure.

4.5.6 Choice of Uncertainty Factor

For this methylmercury RfD the two major areas of uncertainty that can be addressed with a UF are interindividual toxicokinetic variability in ingested dose estimation and pharmacodynamic variability and uncertainty. For the former, EPA relied in part on the NRC analyses of variability in the pharmacokinetic factors underlying the conversion of a biomarker level of methylmercury to an ingested daily dose of methylmercury that corresponds to that level. We chose not to make a numerical adjustment in the dose conversion for the potential differences in cord vs. maternal blood mercury level, but rather consider this an additional area of toxicokinetic uncertainty. A quantitative uncertainty analysis was not feasible for toxicodynamics. A common practice is to apply a threefold UF for toxicodynamic variability and uncertainty.

In the calculation of this methylmercury RfD, a composite UF of 10 is used. This is to account for the following factors:

- Pharmacokinetic variability and uncertainty in estimating an ingested mercury dose from cord blood. A factor of 3 is applied for this area.

- Pharmacodynamic variability and uncertainty. A factor of 3 is applied for this area.

There are additional areas of concern in this risk estimate that lend support to an overall factor of 10. These include the following: inability to quantify long-term sequelae, lack of a two-generation reproductive effects assay, and issues on selection of critical effect (concern that there may be observable methylmercury effects at exposures below the BMDL). Section 4.5.5 discusses some of the concerns on selection of the critical effect. In this context one must also consider the analyses of the Faroese neuropsychological data wherein the observations in the most highly exposed subgroup were excluded from the model. Associations remained significant when the part of the cohort with maternal hair mercury concentrations greater than 10 ppm was excluded from the analyses. This indicates that it would be reasonable to expect some percentage of the population to show effects at or below 10 ppm hair mercury or at levels at or below 40 ppb cord blood. Given the overall robustness of the methylmercury database, but in consideration of the above areas of uncertainty, a composite factor of 10 is warranted.

4.6 CALCULATION OF THE RfD

The critical endpoint is drawn from the series of neuropsychological test results reported from the Faroese cohort. The BMDLs calculated on these endpoints are in Table 4-8. The ingested doses in μg/kg bw/day that correspond to the BMDLs range from 0.447 to 1.92. The ingested dose for the BNT whole-cohort BMDL is 1.081 μg/kg bw/day, rounded to 1.0 μg/kg bw/day.

For methylmercury, the RfD is calculated as follows:

$$RfD = \frac{BMD}{UF \times MF}$$

$$= \frac{1.0\ \mu g/kg-day}{10}$$

$$= 1 \times 10^{-4}\ mg/kg-day$$

$$= 0.1\ \mu g/kg/day.$$

As shown in Table 4-5, an RfD of 0.1 μg/kg bw/day reflects the range of neuropsychological test results in the Faroese children exposed *in utero*. These test scores are all indications of neuropsychological processes that are involved with the ability of a child to learn and process information. In the studies so far published on subtle neuropsychological effects in children, there has been no definitive separation of prenatal and postnatal exposure that would permit dose-response modeling. That is, there are currently no data that would support the derivation of a child (vs. general population) RfD. This RfD is applicable to lifetime daily exposure for all populations including sensitive subgroups. It is not a developmental RfD per se, and its use is not restricted to pregnancy or developmental periods.

5.0 EXPOSURE ASSESSMENT

5.1 OVERVIEW OF RELATIVE SOURCE CONTRIBUTION ANALYSIS

When a water quality criterion is based on noncarcinogenic effects, anticipated exposures from sources other than drinking water and fish ingestion are taken into account so that the entire RfD is not attributed to drinking water and freshwater/estuarine fish consumption alone. The amount of exposure attributed to each source compared with total exposure is called the relative source contribution (RSC) analysis. The RfD used in calculating the criterion incorporates the RSC to ensure that the criterion is protective enough, given the other anticipated sources of exposure. The method of accounting for nonwater exposure sources is described in more detail in the revised 2000 Human Health Methodology (U.S. EPA, 2000a).

The method of determining the RSC differs depending on several factors, including (1) the magnitude of total exposure compared with the RfD, (2) the adequacy of the exposure data available, (3) whether more than one guidance or criterion is to be set for a contaminant, and (4) whether there is more than one significant exposure source for the chemical and population of concern. The population of concern for methylmercury is discussed in Section 5.2. The sources of exposure to methylmercury and estimates of exposure used to determine the RSC for the identified population are discussed in Sections 5.3 through 5.4. Section 5.5 summarizes the exposure uncertainties based on data adequacy. Finally, Section 5.6 provides the RSC estimates for methylmercury.

5.2 POPULATION OF CONCERN

Methylmercury is a highly toxic contaminant that can cause a variety of adverse health effects. Toxicity has been observed in adults exposed through consumption of contaminated food. Toxic effects and subtle neuropsychological effects have been seen in children exposed *in utero* when their mothers consumed contaminated food while pregnant. The RfD (see section 4) is based on changes in neuropsychological measures in children exposed *in utero*. The choice was made to use a developmental endpoint, as this appeared to be the most sensitive indicator of a methylmercury effect. As discussed in section 4, there is concern that other less-studied effects may occur at lower doses. There is also concern (based on recent reports on the Minamata, Japan, population) that exposure *in utero* or in childhood could result in subtle impairments that would not be detectable until middle age or older.

The RfD for methylmercury was not calculated to be a developmental RfD only. It is intended to serve as a level of exposure without expectation of adverse effects when that exposure is encountered on a daily basis for a lifetime.

In the studies on subtle neuropsychological effects in children published so far, there has been no definitive separation of prenatal and postnatal exposure that would permit dose-response modeling. That is, there are currently no data that would support the derivation of a child RfD versus a general population RfD.

Therefore, the population at risk evaluated for the methylmercury criterion is adults in the general population, not only the developing fetus or child.

5.3 OVERVIEW OF POTENTIAL FOR EXPOSURE

The sources and fate of methylmercury are discussed in detail in Volume III of the *Mercury Study Report to Congress* (MSRC) (U.S. EPA, 1997b). The MSRC exposure assessment is in Volume IV (U.S. EPA, 1997c). A brief summary of the information in that document is presented here. Methylmercury occurs naturally in the environment. It is readily produced from inorganic mercury in fresh and marine surface waters and sediments through the methylating action of certain microorganisms. Bacterial methylation rates appear to increase under anaerobic conditions, elevated temperatures, and low pH. Methylmercury generally constitutes no more than 25% of the total mercury in surface water; typically, less than 10% is observed (U.S. EPA, 1997b). According to the MSRC, mercury cycles in the environment as a result of natural and anthropogenic activities. Most of the mercury in the atmosphere is elemental mercury vapor, which can remain there for as much as 1 year and, due to atmospheric mobilization, can be widely dispersed and transported thousands of miles from likely sources of emission (U.S. EPA, 1997b). However, the MSRC also clearly states that methylmercury is the chemical species of concern due to its fate and transport to waterbodies and sediments, and its subsequent bioaccumulation in the aquatic food web.

Because the source of most mercury is deposition from atmospheric mercury emissions, ingestion is an indirect route of exposure. The MSRC included numerous computer-simulated estimates of mercury exposure for selected population scenarios, based on fate and transport models (see U.S. EPA, 1997b,c). These are summarized throughout this chapter in the *Predicted Concentrations* subsections. Further exposure assessment information is presented in Volumes III and IV of the MSRC (U.S. EPA, 1997b,c)

and a characterization of human health from methylmercury exposure is discussed in detail in Volume VII (U.S. EPA, 1997g). That exposure assessment information is summarized throughout this chapter. The primary source of human exposure to methylmercury is through consumption of contaminated fish and seafood. This reflects the tendency of aquatic organisms to rapidly absorb methylmercury and to store it for long periods of time in their muscle tissue, thus accumulating it to levels that are potentially toxic to humans who eat fish and shellfish. The concentrations of methylmercury in fish tissue are highly variable across water bodies. Within a water body, methylmercury concentration generally increases with fish size and trophic level.

Derivation of the water quality criterion requires that intake of methylmercury from other sources of exposure be evaluated for comparison with intake from water and/or freshwater and estuarine fish. In addition to its occurrence in water and freshwater and estuarine fish, methylmercury occurs in soil, air, marine fish and other seafood, and nonfish foods. Intake of these media thus represent potential pathways for exposure. Other potential routes include occupational exposure and erosion of dental amalgams. Estimates of intake from these sources are presented in Section 5.4 below. Assessment of these sources of methylmercury clearly indicates that substantially all exposure to methylmercury occurs from the ingestion of contaminated fish. The other sources of exposure (water, nonfish foods, air, and soil) are all several orders of magnitude less than exposures from fish consumption.

5.4 ESTIMATES OF OCCURRENCE AND EXPOSURE FROM ENVIRONMENTAL MEDIA

This section reports data available for the estimation of methylmercury intake from relevant exposure sources. Exposure may occur from several environmental sources including soil, sediment, ambient surface water, drinking water, food products, and air. Human exposures are estimated by combining information on the occurrence of methylmercury in environmental media with intake rates for these media. Information on intake assumptions, environmental concentrations, and estimated exposure are reported by medium below.

Table 5-1. Exposure parameters used in derivation of the water quality criterion

Parameter	Population			Source
	Children (0-14 years)	Women of Childbearing Age (15-44 years)	Adults in the General Population	
Body Weight, kg	30	67	70	U.S. EPA (2000a)
Drinking Water Intake, L/day	1.0	2.0	2.0	U.S. EPA (2000a)
Freshwater/Estuarine Fish Intake, gm/day	156.3[b]	165.5[b]	17.5[c]	U.S. EPA (2000a)
Inhalation, m^3/day	10.4	11	20	U.S. EPA (1994, 1997h)[d]
Soil Ingestion, g/day	0.0001, 0.01[a]	0.00005	0.00005	U.S. EPA (1997h)
Mean Marine Fish Intake, kg/day	74.9[b]	91.04[b]	12.46[c]	U.S. EPA (2000b)
Median Marine Fish Intake, kg/day	59.71[b]	75.48[b]	0[c]	U.S. EPA (2000b)
90th Percentile Marine Fish Intake, g/day	152.29[b]	188.35[b]	49.16[c]	U.S. EPA (2000b)

[a]Pica child soil ingestion
[b]For children and women of childbearing age, intake rates are estimates of "consumers only" data (as described in U.S. EPA, 2000b).
[c]For adults in the general population, intake rates are estimates of all survey respondents to derive an estimate of long-term consumption (U.S. EPA).
[d]Inhalation rates for children and women of childbearing age from U.S. EPA, 1997h. Inhalation rates for adults in the general population from U.S. EPA (1994).

5.4.1 Exposure Intake Parameters

Exposure parameters selected for derivation of the water quality criterion should reflect the population to be protected. Default values for most exposure parameters are provided in the 2000 Human Health Methodology (U.S. EPA, 2000a). Where necessary, values for parameters not specified in the Methodology were obtained from the Exposure Factors Handbook (U.S. EPA, 1997h). Parameter values used to estimate intake of methylmercury by children aged 0-14 years, women of childbearing age, and adults in the general population are summarized in Table 5-1.

5.4.2 Intake from Drinking Water/Ambient Water

In cases where the water quality criterion is based on fish intake only, drinking water intake is accounted for as a separate exposure. In these instances, information on treated drinking water, if available, is the relevant information to use when accounting for other sources of exposure. Measured concentrations for methylmercury in drinking water and raw surface and ground source waters have been reported in the MSRC (U.S. EPA, 1997c). Predicted concentrations and ingestion rates summarized in this section are based on computer simulation models described in Volume IV of the MSRC (U.S. EPA, 1997c).

5.4.2.1 Measured Concentrations in Water

Raw Surface Water. Studies in the United States and Europe suggest that the concentrations of methylmercury in raw surface water are highly variable (U.S. EPA, 1997b). Properties reported to influence the levels of methylmercury in water bodies include proximity to a point source of mercury, pH, anoxia, dissolved organic carbon, and the presence of wetlands (U.S. EPA, 1997b). Estimates of the percent of total mercury in surface waters that exists as methylmercury are available from a number of studies. The available data suggest that methylmercury generally constitutes less than 20% of the total mercury in the water column (Kudo et al., 1982; Parks et al., 1989; Bloom and Effler, 1990; Watras et al., 1995a). In lakes without point source discharges, methylmercury frequently constitutes 10% or less of total mercury in the water column (Lee and Hultberg, 1990; Bloom et al., 1991; Lindqvist, 1991; Porcella et al., 1991; Watras and Bloom, 1992; Driscoll et al., 1994, 1995; Watras et al., 1995b). U.S. EPA (1997b) reported the use of Monte Carlo simulation to derive a point estimate of 0.078 for the fraction of total mercury present as methylmercury in the epilimnion (water column above the thermocline) of lakes for the purpose of estimating a bioaccumulation factor (BAF) for trophic level 4. Speciation data used as input for the simulation are shown in Table 5-2.

Data for measured concentrations of methylmercury and total mercury in ambient water as presented in the MSRC (U.S. EPA, 1997b) are summarized in Table 5-3. Since publication of the MSRC, Krabbenhoft et al. (1999) reported concentrations of total mercury and methylmercury in surface water samples collected as part of a U.S. Geological Survey (USGS) national scale pilot study to examine relations for total mercury and methylmercury in water, sediment, and fish. Water samples were collected in the summer and fall of 1998 at 106 sites from 21 basins across the United States, including Alaska and Hawaii. The sampling sites spanned the dominant east-to-west mercury deposition gradient

Table 5-2. Data Used in the Monte Carlo Simulation to Estimate the Fraction of Total Dissolved Mercury in the Epilimnion Present as Methylmercury

Fraction of Total Mercury Present as Methylmercury	Location	Reference

0.15	22 lake aggregate, WI	Watras et al. (1995a,b)

Source: U.S. EPA (1997c, Appendix D)

and represented a wide range of environmental settings. The study authors reported that most (number not reported) samples were collected from streams. Total mercury was measured using U.S. EPA Method 1631 with detection by cold vapor atomic fluorescence spectroscopy (CVAFS). Methylmercury was analyzed by distillation and aqueous phase ethylation, with detection by CVAFS. The detection limits for total mercury and methylmercury were 0.04 ng/L and 0.025 ng/L, respectively (Olson and DeWild, 1999). Of the 106 total sites, 21 were classified as background or reference sites. The mean concentration for methylmercury at background sites was 0.13 ng/L, which represented 3.4% of the mean total mercury concentration. When all sites were considered, the mean methylmercury concentration (104 sites) was 0.15 $\pm$ 0.26 ng/L (range 0.01 to 1.481 ng/L). The median value was 0.06 ng/L. The difference in mean and median values was attributed to high mercury concentrations at sites impacted by mining activities, which resulted in a skewed distribution. Methylmercury constituted 1% to 11% of total mercury concentration in the 21 study basins.

Other measured concentrations of total mercury and methylmercury in fresh water as reported in the MSRC (U.S. EPA, 1997b) are summarized in Table 5-3. Reported values for methylmercury measured at two sites in the United States ranged from less than 0.004 ng/L to 0.06 ng/L. The New Jersey Department of Environmental Protection and Energy (NJDEPE) (1993) reported total mercury concentrations for lakes of 0.04 to 74 ng/L and values of 1 to 7 ng/L for rivers and streams. Based on the

Table 5-3. Measured Methylmercury Concentrations in Surface Fresh Water

Study Description	Total Mercury (ng/L)	Methylmercury (ng/L)	Methylmercury % of Total	Reference

[a] As reported in U.S. EPA (1997c)
NA Not available

U.S. EPA (1997b) Monte Carlo estimate for speciation (0.078), these values would correspond to approximate methylmercury concentrations of 0.003 to 6 ng/L for lakes and 0.078 to 0.55 ng/L for rivers and streams. The MSRC did not indicate whether the NJDEPE (1993) data represented measures of central tendency.

Ground Water. Nationally aggregated data for mercury or methylmercury concentrations in ground water were not reported in the MSRC (U.S. EPA, 1997b). Local estimates of concentration are available from three studies. Krabbenhoft and Babiarz (1992) reported mercury levels of 2 to 4 ng/L in near-surface ground water in remote areas of Wisconsin, with a maximum of 0.3 ng/L (roughly 7.5% to 15% of total mercury concentration) occurring as methylmercury. Bloom et al. (1989) reported a value of 0.3 ng/L for total mercury in a Washington state well. In contrast to these comparatively low concentrations, Dooley (1992) reported total mercury levels up to and exceeding 2,000 ng/L in southern New Jersey domestic wells.

Drinking Water. Much of the data reported for total mercury concentration in drinking water is below the detection limit of 100 ng/L associated with older methods of analysis (U.S. EPA, 1997b). Lindqvist and Rodhe (1985) estimated that the concentration range of mercury in drinking water is the same as rain, with an average level of total mercury in drinking water of 25 ng/L. NJDEPE (1993) reported a range of 0.3 to 25 ng/L for total mercury in U.S. drinking and tap water. Speciation data for mercury in drinking water are not available, but may be similar to those observed for rain water (U.S. EPA, 1997c). The percentage of total mercury that is methylmercury in rain water ranged from 0.1% to 6.3% in two studies reported by Lee and Iverfeldt (1991) and Fitzgerald et al. (1991). The high end of this range approaches the point estimate of 7.8% derived for the fraction of methylmercury in the water column of lakes using Monte Carlo simulation (U.S. EPA, 1997b). Assuming that 7.8% of the total mercury is methylmercury (U.S. EPA, 1997b), these data suggest a crude estimate of methylmercury concentration in drinking and tap water ranging from 0.023 ng/L to 1.95 ng/L.

5.4.2.2 Predicted Concentrations in Water

U.S. EPA (1997b) reported the results of watershed fate and transport modeling conducted to predict the background concentration of mercury in water bodies. Atmospheric concentrations and deposition rates were used as inputs to the IEM-2M model. The IEM-2M model is composed of two integrated models that simulate mercury fate using mass balance equations that describe processes in watershed soils and a shallow lake. Using this approach, background levels of total dissolved mercury concentrations in the water column of 0.9 and 0.2 ng/L were predicted for hypothetical Eastern and Western U.S. sites, respectively. More than 80% of the total mercury in the water column was predicted to occur as the inorganic divalent species. As indicated above, the fraction of the predicted background concentration occurring as methylmercury was 7.8% (U.S. EPA, 1997b).

In the MSRC, the background values reported above were used as inputs to a localized model analysis that examined the impact of a variety of anthropogenic emission sources (municipal waste combustors, hospital medical waste incinerators, utility boilers, chlor-alkali plant) on methylmercury concentrations in the water column at distances of 2.5, 10, or 25 km from the source. This effort was undertaken because some monitoring studies suggest that measured mercury concentrations may be higher in areas adjacent to stationary industrial and combustion sources known to emit mercury (U.S. EPA, 1997b). Results of this analysis are of relevance to derivation of the water quality criterion because they include data specifically for predicted methylmercury concentrations, and thus permit comparison with measured concentrations.

The Industrial Source Code air dispersion model (ISC3) was used for simulation. Hypothetical facilities were defined to represent actual emissions from existing industrial processes and combustion sources; these were situated in hypothetical locations intended to simulate a site in either the Western or Eastern United States (U.S. EPA, 1997b). Input values for air concentrations consisted of simulated concentration results (50th and 90th percentile values) obtained using the regional Lagrangian model of air pollution (RELMAP). The assumptions and inputs utilized in this modeling effort are described in detail in Volume III of the MSRC (U.S. EPA, 1997b).

Results for predicted methylmercury concentrations in water are illustrated in Table 5-4. Predicted concentrations for dissolved methylmercury in water across all scenarios ranged from 0.014 to 1.0 ng/L. The highest predicted concentrations occurred at a location 2.5 km from a chlor-alkali plant. The predicted contribution of the hypothetical emission sources to methylmercury concentration ranged from 0 to 99% across all modeling scenarios. Although these results are meant to describe events on a local (adjacent to emission source) rather than nationwide scale, they provide a general frame of reference for comparison with measured values. The predicted range compares to the measured concentration range of 0.01 to 1.481 ng/L reported by Krabbenhoft et al. (1999) for 104 surface water samples collected at sites across the United States. The range of predicted concentrations overlapped the methylmercury concentrations in ground water (less than or equal to 0.3 ng/L, based on one study) and drinking water (0.023 to 1.95 ng/L) estimated from measurement data presented in Section 5.4.2.1.

5.4.2.3 Intake Estimates for Drinking Water and Ambient Water

Using the methylmercury concentration data in treated drinking water, and in ambient water it is possible to estimate exposure from water ingestion. For methylmercury, data on measured concentrations in ground and treated drinking water are limited. The database for surface water is somewhat more extensive. Estimates of intake based on ingestion of drinking water and ambient water are provided below.

Ambient Surface Water

A central tendency value for methylmercury in ambient surface water based on national data is available from a pilot study conducted by the U.S. Geological Survey (Krabbenhoft et al., 1999). Concentrations of methylmercury in ambient surface water ranged from a mean background level of 0.13 ng/L (or 1.3×10^{-7} mg/L) to a mean concentration for all sites of 0.15 ng/L (or 1.5×10^{-7} mg/L).

Combining the mean for methylmercury concentrations at all sites with default exposure assumptions of a 30 kg child aged 0 to 14 years who consumes 1 L/day of ambient surface water yields an estimated exposure of 5.0×10^{-9} mg/kg-day. Combining the mean value for methylmercury concentrations at all sites with default exposure assumptions of 2 L/day for water ingestion rate and 67 kg for body weight yields an exposure estimate of 4.5×10^{-9} mg/kg-day for a woman of childbearing age (15-44 years old). Adults in the general population have an estimated exposure value of 4.3×10^{-9} mg/kg-day, based on a default body weight and water intake rate of 70 kg and 2 L/day, respectively. These values are summarized in Table 5-5.

Table 5-4. Range of Predicted Dissolved Methylmercury Concentrations in Water for Hypothetical Emissions Scenarios

Site	RELMAP Percentile	Methylmercury (ng/L)		Scenario	
		Min	Max	Min	Max
Eastern	50	0.077	1.0	Large hospital incinerator, 25 km	Chlor-alkali plant, 2.5 km
Eastern	90	0.11	1.0	Multiple scenarios	Chlor-alkali plant, 2.5 km
Western	50	0.014	1.0	Multiple scenarios	Chlor-alkali plant, 2.5 km
Western	90	0.034	1.0	Multiple scenarios	Chlor-alkali plant, 2.5 km

Table 5-5. Ambient Surface Water Intake Assumptions and Estimates

Population of Concern	**Methylmercury in Ambient Surface Water[a] (mg/L)**	**Ingestion Rate[b] (L/day)**	**Body Weight[b] (kg)**	**Daily Exposure Estimate (mg/kg-day)**
Children (0-14 yr)	1.5×10^{-7}	1.0	30	5.0×10^{-9}
Childbearing Women	1.5×10^{-7}	2.0	67	4.5×10^{-9}
Adults in the General Population	1.5×10^{-7}	2.0	70	4.3×10^{-9}

[a] Methylmercury concentration is the mean for all sites in the national pilot study as reported in Krabbenhoft et al. (1999)

[b] U.S. EPA (2000a)

Drinking Water

Although drinking water concentrations can be calculated based on surface water and ground-water concentrations (U.S. EPA, 2000a), the available ground-water data were not adequate for this purpose. Therefore, exposure from drinking water was roughly estimated for women of childbearing age, children aged 0-14 years, and adults in the general population based on existing drinking and tapwater concentration data (NJDEPE, 1993). For the purpose of this estimate, it was assumed that the reported data reflected contributions from both ground water and surface water. Combining the estimated range for methylmercury concentrations in drinking water (0.0234 to 1.95 ng/L, or 2.34×10^{-8} to 1.95×10^{-6} mg/L) with default values for a 30 kg child aged 0 to 14 years consuming 1 L/day of drinking water yields an exposure estimate ranging from 7.8×10^{-10} to 6.5×10^{-8} mg/kg-day. Combining the estimated range for methylmercury concentrations in drinking water with default values of 2 L/day for drinking water intake and 67 kg for body weight yields an exposure estimate that ranges from 7.0×10^{-10} to 5.8×10^{-8} mg/kg-day for a woman of childbearing age (15-44 years old). Exposure estimates from ingesting drinking water by adults in the general population range from 6.7×10^{-10} to 5.6×10^{-8} mg/kg-day, based on a default body weight and water intake rate of 70 kg and 2 L/day, respectively. These values and intake assumptions are summarized below in Table 5-6.

Table 5-6. Drinking Water Intake Assumptions and Estimates

Population of Concern	**Methylmercury in Drinking Water (mg/L)**	**Ingestion Rate[a] (L/day)**	**Body Weight[a] (kg)**	**Daily Exposure Estimate (mg/kg-day)**
Children (0-14 yr)	2.3×10^{-8} to 1.9×10^{-6}	1.0	30	7.8×10^{-10} to 6.5×10^{-8}
Childbearing Women	2.3×10^{-8} to 1.9×10^{-6}	2.0	67	7.0×10^{-10} to 5.8×10^{-8}
Adults in the General Population	2.3×10^{-8} to 1.9×10^{-6}	2.0	70	6.7×10^{-10} to 5.6×10^{-8}

5.4.3 Nonfish Dietary Exposures

5.4.3.1 Measured Concentrations in Food Other Than Fish

Historically, measurements of mercury have not been speciated in food items other than fish, primarily because of the lack of adequate methodology (Madson and Thompson, 1998). However, the limited data available suggest that nonfish foods such as dairy products, fruits, and vegetables may potentially contribute to intake of methylmercury. Furthermore, it is possible that the agricultural practice of using fishmeal in animal feeds may result in increased levels of methylmercury in nonfish foods (ATSDR, 1999). This section examines the available data on mercury and methylmercury concentrations in nonfish human food items.

Information on the concentration of total mercury in dietary items is available from the *Total Diet Study* (TDS) conducted by the U.S. Food and Drug Administration (U.S. FDA). The TDS is an on-going nationwide program that determines the levels of nutrients and selected contaminants in foods for the purpose of estimating intakes of these substances by the U.S. population. A total of 839 samples for 47 food items were collected and analyzed for total mercury during the period from 1991 to 1996 (U.S. FDA, 1999). Of the reported results, 756 (90%) were below the detection limit for mercury (0.01 to 0.02 mg/kg depending on food item) and 30 (3.6%) were considered to contain trace amounts of mercury. These trace values represent the best estimates of those who analyzed the data, but in all cases are below the nominal limit of quantitation.

Examination of the data for the 41 nonfish dietary items analyzed (6 items were fish) indicates that the total mercury concentration was below the detection limit for most samples. These samples were assigned a concentration of zero for statistical analysis (U.S. FDA, 1999). Trace amounts of total mercury were found in one sample each (out of 18 total samples for each item) of fried beef liver, cooked oatmeal, and boiled spinach. The maximum detected concentration of mercury in nonfish dietary items was 0.03 mg/kg in fried beef liver. The reported median concentrations for total mercury in all individual nonfish dietary categories were zero. Based on these data, the central tendency estimate for methylmercury intake from nonfish dietary items is zero. For comparison, the mean mercury concentration from all 47 food categories (containing both fish and nonfish dietary items) was 0.006 mg/kg (U.S. FDA, 1999).

The MSRC (U.S. EPA, 1997b) also summarized data for methylmercury concentrations reported in local studies. Measured concentrations of methylmercury in garden produce and crops are summarized in Table 5-7. Because the database for methylmercury content in these foods is limited, information is also presented from studies that report total mercury concentrations. In general, the level of methylmercury in agricultural produce is low, with the highest concentration (30 ng/g dry weight) observed in leafy vegetables. Plants grown in the presence of elevated soil or atmospheric concentrations of mercury are reported to contain elevated concentrations of total mercury (U.S. EPA, 1997b). Temple and Linzon (1977) sampled the mercury content of fresh fruits and vegetables around a large chlor-alkali plant in an urban-residential neighborhood. Among garden produce, leafy crops accumulated the highest levels of mercury. One lettuce sample contained 99 ng/g wet weight of mercury (background: <0.6 ng/g), and a sample of beet greens contained 37 ng/g wet weight (background: 3 ng/g). Tomatoes and cucumbers within 400 m of the chlor-alkali plant averaged 2 and 4.5 ng/g wet weight of mercury, respectively, compared with measured background levels of 1 ng/g.

Because the mercury content in plants tends to be low, livestock typically accumulate little mercury from forage or silage (U.S. EPA, 1997b). However, use of fishmeal as food for poultry and other livestock may result in increased mercury levels in these animals (ATSDR, 1999). Measured concentrations of mercury and methylmercury in meat products are summarized in Table 5-8. Although the database is limited, the available data suggest that methylmercury concentrations in meats are generally low in comparison with levels observed in fish (U.S. EPA, 1997b).

Pedersen et al. (1994) monitored the level of mercury in wine, beer, soft drinks, and various juices. Total mercury levels in these beverages were at or below the detection limit of 6 μg/L in all samples tested.

Infant postnatal exposure to methylmercury through ingestion of breast milk is a pathway of potential concern. As noted in Section 3.4, methylmercury is excreted in breast milk (Bakir et al., 1973; Sundberg and Oskarsson, 1992). The ratio of mercury in breast milk to mercury in whole blood was approximately 1:20 in women exposed to methylmercury via contaminated grain in Iraq between 1971 and 1972 (Bakir et al., 1973). Skerfving (1988) found that 16% of mercury in human breast milk is methylmercury. Note that the MSRC found the data on breast milk to be insufficient to support estimation of exposure by this route.

5.4.3.2 Predicted Concentrations in Foods Other than Fish

U.S. EPA (1997d) reported predicted concentrations in fruits, vegetables, beef, pork, poultry, dairy products, and eggs. As described in previous sections on predicted concentrations in various media, this effort was undertaken because some monitoring studies suggest that measured mercury concentrations may be higher in areas adjacent to stationary industrial and combustion sources known to emit mercury (U.S. EPA, 1997b). Results of this local study are of relevance to derivation of the water quality criterion because they include data specifically for predicted methylmercury concentrations, and thus permit comparison with measured concentrations.

The Industrial Source Code air dispersion model (ISC3) was used for the computer simulation to estimate nonfish dietary exposure. Model plants (defined as hypothetical facilities which were developed to represent actual emissions from existing industrial processes and combustion sources), were situated in hypothetical locations intended to simulate a site in either the Western or Eastern United States (U.S. EPA, 1997b). Input values for air concentrations consisted of simulated concentration results (50^{th} and 90^{th} percentile values) obtained using the regional Lagrangian model of air pollution (RELMAP). The assumptions and inputs utilized in this modeling effort are described in detail in Volume III of the MSRC (U.S. EPA, 1997b).

Predicted concentrations in a variety of nonfish foods are reported in Table 5-9. Because the computer models used to generate these concentrations incorporated a point source for mercury emissions, these predictions likely approach a worst-case scenario for methylmercury levels in foods. Based on a large hospital waste incinerator scenario in the Eastern United States (50th percentile), concentrations of methylmercury (expressed on a dry-weight basis) ranged from 0.095 ng/g to 7.1 ng/g in fruits and vegetables, with the highest concentration observed in leafy vegetables. Concentrations of methylmercury animal products ranged from 0.0013 ng/g to 4.2 ng/g, with the highest concentrations observed in beef and dairy products. The hypothetical facility was considered to contribute less than 10% to the total plant mercury concentration (U.S. EPA, 1997b). The local source was considered to contribute 7% to 11% of the total mercury in beef, dairy products, and pork and 41% of total mercury in poultry and eggs (U.S. EPA, 1997b).

5.4.3.3 Intake Estimates for Food Other Than Fish

Data from the U.S. FDA TDS (described in Section 5.4.3.1) suggest that nonfish dietary items generally account for a very small fraction of total mercury intake. For the purpose of estimating methylmercury intake from nonfish foods, the central tendency estimate of methylmercury concentration is assumed to be zero. Thus, the average daily intake is zero mg/kg-day for adults in the general

Table 5-9. Predicted Methylmercury Concentrations in Produce and Animal Products Based on a Large Hospital Waste Incinerator Scenario

Item	Total Mercury (ng/g dry wt.)	% Methylmercury	Methylmercury (ng/g dry wt.)
Produce			
Root vegetables	1.9	5	0.095
Fruits	35	5	1.7
Fruiting vegetables	35	5	1.7
Leafy vegetables	34	21	7.1
Animal Products			
Beef	8.6	19	1.6
Beef liver	22	19	4.2
Dairy	11	19	2.1
Pork	0.007	18	0.0013
Poultry	0.12	3	0.0036
Eggs	0.12	3	0.0036
Lamb	3.9	19	0.74

population, children, and women of childbearing age. This estimate is in agreement with WHO (1990), which reported that nonfish foods accounted for 0% of average daily intake of methylmercury.

Methylmercury intake from animal products and produce has been estimated by computer model simulation for four hypothetical high-end exposure scenarios: rural subsistence farmer (adult and child), rural home gardener (adult and child), urban high-end adult, and high-end fisher (adult and child) (U.S. EPA, 1997c). These predicted methylmercury intakes are presented in Table 5-10. Methylmercury intake from animal products was estimated only for the rural subsistence farmer. Intake from animal products and produce was not considered in the remaining scenarios. The subsistence farmer was anticipated to represent a very high-end exposure scenario. Simulation of intake for these scenarios employed a body-weight exposure assumption for children (i.e., 17 kg) that differs from the currently recommended value (i.e., 30 kg) for derivation of water quality criterion values (see Table 5-1). Estimated exposure from produce for several high-end scenarios ranged from 2.3×10^{-7} mg/kg-day for the

high-end urban adult to 5.8 x 10^{-5} mg/kg-day for the adult high-end fisher. Estimated exposures from animal products for the rural subsistence farmer scenario were 2.1 x 10^{-6} mg/kg-day and 5.3 x 10^{-6} mg/kg-day for an adult and child, respectively. These model-predicted estimates support the finding of generally low methylmercury intake from nonfish foods indicated by measurement data from the TDS (U.S. FDA, 1999) and the conclusion in the MSRC that substantially all exposure to methylmercury is from fish consumption.

5.4.4 Fish Consumption Estimates

The MSRC concluded that most human exposure to methylmercury is from food and that it is primarily from fish consumption (U.S. EPA, 1997g). Ingestion of contaminated fish is also reported by many other authors to be the only significant source of methylmercury exposure to the general human population (Stern, 1993; Swedish EPA, 1991; WHO, 1990). This conclusion is based on the observation that in many nonfish foods, the mercury content is typically near detection limits and is comprised mainly of inorganic species (WHO, 1990). In contrast, most of the mercury in fish is methylated.

This section provides information on measured and predicted tissue concentrations of methylmercury in freshwater fish and marine fish, and estimates of intake for several target populations. The MSRC presented data for freshwater fish and marine fish. The MSRC did not include a separate evaluation of estuarine fish, although the data on marine species presented in the MSRC (from the National Marine Fisheries Service) include some estuarine species. Sections 5.4.4.1 and 5.4.4.2, below, summarize the major studies presented in the MSRC for freshwater fish. Section 5.4.4.3 presents an estimate of intake for both freshwater and estuarine species. Although the intake estimate is based on the freshwater fish methylmercury concentrations only, EPA believes that the freshwater fish concentrations are similar to the concentrations in these estuarine species presented in the MSRC. EPA, therefore, believes that calculating an intake estimate using the freshwater/estuarine default consumption rates provides a reasonable approximation of combined freshwater/estuarine fish methylmercury exposure. A more accurate estimate of marine fish methylmercury intake has been made (Section 5.4.4.7) since this source of exposure is included in the RSC estimate that is factored into the final water quality criterion calculation.

Table 5-10. Predicted Methylmercury Intake from Dietary Items Based on Five Hypothetical High-End Exposure Scenarios

Parameter	Exposure Scenario[a]										
	Rural Subsistence Farmer		Rural Home Gardener		Urban				High End Fisher		Recreational Angler
	Adult	Child	Adult	Child	Adult Average	Adult High-end	Child Average	Child High-end	Adult	Child	Adult

5.4.4.1 Measured Concentrations in Freshwater Fish

Data for mercury concentrations in freshwater fish have been previously compiled and evaluated by EPA in Volume IV of the MSRC (U.S. EPA, 1997c). The discussion below provides information on the national studies considered and the database selected by U.S. EPA after careful consideration of data quality issues to provide concentration data for estimating human exposure to methylmercury (U.S. EPA, 1997c).

Two national studies were considered by U.S. EPA (1997c) for estimation of mercury concentrations in freshwater finfish populations. Lowe et al. (1985) reported mercury concentrations in fish from the National Contaminant Biomonitoring Program. The freshwater fish data were collected between 1978-1981 at 112 stations located across the United States. Mercury was measured by a flameless cold vapor technique, with a detection limit of 0.01 μg/g wet weight. Most of the sampled fish were taken from rivers (93 of the 112 sample sites were rivers); the other 19 sites included larger lakes, canals, and streams. Fish weights and lengths were consistently recorded. The mercury concentrations measured in this study are shown in Table 5-11. Several varieties of fish were sampled. Carp, large mouth bass, and white sucker were most common. The geometric mean mercury concentration of all sampled fish was 0.11 μg/g wet weight; the minimum and maximum concentrations reported were 0.01 and 0.77 μg/g wet weight, respectively. The highest reported mercury concentrations (0.77 μg/g wet weight) occurred in a northern squawfish collected from the Columbia River. Mean mercury concentrations (whether geometric or arithmetic mean not specified) by species are reported in the MSRC (U.S. EPA, 1997c).

A national study of chemical residues in freshwater fish was conducted by U.S. EPA (1992b) and also reported by Bahnick et al. (1994). As reported in the MSRC (U.S. EPA, 1997c), five bottom-feeding species (e.g., carp) and five game fish species (e.g., bass) were sampled at each of the 314 sampling sites in the United States. These sites were selected based on proximity to either point or nonpoint pollution sources. Thirty-five "remote" sites among the 314 total sites were included to provide nonimpacted background pollutant concentrations. The study primarily targeted sites that were expected to be impacted by increased dioxin levels. The point sources proximate to sites of fish collection included the following: pulp and paper mills, Superfund sites, publicly owned treatment works (POTWs), and other industrial sites. Data describing fish age, weight, and sex were not consistently collected. Whole body mercury concentrations were determined for bottom feeders, and mercury concentrations in fillets were analyzed for the game fish. Total mercury levels were analyzed using flameless atomic absorption,

with reported detection limits of 0.05 μg/g early in the study (465 samples analyzed prior to 1990) and 0.0013 μg/g later in the study (195 samples), as the analytical technique improved. Nondetects were reported as a zero value and averaged as zeros. The estimated standard deviation for replicate samples was 0.047 μg/g in the concentration range of 0.08 to 1.79 μg/g. Mercury was detected in fish collected from 92% of the sample sites. Concentration data are provided in Table 5-12. The maximum mercury level detected was 1.8 μg/g, and the mean concentration in 669 fish samples across all sites was 0.26 μg/g. The highest measurements occurred in walleye, largemouth bass, and carp. The mercury concentrations in measured in fish around POTWs were the highest among all point source data; the median value for mercury concentration was 0.61 μg/g.

The intake estimates presented in this document, similar to the MSRC, are based on the mean concentration values from the studies described above; that is, the fish mercury concentration data based on the Bahnick et al. (1994) and Lowe et al. (1985) studies were used for the estimates. However, the MSRC also includes summary data from numerous other studies that indicate significantly higher levels of methylmercury in freshwater fish. For example, concentrations of methylmercury in bass, crappie, northern pike, and trout of 2.0, 1.39, 1.71, and 1.19 μg/g, respectively, represent a few of the higher species concentrations reported (see U.S. EPA, 1997d, Table 4-48).

Measurements of elevated levels of mercury in fish have been reported elsewhere. For example, the North East States Coordinated Air Use Management (NESCAUM) summarized data from New England's freshwater fish in the "Mercury Study: A Framework for Action" by the Northeast States and Eastern Canadian Provinces (1998) (see Table 5-11).

Additional data are available for New York State (Simonin and Meyer, 1998). In New York State, maximum mercury concentrations over 2 ppm were seen for the following species: walleye (3.2 ppm), striped bass (5.4 ppm), white perch (3.2 ppm) Northern pike (2.1 ppm), smallmouth bass (3.34 ppm), largemouth bass (2.39 ppm), rock bass (2.7 ppm), drum (1.4 ppm), channel catfish (2.0 ppm), sunfish (1.2 ppm), American eel (1.6 ppm), Lake trout (2.7 ppm), white sucker (1.2 ppm), black crappie (1.4 ppm), and carp (5.8 ppm).

5.4.4.2 Predicted Concentrations in Freshwater Fish

As previously indicated, the MSRC included numerous computer-simulated estimates of mercury exposure for selected population scenarios (U.S. EPA, 1997c). These included predicted concentrations

in Tier 4 (predatory) fish based on exposure modeling. The Industrial Source Code air dispersion model (ISC3) was used for simulation of methylmercury concentrations in water and biota near mercury emissions sources. Model plants (large and small municipal waste combustors, large and small hazardous materials incinerators, coal and oil-fired utility boilers, chlor-alkali plant), defined as hypothetical facilities which were developed to represent actual emissions from existing industrial processes and combustion sources, were situated in hypothetical locations intended to simulate a site in either the Western or Eastern United States (U.S. EPA, 1997b). Input values for air concentrations consisted of simulated concentration results (50^{th} and 90^{th} percentile values) obtained using the regional Lagrangian model of air pollution (RELMAP). The assumptions and inputs utilized in this modeling effort are described in detail in Volume III of the MSRC (U.S. EPA, 1997b).

Fish tissue methylmercury concentrations of 5.3×10^{-1} µg/g and 9.7×10^{-2} µg/g were predicted for the simulated Eastern and Western sites, respectively, in scenarios where the hypothetical emission sources had zero percent impact on local mercury levels (i.e., the predicted concentration resulted only from background levels of mercury in the environment and regional anthropogenic sources). These levels are of the same order of magnitude as the mean measured values of 0.11 and 0.26 µg/g (1.1×10^{-1} and 2.6×10^{-1} µg/g) reported by Lowe et al. (1985) and Bahnick et al. (1994) respectively. The maximum predicted tissue concentration of 68 µg/g was associated with the Eastern site chlor-alkali plant scenario.

5.4.4.3 Intake Estimates from Freshwater/Estuarine Fish

The mercury concentration data reported in U.S. EPA (1992b) and Bahnick et al. (1994) were selected to determine a rough estimate of methylmercury intake from freshwater and estuarine fish. In contrast to the data reported by Lowe et al. (1985), the selected study provides an arithmetic mean as a measure of central tendency. These data have previously been used by U.S. EPA (1997d) to calculate methylmercury intake estimates under different fish ingestion scenarios. In this section, new estimates of methylmercury intake are calculated in accordance with technical guidance provided in the 2000 Human Health Methodology (U.S. EPA, 2000a). Using the mean mercury concentration of 0.26 µg mercury/g fish wet weight (or mg/kg) reported by U.S. EPA (1992b) and Bahnick et al. (1994), and assuming that approximately 100 percent is methylmercury (U.S. EPA, 1997d), the average estimated methylmercury concentration in freshwater/estuarine fish is 0.26 mg/kg.

Table 5-11. Freshwater Fish Mercury Concentrations from Lowe et al. (1985) and Northeast States and Eastern Canadian Provinces (1998)

Lowe et al. (1985)	
Fish Species	***Mean Mercury Concentration (μg/g Wet Wt)***
Bass	0.157
Bloater	0.093
Bluegill	0.033
Smallmouth Buffalo	0.096
Carp, Common	0.093
Catfish (channel, largemouth, rock, striped, white)	0.088
Crappie (black, white)	0.114
Freshwater Drum	0.117
Northern Squawfish	0.33
Northern Pike	0.127
Perch (white and yellow)	0.11
Sauger	0.23
Sucker (bridgelip, carpsucker, klamath, largescale, longnose, rivercarpsucker, tahoe)	0.114
Trout (brown, lake, rainbow)	0.149
Walleye	0.1
Mean of Measured Fish	0.11[a]
Northeast States and Eastern Canadian Provinces (1998)	
Fish Species	***Maximum Mercury Concentration in ppm***
Largemouth bass	8.94
Smallmouth bass	5.0
Yellow perch	3.15
Chain pickerel	2.81
Lake trout	2.70
Walleye	2.04
Brown bullhead	1.10
Brook trout	0.98

[a] Geometric mean; U.S. EPA (1997c) did not specify whether means for individual species or species categories were geometric or arithmetic means.
Source: U.S. EPA (1997c), Northeast States and Eastern Canadian Provinces (1998).

To estimate daily exposure from methylmercury in freshwater/estuarine fish, average body weights and high-end fish ingestion rates (90th percentile) for the populations of concern are estimated, as recommended in the 2000 Human Health Methodology. Default intake values for fish intake by children, women of child-bearing age, and adults in the general population are provided in U.S. EPA (2000a). These intake values were estimated from the on-going, nationally based Continuing Survey of Food Intake for Individuals (CSFII) conducted by the U.S. Department of Agriculture. The CSFII is conducted annually, and dietary data from all 50 States are collected (U.S. EPA, 2000a). The estimates of intake based on CSFII incorporated data for both consumers and nonconsumers of fish, and represent intake of all fish whether store-bought or sport-caught (U.S. EPA, 2000a). The freshwater/estuarine fish ingestion rates for children, women of child-bearing age, and adults in the general population are estimated to be 156.3 g/day, 165.5 g/day, and 17.5 g/day, respectively (U.S. EPA, 2000a). Note that the estimates for both children and women of childbearing age are based on short-term consumption, whereas the estimate for adults in the general population is based on average long-term consumption.

Table 5-12. Freshwater Fish Mercury Concentrations from Bahnick et al. (1994).

Species	**Mean Mercury Concentration (μg/g Wet Wt)**
Carp	0.11
Sucker (white, redhorse, spotter)	0.167
Catfish (channel and flathead)	0.16
Bass (white, largemouth, smallmouth)	0.38
Walleye	0.52
Northern Pike	0.31
Crappie	0.22
Brown Trout	0.14
Mean of Measured Fish	0.26

Source: U.S. EPA (1997c)

The recommended body weights for children 0 to 14 years, women of childbearing age, and adults in the general population are 30 kg, 67 kg, and 70 kg, respectively (U.S. EPA, 2000a). Based on these exposure assumptions, the daily exposure estimates of methylmercury intake from ingestion of freshwater/estuarine fish for children, women of childbearing age, and adults in the general population are 1.4×10^{-3} mg/kg-day, 6.4×10^{-4} mg/kg-day, and 6.5×10^{-5} mg/kg-day, respectively. Input assumptions and calculated daily exposure estimates for freshwater/estuarine fish are summarized in Table 5-13.

5.4.4.4 Measured Concentrations in Marine Fish and Shellfish

The MSRC (U.S. EPA, 1997b,c) has summarized data on concentrations of total mercury and methylmercury in marine fish and shellfish. Analyses of total mercury concentrations in marine fish and shellfish have been carried out over the past two to three decades. Data describing methylmercury concentrations in marine fish are predominantly based on the National Marine Fisheries Service (NMFS) database, the largest publicly available database on mercury

Table 5-13. Freshwater/Estuarine Fish Intake Assumptions and Estimates

Population of Concern	Mercury in Fish[a] (mg/kg)	Methyl-mercury/ Mercury in Fish[b] (%)	Methyl-mercury in Fish (mg/kg)	Ingestion Rate[c] (kg/day)	Body Weight[c] (kg)	Daily Exposure Estimate (mg/kg-day)
Children	0.26	100	0.26	0.1563	30	1.4×10^{-3}
Women of Childbearing Age	0.26	100	0.26	0.1655	67	6.4×10^{-4}
Adults in the General Population	0.26	100	0.26	0.0175	70	6.5×10^{-5}

[a] U.S. EPA (1992b) and Bahnick et al. (1994)
[b] U.S. EPA (1997c)
[c] U.S. EPA (2000a)

concentrations in marine fish. In the early 1970s, the NMFS conducted testing for total mercury in more than 200 seafood species of commercial and recreational interest (Hall et al., 1978). The determination of mercury in fish was based on flameless (cold vapor) atomic absorption spectrophotometry following chemical digestion of the fish sample. These analytical methods are described in Hall et al. (1978).

The NMFS Report provides data on number of samples, the number of samples where mercury was not detected ("nondetects"), and mean, standard deviation, minimum, and maximum detected mercury levels (in parts per million wet weight) for 1,333 combinations of fish/shellfish species, variety, location caught, and tissue (Hall et al., 1978). This database consists of 777 fish/shellfish species for which mercury concentration data are provided. This represents 5,707 analyses of fish and shellfish tissues for total mercury, of which 1,467 or 26%, were reported at nondetectable levels. A discussion of the issues associated with evaluation and use of nondetect data for methylmercury in the NMFS database is provided in the MSRC (U.S. EPA, 1997c). A summary of NMFS concentration data is provided in Table 5-14.

Two additional databases for mercury concentration in marine fish and shellfish are cited in the MSRC (U.S. EPA, 1997d). These are the *Report on the Chance of U.S. Seafood Consumers Exceeding "The Current Daily Intake for Mercury and Recommended Controls"* (U.S. FDA, 1978) and a report by Stern et al. (1996) that examined exposure of New Jersey residents to mercury via fish consumption. Although concentration data from these databases are reported in the MSRC (U.S. EPA, 1997c), detailed descriptions and evaluations of study quality are not provided.

The intake estimates presented in this document, similar to the MSRC, are based on the mean concentration values from the studies described above; that is, the fish mercury concentration data based on the NMFS, Stern et al., and U.S. FDA studies were used for the estimates. However, the MSRC also includes summary data from numerous other studies that indicate significantly higher levels of methylmercury in marine fish. For example, concentrations of methylmercury in mackerel, pompano, shark, snapper, and swordfish of 2.9, 8.42, 4.53, 2.17, and 2.72 μg/g, respectively, represent a few of the higher species concentrations reported (see U.S. EPA, 1997c).

5.4.4.5 Other Measured Concentration Data for Marine Fish and Shellfish

Additional national-scope information on methylmercury in marine biota is available from Project Mussel Watch. Project Mussel Watch measures concentrations of organic and trace metal contaminants

in fresh, whole soft-parts of bivalve mollusks (i.e., mussels and oysters) at more than 240 coastal and estuarine sites. Data are currently available from 1986 through 1993 and are summarized in the MSRC (U.S. EPA, 1997b). Average concentrations along the North Atlantic, Eastern Gulf, and Pacific coasts (0.15, 0.14, and 0.11 μg/g dry weight, respectively) are higher than those collected along the Middle Atlantic, South Atlantic, and Western Gulf coasts (0.06, 0.09, and 0.08 μg/g dry weight, respectively). The highest concentrations exceeded 1.0 μg/g dry weight and were collected along the Western Gulf and Pacific coasts (1.80 and 1.01 μg/g dry weight, respectively).

Annual Mussel Watch data on mercury concentrations in bivalve mollusks at specific sites have been aggregated to national geometric means for the purpose of analyzing temporal trends (O'Conner and Beliaeff, 1995). The national means do not show any temporal trend in mercury concentrations in mussels and oysters for the period 1986-1993. Temporal trend analysis was also conducted on a site-by-site basis for 154 Mussel Watch sites for which there were data for at least 6 years during the period of 1986-1993 (O'Conner and Beliaeff, 1995). Seven sites exhibited an increasing trend in mercury concentrations, and eight sites exhibited a decreasing trend in mercury concentrations, with 95% statistical confidence.

5.4.4.6 Predicted Concentrations in Marine Fish and Shellfish

The computer simulations conducted by EPA and reported in the MSRC (U.S. EPA, 1997c) did not provide predictions for methylmercury concentrations in marine fish or shellfish.

5.4.4.7 Intake Estimates from Marine Fish and Shellfish

In accord with technical guidance provided in U.S. EPA (2000a), mean, median, and 90th percentile concentrations of methylmercury in marine fish were used to estimate daily exposure from methylmercury in marine fish. Species-specific mean concentrations of mercury in marine fish from the National Marine Fisheries Service (NMFS, 1978) are presented in EPA's MSRC (U.S. EPA, 1997c). These data are summarized in Table 5-14. For species where concentration was not reported in NMFS (1978), concentrations were estimated from data reported by Stern et al. (1996), U.S. FDA Compliance Testing data, or U.S. FDA (1978) as cited in U.S. EPA (1997c).

Table 5-14. Average Mercury Concentrations in Marine Fish and Shellfish

Species	Concentration[a] (µg Hg/g Wet Wt.)	Species	Concentration (µg Hg/g Wet Wt.)
Finfish			
Anchovy	0.047	Pompano*	0.104
Barracuda, Pacific	0.177	Porgy*	0.522[b]

*Denotes species used in calculation of methylmercury intake from marine fish for one or more populations of concern, based on existence of data for consumption in the CSFII (U.S. EPA, 2000b).

[a] Mercury concentrations are from NMFS (1978) as reported in U.S. EPA (1997d) unless otherwise noted, measured as µg of total mercury per gram wet weight of fish tissue.

[b] Mercury concentration data are from Stern et al. (1996) as cited in U.S. EPA (1997c).

[c] Mercury concentration data are from U.S. FDA Compliance Testing as cited in U.S. EPA (1997c).

[d] Mercury concentration data are from U.S. FDA (1978) as cited in U.S. EPA (1997c).

[e] Mercury data for flounder were used as an estimate of mercury concentration in marine flatfish in marine intake calculations

A consumption-weighted mean concentration of mercury for all marine fish was calculated as follows. Each of the marine species selected for inclusion in the analysis was weighted based on species-specific U.S. population intake rates among the three populations of concern (U.S. EPA, 2000b). This weighting system accounts for variability of consumption among different species and across different populations of concern. The consumption weighting factor for each of the selected marine species was calculated as follows. The consumption rates for individual marine species were summed to give a total consumption rate for a particular population of concern. The weighting factor was then calculated as the quotient of the species-specific consumption rate divided by the total consumption rate:

$$\text{Weighting factor for species A} = \frac{\text{Species A consumption rate (g/day)}}{\text{Sum of consumption rates for all selected species (g/day)}}$$

For each population of concern, the average mercury concentration for each species was multiplied by its consumption weighting factor. This product was then summed across all selected marine species to estimate the mean concentration of mercury in all marine fish for that particular population of concern:

$$\text{Mean conc}(\mu g/g) = \sum [\text{species-specific conc}(\mu g/g) \times \text{species-specific weighting factor}]$$

Assuming that approximately 100% of the mercury in marine fish is present as methylmercury (U.S. EPA, 1997c), the weighted-average methylmercury concentrations in marine fish consumed by each of the populations of concern are 0.167 mg/kg, 0.147 mg/kg, and 0.157 mg/kg for children (aged 0-14 years), women of childbearing age, and adults in the general population, respectively.

Specific body weights and several fish ingestion rates (arithmetic mean, median and 90th percentile) for the populations of concern were used to estimate daily exposure from methylmercury in marine fish. Marine fish intake values for children, women of childbearing age, and adults in the general population are provided in U.S. EPA (2000b). For children and women of childbearing age, these intake values were estimated using 3 years of "consumers only" data (1994-1996) from the on-going, nationally based Continuing Survey of Food Intake for Individuals (CSFII) conducted by the U.S. Department of Agriculture. Intake values for adults in the general population were obtained using all survey respondents to derive an estimate of long-term consumption. The marine fish ingestion rates for children, women of childbearing age, and adults in the general population are presented in Table 5-15.

The current default body weights for children 0 to 14 years, women of childbearing age, and adults in the general population are 30 kg, 67 kg, and 70 kg, respectively (U.S. EPA, 2000a). Based on these exposure assumptions, the mean daily exposure estimates of methylmercury intake from ingestion of marine fish for children, women of childbearing age, and adults in the general population are 4.1×10^{-4} mg/kg-day, 2.0×10^{-4} mg/kg-day, and 2.7×10^{-5} mg/kg-day, respectively. The median daily exposure estimates of methylmercury intake from ingestion of marine fish for children, women of childbearing age, and adults in the general population are 3.2×10^{-4} mg/kg-day, 1.6×10^{-4} mg/kg-day, and 0 mg/kg-day, respectively. In addition, the 90th percentile daily exposure estimates of methylmercury intake from ingestion of marine fish for children, women of childbearing age, and adults in the general population are 8.5×10^{-4} mg/kg-day, 4.1×10^{-4} mg/kg-day, and 1.1×10^{-4} mg/kg-day, respectively. Input assumptions and calculated daily exposure estimates for marine fish are summarized in Table 5-16.

5.4.5 Respiratory Exposures

5.4.5.1 Measured Concentrations in Air

Outdoor Air. Vapor-phase elemental mercury is the predominant form of mercury in the atmosphere and constitutes up to 98% of the total mercury concentration (U.S. EPA, 1997b). Increased

Source: U.S. EPA (2000b)

concentrations of the divalent form of mercury may be present near emission sources. Small fractions of particulate mercury and methylmercury may also be present. Atmospheric mercury concentrations in the United States are generally very low (U.S. EPA, 1997b). U.S. EPA (1993) as cited in the MSRC summarized information on total mercury concentrations in outdoor air and reported ranges of 1 to 4 ng/m^3 for rural areas and 10 to 170 ng/m^3 for urban areas. Methylmercury concentrations from these samples constituted 0% to 21% of the total mercury concentration, with percentage values reported to generally be on the low end of this range. A measure of central tendency was not provided with this estimate. Particulate mercury typically constituted less than 4% of total atmospheric mercury in rural areas, although this fraction was increased in urban areas. The current background mercury concentration over the Northern Hemisphere is considered to be between 1.5 and 2.0 ng/m^3 (Expert Panel on Mercury Atmospheric Processes, 1994). A background concentration of 1.6 ng/m^3 was reported by Fitzgerald (1994). This value was subsequently used by U.S. EPA (1997b) to model mercury fate in watershed soils and surface waters.

Bloom and Fitzgerald (1988) measured vapor-phase mercury concentrations in outdoor air samples collected from Long Island Sound, CT. Total mercury concentrations ranged from 1.4 to 5.3 ng/m^3. The fraction of total mercury present as methylmercury was estimated to be 0% to 1%. During the month of October, the mean methylmercury concentration was 12 pg/m^3 (range 4 to 38 pg/m^3). This concentration represented 0.7% of the total gaseous mercury concentration. During the month of November, the measured methylmercury concentration was less than 10 pg/m^3 and from December through August, the concentration was below the detection limit of 5 pg/m^3.

Indoor Air. No data were identified for indoor air concentrations of methylmercury.

5.4.5.2 Predicted Concentrations in Air

EPA has modeled mercury air concentrations for the continental United States using RELMAP simulation, meteorological data for the year 1989, and current mercury emission data. The background level of mercury in the atmosphere was assumed to be 1.6 ng/m^3. The results of this simulation are reported in (U.S. EPA, 1997b). Predicted concentrations for total mercury are given in Table 5-17. The predicted total mercury concentrations ranged from approximately 1.6 to 1.9 ng/m^3, with the highest concentrations predicted for the Eastern United States. The tabulated results indicate that total

Source: U.S. EPA (1997b)

mercury concentration never exceeded the background level by a large percentage (25% maximum) under the conditions of this simulation. Methylmercury concentration estimates were not provided in the model output as reported in the MSRC (U.S. EPA, 1997b) but, again, is presumed to be present predominantly as elemental mercury.

5.4.5.3 Intake Estimates for Air

The primary species of mercury to which humans are exposed through inhalation is vapor-phase elemental mercury (U.S. EPA, 1997g). Thus, inhalation exposure to methylmercury is not expected to be a significant route of concern when compared to intake via fish consumption.

Assuming the background mercury concentration of 0.0016 $\mu g/m^3$ (or 1.6 ng/m^3) reported by Fitzgerald (1994), of which approximately one percent is methylmercury (Bloom and Fitzgerald, 1988), the average methylmercury concentration in air is 0.000016 $\mu g/m^3$ (or 1.6×10^{-8} mg/m^3). Estimates of daily exposure from methylmercury in air were calculated using inhalation rates and body weights specific to the populations of concern. The long-term inhalation rate based on a time-weighted average for children 0 to 14 years is estimated to be 10.4 m^3/day (U.S. EPA, 1997h). The average, long-term inhalation rates for women of childbearing age and adults in the general population are estimated to be 11 m^3/day and 20 m^3/day, respectively (U.S. EPA, 1994, 1997h). The recommended body weights for children 0 to 14 years, women of childbearing age, and adults in the general population are 30 kg, 67 kg, and 70 kg, respectively (U.S. EPA, 2000a). Based on these exposure input assumptions, the daily exposure estimates from methylmercury in air for children 0 to 14 years, women of childbearing age, and adults in the general population are 5.5×10^{-9} mg/kg-day, 2.6×10^{-9} mg/kg-day, and 4.6×10^{-9} mg/kg-day, respectively. These input assumptions and calculated daily exposure estimates for air are presented in Table 5-18.

U.S. EPA (1997c) reported inhalation exposure estimates based on ISC simulation for a humid site 2.5 km from a large hospital medical waste incinerator (HMI) and input from RELMAP (Eastern U.S., 50th percentile) (Table 5-19). The inhalation parameters used in the simulation for children (16 m^3/day) differed from the rate adopted from U.S. EPA (1997h) for calculation of inhalation intake from measured concentrations (see Table 15-1). Estimated intake for all five exposure scenarios was zero mg/kg-day. This prediction supports the finding of low methylmercury intake via inhalation as calculated from measured concentrations.

5.4.6 Soil/Sediment Exposures

5.4.6.1 Measured Concentrations in Soil/Sediment

The available data for measured methylmercury and total mercury concentrations in soils and sediments are summarized in Table 5-20, including a small number of studies that provide some data that are national in scope. In general, soil mercury levels are usually less than 200 ng/g in the top soil layer, but values exceeding this level are not uncommon, especially in areas affected by anthropogenic activities (U.S. EPA, 1997b). Soil mercury levels vary greatly with depth, with nearly all the mercury found in the top 20 cm of soil. Mercury levels are positively correlated with the percentage of organic matter in soil (Nriagu, 1979).

Some information is available on estimated typical or background levels of total mercury in U.S. soils and may be used with speciation data to estimate soil methylmercury concentrations. The MSRC (U.S. EPA, 1997b) states that approximately 1 to 3% of the total mercury in surface soil is methylmercury. The other 97% to 99% of total soil mercury can be considered to be largely Hg(II) complexes, although a small fraction of mercury in typical soil will be Hg^0 (Revis et al., 1990). The methylmercury percentage has been observed to exceed 3% in garden soil with high organic content under slightly acidic conditions (Cappon, 1987). Computer simulations of mercury fate and transport predict that methylmercury constitutes 2% of the total mercury in watershed soils (U.S. EPA, 1997b).

Davis et al. (1997) reported a range of 50 to 200 ng/g for total mercury concentrations in nonmercuriferous soils and sediments in background areas not directly impacted by volcanic emissions or anthropogenic releases. The authors stated that methylmercury typically constitutes 0.01% to 2 % of the total mercury concentration. Supporting information on the derivation of this estimate was not provided by the authors. The MSRC (U.S. EPA, 1997b) cited data from NJDEPE (1993) that indicates that typical U.S. soils contain 8 to 117 ng/g of total mercury. Neither an estimate of mean mercury concentration nor speciation data were provided in the description of this study as summarized in the MSRC. Assuming that approximately 2% of the total mercury concentration is present as methylmercury, these data suggest that typical U.S. soils contain 0.16 to 2.3 ng/g as methylmercury.

Shacklette and Boerngen (1984) reported mean concentrations, geometric standard deviations, and ranges for total mercury in soils and other surficial materials based on samples collected at 1318 sites across the conterminous United States. The geometric mean concentration for the conterminous United States was 58 ± 2,520 ng/g (ppb), and the estimated arithmetic mean was 89 ng/g. Additional data

indicate that the mean concentration of mercury in soils varies by region. In soils from the Western United States (west of the 96th meridian), the geometric mean concentration was 46 ± 2,330 ng/g (range <10 to 4,600 ng/g) and the estimated arithmetic mean was 65 ng/g. In soils from the Eastern United States (east of the 96th meridian), the geometric mean concentration was 81 ± 2,520 ng/g (range 10 to 3,400 ng/g), with an estimated arithmetic mean of 120 ng/g. Speciation data were not reported by these authors. Assuming that methylmercury constitutes approximately 2% of the total mercury concentration, the geometric and arithmetic mean levels of mercury present as methylmercury in soils in the conterminous United States would be approximately 1.2 ng/g and 1.8 ng/g, respectively.

Additional data are available on soil mercury and methylmercury concentrations for sites in the United States. As reported in the MSRC (U.S. EPA, 1997b), methylmercury concentrations in soil samples at locations in New York and Washington ranged from 0.3 to 22.9 ng/g dry weight and constituted 0.5% to 5.3% of the total soil mercury content. No other information on these studies was provided.

As characterized in the MSRC (U.S. EPA, 1997b), sediment mercury levels are typically higher than soil levels, and concentrations exceeding 200 ng/g are not unusual. Sediment mercury levels follow the same trends as soil in regards to depth, humic matter, and methylmercury percentage. There is some evidence suggesting that the methylmercury percentage increases with increasing total mercury contamination (Parks et al., 1989). Concentrations of mercury and (where available) methylmercury are tabulated in Table 5-20.

5.4.6.2 Predicted Concentrations in Soil

The MSRC (U.S. EPA, 1997b) reported the results of watershed fate and transport modeling conducted to predict the concentration of mercury in watershed soils. Atmospheric concentrations and deposition rates were used as inputs to the IEM-2M model. The IEM-2M model is composed of two integrated models that simulate mercury fate using mass balance equations which describe processes in watershed soils and a shallow lake. Using this approach, total mercury concentrations of 47 and 8 ng/g were predicted for soils at hypothetical Eastern and Western U.S. sites, respectively. These predicted concentrations for total mercury in soils are lower than the measured concentrations reported by Shacklette and Boergen (1984) for conterminous and regional U.S. soils. More than 90% of the total mercury in soil was predicted to occur as the inorganic divalent species. The fraction of the predicted background concentration occurring as methylmercury was 2% for the Eastern site (U.S. EPA, 1997c), suggesting a soil methylmercury concentration of 0.9 ng/g based on modeling predictions for speciation. Corresponding speciation data was not reported for the Western site.

5.4.6.3 Intake Estimates for Soil/Sediment

The primary species of mercury in soil is largely considered to be Hg(II) complexes, although a small fraction of mercury in typical soil will be Hg^0 (Revis et al., 1990). Thus, ingestion exposure to methylmercury in soil is not expected to be a significant route of concern when compared to exposure via fish ingestion.

Assuming the background mercury arithmetic mean concentration of 89 ng/g (or 0.089 mg/kg) reported by Shacklette and Boerngen (1984), of which approximately 2% is methylmercury (U.S. EPA, 1997b,c; Cappon, 1987; Davis et al., 1997), the average estimated methylmercury concentration in soil is 1.78 ng/g (or 0.00178 mg/kg). To estimate daily exposure from methylmercury in soil, ingestion rates and body weights for populations of concerns must also be estimated. The average incidental soil ingestion rate for children is estimated to be 1×10^{-4} kg/day (U.S. EPA, 1997h). In addition, the average soil ingestion rate for pica children is estimated to be 1×10^{-2} kg/day (U.S. EPA, 1997h). The average soil ingestion rates for women of child-bearing age and the general adult population are both estimated to

be 5 x 10^{-5} kg/day (U.S. EPA, 1997h). The default body weights for children 0 to 14 years, women of child-bearing age, and adults in the general population are 30 kg, 67 kg, and 70 kg, respectively (U.S. EPA, 2000a). Based on these exposure input assumptions, the daily exposure estimates from methylmercury in soil for children, pica children, women of child-bearing age, and adults in the general population are 5.9 x10^{-9} mg/kg-day, 5.9 x 10^{-7} mg/kg-day, 1.3 x10^{-9} mg/kg-day, and 1.3 x10^{-9} mg/kg-day, respectively. These input assumptions and calculated daily exposure estimates for soil are presented in Table 5-21.

Table 5-21. Summary of Soil Ingestion Intake Assumptions and Estimates

Population of Concern	**Mercury in Soil[a] (mg/kg)**	**Methyl-mercury/ Mercury in Soil[b] (%)**	**Methyl-mercury in Soil (mg/kg)**	**Ingestion Rate[c] (kg/day)**	**Body Weight[d] (kg)**	**Daily Exposure Estimate (mg/kg-day)**
Children	0.089	2	0.00178	0.0001	30	5.9 x10^{-9}
Pica Children	0.089	2	0.00178	0.01	30	5.9 x10^{-7}

[d] U.S. EPA (2000a).

Estimates of soil ingestion based on exposure modeling reported in the MSRC (U.S. EPA, 1997c) are summarized in Table 5-22. Predicted exposures are based on an ISC model simulation for a receptors at a humid site 2.5 km from a large hospital medical waste incinerator (HMI) and input from RELMAP (East 50th Percentile). Soil intake among the hypothetical receptors was highest for the urban pica child (1.2×10^{-6} mg/kg-day). The remaining estimates ranged from 3×10^{-9} to 2.4×10^{-8} mg/kg-day. These approximations are comparable to exposure estimates based on measured concentrations of mercury in soils in Table 5-21 when the twofold difference in assumed soil ingestion rate is considered.

5.4.7 Occupational and Other Exposures

Occupational Exposure. Occupational exposures are not routinely factored into the derivation of water quality criterion but may be considered on a chemical-specific basis. Information on occupational exposure to mercury has been summarized in the MSRC (U.S. EPA, 1997c). OSHA (1975) estimated that approximately 150,000 U.S. workers are exposed to mercury in at least 56 occupations. More recently, Campbell et al. (1992) reported that about 70,000 workers are annually exposed to mercury. Occupational settings in which exposure to mercury may occur include chemical and drug synthesis, hospitals, laboratories, dental practices, instrument manufacture, and battery manufacture (NIOSH, 1977). Jobs and processes involving mercury exposure include manufacture of measuring instruments (barometers, thermometers, etc.), mercury arc lamps, mercury switches, fluorescent lamps, mercury broilers, mirrors, electric rectifiers, electrolysis cathodes, pulp and paper, zinc carbon and mercury cell batteries, dental amalgams, antifouling paints, explosives, photographs, disinfectants, and fur processing.

Inorganic mercury accounts for nearly all occupational exposures (U.S. EPA, 1997c). Airborne elemental mercury vapor is the main pathway of concern, particularly in those industries with the greatest number of mercury exposures. Occupational exposure to methylmercury appears to be insignificant or rare. Thus, occupational exposures are not considered relevant to the derivation of ambient water criteria for methylmercury.

Table 5-22. Predicted Mercury Intake from Soil for Five Hypothetical High-End Exposure Scenarios

Parameter	Exposure Scenario[a]

[a]Data based on ISC simulation for a receptors at a humid site 2.5 km from a large hospital medical waste incinerator (HMI) and input from RELMAP (East 50th Percentile).

*Soil ingestion rates for rural home gardener and urban child (average) were not available. An ingestion rate of 0.2 g/day was assumed based on the soil ingestion rates for the rural subsistence farmer and high-end fisher children.

Source U.S. EPA (1997c)

Exposure from Dental Amalgam. Gradual erosion of dental amalgam represents a pathway by which many people are routinely exposed to extremely small amounts of mercury. Dental amalgam fillings contain approximately 50% mercury by weight. The mercury in the amalgam is continuously released over time. Speciation data indicate that release occurs primarily as elemental mercury vapor (Begerow et al., 1994). Exposure to methylmercury via this route is thus expected to be insignificant. Therefore, exposure to methylmercury via this pathway is not considered relevant to RSC analysis for derivation of the water quality criterion.

5.5 EXPOSURE DATA ADEQUACY AND ESTIMATE UNCERTAINTIES

After identifying relevant exposure pathways and obtaining available data for quantifying exposure via each pathway, it is important to consider whether the data are adequate to describe exposure estimates for each exposure medium. The adequacy of the contaminant concentration data, in part, determines the specific method with which the RSC estimates will be determined. Important factors include sample size, accurate representation of the sample (e.g., whether sample selection was biased and whether data are current), the accuracy in the sample analysis procedures (i.e., whether errors occurred during measurement), and the sensitivity of the measurement relative to the environmental levels of concern (i.e., whether detection limits are low enough such that the concentration can be detected in most samples within a data set). Additional discussion on data adequacy is provided in the 2000 Human Health Methodology (U.S. EPA, 2000a).

5.5.1 Adequacy of Intake Estimate for Drinking Water

Ground water. Nationally distributed data for methylmercury or total mercury in ground water were not located. The MSRC (U.S. EPA, 1997b) reports data from three local studies in the United States. However, supporting information on sample size, detection limits, analytical methodology, and other information relevant to data adequacy are not provided in the MSRC. Therefore, these data (as presented in the MSRC) do not satisfy the adequacy requirements of the 2000 Human Health Methodology.

Drinking Water. The MSRC (U.S. EPA, 1997b) cited a typical level of 25 ng/L for total mercury concentration in drinking and tap water (Lindqvist and Rodhe, 1985). A range of 0.3 to 25 ng/L for total mercury in drinking water was also reported (NJDEPE, 1993). The presentation of these data in the MSRC did not provide information on the composition of this water (e.g., fraction from ground water and surface water) or treatment status. Furthermore, the presentation of data in the MSRC did not

provide information on the method of calculation or a detailed description of data quality (including source of data, sample size, detection limits, and analysis procedures) for this estimate. Thus, the data for drinking water (as presented in the MSRC) are considered sufficient only for a rough estimate of intake. Yet, using the higher-end value of 25 ng/L results in an estimate within the range estimated for surface water.

Raw surface water. National data for surface water concentrations (primarily stream data) are available from the U.S. Geological Survey National Pilot Study of Mercury Contamination (Krabbenhoft et al., 1999). Water samples were collected in the summer and fall of 1998 and thus are representative of current concentrations. Sampling occurred at 106 sites clustered in 21 basins across the United States, including Alaska and Hawaii. Data from 104 sites were used to determine values for mean, median, maximum, and minimum methylmercury concentrations. The sampling sites spanned the dominant east-to-west mercury deposition gradient and represented a wide range of environmental settings. Total mercury and methylmercury were measured using sensitive analytical methodology (U.S. EPA Method 1631). The detection limits for total mercury and methylmercury were reported in a separate document (Olson and DeWild, 1999) referenced in the report. Some samples were collected at sites impacted by mining activity. The high concentration of mercury in samples collected at those sites resulted in a positively skewed distribution, and this is reflected in the difference between the arithmetic mean and median values for samples collected at all sites (0.15 $\pm$ 0.26 ng/L vs. 0.06 ng/L, respectively). The measures of central tendency from this study compare favorably to a methylmercury concentration of 0.07 ng/L in surface water predicted by IEM-2M computer simulation (U.S. EPA, 1997b). The data reported by Krabbenhoft et al. (1999) are therefore considered to be adequate to estimate intake from surface water.

5.5.2 Intake from Nonfish Dietary Sources

Data for measured methylmercury concentrations in nonfish foods are available from several local studies and one national study. Estimates of methylmercury concentration in selected produce and animal products are also available from computer simulations (U.S. EPA, 1997c). Data from the local studies provide supporting information on methylmercury speciation and concentration in a variety of foods, but are considered too limited in scope for estimation of intakes for use in RSC analysis. Information on mercury content of fish and nonfish foods is available from the Total Diet Study (1991-1997) conducted by U.S. FDA (1999). This is an on-going, nationally based study conducted for determining intake of nutrients and contaminants by the U.S. population. Based on data adequacy requirements of the 2000 Human Health Methodology (U.S. EPA, 2000a), the sample size of the U.S.

EPA study is sufficient for calculation of central tendency and 90th percentile values. Detection limits and the number of samples with mercury concentrations below detection the limit are reported by food item. The procedure for treating these samples for statistical analysis is reported. These data are thus considered adequate to estimate central tendency and high-end intakes from nonfish food items.

5.5.3 Intake From Fish

The MSRC (U.S. EPA, 1997c) assessed data sources for estimates of both freshwater and marine fish intake. Reliable mercury concentration data are available from databases maintained for marine fish and shellfish by the National Marine Fisheries Service (NMFS, 1978) and two databases for freshwater fish (Lowe et al., 1985; Bahnick et al., 1994). These studies are national in scope, in contrast to many studies that have a local or regional focus. In addition, the studies were not initiated in response to specific incidents of mercury contamination, and thus may avoid potential bias toward high values. Results in these studies are reported as total mercury. However, the MSRC concluded, based on research conducted by Bloom (1992) and Morgan et al. (1994), that over 90% of the mercury present in fish and seafood is methylmercury. Thus, total mercury concentrations are considered appropriate for evaluation of methylmercury exposure in human populations. Detailed information on mercury concentration by species and statistical considerations in use of the available data are presented in U.S. EPA (1997c).

Issues relating to data adequacy for methylmercury concentrations in marine fish and shellfish have been addressed in the MSRC (U.S. EPA, 1997c). Although the NMFS data were initially compiled beginning in the 1970s, comparisons of the mercury concentrations identified in the NMFS database with compliance samples obtained by the U.S. FDA indicate that the NMFS data are appropriate to use in estimating intake of mercury from marine fish at the national level of data aggregation. Cramer (1994) reported on *Exposure of U.S. Consumers to Methylmercury from Fish* and noted that recent information from NMFS indicated that the fish mercury concentrations reported in the 1978 report do not appear to have changed significantly. The U.S. FDA also monitors methylmercury concentration in seafood. Cramer (1994) observed that results of recent U.S. FDA surveys indicate results parallel to earlier findings by U.S. FDA and NMFS. The National Academy of Sciences' National Research Council's Subcommittee on Seafood Safety (1991) also assessed the applicability of the NMFS 1978 database to current estimates of mercury concentrations in fish. This subcommittee similarly concluded that the mercury concentrations in the 1978 database differed little in from the U.S. FDA compliance samples estimating mercury concentrations in fish. An assessment of the NMFS database by persons with expertise in analytical chemistry and patterns of mercury contamination in the environment indicates that temporal patterns of mercury concentrations in fish do not preclude use of this database in current risk

assessment activities (EPA's Science Advisory Board's ad hoc Mercury Subcommittee; Interagency Peer Review Group, External Peer Review Group).

An issue raised by some reviewers of the MSRC (U.S. EPA, 1997c) concerned use of data in the NMFS database where mercury concentration was below the analytical detection limit. A detailed analysis of the methods for reporting and analyzing nondetect data (U.S. EPA, 1997c, Appendix C) indicated that differences among methods used to handle nondetect samples had negligible impact on the reported mean concentrations in marine fish tissue. Additional information on analytical and statistical considerations in use of the NMFS data is available in EPA's MSRC (U.S. EPA, 1997d). Overall, EPA finds that these data are adequate for estimating exposure from marine fish for derivation of the methylmercury water quality criterion.

Two compilations of data on mercury concentrations in freshwater fish were considered for use in development of the water quality criterion for methylmercury. The strengths and weaknesses of these studies have been evaluated and reported in the MSRC (U.S. EPA, 1997c). The studies reported by Lowe et al. (1985) and by Bahnick et al. (1994) appear to be systematic, national collections of fish pollutant concentration data. However, higher mercury concentrations in fish have been detected in other studies, and the values obtained in the Lowe et al. (1985) and Bahnick et al. (1994) studies should be interpreted as approximations of the mean concentrations in freshwater finfish (U.S. EPA, 1997c). The mean mercury concentrations for each study in all fish sampled vary by a factor of two. The mean mercury concentration reported by Lowe et al. (1985) was 0.11 μg/g, whereas the mean mercury concentration reported by Bahnick et al. (1994) was 0.26 μg/g. The basis for these differences in methylmercury concentrations is unknown. Differences in sampling of fish by trophic position, size, or age might have been responsible for the differences in mean mercury concentrations reported in the two studies. Older and larger fish, which occupy higher trophic positions in the aquatic food chain, would be expected to have higher mercury concentrations. The type of water body from which fish were collected may also influence fish mercury concentrations. Most of the fish collected by Lowe et al. (1985) were from rivers. The fate and transport of mercury in river systems is not as well characterized as in small lakes. In comparison, most of the data reported by Bahnick et al. (1994) were collected with a bias toward more contaminated/industrialized sites, although sampled sites were not specifically contaminated with mercury. Thus, it is possible that there is more mercury available to the aquatic food chains at the sites sampled by Bahnick et al. (1994). Another possibility is that the higher mercury concentrations reported by Bahnick et al. (1994) when compared with those reported by Lowe et al. (1985) reflect increases in mercury contamination over the time period between the studies. Trend data for methylmercury concentrations in freshwater fish over time do not exist, although there are data for fish

collected from coastal and estuarine sites (U.S. EPA, 1997c) as discussed above and in Section 5.4.4.5. Those data suggest that there are no clear temporal trends in tissue mercury concentrations in fish and shellfish over the past two decades. Overall, the data from either study were considered adequate for calculating central tendency and high-end estimates of methylmercury intake from freshwater fish.

5.5.4 Intake from Air

The MSRC (U.S. EPA, 1997b) reported concentration ranges for mercury in urban and rural air. Information on geographic location, sample sizes, and detection limits were not provided. A range of 0 to 21% for methylmercury speciation was presented without an estimate of central tendency. Thus, these data as presented in the MSRC do not satisfy the adequacy requirements of the 2000 Human Health Methodology. A value of 1.6 ng/m^3 was presented in the MSRC as representative of national background levels for total mercury. Details on the derivation of this concentration were not provided; however, this value was considered of sufficient reliability to be used as input for fate and transport modeling reported in the MSRC (U.S. EPA, 1997b,c). Concentration measurements and exposure modeling data presented in the MSRC (U.S. EPA, 1997c) were also evaluated as an alternative estimate of methylmercury concentration in air. Many factors (including selection of modeling equations, input assumptions, and source data) in the modeling analysis affect the predicted concentrations and resulting exposures. These factors are summarized and discussed in U.S. EPA (1997b,c,g). No data were located for methylmercury concentrations in indoor air. Thus, this potential source of exposure was not considered in the estimate of intake from air.

The information available on both measured and predicted air concentrations of methylmercury from the MSRC is insufficient to fully determine data adequacy for estimating central tendency and high-end exposures to methylmercury via inhalation. Estimates of inhalation exposure are presented, although they are considered to represent rough approximations of actual (or likely) intake. Yet, the available data summarized in the MSRC (including the computer-simulated estimates) indicate that exposure to methylmercury in ambient air is negligible.

5.5.5 Intake From Soil

Three studies report aggregate values for measured soil mercury concentration. Shacklette and Boerngen (1984) reported arithmetic and geometric mean concentrations, geometric standard deviations, and ranges for total mercury in soils and other surficial materials based on samples collected at 1,318 sites across the conterminous United States. Sample size for these estimates is adequate, and the data are

representative of concentrations in the United States, although detailed information on analytical methodology, detection limit, and the number and statistical treatment of samples below detection limit was not provided.

Davis et al. (1997) reported a range of 50 to 200 ng/g for total mercury concentration and an estimate of the percent present as methylmercury in nonmercuriferous soils and sediments in background areas not directly impacted by volcanic emissions or anthropogenic releases. However, supporting information on the derivation of this estimate was not provided by the authors. The MSRC (U.S. EPA, 1997b) cited data from NJDEPE (1993) which indicates that typical U.S. soils contain 8 to 117 ng/g of total mercury. Information necessary for assessment of data adequacy was not provided in the summary of this study.

Additional data are available on soil mercury and methylmercury concentrations for sites in the United States. The MSRC (U.S. EPA, 1997b) summarized two reports on methylmercury speciation in soils collected at sites in New York and Washington state. Because each of these studies addressed soil concentrations in only one state, they were not considered adequate for estimating methylmercury exposure from soil.

Computer simulation data for predicted soil concentration, methylmercury speciation, and exposure estimates are available for comparison to measured values. Predicted concentrations were calculated on a regional (Eastern and Western U.S.) basis. As noted by U.S. EPA (1997b,c,g), many factors in the simulation analysis (including modeling equations, input assumptions, and source data) potentially affect the predicted concentrations.

Overall, the currently available soil concentration data are considered adequate to obtain central tendency and high-end estimates of exposure. Although some information was not readily available from the summarized studies in the MSRC (e.g., detection limits), the estimates of exposure from soil ingestion presented in this document are considered adequate given the sampling size (especially the Shacklette and Boerngen study) and geographic representativeness. There is also a clear indication from all available studies that the amount of methylmercury in soil that is methylmercury is approximately 2%.

5.6 TOTAL EXPOSURE ESTIMATES

Total exposure (calculated as the sum of exposure from water, freshwater and estuarine fish, marine fish, nonfish foods, air, and soil) for the three population groups in comparison to the RfD is shown in

Table 5-23. To evaluate potential differences in exposure from ambient water and drinking water, total exposure was calculated using methylmercury exposure estimates for each source. Because the contribution of ambient water or drinking water intake to total exposure is negligible in comparison to the sum of intake from other sources, there is no difference in the total exposure estimated using these two alternatives.

The contribution of exposure from different media as a percentage of total exposure for three types of individuals is summarized in Tables 5-24 through 5-26. Daily exposure estimates on a mg/kg-day basis are presented in Tables 5-27 through 5-29. The information in these tables reflects use of three different intake assumptions for consumption of marine fish: mean, median and 90th percentile.

Table 5-23. Total Exposure Compared with the RfD for Methylmercury

Population of Concern	Exposure Parameters								Total Exposures with Ambient Water (mg/kg-day)			Total Exposures with Drinking Water (mg/kg-day)		
	Body Weight (kg)	Drinking Water Intake (L/day)	Fresh/ Estuarine Fish Intake (kg/day)	Inhalation (m^3/day)	Soil Ingestion (kg/day)	Mean Marine Fish Intake (kg/day)	Median Marine Fish Intake (kg/day)	90% Marine Fish Intake (kg/day)	Marine Mean[a]	Marine Median[b]	Marine 90%[c]	Marine Mean[a]	Marine Median[b]	Marine 90%[c]

5.7 RELATIVE SOURCE CONTRIBUTION (RSC) ESTIMATES

5.7.1 RSC Policy Summary

As described in Section 5.1, water quality criteria for noncarcinogens account for anticipated exposures from sources other than drinking water and freshwater/estuarine fish ingestion. These exposures can include other dietary intakes, air, and soil. By accounting for other exposures, the entire RfD is not attributed to drinking water and freshwater/estuarine fish consumption alone. The relative source contribution (RSC) approach apportions the RfD to ensure that the water quality criterion is sufficiently protective, given the other anticipated sources of exposure. Thus, accounting for nonwater exposure sources results in a more stringent water quality criterion than if those sources were not considered. Details of the RSC approach (the Exposure Decision Tree) are described in more detail in the 2000 Human Health Methodology (U.S. EPA, 2000a).

The RSC determination differs from chemical to chemical depending on several factors: (a) the magnitude of total exposure compared with the RfD; (b) the adequacy of data available; (c) whether more than one guidance or criterion is to be set for the chemical in question; and (d) whether there is more than one significant exposure source for the chemical and population of concern. The target population for this methylmercury criterion is discussed in Section 5.2; the sources of methylmercury exposure, exposure estimates, and data adequacy are discussed in Sections 5.3 through 5.5.

5.7.2 Target Population for RSC/Rationale for Approach to Methylmercury

The target population for the RSC estimate is the general population. The health risk measure, the RfD, is intended to be protective of the whole population, including (but not restricted to) sensitive subpopulations. This is not a developmental RfD *per se*. Even though the critical endpoint was neurotoxic effects observed in children exposed *in utero*, application of the RfD is not restricted to pregnancy only, or to developmental periods only.

As discussed in the 2000 Human Health Methodology, the RSC policy approach allows for use of a subtraction method to account for other exposures when one health-based criterion is relevant for the chemical in question. In this circumstance, other sources of exposure can be considered "background" and can be subtracted from the RfD. Such is the case with methylmercury; that is, there are no health-based criteria, pesticide tolerances, or other regulatory activities to warrant apportionment using the alternate percentage method.

5.7.3 Data Adequacy for RSC Estimate

Section 5.4 describes information on levels of occurrence and provides estimates of exposure to methylmercury in ambient surface water, drinking water, fish, nonfish foods, air, soil, and sediment. The information in Section 5.4 indicates that, for almost all media sources, the sampling data meet the adequacy requirements (e.g., sample sizes, representativeness) for describing both central tendency and high-end concentrations for those sources (Box 3 of the Methodology Decision Tree approach [U.S. EPA, 2000a]). Thus, the data summarized for ambient surface water concentrations, nonfish dietary concentrations, marine fish concentrations, and soil concentrations are adequate to use for estimating overall exposure and RSC. Available data on methylmercury in ground water and estimates of methylmercury in drinking water are not as adequate, as defined by the data adequacy requirements in the 2000 Human Health Methodology. However, the estimates made for both ground water and drinking water in Section 5.4.2.3 indicate levels no higher in magnitude than the surface water estimates, even when using most high-end values. Information on ambient air concentrations summarized from the MSRC failed to indicate sample sizes, geographic representativeness, or detection limits and, thus, are not considered adequate in terms of the Methodology's Decision Tree (Box 3) requirements. However, 98% of mercury in ambient air occurs in the form of vapor-phase elemental mercury, according to the MSRC. Therefore, exposures to methylmercury in ambient air are probably negligible. This assumption is supported by the estimates presented in Section 5.4.5, including the MSRC model simulations predicting exposures of zero near a waste incinerator.

5.7.4 RSC Estimate/Apportionment of the RFD

Once it has been determined that the data are adequate to describe exposure intakes for relevant exposure sources and that there are no other health-based criteria to apportion, exposure intakes from sources other than the source addressed by the criterion are subtracted from the RfD (Box 12 of the Decision Tree, see U.S. EPA, 2000a). Based on the available data, human exposures to methylmercury from all media sources except freshwater/estuarine and marine fish are negligible, both in comparison to exposures from fish and compared to the RfD. Estimated exposure from ambient water, drinking water, nonfish dietary foods, air, and soil are all, on average, at least several orders of magnitude less than those from freshwater/estuarine fish intakes. Nonfish sources of intake are in the range of 10^{-5} to 10^{-9} μg methylmercury/kg body weight-day for adults in the general population. The combined methylmercury exposure intakes from water ingestion, (nonfish) diet, air, and soil represent approximately 0.07% of total estimated exposure to methylmercury (and less than 1/100 of 1% of the RfD) for adults in the general

population. Therefore, these exposures are not factored into the RSC because they will not quantitatively affect the final criterion value.

Ingestion of marine fish is a significant contributor to total methylmercury exposure. The MSRC (U.S. EPA, 1997c) indicates that in the general population of fish consumers, those that consume freshwater/estuarine species of fish are also consumers of marine species of fish. EPA has, therefore, made the assumption in the derivation of the methylmercury fish tissue criterion. In making this assumption, EPA does not believe that, by and large, the high-end consumer of freshwater/estuarine fish is also a high-end consumer of marine fish. The Agency believes that it is more appropriate, and a reasonably conservative assumption, to use the average intake rate (approximately 12.5 g/day) for the marine fish component of the RSC estimate.

The marine fish exposure source is estimated using species-specific mean methylmercury fish tissue data from NMFS (see Section 5.4.4.4) and calculating species-weighted intakes from the CSFII consumption rates (see Section 5.4.4.7). Following the MSRC (U.S. EPA, 1997c), nearly 100% of the mercury in marine fish was assumed to be present as methylmercury. The RSC estimate from marine fish has been calculated with an overall assumed average intake of 12.46 g/day of marine fish based on the CSFII, for all respondents aged 18 and over. The estimated weighted-average methylmercury concentration in marine fish is 0.157 mg methylmercury/kg fish, and the estimated average exposure to methylmercury from marine fish is 2.7×10^{-5} mg methylmercury/kg body weight-day. This exposure represents 27% of the RfD.

All exposure intake values estimated for methylmercury are presented in Table 5-30. The RSC factor in this case is determined by adding the estimated intakes that are quantitatively relevant for methylmercury; that is, only the intake from marine fish consumption of 2.7×10^{-5} mg/kg-day has any affect on the calculation. This amount is subtracted from the RfD of 0.1 µg methylmercury/kg body weight-day or 1.0×10^{-4} mg methylmercury/kg body weight-day. The remainder of the RfD is used to calculate the fish tissue residue concentration in terms of the assumed body weight and freshwater/estuarine fish ingestion. This results in an amount of methylmercury that is allowable in freshwater/estuarine fish and that will not exceed the RfD, considering the additional exposure from marine fish consumption.

Table 5-30. Exposure estimates for methylmercury and percent of total exposure based on adults in the general population

Exposure Source	Exposure Estimate (mg/kg-day)	Percent of Total Exposure	Percent of RfD
Ambient water intake	4.3×10^{-9}	0.0047	0.004
Drinking water intake[a]	5.6×10^{-8}	0.0605	0.006
Nonfish dietary intake	0	0	0
Marine fish intake	2.7×10^{-5}	29.33	27
Air intake	4.6×10^{-9}	0.005	0.005
Soil Intake	1.3×10^{-9}	0.0014	0.001
Total intake	9.2×10^{-5}	100	27.01

[a] This represents the high-end of the range of estimates. Because the contribution of ambient water or drinking water intake to total exposure is so negligible in comparison to the sum of intake from other sources, there is no difference in the total exposure estimated using either of these two alternatives.

6.0 METHYLMERCURY BIOACCUMULATION

6.1 INTRODUCTION

Aquatic organisms can accumulate and retain certain chemicals in their bodies when exposed to these chemicals through water, their diet and other sources. This process is called bioaccumulation. In order to prevent harmful exposures to waterborne pollutants through the consumption of contaminated fish and shellfish, national 304(a) water quality criteria for the protection of human health must address the process of chemical bioaccumulation in aquatic organisms. For deriving national 304(a) ambient water column criteria to protect human health, EPA accounts for potential bioaccumulation of pollutants in fish and shellfish through the use of national bioaccumulation factors (BAFs). A national BAF is a ratio (in L/kg) which relates the concentration of a chemical in water to its expected concentration in commonly consumed aquatic organisms in a specified trophic level. The magnitude of bioaccumulation by aquatic organisms varies widely depending on the chemical but can be extremely high for some highly persistent and hydrophobic chemicals. For such highly bioaccumulative chemicals, concentrations in aquatic organisms may pose unacceptable human health risks from fish and shellfish consumption even when concentrations in water are too low to cause unacceptable health risks from drinking water consumption alone. These chemicals may also biomagnify in aquatic food webs, a process whereby chemical concentrations increase in aquatic organisms of each successive trophic level due to increasing dietary exposures (e.g., increasing concentrations from algae, to zooplankton, to forage fish, to predator fish). Methylmercury is a chemical that bioaccumulates and biomagnifies to a relatively high extent. Methylmercury BAFs for upper trophic level freshwater and estuarine fish and shellfish typically consumed by humans generally range between 500,000 and 10,000,000 (Glass et al., 1999; Lores et al., 1998; Miles and Fink, 1998; Monson and Brezonik, 1998; Watras et al., 1998; Mason and Sullivan, 1997).

6.2 ISSUES IN DEVELOPING METHYLMERCURY BAFS

The fates of mercury and methylmercury in the environment are complex processes affected by numerous biotic and abiotic factors that are subjects of ongoing research by various government, private, and academic groups around the world. Methylation of mercury is a key step in the entrance of mercury into food chains. The biotransformation of inorganic mercury species to methylated organic species in water bodies can occur in the sediment and the water column. Inorganic mercury can be absorbed by aquatic organisms but is generally taken up at a slower rate and with lower efficiency than is

methylmercury. Methylmercury continues to accumulate in fish as they age. Predatory organisms at the top of aquatic and terrestrial food webs generally have higher methylmercury concentrations because methylmercury is typically not completely eliminated by organisms and is transferred up the food chain when predators feed on prey; for example, when a largemouth bass feeds on a bluegill sunfish, which fed on aquatic insects and smaller fish, all of the prey could contain some amount of methylmercury that gets transferred to the predator. Nearly 100% of the mercury that bioaccumulates in upper trophic level fish (predator) tissue is methylmercury (Bloom, 1992; Akagi, 1995; Kim, 1995; Becker and Bigham, 1995).

Numerous factors can influence the bioaccumulation of mercury in aquatic biota. These include, but are not limited to, the acidity (pH) of the water, length of the aquatic food chain, temperature, and dissolved organic material. Physical and chemical characteristics of a watershed, such as soil type and erosion or proportion of area that is wetlands, can affect the amount of mercury that is transported from soils to water bodies. Interrelationships among these factors are poorly understood and are likely to be site-specific. No single factor (including pH) has been correlated with extent of mercury bioaccumulation in all cases examined. Two lakes that are similar biologically, physically, and chemically can have different methylmercury concentrations in water, fish, and other aquatic organisms (Cope et al., 1990; Grieb et al., 1990; Jackson, 1991; Lange et al., 1993). For more in-depth discussions about the chemical, physical, and biological interactions affecting methylmercury bioaccumulation in aquatic organisms see the *Mercury Study Report to Congress* (MSRC), Volume III and Volume III Appendix D (U.S. EPA, 1997c), and the compilation of papers in *Mercury Pollution: Integration and Synthesis* (Watras and Huckabee, 1994).

To derive section 304(a) water quality criteria for the protection of human health, EPA needs to conduct a human health risk assessment on the pollutant in question and to gather information on the target population's exposure to the pollutant. Traditionally, EPA has expressed its section 304(a) water quality criteria guidance to protect human health in the form of pollutant concentrations in ambient surface water. To account for human exposure through the aquatic food pathway when deriving a water column-based water quality criterion, EPA uses national BAFs (U.S. EPA 2000). A BAF is a ratio (in L/kg) that relates the concentration of a chemical in water to its expected concentration in commonly consumed aquatic organisms in a specified trophic level (U.S. EPA 2000). A national BAF is meant to be broadly applicable to all waters in the United States, whereas a site-specific BAF is based on local data and integrates local spacial and temporal factors that can influence bioaccumulation. For pollutants that biomagnify, such as methylmercury, EPA's preferred approach for deriving national BAFs for use in deriving section 304(a) water quality criteria is to use empirical field data collected in the natural

environment. EPA prefers this approach because BAFs derived with field data integrate the chemical, biological, and physical factors that can affect bioaccumulation in fish and shellfish. With this preference in mind, EPA explored the feasibility of developing field-derived national methylmercury BAFs for each trophic level of the aquatic food chain consumed by humans (i.e., trophic levels 2-4). Using Agency guidance on BAFs contained in the 2000 Human Health Methodology and procedures outlined in Volume III, Appendix D of the peer-reviewed MSRC (U.S. EPA, 1997c), EPA empirically derived draft national methylmercury BAFs for each trophic level of the aquatic food chain. The draft national BAFs were single value trophic level-specific BAFs calculated as the geometric mean of field data collected across the United States and reported in the open literature as well as other publically available reports. These draft methylmercury BAFs were compiled in a draft internal report and submitted to a panel of external scientific experts for peer review. The Appendix contains a summary of the internal BAF report and BAF peer review report. The entire internal draft methylmercury BAF report and peer review report can be obtained from the Water Docket W-00-20.

Within any given trophic level, the individual empirically derived draft methylmercury BAFs generally ranged up to two orders of magnitude. This range in BAFs reflects the various biotic factors (such as food chain interactions and fish age/size) and abiotic factors (such as pH and dissolved organic carbon). The large range in the individual empirically derived draft methylmercury BAFs results in uncertainty as to the ability of single trophic level-specific national methylmercury BAFs to accurately predict bioaccumulation of methylmercury in general across the waters of the United States. Presently, it is EPA's understanding that the mechanisms that underlie many of the influencing factors are not well understood and can not be accurately predicted. As the science of methylmercury improves, in the future it may be possible predict or model these processes and use such information to more accurately predict bioaccumulation. Until such time, EPA is unable to improve the predictive power of the methylmercury BAFs by universally accounting for influencing factors. This is not the case for other highly bioaccumulative pollutants; for example polychlorinated biphenyls (PCBs). For such pollutants, EPA has methods that improve the predictive capability of empirically derived or model predicted BAFs (such as normalizing fish tissue concentrations to lipid and normalizing ambient water concentrations to dissolved and particulate organic carbon). EPA is actively involved in, and will continue to support, various types of research aimed at better understanding the fate of mercury in the environment and the processes that underlie methylmercury bioaccumulation. EPA hopes that results of new research will enable better predictions of methylmercury bioaccumulation.

The BAF peer reviewers recognized the need for methylmercury BAFs and were supportive of most aspects of the methodology used to derive the draft national methylmercury BAFs. The peer reviewers did have issues with certain data used to derive the methylmercury BAFs and certain assumptions about food chain relationships. Overall, most of the peer reviewers believed that derivation of single-value trophic level-specific national BAFs for methylmercury that would be generally applicable to all waters of the United States under all conditions is difficult at best, and perhaps impossible. This opinion was based on consideration of the highly site-specific nature of methylmercury bioaccumulation in aquatic environments and the large range in the empirically derived draft methylmercury BAFs. These peer reviewers recommended developing methylmercury BAFs on a more local or regional scale, if not on a site-specific basis. Although EPA generally agrees with this suggestion, the data needed to derive BAFs at more localized scales across the U.S. are not available. See Appendix A for a summary of the internal BAF report and the BAF peer review report.

6.3 CONSIDERATION OF A FISH TISSUE RESIDUE CRITERION

After considering the various issues about mercury fate in the environment, the recent report by the National Research Council (NRC, 2000) on the toxicological effects of mercury, and the methylmercury BAF peer review comments, EPA concluded that it is more appropriate at this time to derive a fish tissue (including shellfish) residue water quality criterion for methylmercury rather than a water column-based water quality criterion. EPA believes a fish tissue residue water quality criterion for methylmercury is appropriate for many reasons. A fish tissue residue water quality criterion integrates spatial and temporal complexity that occurs in aquatic systems and that affect methylmercury bioaccumulation. A fish tissue residue water quality criterion in this instance is more closely tied to the CWA goal of protecting the public health because it is based directly on the dominant human exposure route for methylmercury. The concentration of methylmercury is also generally easier to quantify in fish tissue than in water and is less variable in fish and shellfish tissue over the time periods in which water quality standards are typically implemented in water quality-based controls, such as NPDES permits. Thus, the data used in permitting activities can be based on a more consistent and measurable endpoint. Finally, this approach is consistent with the way in which fish advisories are issued. Fish advisories for mercury are also based on the amount of methylmercury in fish tissue that is considered acceptable, although such advisories are usually issued for a certain fish or shellfish species in terms of a meal size. A fish tissue residue water quality criterion should enhance harmonization between these two approaches for protecting the public health.

Because EPA did not use national, empirically derived methylmercury BAFs to establish today's section 304(a) recommended methylmercury water quality criterion, EPA has deferred further efforts to derive national BAFs for methylmercury at this time. EPA notes, however, that there may be adequate field data for some waterbodies or geographical regions on which to base accurate predictive, site-specific methylmercury BAFs. EPA may reconsider developing national methylmercury BAFs in the future once more field data is available for a broader range of species and aquatic ecosystems, or once more information is available describing the mechanisms that affect bioaccumulation. Such information could enable EPA to more accurately predict methylmercury bioaccumulation on a broader scale given a certain total mercury concentration in water.

7.0 WATER QUALITY CRITERION CALCULATION

7.1 EQUATION FOR TISSUE RESIDUE CONCENTRATION AND PARAMETERS USED

The equation for calculating the methylmercury fish tissue residue criterion is:

$$TRC = \frac{BW \times (RfD - RSC)}{\sum_{i=2}^{4} FI_i}$$

Where:

TRC	=	Fish tissue residue criterion (mg methylmercury/kg fish) for freshwater and estuarine fish
RfD	=	Reference dose (based on noncancer human health effects) of 0.0001 mg methylmercury/kg body weight-day
RSC	=	Relative source contribution (subtracted from the RfD to account for marine fish consumption) estimated to be 2.7×10^{-5} mg methylmercury/kg body weight-day
BW	=	Human body weight default value of 70 kg (for adults)
FI	=	Fish intake at trophic level (TL) i (i = 2, 3, 4); total default intake is 0.0175 kg fish/day for general adult population. Trophic level breakouts for the general population are: TL2 = 0.0038 kg fish/day; TL3 = 0.0080 kg fish/day; and TL4 = 0.0057 kg fish/day.

This yields a methylmercury TRC value of 0.3 mg methylmercury/kg fish (rounded to one significant digit from 0.288 mg methylmercury/kg fish).

This equation is essentially the same equation used in the 2000 Human Health Methodology to calculate a water quality criterion, but is rearranged to solve for a protective concentration in fish tissue rather than in water. Thus, it does not include a BAF or drinking water intake value (as discussed above, exposure from drinking water is negligible). The TRC of 0.3 mg methylmercury/kg fish is the concentration in fish tissue that should not be exceeded based on a total consumption of 0.0175 kg fish/day.

7.2 SITE-SPECIFIC OR REGIONAL ADJUSTMENTS TO CRITERIA

Several parameters in the Water Quality Criterion equation can be adjusted on a site-specific or regional basis to reflect regional or local conditions and/or specific populations of concern. These include the fish consumption rates and the RSC estimate. States and authorized Tribes can also choose to apportion an intake rate to the highest trophic level consumed for their population or modify EPA's default intake rate based on local or regional consumption patterns. EPA strongly encourages States and authorized Tribes to consider developing a criterion using local or regional data over the default values if they believe that they would be more appropriate for their target population. States and authorized Tribes are encouraged to make such adjustments using the guidance provided in the 2000 Human Health Methodology (U.S. EPA, 2000a).

APPENDIX A

SECTION I. DRAFT NATIONAL METHYLMERCURY BIOACCUMULATION FACTORS

This appendix is a brief summary of the initial effort conducted to determine the feasibility of deriving draft National bioaccumulation factors for methylmercury. This appendix is based on the draft bioaccumulation report. The complete version of the original draft bioaccumulation factor report, with more in-depth discussions of the methodology, a list of the references cited, rationales for using data, and an uncertainty discussion can be obtained from the Water Docket W-00-20.

This appendix does not reflect comments or changes suggested by the peer reviewers. No changes were made to the draft report that served as the basis for this appendix. Data interpretations, findings, or conclusions discussed in this appendix are preliminary and may be changed in the future.

Introduction

The methylmercury bioaccumulation factors (BAFs) were estimated using guidance presented in the *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (U.S. EPA, 2000a; hereafter "the 2000 Human Health Methodology") and supplemented with methods presented in the Mercury Study Report to Congress (MSRC; U.S. EPA, 1997c). The generalized equation for estimating a BAF is as follows:

$$BAF = \frac{C_t}{C_w} \qquad \textbf{Equation-1}$$

where:

C_t = Concentration of the chemical in the wet tissue (either whole organism or specified tissue)

C_w = Concentration of chemical in water

Literature searches were conducted to obtain data on bioaccumulation, concentrations of different forms of mercury in water, percent methylmercury in tissue, and mercury predator-prey data. The data sources primarily included articles from peer reviewed journals published between 1990 and April of 1999 and publicly available reports (e.g., State, Federal, or trade/industry group reports; dissertations;

proceedings from professional meetings). Data from a variety of aquatic ecosystems (i.e., lakes, rivers, estuaries) and on lower trophic levels was specifically looked for since the MSRC focused only on lakes (primarily northern oligotrophic lakes) and trophic levels 3 and 4 fish.

BAFs are used in the ambient water quality criteria (AWQC) equation to estimate human mercury exposure from consumption of contaminated fish. Equation 2 is the generalized AWQC equation for a noncarcinogen and shows where the BAF fits into the calculation.

$$AWQC = RfD \times RSC\left[\frac{BW}{DI + \sum_{i}^{x}(FI \times BAF_i)}\right] \qquad \textbf{Equation 2}$$

Where:

RfD = reference dose for noncancer human health effects

RSC = relative source contribution to account for non-water sources of exposure

BW = human body weight

DI = drinking water intake

FI = fish intake

BAF_i = bioaccumulation factor for chemical "i".

The methylmercury BAFs that would be used in the above equation are presented in the accompanying table A-9, and are calculated as the geometric mean BAF of all BAFs calculated for a given trophic level.

Attachment A at the end of this appendix also contains the general comments made by the external peer reviewers on the draft national methylmercury BAFs.

Methods for Estimating Bioaccumulation Factors

Three approaches were used to derive draft BAFs that could be used to derive draft national methylmercury BAFs. These are direct, indirect, and conversion (modified direct) approaches. Each of

these approaches has its own limitations, biases, and uncertainties associate with it. These approaches and the BAFs derived using them are summarized below.

EPA's BAF derivation guidance is based on a data hierarchical preference approach. Under the hierarchy, the preferred method for deriving a BAF for an organometallic compound such as methylmercury is to use field-measured data to directly calculate a BAF (i.e., the direct method). BAFs estimated using this direct approach are calculated using the simple ratio of the chemical concentration in tissue and water. When such field data do not exist, or if the available field data are considered unreliable, the next preferred method in the hierarchy estimates a BAF by multiplying a bioconcentration factor (BCF) by a food chain multiplier (FCM) (i.e., the indirect method). The FCM is a factor used to account for food chain interactions and biomagnification. EPA has used this indirect method to estimate BAFs to support the development of wildlife criteria values in the Great Lakes Water Quality Initiative or GLWQI (EPA, 1993) and in the MSRC (EPA, 1997). With few exceptions, field-derived FCMs were calculated using concentrations of methylmercury in predator and prey species using the following equations:

$$FCM_{TL2} = BMF_{TL2} \qquad \text{Equation-3}$$

$$FCM_{TL3} = (BMF_{TL3})\,(BMF_{TL2}) \qquad \text{Equation-4}$$

$$FCM_{TL4} = (BMF_{TL4})\,(BMF_{TL3})\,(BMF_{TL2}) \qquad \text{Equation-5}$$

where:

FCM = Food chain multiplier for designated trophic level (TL2, TL3, or TL4)
BMF = Biomagnification factor for designated trophic level (TL2, TL3, or TL4)

The basic difference between FCMs and BMFs is that FCMs relate back to trophic level one, whereas BMFs always relate back to the next lowest trophic level. Biomagnification factors are calculated from methylmercury tissue residue concentrations determined in biota at a site according to the following equations:

$$BMF_{TL2} = C_t, TL2) / (C_t, TL1) \qquad \text{Equation-6}$$

$$BMF_{TL3} = (C_t, TL3) / (C_t, TL2) \qquad \text{Equation-7}$$

$$BMF_{TL4} = (C_t, TL4) / (C_t, TL3) \qquad \text{Equation-8}$$

where:

C_t = concentration of chemical in tissue of appropriate biota that occupy the specified trophic level (TL2, TL3, or TL4).

With the indirect BAF approach, it is important that when either selecting predator prey field data from the literature or when conducting a site-specific field study to obtain such data, that the feeding relationships between predator and prey are based on functional feeding relationships. It should be verified that a given predator is feeding on a given prey item at the location in question so that the BMFs and FCMs reflect actual trophic transfer of the chemical as close as possible. Usually, it is not enough to simply know that organisms are from two different trophic levels. Unfortunately, for the analyses presented here, much of the available data obtained from the published literature were insufficient to document functional feeding relationships. Thus, BAFs derived using the indirect approach were not used in determining the draft national methylmercury BAFs, but are presented only for comparison purposes.

In the MSRC, in cases where the direct empirical BAF derivation method could be used, but the available data was for a form of mercury other than dissolved methylmercury, a modified direct approach was also used. The modified direct approach was used when either the water data or organism tissue data was not in the methylmercury form (e.g., total mercury, dissolved total mercury, total methylmercury) but could be converted to methylmercury using translating factors. Data for mercury in water was converted to dissolved methylmercury by using chemical translators (see Section II of this Appendix). Mercury in tissue reported as total mercury was converted to methylmercury by multiplying by a factor that estimates the fraction of total mercury present in the methylated form (i.e., fmmf translator). The fmmfs were developed from field studies where both total mercury and methylmercury were measured in biota tissue.

Using the methods outlined above, BAFs were estimated initially by trophic level for lakes (lentic aquatic systems), rivers and streams (lotic aquatic systems), and estuaries. An ecosystem-based approach to deriving the BAFs was used because differences in general bioaccumulation trends would be expected among the aquatic ecosystems due to inherent differences in methylation processes, food web dynamics,

mercury loadings, and watershed interactions, among other factors. However, due to the lack of data in terms of both quality and quantity, no clear differences in bioaccumulation trends were observed between lentic and lotic ecosystems based on the available data (see Figure A-3). Based on qualitative and semi-quantitative comparisons of the data, no significant difference was found between the lentic and lotic BAFs. Thus, they were combined for each trophic level to obtain the trophic level-specific draft national BAFs. A near complete lack of adequate data prohibited derivation of draft national BAFs for estuarine systems.

Summary of BAFs for Methylmercury in Lentic Ecosystems

Table A-1 compares the BAFs estimated using the two primary approaches (direct and indirect) methods for estimating BAFs for trophic levels 2, 3, and 4 species. Although the BAFs based on the indirect approach are not used in the national draft BAF calculations because they are not based on verifiable functional predator-prey feeding relation ships, they are nonetheless useful for comparing and assessing general tends in bioaccumulation. Other than the BAF_2, the BAFs are within a factor of two of one another. Both the direct and indirectly estimated BAFs show an expected increase in methylmercury bioaccumulation with increasing trophic position. This suggests that if functional predator-prey feeding relationships can be developed, that indirect BAFs could provide reasonably good approximations of methylmercury bioaccumulation in organisms in the field.

Table A-1: Summary of Bioaccumulation Factors for Methylmercury Mercury in Lentic Ecosystems

Parameter	Methylmercury (1)	
	Direct ($L \cdot kg^{-1}$)	Indirect ($L \cdot kg^{-1}$)
BCF	5.9×10^4	NA
BAF_2	8.6×10^4	3.1×10^5
BAF_3	1.3×10^6	2.2×10^6
BAF_4	6.8×10^6	1.1×10^7

(1) All values are geometric means

Summary of BAFs for Methylmercury in Lotic Ecosystems

Table A-2 compares the lotic BAFs estimated using the direct and indirect methods. The BAFs based on the indirect approach are not used in the draft national BAF calculation because they are not based on verifiable functional predator-prey feeding relation ships; they are nonetheless useful for comparing and assessing general tends in bioaccumulation. As was the case with the lentic indirectly estimated BAFs, the indirect lotic BAFs are close approximations of the directly estimated BAFs (within a factor of 3 or less). Also, as was observed for lentic ecosystems, both the direct and indirectly estimated lotic BAFs show an expected increase in methylmercury bioaccumulation with increasing trophic position. This suggests that if functional predator-prey feeding relation ships can be developed,

Table A-2: Summary of Dissolved Methylmercury Bioaccumulation Factors for Lotic Ecosystems

Parameter	Methylmercury (1)	
	Direct ($L \cdot kg^{-1}$)	Indirect ($L \cdot kg^{-1}$)
BCF	1.2×10^4	NA
BAF_2	4.4×10^5	1.9×10^5
BAF_3	1.6×10^6	5.6×10^5
BAF_4	2.5×10^6	3.2×10^6

(1) values are geometric means

that indirect BAFs could provide reasonably good approximations of methylmercury bioaccumulation in organisms in the field.

Methylmercury BAFs Translated from Other Mercury Forms

Converted BAFs (that is, in terms of other mercury forms) were derived for dissolved methylmercury using translator factors (see Section II, Chemical Translators for Mercury and Methylmercury) and by using factors to convert total mercury measured in organism tissues to methylmercury in tissues.

Mercury Translators

For those studies that met the data quality objectives but did not analyze or report water mercury concentrations in the dissolved methylmercury form, the reported form of mercury was converted to the mean fraction of dissolved methylmercury (f_d $MeHg_d$) by using one or more of the "translators" listed in Table A-3. Section II below discusses the methodology and data used to derive the translators. Section II of this appendix also provides partition coefficients (K_D) that were not necessary for this analysis, but that can be used along with total suspended solids information to estimate the desired fraction of mercury in water.

Table A-3: Summary of Mercury Translators for Mercury in Water

f_d value	Lentic	Lotic
f_d Hg_d/Hg_t	0.600	0.370
f_d $MeHg_d/Hg_t$	0.032	0.014
f_d $MeHg_d/MeHg_t$	0.613	0.490

Conversion Factors for Mercury in Organism Tissue

Similar to the water data, if mercury in biota tissue (muscle or whole body) was reported as total mercury then the appropriate mean (arithmetic) estimate of the fraction present in the methylated form (fmmf) for the respective trophic level was used to convert it to methylmercury. Table A-4 summarizes the fmmfs used to estimate converted BAFs.

Table A-4: Summary of fmmfs for Lentic and Lotic Ecosystems

Trophic Level	Lentic	Lotic
1	0.18	0.05
2	0.44	0.49
3	1.00	1.00
4	1.00	1.00

Summary and Comparison of Converted BAFs and BCFs derived for Lentic and Lotic Ecosystems

Methylmercury translator factors (see Section II, *Chemical Translators for Mercury and Methylmercury*) were used to estimate dissolved methylmercury BCFs and BAFs in lotic and lentic ecosystems. Table A-5 summarizes the converted BAFs. The converted lentic BAFs range from approximately 2 to 37 times greater than the converted lotic BAFs.

Figures A-1 and A-2 compare the direct and converted estimates of BAFs and BCFs for lentic and lotic ecosystems, respectively. Although the data sets are relatively small, the ranges of converted BAFs are in agreement with BAFs directly estimated. Tables A-6 and A-7 summarize and compare the point estimates of each data set. In lentic ecosystems, the difference between the mean directly estimated BAFs and mean converted BAFs is generally less than a factor of two. For lotic ecosystems, the difference is slightly larger, ranging from a factor of two to a factor of seven, with an overall mean difference of four. This information suggests that the converted BAFs in each ecosystem are good estimates of directly measured BAFs for all trophic levels. However, because the set of BAFs estimated using the two different approaches are small for each ecosystem, insufficient data were available to perform any rigorous statistical evaluation to determine if a significant difference exists between the BAFs of each system. Nonetheless, graphically the data suggest that the direct and converted BAFs can be combined to derive overall BAFs for each trophic level in each ecosystem. The BAFs based on the combined data sets are presented in Table A-8.

Figure A-3 compares the combined data sets (e.g., directly-measured and converted BAFs and BCFs) for lentic and lotic ecosystems. While the lotic BAFs clearly span a greater range than the lentic BAFs, the differences between the mean lotic BAFs and the mean lentic BAFs for each trophic level are fairly small (differences range between 1 and 5). To investigate if there were significant differences between the BAFs for the two ecosystems significant, a student's T-test was performed on the combined data for each trophic level-specific BAF and BCF using the computer software WINKS (Texasoft, 1999). Although differences in mercury bioaccumulation between lentic and lotic ecosystems could be expected due to differences in mercury loading characteristics, bioavailability, food web dynamics, and methylation processes, among other factors, no significant statistical differences ($p>0.05$) were found between the lentic and lotic BAFs and BCFs. Furthermore, a closer inspection of the converted lentic BAF_4 data for several Minnesota Lakes (Glass et al., 1999) suggests that, given a larger sample size, the lower range of field-measured lentic BAF_4 values could be similar to the lower range of values observed for lotic ecosystems. Whether these observations are artifacts of the available data or trends due to real

processes is not distinguishable. Because the range of available BAF values for lentic and lotic systems overlap one another, the individual BAFs for the two systems were combined in one data set to derive the trophic level-specific draft national methylmercury BAFs.

Draft National Bioaccumulation Factors for Methylmercury

Based on the data presented above, and because the goal of the draft national BAFs is to be applicable under as many circumstances and to as many water bodies as possible, the BAFs based on the combined data sets (e.g., direct and converted, lentic and lotic) were chosen to be the empirically-derived draft national BAFs for methylmercury. The draft National BAFs, along with the draft BCF, and their empirical distributions are presented in Table A-9.

Table A-9: Summary of Draft National BAFs and BCF for Dissolved Methylmercury

Value[a]	BCF	BAF_2	BAF_3	BAF_4
5th percentile	5,300	18,000	74,300	250,000
50th (GM) percentile	33,000	117,000	680,000	2,670,000

Discussion of Uncertainty and Variability in the BAF Estimates

The BAFs in this document were designed to estimate the central tendency of the concentration of mercury in fish of a given trophic level from an average concentration of dissolved mercury for water bodies located in the continental U.S. As shown in figures A1-A3, there is at least an order of magnitude in the variability of the individual BAF estimates for a given trophic level, which leads to uncertainty in the overall central tendency estimate. This is further reflected in the range of 90 percent (5th and 95th percentiles) confidence intervals. Although the empirical range of any given 90 percent confidence interval may largely overestimate the true extent of variability, the distributions do provide a rough estimate of the total uncertainty in the aggregate processes and an idea of the precision (or lack thereof) of the BAF estimates. The uncertainty in the BAF estimates is related to two basic sources. First is the uncertainty arising from natural variability, such as size of individual fish or differences in metabolic processes. Second is the uncertainty due to measurement error, such as error in measurements of mercury in water and fish samples or lack of knowledge of the true variance of a process (e.g., methylation). These two sources of uncertainty are generally referred to as "variability" and

"uncertainty", respectively. In this analysis, there was no distinction made between variability and uncertainty; they are aggregated in the final BAF distributions and point estimates. Thus, it cannot be determined where natural variability stops and uncertainty starts. However, some of the more important sources of variability and uncertainty are highlighted below in order to assist risk managers in understanding what the limitations are surrounding the BAFs, to see how the uncertainty in the BAF estimates might be reduced should they derive more data, and to assist them in decisions on development of site-specific BAFs.

Uncertainty Due to Sampling and Chemical Analysis

In many cases, water methylmercury concentrations reported in the available studies incorporated limited or no cross-seasonal variability, incorporated little or no spacial variability, and were often based on a single sampling event. Because fish integrate exposure of mercury over a life time, comparing fish concentrations to a single sample or mean annual concentrations introduces bias to the estimates. The geographic range represented by the water bodies is also limited. The available lentic data are biased towards northern oligotrophic lakes, primarily located in the Great Lakes region. The lotic BAFs are primarily based on data from canals of the Everglades (assumed to act as flowing aquatic ecosystems) and from a point-source-contaminated stream in Tennessee. Because of this general lack of data, a few studies on water bodies in other countries were included in the analysis, requiring one to assume that biotic and abiotic processes in these lakes are similar to lakes in the continental U.S.

The same sampling and analytical methods for water and tissue samples were not used in each acceptable study. Although all studies used met general requirements for data quality, studies with different analytical detection limits were combined to estimate the BAFs. The range of species used in the BAF estimates is relatively small compared to the suite of fish and invertebrates consumed by the general human population. Much of the available trophic level 4 data for both lentic and lotic ecosystems is limited to walleye, pike, or bass. For trophic level 3 much of the data is for bluegill and perch. For trophic level 2, most of the data was for zooplankton in lentic waters and for planktivorous fish in lotic waters. The lack of data complicated comparisons between the two aquatic ecosystems and introduces uncertainty into application of the BAFs.

Uncertainty Due to Estimation Method

Each of the approaches use to estimate BAFs have their own inherent uncertainties. Both the direct and indirect approaches assume that the underlying process and mechanisms of mercury bioaccumulation are the same for all species in a given trophic level and for all water bodies. The indirect approach deals with this assumption more specifically by assuming that the translators and fmmfs used to convert BAFs are equally applicable to all ecosystems. In reality, these factors are based on a limited set of data. Although the translators and fmmfs used in the analysis are consistent with those reported elsewhere (Porcella, 1994), they may over- or underestimate bioavailability and bioaccumulation in specific water bodies. Ideally, site-specific conversion factors would be used to estimate BAFs more reflective of conditions in a given water body. The approach used here aggregates all of the species-specific BAFs into a single trophic level-specific BAF; this also increases the over all variability in the BAF estimates.

Uncertainty Due to Biological Factors

Other than deriving BAFs based on organism trophic level, and initially by general water body type (i.e., lentic and lotic), there were no distinctions in the BAFs as to size/age of fish, water body trophic status, or underlying mercury uptake processes. It has been shown that methylmercury bioaccumulation for a given species can vary as a function of the ages (body size) of the organisms examined (Glass et al, 1999; Watras et al., 1998; Suchanek et al., 1993; Lange et al. 1993). As a result, it has been suggested that to reduce some of the lake-to-lake variability seen in BAFs for a given species, comparisons between water bodies should be made using "standardized" fish values (i.e., a value for a hypothetical 1 kg northern pike; Glass et al., 1999). Typically such data "normalization" is derived by linear regression of residue data collected from individuals of varying size and/or age. However, the currently available data are too limited to perform this kind of normalization; most of the water body-specific BAFs, and resulting trophic level distributions, are based on "opportunity" (whatever you catch, you include) and do not report age or size of individuals sampled.

Uncertainty Due to Universal Application of BAFs

Perhaps the greatest source of variability is that of model uncertainty. That is, uncertainty introduced by failure of the model (in this analysis a single trophic level-specific BAF) to represent significant real-world processes that vary from water body to water body. The simple linear BAF model relating methylmercury in fish to total mercury in water simplifies a number of nonlinear processes that

lead to the formation of bioavailable methylmercury in the water column and subsequent accumulation. Much of the variability in field data applicable to the estimation of mercury BAFs can be attributed to differences in biotic factors (e.g., food chain, organism age/size, primary production, methylation/demethylation rates), and abiotic factors (e.g., pH, organic matter, mercury loadings, nutrients, watershed type/size) between aquatic systems. As an example, in lake surveys conducted within a relatively restricted geographic region, large differences can exist between lakes with respect to mercury concentrations in a given species of fish (Cope et al., 1990; Grieb et al., 1990; Sorenson et al., 1990; Jackson, 1991; Lange et al., 1994; Glass et al., 1999). These observations have led to the suggestion that a considerable portion of this variability is due to differences in within-lake processes that determine the percentage of total mercury that exists as the methylated form. Limited data also indicate that within a given water body, concentrations of methylmercury are likely to vary with depth and season. Unfortunately, while the concentration of methylmercury in fish tissue is presumably a function of these varying concentrations, published BAFs are generally estimated from a small number of measured water values, whose representativeness of long-term exposure is poorly known. Furthermore, although it is known that biotic and abiotic factors control mercury exposure and bioaccumulation, the processes are not well understood, and the science is not yet available to accurately model bioaccumulation on a broad scale.

Summary

Three different approaches were use to estimate methylmercury bioaccumulation factors for use in deriving national 304(a) ambient water quality criteria for mercury. All three approaches resulted in BAFs with central tendency point estimates in good agreement with one another. Based on data comparability and EPA's national guidance for deriving BAFs, methylmercury BAFs estimated using directly measured and converted field data were used as the basis for deriving the draft national BAFs. Given the large range in the data, at this time lotic BAFs can not be distinguished from lentic BAFs, though the data suggests slightly reduced methylmercury accumulation may occur in higher trophic level organisms in lotic/wetland environments. The same trend is observed when BAFs are compared on a total mercury basis. Some of this difference might be accounted for by the lower accumulation of methylmercury at the base of the food chain in lotic/wetland ecosystems. A plausible explanation for this difference is the observation that the bioavailability of methylmercury in lentic environments (usually a low dissolved organic carbon content) may exceed the bioavailability of methylmercury in lotic/wetland environments (usually a high dissolved organic carbon content). Methylmercury and mercury have a high binding capacity to dissolved organic carbon which can affect their bioconcentration in

phytoplankton/periphyton. Watras et al. (1998) used modeling to show that BAFs based on the bioavailable fraction of methylmercury in water exceed BAFs based on the operationally defined (filtered) dissolved methylmercury in water. Bioavailability is perhaps the single most important factor affecting BAFs for mercury.

EPA fully recognizes that the approach taken to derive mercury BAFs collapses a very complicated non-linear process, which is affected by numerous physical, chemical, and biological factors, into a rather simplistic linear process. EPA also recognizes that uncertainty exists in applying a National BAF universally to all water bodies of the United States. Therefore, in the revised 2000 Human Health Methodology (EPA , 2000) we encourage and provide guidance for States, Territories, Authorized Tribes, and other stakeholders to derive site-specific field-measured BAFs when possible. In addition, should stakeholders believe some other type of model may better predict mercury bioaccumulation on a site-specific basis they are encouraged to use one, provided it is scientifically justifiable and clearly documented with sufficient data.

SECTION II. CHEMICAL TRANSLATORS FOR MERCURY AND METHYLMERCURY

Introduction

By regulation (40 CFR 122.45(c)), the permit limit, in most instances, must be expressed as total recoverable metal. Because chemical differences between the discharged effluent and the receiving water are expected to result in changes in the partitioning between dissolved and adsorbed forms of metal, an additional calculation using what is called a translator is required.

The translator is used to convert the dissolved concentration of a metal to a total metal concentration for use in waste load limit calculations. The translator is the fraction of the total recoverable metal in the downstream water that is dissolved, f_d. The translator can be used to estimate the concentration of total recoverable metal in a water body.

Methods

Two procedures were used to develop site-specific translators. The most straightforward approach for translating from a dissolved water quality criterion to a total recoverable effluent concentration is to analyze directly the dissolved and total recoverable fractions. The translator is the fraction of total recoverable metal that is dissolved. It may be determined directly by measurements of dissolved and total recoverable metal concentrations in water samples taken from the well mixed effluent and receiving water (i.e., at or below the edge of the mixing zone). In this approach, a number of samples are taken over time and an f_d value is determined for each sample:

$$f_d = Cd/Ct \quad [Eqn. 1]$$

where:

Cd = the dissolved concentration, and
Ct = the total metal concentration.

The translator is then calculated as the geometric mean (GM) of the dissolved fractions.

The second approach derives an f_d from the use of a partition coefficient K_D where usually the coefficient is determined as a function of total suspended solids (TSS) (although some other basis such as humic substances or particulate organic carbons may be used). The partition coefficient is the ratio of the particulate-sorbed and dissolved metal species multiplied by the adsorbent concentration, i.e. Cd + TSS ⇌ Cp, where Cp is the bulk particulate-sorbed concentration, and is expressed as:

$$K_D = Cp/(Cd \cdot TSS) \qquad [Eqn.2].$$

The dissolved fraction and the partition coefficient are related as shown in equation 3.

$$f_d = (1 + K_D \cdot TSS)^{-1} \qquad [Eqn.3]$$

As in the first approach, numerous samples are collected over time, and the f_d and TSS values found at the site are fit to a least squares regression, the slope of which is K_D. The established K_D is then used to determine the translator using Eqn. 3 with a TSS value representative of some critical condition, e.g., low flow conditions.

Although development of site-specific translators is recommended, EPA also envisions the possible need for national or default translators for use in translating dissolved mercury and dissolved methylmercury criteria into total mercury and methylmercury water quality permit limitations. Translators and/or related K_D values can be generated from an acceptable existing literature-derived data base. EPA's MSRC (U.S. EPA, 1997) contains extensive data, obtained primarily from lake systems, that are relevant to developing translators for mercury (e.g., percent total as methylmercury, percent total as dissolved mercury). Supplementation of these translators with additional, acceptable data from lotic and estuarine systems and update of lentic systems provides the necessary data base for the translators. To gather this data base, peer-reviewed literature papers from 1990 to present, were searched and reviewed. Since awareness of the contamination problems with mercury at low levels and the existence of analytical methods capable of accurately and precisely measuring mercury and methylmercury at low levels are relatively recent, the literature review was not conducted for publications prior to 1990. All data from the literature for use in developing the translators were required to meet the following criteria:

- Clean techniques, or equivalent, to reduce contamination were used in sampling and analysis.
- Adequate QA/QC procedures were used.
- Analytical methods used provided sufficiently low enough detection level.

Draft Translators

Table A-10 summarizes the numerous tables from the EPA internal draft BAF report (see Water-Docket W-00-20). These results are presented separately for lake, river and estuarine systems, and for each system, where sufficient data were available, both f_d and K_D values were tabulated. The K_D values were calculated using Eqn. 2. The K_D values could not be derived using the f_d-TSS correlation approach due to the limited data, i.e., multiple sampling events over time with measurements of both f_d and TSS were not conducted in most of the studies. The results are presented separately for both mercury and methylmercury. Table A-10 provides a summary of the GM values calculated for each system for f_d and K_D values, again for both mercury and methylmercury.

It is possible to calculate a "pseudo" K_D value for the partitioning of dissolved methylmercury with particulate total mercury using f_d and K_D data for a waterbody utilizing the following equation (see Attachment B for derivation and example calculation):

$$\text{"Pseudo" } K_D \text{ MeHgd/Hgt} = K_D \text{ MeHgd} \cdot \text{MeHgt} \bullet \text{Ratio Hgd/MeHg}_p \bullet \text{Ratio MeHgd/MeHg}_p$$

[Eqn. 4]

Table A-10: Summary of F_d and K_d Values for Lakes, Rivers, and Estuaries[a]

f_d and K_D Values	Lakes	Rivers	Estuaries
f_d Hg	0.60	0.37	0.353
f_d $MeHg_d/Hg_t$	0.032	0.014	0.190[b]
f_d $MeHg_d/MeHg_t$	0.613	0.49	0.612[b]
Log K_D Hg	5.43	5.06	5.52
Log K_D MeHg	5.53	4.81	NF[c]
"pseudo" Log K_D $MeHg_d/Hg_t$	6.83	6.44	NC[d]

a Values calculated as GM
b Only two sites
c No data found from the literature search
d Not able to calculate due to insufficient data

The K_D so derived is a "pseudo" value since dissolved methylmercury partitioning with particulate total mercury is just a synthetic or functional type description. These values are also given in Table A-10. The "pseudo" K_D values, however, allow for direct translation of dissolved methylmercury criteria to total mercury permit limits employing some designated TSS level. Insufficient data were found, e.g., K_DMeHg, to allow for calculation of "pseudo" K_Ds for estuaries. It should be understood that all values in Table A-10 represents values generated from the above-described literature-gleaned data base. Insufficient data were obtained to provide either reliable f_d (translator) or K_D "default" values for methylmercury for estuarine systems (only two sites). Examination of the translator values for lakes and rivers shows that in all instances the river values for both f_ds and K_Ds are lower than the lake values. The lower translator values can be generally explained by the generally higher TSS levels found in rivers as compared to lakes. For example, typical TSS values for eastern Washington state lakes are 0.5 to 5 mg/L, whereas river levels can be typically 5-50 mg/L (Pankow and McKenzie, 1991). Higher TSS levels lead to lower f_d values.

The lower K_D values for rivers vs. lakes are not as readily explainable. K_D values are not constant and are sensitive to environmental conditions and water chemistry (Sung, 1995). Inclusion of the colloidal fraction in the dissolved phase that is used in determining the K_D has been used to explain variation of K_D values and for deviation of the values from any true K_D (Pankow and McKenzie, 1991; Sung, 1995). Higher colloidal contents or higher DOC levels in the river samples compared with lake samples would produce lower apparent (as measured) K_D values. However, the following other factors have been suggested to play major roles in K_D determinations, and one or all of these may contribute significantly to the reason why the river K_Ds are less than the lake K_Ds for both mercury and methylmercury:

- Biotic or organic content of the TSS
- Dissolved organic content of the water
- Geochemistry and residual metal content of the TSS
- TSS particle size
- Pollution level existing in the waters

Regardless of the reason(s) for the differences between the lake and river values, differences do exist and are sufficiently significant that it is recommended that the two systems be treated separately with regard to translator values. Until additional data are available for estuarine systems, and a satisfactory comparison to lake and river systems can be made, it is recommended that separate values be retained for estuaries also.

One can estimate the TSS level that is represented by the f_d values for each system through the use of Eqn. 3 and employing the default K_D values provided in Table A-10. The results of calculations of these estimated levels and an example calculation are presented in Table A-11. The data show the following:

- In lakes, the f_d for mercury (0.60) would reflect TSS levels of 2.5 mg/L. The f_d for methylmercury (0.032) would reflect TSS levels of 1.8 mg/L. At TSS levels lower than these values, a greater fraction of the mercury and methylmercury would be expected to be dissolved than indicated by the f_d.

- In rivers, the f_d for mercury (0.37) would reflect TSS levels of 14.8 mg/L. The f_d for methylmercury (0.014) would reflect TSS levels of 16.3 mg/L. At TSS levels lower than these values, a greater fraction of the mercury and methylmercury would be expected to be dissolved than indicated by the f_d.

- In estuaries, the f_d for mercury (0.35) would reflect TSS levels of 5.5 mg/L.

Existing TSS levels less than those above would, in any instance, that the dissolved fraction present in the water could be greater than the value suggests.

Use of the partition coefficient approach may provide advantages over the dissolved fraction. EPA suggests (EPA, 1996) that when using dynamic simulation for Waste Load Allocation (WLA) or the Total Maximum Daily Load (TMDL) calculations and permit limit determinations, K_D allows for greater mechanistic representation of the effects that changing environmental variables have on f_d (the significance of the TSS variable has been shown in Table A-11 data and discussed above, and this variable is addressed or can be handled in the K_D approach).

Table A-11: Estimation of TSS Level at f_d Values

	Lakes		Rivers		Estuaries	
	f_d	Est. TSS, mg/L	f_d	Est. TSS, mg/L	f_d	Est. TSS, mg/L
Mercury[a]	0.60	2.5*	0.37	14.8	0.35	5.5
Methylmercury[b]	0.032	1.8	0.014	16.3	0.190	NC[c]

(a) Calculated using default K_D values and equation: $f_d = 1/(1+K_D \times TSS)$

(b) Calculated using default "pseudo" K_D values and equation: $f_d = 1/(Hg_d/HgMe_d + K_D \times TSS)$

(c) Not able to calculate; insufficient data.

* Calculation:

$f_d = 1/(1 + K_D \times TSS \times 10^{-6})$ note: 10^{-6} used to provide TSS in mg/L units

default K_DHg (lakes) = 269,153

substituting: $0.60 = 1/(1 + 269{,}153 \times TSS \times 10^{-6})$

$0.60 + 0.161 \times TSS = 1$

$0.161 \times TSS = 0.40$

$TSS = 2.5$

Although the K_D approach may be advantageous in use, employment of a default K_D value has inherent problems as does the use of a f_d. For example, mercury K_Ds have been shown to range from about 10^4 to about 10^6 (Watras et al., 1995). At an average K_D value of about 10^5 (the value found for rivers), and a critical TSS level of 10 mg/L, a translator value of 0.5 is derived from the K_D approach.

However, if the site K_D, for example, is close to the lower end of the K_D range, the translator value should be about 0.9. Thus the value is inaccurate at this site. Only at sites where the existing K_D is 10^5 or greater (at 10 mg/L TSS) would the use of the default K_D yield a translator value that does not underestimate the dissolved mercury level.

An additional problem with the use of the K_D approach is that even at a given site, K_D values can vary. Usually, K_D values decrease at a site as TSS increases, as has been shown recently for mercury and methylmercury in a Virginia river (Mason and Sullivan, 1998). In addition, the K_D translator approach necessitates that f_d correlate with TSS. A poor correlation, however, has been found to exist for many metals in a recent analysis of data obtained from State of Michigan surface waters (MDEQ, 1996).

Although the K_D approach has its advantages, the f_d approach is the most straightforward. Both approaches have their disadvantages, as discussed previously. The K_D is derived from f_d values and so the two approaches are truly linked. Therefore, preferential recommendation of either one approach over the other at present cannot be made.

Use of either f_d or K_D default values can be made as long as one recognizes the short comings of the approach taken. Perhaps the approach taken should be the one with the stronger data base, if a clear difference exists. As additional data appears in the literature, it is reasonable to assume that a fine-tuning of both the f_d and K_D default values will result. EPA recommends that translators be derived from site-specific studies when possible, but the values in Table A-10 could be used in absence of any site-specific data.

ATTACHMENT A: BAF PEER REVIEWERS' GENERAL COMMENTS

The following was excerpted from the BAF Peer Review Comments Report, August 23, 2000. See Water Docket W-00-20 for a complete version of the peer review report.

2.0 REVIEWERS' COMMENTS

2.1 General Comments

Nicolas Bloom

Overall, I found the document quite clear and well written compared to other EPA mercury documents that I have recently reviewed, a fact that made my job considerably easier. On the other hand, it seems quite clear that there is insufficient data currently available for the EPA to make any more than the broadest generalizations about methyl mercury bioaccumulation factors. The current greater than one order of magnitude spread in estimated BAFs will not be very useful in any actual case, although it serves to describe the situation in general terms. The EPA should be impelled to proceed by instigating research and/or requiring site-specific bioaccumulation factors to be developed until such time that a sufficient database is accumulated to allow some meaningful resolution between BAFs from different water body types, climates, and trophic levels.

I oppose the general use of the confusingly similar terms "lentic" and "lotic," which although probably clear to fish ecologists, never-the-less provide endless confusion to the rest of us. I conducted a poll of the 51 employees of our aquatic sciences research company, and no one could define these words correctly, although a few did say that they had heard of them back in college. Additionally, even though physically, the term "lentic" can be used to lump together the Everglades with a swiftly moving glacial stream, I see no logical biogeochemical reason to do so.

There is also the overwhelming sense, in the description of the trophic levels considered, that the only valid food chain model being considered is the water to plankton to zooplankton to fish model. However, many systems (i.e., Lavaca Bay, TX) are dominated by a sediment porewater to benthic invertebrates to fish model, which means that sediment issues (methyl concentrations, methylation depth profiles, redox condition, seasonality, etc.) loom way more important that water column concentrations.

James Hurley

First and foremost, the development of a national AWQC for methylmercury must be based on sound data with strict quality control/quality assurance to ensure that the calculation of bioaccumulation factors (BAFs) is scientifically valid. This is a difficult task when conducting literature searches for data that form the backbone of the report. Among the data chosen, methods must be comparable to allow transferability. Individual investigators also apply different definitions of biological assemblages and food chain pathways. This makes the task of synthesizing appropriate data a difficult task at best.

My overall concern with data used for determination of the national BAF is that not one study from which data was obtained for this report was actually with the specific purpose of generating MeHg-based BAFs through all trophic levels. I fully understand that EPA also recognizes this problem and commend them for assembling the data presented. However, I do think that EPA should consider a research effort designed to produce results directly related to their MeHg BAF goals. This would ensure that sample types and methodologies were consistent with the overall goal of development of national BAFs for methylmercury. Development of a scientifically sound BAF is a critical step in development of a management plan for this Level I contaminant in the U.S.

In addition to developing a field effort, EPA should also consider development of dedicated laboratory studies that address Hg and MeHg partitioning and transport in trophic levels 1 and 2. Although EPA decided to choose an approach that incorporates field-derived BAFs, laboratory studies using cultures of phytoplankton and zooplankton, coupled with key contrasting water chemistries, would certainly aid in reducing the variability that is inherent in using field-derived data on partitioning. Results of these studies alone would avoid the ambiguity that is inherent in using the terms "seston" and "phytoplankton" interchangeably for BCFs.

The current report divides the data into two environments (lentic and lotic) but then combines BAFs to determine a national BAF in the final section of the report. I strongly encourage EPA to establish a series of National BAFs that are watershed-type based, in slightly more detail than a simple lentic/lotic division. Data from lotic systems in the report combine wetlands with flowing rivers. As a result, the lotic grouping contains high dissolved organic carbon (DOC) systems such as wetlands, with low DOC headwater streams. This type of grouping of sites with such disparate Hg-cycling environments most likely accounts for both the spread of data for directly-calculated BCFs and the lack of agreement between directly calculated and converted BCFs depicted in Figure 5-2.

While I agree that translators are appropriate in some instances, they too should be calculated on a more site-specific basis. Use of the translators to calculate the fraction (f_d) of total Hg as MeHg should be refined to address factors such as trophic state and watershed type. The grand mean of 3.2% for this translator encompasses a range from 0.2% to 13.9% in lake waters. Similarly, the grand mean from rivers of 1.4% encompasses a range from 0.2 to 5.11% in rivers. Better grouping of the data would reduce variability for this data set. For instance, Kd's for several contaminants have been shown to decrease with increasing DOC. The processes controlling methylation and particle partitioning are site-specific, and the current report attempts to define complex chemical and biological processes across gradients by the use of a simple fraction. Since this factor (the amount of inorganic Hg that is converted to the bioaccumulative methyl form) is perhaps the most critical step in developing a BCF, a simple default conversion factor is not the best approach.

Finally, development of an acceptable model is mentioned within the report as a future goal, but I feel that model development and acceptance should be fast-tracked along with development of a National MeHg BAF. Models, such as the recent revisions of the Mercury Cycling Model (MCM), that incorporate processes such as methylation, aquatic speciation, and bioenergetics are keys to validation of the BAFs among contrasting sites. Having worked specifically with the MCM Model, I am confident that is has been tested on a number of contrasting environments (northern Wisconsin lakes, Everglades, Great Lakes) and could be used to validate BAFs for differing aquatic environments.

David Krabbenhoft

Overall, I found the document to be in very good order structurally, grammatically, and was of an appropriate length for the subject matter; my compliments to the authors. A quality manuscript makes the reviewer's job much easier, and a better technical review results when he or she is not "put off" for having to do editorial service too. I heartily support the U.S. EPA's decision to pursue changes to the AWQC for mercury and have methylmercury (MeHg) be the basis for such regulations. Although this has been a long time in coming, I do recognize that the peer reviewed data for this type of proposed change has been limited to just a few study locations until the past few years. That being said, however, I have serious reservations as to whether enough high quality data has been made available by the scientific community for the EPA to make an important decision like assigning "National BAF's". The authors of this report have largely done an admirable job with what is available, but it may be slightly ahead of its time. It may be that with the very recent release of the National Academy of Sciences report on human health and mercury, and the proposed decision time line of the EPA to enact emissions

regulations in the 5-year time frame, that a well-conducted, national-synoptic study to for the proper basis for a MeHg BAF's is in order.

David Maschwitz/Edward Swain

1. An update of the mercury bioaccumulation factor (BAF) is very much needed, for the reasons cited on page 1 of Section I. The new analytical methods that can measure ambient mercury in water at sub-nanogram per liter levels, and the large number of recent studies that provide field measured BAF data make the determination of a new BAF a necessity, if EPA plans to update the human health-based mercury criterion. The BCFs/BAFs used in previous EPA mercury criteria are clearly outdated. A new mercury BAF and criterion will be a great help to states and tribes (hereinafter, state). The determination of a BAF is often the biggest road block to the calculation of a human health-based water quality standard for state regulatory agencies.

2. The following comments are on *National Bioaccumulation Factors for Methylmercury* (Section I) and *Default Chemical Translator for Mercury and Methylmercury* (Section II). We have not reviewed for comment the background document.

3. The overall organization of Sections I and II, is logical, straight forward and easy to follow.

4. The EPA search for both available published and unpublished BAF data uncovered a substantial amount of new information; and, short of carrying out an independent literature search to confirm this comment, it should be reasonably complete and current.

5. The discussion of uncertainty associated with the final recommended BAFs (beginning on page 73, Section I), including a discussion of the limitations associated with reducing highly variable BAF data to a single national BAF (for each trophic level), and the myriad of variables that can affect BAFs, is appropriate. Further, EPA's rationale that, in spite of the uncertainty (actually, because of it), the recommendation of a single default BAF for each trophic level is valid. The recommendation that states should use local BAF data is good as well, but EPA must realize that local BAF data is not likely to be available in many situations. Thus, the default BAFs will get substantial use.

6. The decision to use only the preferred, field measured, BAF data (including the converted direct BAFs) and not use the indirectly determined BAFs (BCFs or BAFs times a FCM or BFM) is appropriate given the quality and quantity of the former. This is consistent with the proposed new EPA human health criteria methodology (EPA, 1998). However, including the comparison of direct and indirect BAFs in Section I (Tables 3-10 and 4-11) is valuable information.

7. To eliminate any uncertainty about the proper application of the translators listed in Tables 5-1 and 5-2, it is suggested that EPA include in Tables 5-3 through 5-10 columns showing the translators used in the conversions, and/or a column showing the "raw" as well as the converted BAFs. An alternative to expanding these tables is to add to the summary information at the beginning of each subsection (i.e., Variable, Definition, Estimate, Distribution) a section on "Translators" or "Conversion" that shows the translator(s) and conversion calculations (this option assumes the translators used and all the conversion calculations are the same for all the individual BCFs/BAFs). A third, but less desirable alternative, is to provide example calculations in the introductory discussion of converted methylmercury BAFs, beginning on page 49 of Section I.

8. Overall, we believe the final recommended BAFs (Table 5-15) are supported and a reasonable conclusion of the data analysis.

9. The introduction to Section II (page 1) talks about EPA's policy to use dissolved analyses for trace metals to measure compliance with the standard. This policy was developed in the context of the toxicity of particulate and chemically bound, versus the toxicity of "dissolved" or ionic forms, of trace metals to aquatic life. The science behind EPA's dissolved metal policy may not be as relevant to a highly bioaccumulative metal like mercury, for which the concern is the methyl form, and the risk is to human health through fish consumption rather than to aquatic life directly. EPA should expand this section to discuss if and how mercury differs from non-bioaccumulative trace metals with regard to the need or desirability of measuring dissolved metal in water.

10. EPA discusses in the "Background" part of Section II, total to dissolved metal conversion factors. Along the lines of comment number nine, the conversion factor of 0.85 for the current mercury criteria (CMC and CCC) are applicable to toxicity-based mercury criteria, not the human health-based chronic criterion (*Federal Register* 63: 68354-68364). The conversion factor for the chronic human health-based mercury criterion is 1.0 (see also *Federal Register* 60: 15392). EPA needs to

revise their discussion of conversion factors to reflect the conversion factor for the human health criterion, and to address the points made in comment number nine.

11. Separate average translators and K_D values for lakes, rivers and estuaries as derived in Section II seem to be reasonable and supported by the data presented.

Darell Slotton

I found the reports to be clear in their intent and in their explanation of approaches used. I especially appreciated the straightforward acknowledgment of the myriad sources of uncertainty and variability. My overall response to the entire exercise is that those sources of uncertainty and variability (geographic, water quality, water trophic status, analytical, individual organism, true trophic "level", food web complexity, etc.) make this a very difficult if not impossible proposition. I strongly support the development of tissue-based mercury criteria as the preferred mechanism for addressing mercury risk assessment and regulatory concerns throughout the huge range of aquatic systems affected. That said, if EPA has a legal charge to also develop the best predictive relationships it can as defaults, etc., the approach being used is probably as good as can be expected. It may be significantly more useful as a regional tool, though (e.g., northern midwestern lake systems, California rivers, Florida, etc). A truly applicable, nation-wide set of factors may be unattainable. I strongly concur with the suggestion that site-specific research is preferable in the event that BAFs are to be used.

ATTACHMENT B: DERIVATION AND CALCULATION OF "PSEUDO" K_DS FOR METHYLMERCURY

Derivation

$MeHg_d + TSS \rightleftharpoons Hg_p$, including $MeHg_p$

$$\text{"Pseudo"}K_D\text{MeHg / Hg} = \frac{Hg_P}{MeHg_D \bullet TSS} \quad \text{[Eqn. A.1]}$$

$$\text{Also: } K_D\text{MeHg} = \frac{MeHg_P}{MeHg_D \bullet TSS} \quad \text{[Eqn. A.2]}$$

Equating TSS and combining Eqn. A.1. and Eqn. A.2 yields:

$$\text{"Pseudo"}K_D\text{MeHg / Hg} \bullet \frac{MeHg_d}{Hg_P} = K_D\text{MeHg} \bullet \frac{MeHg_d}{MeHg_P}$$

Rearranging:

$$\text{"Pseudo"}K_D\text{MeHg / Hg} = \frac{Hg_P}{MeHg_d} \bullet \text{KMeHg} \bullet \frac{MeHg_d}{MeHg_P} \quad \text{[Eqn. A.3]}$$

Example Calculation for Lakes (see text of original draft report for source of data)

- K_DMeHg = 338,844
- When $Hg_T = 1$, $MeHg_d = 0.032$, $Hg_d = 0.60$ and therefore $Hg_p = 0.40$
  and the ratio $Hg_p/MeHg_d = 0.40/0.032 = 12.5$
- When MeHg = 1, $MeHg_d = 0.613$, and therefore $MeHg_p = 0.387$
  and the ratio $MeHg_d/MeHg_p = 0.613/0.387 = 1.58$
- Substituting the above values in Eqn. A.3 gives:
  "Pseudo" K_DMeHg / Hg = 12.5 • 338,844 • 1.58 = 6,692,169
  Log "Pseudo" K_DMeHg / Hg = 6.83

Example Calculation for Rivers (see text of draft report for source of data)

- $K_D MeHg = 64{,}565$
- When $Hg_T = 1$, $MeHg_d = 0.014$, $Hg_d = 0.37$ and therefore $Hg_p = 0.63$
  and the ratio $Hg_p/MeHg_d = 0.63/0.014 = 45.0$
- When $MeHg = 1$, $MeHg_d = 0.49$, and therefore $MeHg_p = 0.51$
  and the ratio $MeHg_d/MeHg_p = 0.49/0.51 = 0.96$
- Substituting the above values in Eqn. A.3 gives:
  "Pseudo" $K_D MeHg / Hg = 45.0 \bullet 64{,}565 \bullet 0.96 = 2{,}789{,}208$
  Log "Pseudo" $K_D MeHg / Hg = 6.44$

Effects of tidal current phase at the junction of two straits

Received 19 December 2000; accepted 20 August 2001

Abstract

Estuaries typically have a monotonic increase in salinity from freshwater at the head of the estuary to ocean water at the mouth, creating a consistent direction for the longitudinal baroclinic pressure gradient. However, Mare Island Strait in San Francisco Bay has a local salinity minimum created by the phasing of the currents at the junction of Mare Island and Carquinez Straits. The salinity minimum creates converging baroclinic pressure gradients in Mare Island Strait. Equipment was deployed at four stations in the straits for 6 months from September 1997 to March 1998 to measure tidal variability of velocity, conductivity, temperature, depth, and suspended sediment concentration. Analysis of the measured time series shows that on a tidal time scale in Mare Island Strait, the landward and seaward baroclinic pressure gradients in the local salinity minimum interact with the barotropic gradient, creating regions of enhanced shear in the water column during the flood and reduced shear during the ebb. On a tidally averaged time scale, baroclinic pressure gradients converge on the tidally averaged salinity minimum and drive a converging near-bed and diverging surface current circulation pattern, forming a "baroclinic convergence zone" in Mare Island Strait. Historically large sedimentation rates in this area are attributed to the convergence zone.

Keywords: Salinity minimum; Convergence; Current shear; Baroclinic gradients; USA; California; San Francisco Bay

1. Introduction

The classic estuarine setting includes a longitudinal baroclinic pressure gradient heading in a consistent direction, driving a tidally averaged flow pattern of estuarine circulation (Hansen and Rattray, 1965). However, various mechanisms have been identified that alter the magnitude and direction of the longitudinal baroclinic pressure gradient, thus, modifying the residual flow pattern. For example, Largier et al. (1996) discuss the baroclinic structure of low-inflow estuaries that consist of four evaporation-created density regimes; Wolanski (1988) demonstrates a salinity maximum region that is driving a diverging near-bed flow pattern and converging surface currents; Abraham et al. (1986) discuss association of dissimilar water masses due to tidal current phasing in the Rotterdam Waterway, which alters the longitudinal density gradient; Nunes and Simpson (1985) describe axial convergence in a well mixed estuary; and Geyer et al. (1997) show sediment trapping enhanced by lateral baroclinic pressure gradients.

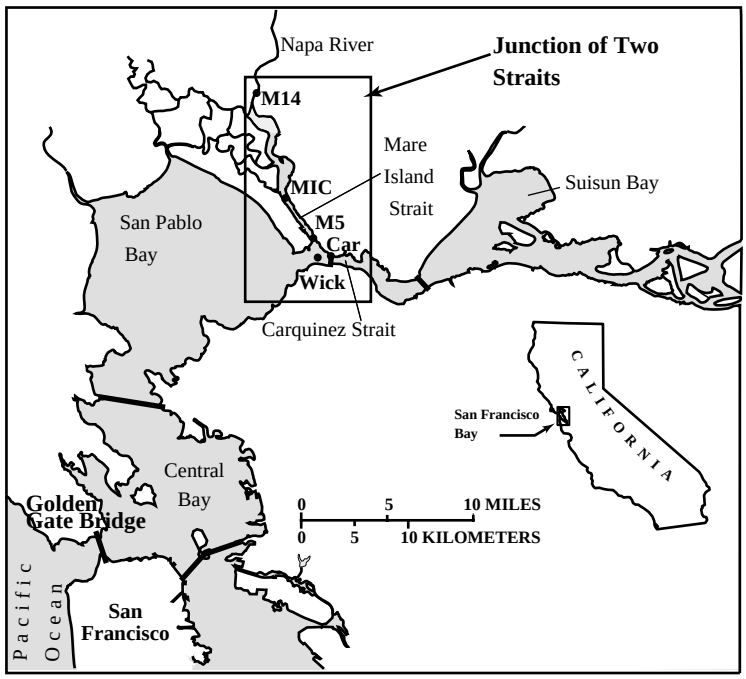

Fig. 1. Site map of San Francisco Bay, California.

In San Francisco Bay, the tide flows first through the Golden Gate into Central Bay (Fig. 1) and then northward to San Pablo and Suisun Bays before reaching the Sacramento/San Joaquin River Delta. Carquinez Strait connects the two northern bays, and the western end of the strait also serves as the junction with Mare Island Strait (the southern terminus of the Napa River). The tides are semi-diurnal with two high tides and two low tides per day. The M2, S2, O1, and K1 are the principal tidal constituents with a tidal form number of approximately 0.6 yielding a mixed tidal regime (Walters and Gartner, 1985). Unequal tidal prisms and basin geometries beyond the junction allow the behavior of the tide in Carquinez Strait to remain as a partially progressive wave and the behavior in Mare Island Strait to respond as a standing wave. These different wave forms create a phase difference of the currents at the junction.

In this paper, we use time series of measured data to illustrate the current phasing and to demonstrate the creation of a local salinity minimum in Mare Island Strait. On a tidal time scale, the local salinity minimum contains baroclinic pressure gradients in the landward and seaward directions that interact with the barotropic gradient, creating regions of enhanced and reduced shear in the water column. On a tidally averaged time scale, baroclinic pressure gradients converge on a tidally averaged local salinity minimum in Mare Island Strait, creating a circulation pattern of converging near-bed and diverging surface currents. Because the circulation pattern is created by converging baroclinic gradients, the region is termed a ''baroclinic convergence zone''. Historical increased sediment deposition rates are attributed to the zone.

2. Data collection and analysis

Data were collected at three sites along the Napa River and at one site in Carquinez Strait (Fig. 1). The sites are channel marker 14 (M14), Mare Island Causeway (MIC), channel marker 5 (M5), and Carquinez (Car). Additionally, data from a previous US Geological Survey instrument

deployment is referenced for the Wickland (Wick) site (Burau et al., 1993).

Instruments that measured velocity, conductivity, temperature, depth, and suspended sediment concentration were deployed from September 3, 1997, to March 13, 1998, at sites M14, MIC, M5, and Car (Warner et al., 1999). Due to biological fouling, equipment difficulties, and large storms, full data sets were not recovered from all the sites. To measure velocity, acoustic Doppler current profilers (ADCPs) were deployed at M14, MIC, M5, and Car (the ADCP at Car was never recovered). Conductivity-temperature-depth (CTD) sensors were deployed on taught-wire moorings at all four sites. At M14, the CTD sensor heights were 1 m above the bed. Two sensors were at MIC, M5, and Car; one near the bed and one near the surface: 1 and 7 m above the bed at MIC, 1 and 6 m above the bed at M5, and 1 and 20 m above the bed at Car. Optical backscatterance sensors (OBS) were connected to the CTDs to measure suspended sediment concentration (SSC) at all sites. The OBS sensors were calibrated with water samples taken during the deployment.

Harmonic analyses (Foreman, 1978) were performed on the measured time series of water level and velocity for time periods of low freshwater inflows. From the analysis, the M2 partial tide was selected to characterize the phasing of the water level and currents because it is the largest semi-diurnal component in the bay and the most representative tidal component (Walters et al., 1985). Tidally averaged quantities were calculated with a sixth-order low-pass Butterworth filter with a cutoff frequency of 0.025/h (period = 40 h). The parameter, hrmsf, was used as a measure of tidal energy and was calculated from the depth by removing the mean, squaring, and filtering (tidally averaging), and by taking the square root. Crests of the hrmsf time series represent increased tidal energy, and they are the spring tidal periods and the neap periods at the troughs. Finally, for analysis of baroclinic pressure gradients, only salinities are discussed because of their dominant influence on density. Daily temperature variations, on the order of 3°, and tidally averaged suspended sediment concentrations, on the order of 100 mg/l, were neglected in the density field calculation.

3. Results

3.1. Current phasing

Along the main estuary axis of San Francisco Bay, the phase difference between the M2 constituent of water level and current fluctuates between approximately 20° and 50°, representing a partially progressive wave pattern (Walters et al., 1985). For example, at site Wick in Carquinez Strait, the phase difference is approximately 20° (Fig. 2). However, in Mare Island Strait, the phase difference between the current and water level is representative of a standing wave pattern (which has a 90° phase difference). For example, site M5 has an 85° difference between the water level and velocity (Fig. 2). This behavior is caused by the almost complete reflection of the tidal signal in the Napa River, due to changes in channel geometry, increased friction, decreasing depths, and the shortness of the basin length. The standing wave in Mare Island Strait and the partially progressive wave behavior in Carquinez Strait create a 60° (2-h) phase difference for the M2 partial tide between the currents at the junction of the two straits. The effect of this difference is to cause the currents to turn 2 h earlier in Mare Island Strait than in Carquinez Strait.

3.2. Salt transport

The phase difference between the currents in Mare Island and Carquinez Straits creates a local salinity minimum that is advected up Mare Island Strait. A schematic of the junction shows Mare Island Strait as a vertical line and Carquinez Strait as a horizontal line (Fig. 3). A monotonically decreasing salinity up the estuary is assumed for Carquinez Strait, as shown by the boxes in Fig. 3 having progressively lighter colors. Two boxes are marked "1" and "2" to pronounce their original order. The box with an "X" represents the salinity level in Mare Island Strait at slack before flood (Fig. 3A), when Carquinez Strait is ebbing (flow to the left). As the Mare Island Strait current turns to flood, a decreasing salinity is advected to the left of the junction and up Mare Island Strait, pronounced with the boxes marked "1" and "2"

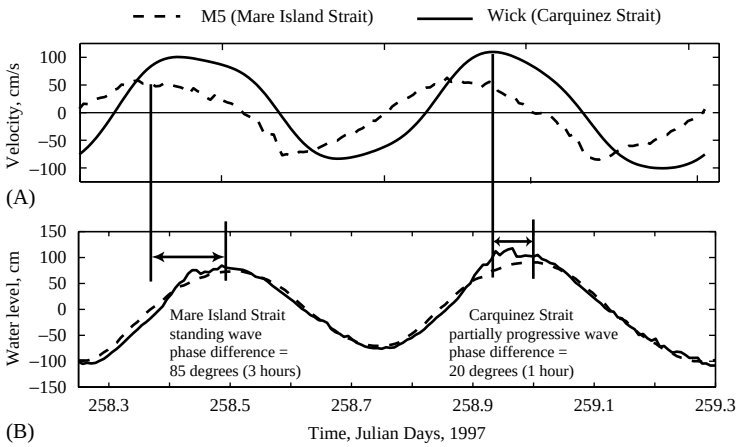

Fig. 2. Phase relation between water level and currents in Mare Island Strait (standing wave) and in Carquinez Strait (partially progressive wave). The velocity time series for site M5 displays directly measured data, whereas the time series of velocity from site Wick was harmonically reconstructed (derived from data measured several years earlier). The water level time series were calculated by removing the mean from both time series.

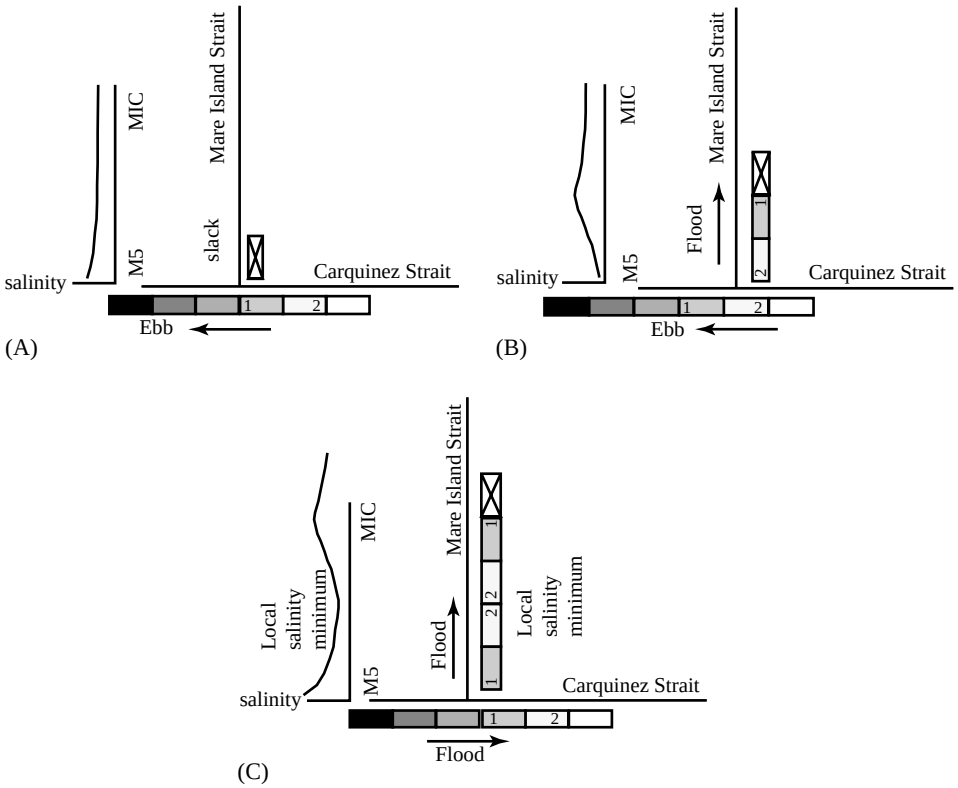

Fig. 3. Junction of Mare Island and Carquinez Straits showing the development of the local salinity minimum. Darker shading denotes saltier water.

(Fig. 3B). This creates a region of decreasing salinity in Mare Island Strait. Next, Carquinez Strait currents go to slack and then turn to flood (flow to the right, Fig. 3C). Mare Island Strait is still flooding, and increasing salinity is advected up Mare Island Strait, pronounced with the boxes marked "2" and "1". This creates a region of increasing salinity and completes the local salinity minimum in Mare Island Strait, as depicted in the axis plot on the left side. To complete the tidal cycle, the ebb current from Mare Island Strait (not shown) advects the salinity minimum into Carquinez Strait. The current in Mare Island Strait then goes to slack (Fig. 3A) and the process continues.

The current phasing yields two salinity features. First, a local salinity minimum is created and advected up Mare Island Strait, with the minimum value of salinity created when Carquinez Strait was at slack after ebb. Second, the magnitude of the salinity in Mare Island Strait (the box with the "X" in Fig. 3A) can be dissimilar to the initial magnitude of salinity advected up from Carquinez Strait. These two features are addressed below.

Field data verifies the creation of the local salinity minimum. Time-series analysis indicates that salinity was in quadrature with the velocity, implying that advection is the dominant mode for transport of salinity (Officer, 1976, p. 78). Therefore, the magnitude of the current in Mare Island Strait is utilized to demonstrate the advection of the local salinity minimum up Mare Island Strait and verify that the variability in the observed time series of salinity is predominately due to the advection of the salinity minimum. The advection is simulated by representing the salinity minimum as a parcel of water with a starting coordinate of zero at the junction of the two straits (with a positive upstream flood direction in Mare Island Strait). Parcel location is calculated by integrating the mean velocity from sites MIC and M5, with respect to time (Fig. 4D). The first parcel (Parcel 1) is released at the junction of the two straits when Carquinez Strait is at slack after ebb (Julian Day 259.35) coinciding with the midpoint of the local salinity minimum. When this parcel has traveled 1.5 km (up Mare Island Strait) the salinity minimum should be at station M5. A vertical arrow from Fig. 4D to C shows at this time that the salinity time series for site M5 has a local minimum value. Continuing in time, Fig. 4D shows that at Julian Day 259.45, Parcel 1 should be at 5.5 km (site MIC). Following the vertical arrow at this time to Fig. 4C shows a local minimum value of salinity at site MIC at this time. All the vertical arrows from Fig. 4D to C correspond to times when the parcel is at either site M5 (1.5 km, solid arrow) or MIC (5.5 km, dashed arrow). At these times local salinity minima appear at the sites, showing that the salinity structure is being advected up Mare Island Strait past sites M5 and MIC on the flood, and it returns past both sites on the ebb. These characteristics in the data affirm that the minimum value of salinity was created when Carquinez Strait was at slack after ebb. Additionally, this analysis confirms that the salinity is dominated by advection, because the parcel location matches very closely the observed salinity minimums.

The second feature is the potential dissimilarity between the salinity in Mare Island Strait (the box with the "X" in Fig. 3) and the salinity of the water that is initially advected up Mare Island Strait from Carquinez Strait. Fig. 4B shows the time series of salinity at site Car and the bold arrows denote the salinity signal corresponding to water being advected up Mare Island Strait. At Julian Day 259.35, Fig. 4B shows the water at site Car that was advected up Mare Island Strait has an initial salinity of approximately 18, reduces to a magnitude of 16, and then increases to 23. In Mare Island Strait, the magnitude of the salinity at Julian Day 259.35 was 18, as well (Fig. 4C). Therefore, the water that was advected up from Carquinez Strait at the beginning of the Mare Island Strait flood had the same salinity as that water preexisting in Mare Island Strait. Hence, the time series of salinity in Mare Island Strait first appeared as a constant and then decreased as the salinity structure appeared.

The movement of Parcel 2 (Fig. 4D) begins when Carquinez Strait is at slack after ebb on Julian Day 259.85. However, the magnitude of the salinity from Carquinez Strait that first enters Mare Island Strait is approximately 19, a salinity value greater than existed in Mare Island Strait (approximately 18). Therefore, the data show an

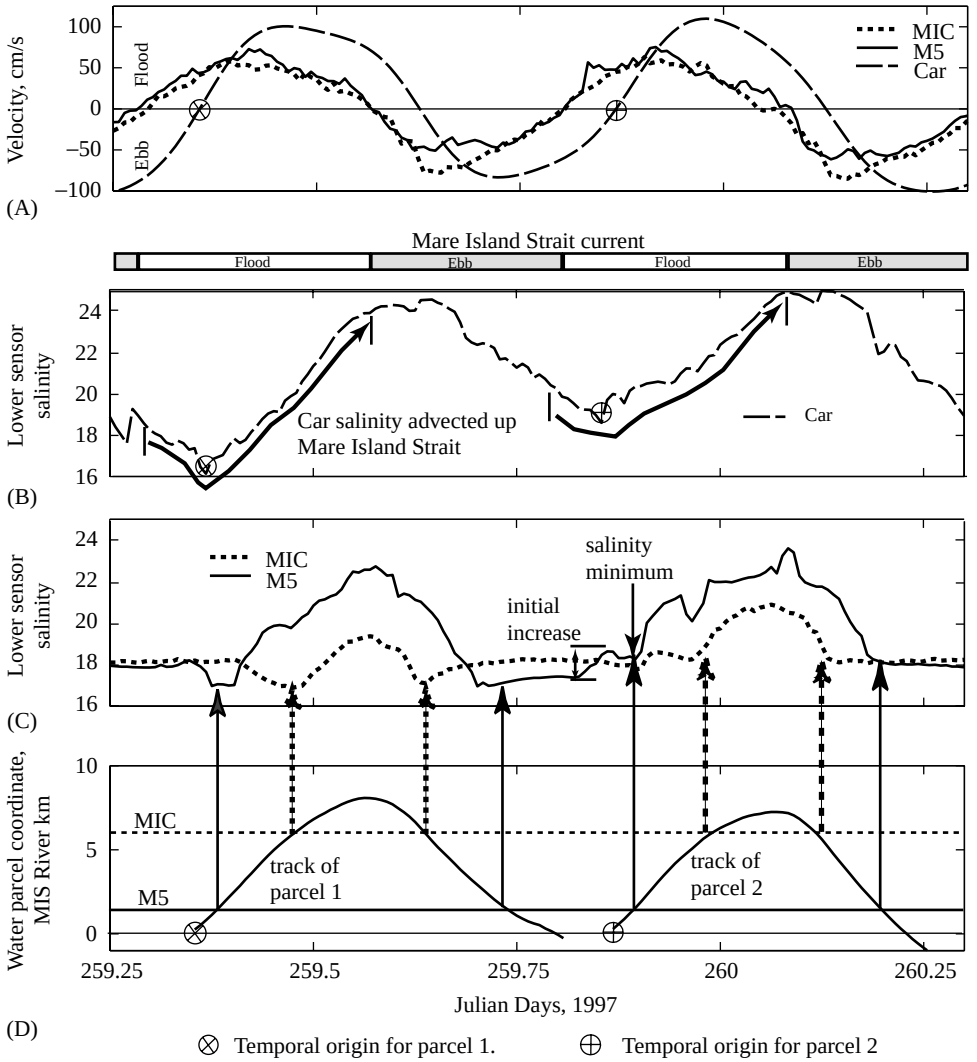

Fig. 4. Location of a water parcel tracking the local salinity minimum: (A) time series of velocity for sites MIC, M5, and Car; (B) time series of salinity from site Car; (C) time series of salinity for sites MIC and M5; and (D) the track of a parcel representing midpoint of salinity minimum. Arrows from panel d to c relate track of salinity minimum to observed time series of salinity.

initial increase in salinity in Mare Island Strait, followed by the salinity minimum. This feature is created by the diurnal inequality of the tidal regime and occurs after the higher low tide and, hence, after a shorter tidal excursion that reduces the advection of the salt field in Carquinez Strait. Larger tidal excursions occur during the tidal transition from higher high to the lower low tides and during spring tides that advect the salt field farther, enhancing the dissimilarity of salinity between the two straits.

Based on field observations, the ebb water from Mare Island Strait does not appear to influence the magnitude of salinity in Carquinez Strait. Carquinez Strait is approximately 1000 m wide and 25 m deep with surface currents that can exceed 1.5 m/s during spring tides. In contrast, Mare Island Strait is 300 m wide and 10 m deep with maximum spring

tidal currents of 0.80 m/s. The ratio of cross-sectional areas is on the order of 0.1. Salinity from site Car does not show any substantial variation that could be attributed to the ebb from Mare Island Strait. Additionally, during the first 2 h of the Mare Island Strait ebb, the salinity in the flood currents of Carquinez Strait continues to increase, contributing to the greater tidally averaged salinity in Carquinez Strait. Smith et al. (1991) show the complexity of the flow pattern at the junction due to both lateral and vertical variations in the current patterns. Therefore, the ebb water out of Mare Island Strait will be considered to fully mix with Carquinez Strait water.

4. Discussion

4.1. Tidal time scale

On a tidal time scale, the effect of the local salinity minimum is to enhance the vertical shear of the water column in Mare Island Strait. This effect is caused by the interaction of the fluctuating baroclinic gradient of the local salinity minimum with the unidirectional barotropic gradient during each phase of the tidal cycle. The influence of each of these components is best described by analyzing the vertical structure of the terms in the governing equations. The laterally averaged momentum equation in the x-direction is

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} = -\frac{1}{\rho_0}\frac{\partial P}{\partial x} - \frac{1}{\rho_0}\frac{\partial \tau^{xz}}{\partial z}, \tag{1}$$

where $u(x,z,t)$ is the laterally averaged longitudinal velocity, t is time, ρ_0 is the reference density, $P(x,z,t)$ is pressure, $\tau^{xz}(x,z,t)$ is the horizontal shear stress, and z is the vertical coordinate, measured as positive upwards from the mean water surface. Because the along-channel bathymetric variations vary slowly in Mare Island Strait, the advective acceleration terms are weak and will be neglected. Vertical accelerations also are weak, so that the pressure can be reasonably assumed to be hydrostatic. The horizontal gradient of the pressure is obtained from integration of the z-momentum equation (assuming the horizontal density gradient to be invariant with depth) to obtain

$$\frac{\partial P_{z'}}{\partial x} = g(\eta - z')\frac{\partial \rho}{\partial x} + \rho_a g\frac{\partial \eta}{\partial x}, \tag{2}$$

where $\eta(x,t)$ is the displacement from the undisturbed (mean) water level at $z=0$, $\rho(x,z,t)$ is the density, and ρ_a is the water density at the surface. Combining these equations with the approximation that $\rho_0 \sim \rho_a$, and with the equation of state $\rho = \rho_0(1+\alpha s)$, where s = salinity, and α = coefficient of haline contraction (7.6×10^{-4}, Cushman-Roisin, 1994) yields

$$\frac{\partial u}{\partial t} = \underbrace{-\alpha g(\eta - z')\frac{\partial s}{\partial x}}_{\text{baroclinic}} \underbrace{- g\frac{\partial \eta}{\partial x}}_{\text{barotropic}} \underbrace{- \frac{1}{\rho_0}\frac{\partial \tau^{xz}}{\partial z}}_{\text{turbulent shear}}. \tag{3}$$

To scale the magnitude of these terms, the shear scales as ρu^{*2}, where the velocity u^* is assumed to be 0.1 times the depth-averaged mean tidal velocity $\langle u \rangle$ (Fischer et al., 1979). From sites M5 and MIC, time series of measured velocity, an estimate of $\langle u \rangle$ is 0.40 m/s, and using $\mathrm{d}z \sim 10$ m leads to a maximum size of the turbulent shear term to be on the order of $2\times10^{-4}\,\mathrm{m/s^2}$. To estimate the order of magnitude of the barotropic term, first water surface elevations were estimated from the difference between the measured depth time series and the low pass filter of the depth time series. Then the differences of water surface elevations from site M5 to MIC divided by a distance of 4 km yielded the barotropic term on the order of $2\times10^{-4}\,\mathrm{m/s^2}$. The baroclinic term has a maximum value at depth on the order of $5\times10^{-5}\,\mathrm{m/s^2}$, which is scaled by assuming a salinity gradient of $0.5\,\mathrm{km^{-1}}$, a typical value in San Francisco Bay (Jassby et al., 1995), and a depth of 10 m. This scaling shows a baroclinic-to-barotropic ratio of 0.25 on the tidal time scale, inferring the importance of the baroclinic term to the dynamic balance.

The interaction of the barotropic and baroclinic terms can create tidal asymmetry between the ebb and the flood (Jay, 1991). In an estuary, the baroclinic term typically is acting in one direction, heading landward. During the flood current, the barotropic term also is heading landward and these two terms typically will be additive and produce weaker shear throughout the water

column. During the ebb the two gradients are in opposition which enhances shear in water column. Fig. 5 is a schematic of Mare Island Strait that illustrates the longitudinal development of shear by the gradients. During the flood current, the baroclinic and barotropic gradients are negative and act together at two locations along the strait, creating a relatively weak shear in the water column (Figs. 5A, 1 and 3). However, the local salinity minimum is a region with a positive baroclinic gradient ($\partial\rho/\partial x =$ positive) that opposes the barotropic gradient, creating a relatively

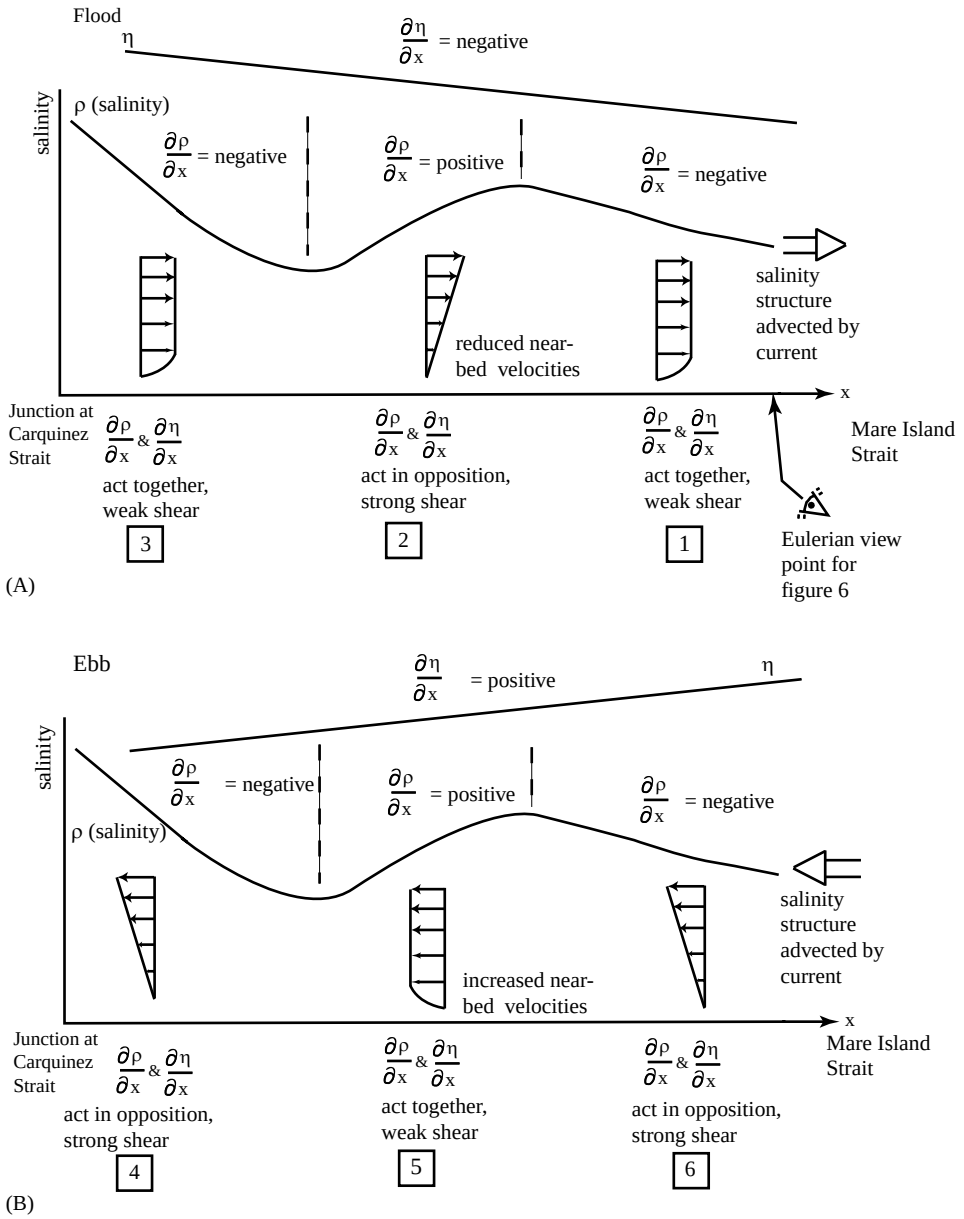

Fig. 5. Longitudinal profile of Mare Island Strait showing velocity structure created by interaction of baroclinic and barotropic pressure gradients during (A) flood, and (B), ebb current. Boxes labeled 1–6 correspond also with Fig. 6.

strong shear in the water column (Fig. 5A, 2). This region of strong shear reduces the near-bed velocities in the strait.

During the ebb current, the baroclinic gradient is negative and the barotropic gradient is positive at two locations along the strait (Fig. 5B, 4 and 6). As these gradients act in opposition, they create strong shear in the water column, as is typical in an estuary. Again, the salinity minimum structure contains a region with a positive baroclinic gradient ($\partial\rho/\partial x =$ positive), which acts together with the barotropic gradient, to create a region of weak shear (Fig. 5B, 5). This region of weak shear increases the near-bed velocities.

Using the Eulerian reference frame of the instrumentation, measured time series of velocity and salinity in Mare Island Strait from site MIC (Fig. 6) show the effects of changes in shear in the water column with the passage of the salinity minimum. A four day neap–spring transition period was selected to plot the shear in the water column (Fig. 6A) calculated as the surface minus the bottom velocity (top bin − bottom bin), with positive values for flood and negative for the ebb. The flood and ebb tides from 259.25 to 259.85 represent well the changing shear as the salinity minimum advects past the site. Times of greatest shear occur at labels 2 and 4, when the baroclinic

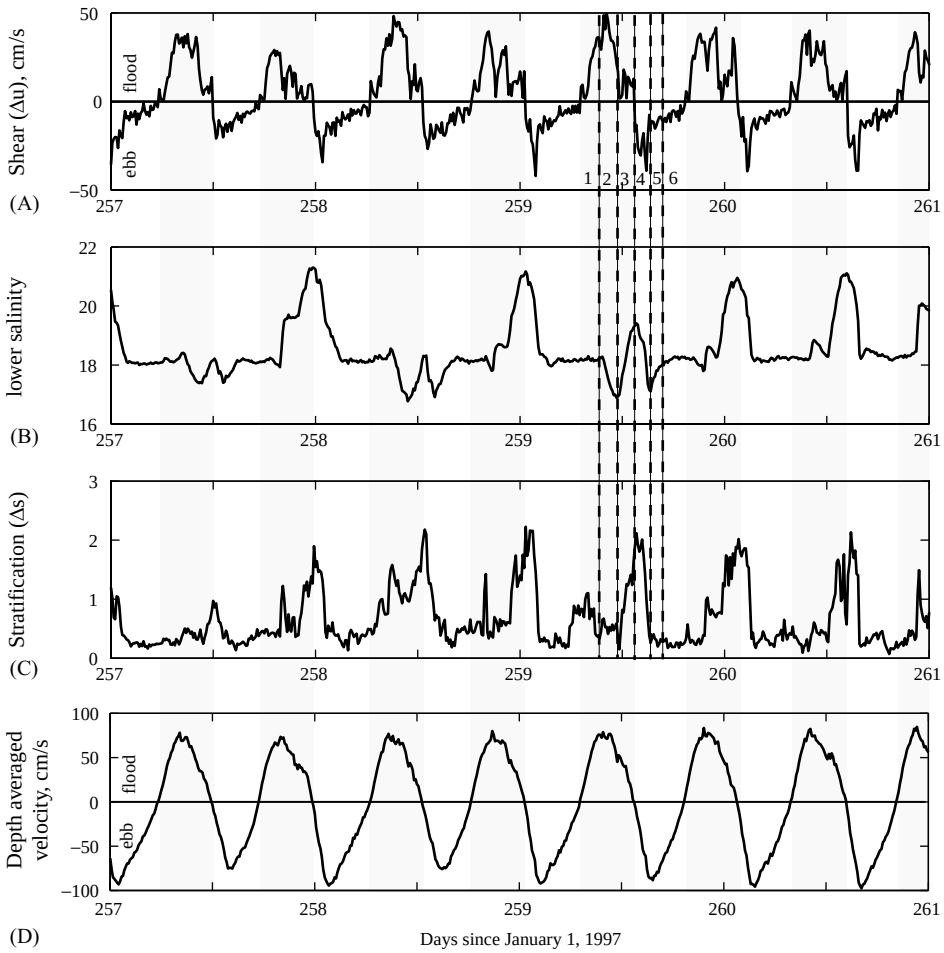

Fig. 6. Four day time series at site MIC: (A) shear in the water column calculated as top bin velocity minus lower bin velocity; (B) salinity from lower sensor; (C) stratification lower sensor minus upper sensor; and (D) depth averaged velocity.

and barotropic gradients act in opposing directions (corresponding labels in Figs. 5 and 6). Almost immediately after the baroclinic gradient changes directions (label 3 and label 5), the shear diminishes in the water column. This shows that by the time the salinity minimum advects from Carquinez Strait to site MIC, the shear stress in the water mass has adjusted to the new pressure gradient balance. Conceptually (as shown in Fig. 5) labels 1 and 3 develop similar shear, however, the actual baroclinic gradient in Mare Island Strait is near zero at the beginning of the flood and therefore label 1 shows more shear in the measured data (Fig. 6, label 1). Similarly, labels 4 and 6 conceptually have similar shear, however, the baroclinic gradient at the end of the ebb is near zero so there is less shear developed at label 6 (Fig. 6, label 6). At site MIC the reduction of the near-bed velocity during the flood and the increase in the near-bed velocity during the ebb leads to a tidally averaged near-bed velocity in the seaward direction.

Stratification at site MIC (Fig. 6C) is predominately characterized as well mixed throughout most of the tidal cycle with a period of stratification at the end of the flood. The stratification occurs when the pressure gradients act in the same direction, the shear in the water column is reduced, and turbulent mixing is weak (i.e. label 3). The shear during the initial phase of the ebb appears to create adequate mixing to remove the stratification because at the end of the ebb the water column is well mixed at both sites MIC and M5.

The strength of the shear scales with the magnitude of the salinity minimum. An initial dissimilarity between the salinity in Mare Island and Carquinez Strait (for example at day 259.85) tends to reduce the maximum shear that occurs in the water column. Additional field measurements are necessary to obtain closer spatial observations to better characterize the salt field and vertical shear dynamics in Mare Island Strait.

4.2. Tidally averaged time scale

On the tidal time scale, the local salinity minimum affects the shear in the water column that alters the tidally averaged flow pattern. Fig. 7 shows tidally averaged velocities for the upper and lower portions of the water column for sites M14, MIC, and M5 (panels B, C, and D), along with the discharge in the Napa River and hrmsf (panel A). Three representative time periods (1, 2, and 3) labeled in Fig. 7 are shown longitudinally in Fig. 8.

At time-period 1, the tidally averaged longitudinal density structure in Mare Island Strait consists of a local salinity minimum. At site M5, the tidally averaged velocity from the lower bin is directed upstream, and the tidally averaged velocity from the upper bin is directed downstream. This flow pattern is the classical structure of estuarine circulation (Figs. 7 and 8, time-period 1) that occurs because on a tidally averaged time scale, the salinity in Carquinez Strait (at the mouth of Mare Island Strait) is greater than the tidally averaged salinity in the mouth of Mare Island. However, as one travels further up Mare Island Strait, the influence of the salinity minimum structure is observed in the tidally averaged flow pattern. At site MIC, the tidally averaged, near-bed velocity is in the downstream direction with the tidally averaged, near-surface velocity fluctuating from upstream to downstream. Because site MIC near-bed velocities are tidally averaged downstream, and site M5 near-bed velocities are tidally averaged upstream, one obtains a convergence of near-bed velocities that are created by converging baroclinic pressure gradients. Thus, the location between sites M5 and MIC is termed a "baroclinic convergence zone". Site M14 is approximately 20 km upstream from the mouth of the river and this distance is beyond one tidal excursion from the mouth (approximately 10 km). Therefore, site M14 is not directly affected by the salinity minimum during each tide. Additionally, a low (approximately $1\,m^3/s$) freshwater inflow creates a weak longitudinal density gradient and site M14 exhibits a very minimal residual flow pattern. Time-period 1 represents a typical tidally averaged flow pattern from day 255 to 320.

On day 320, however, a small increase in freshwater inflow occurs in the Napa River. This buoyancy flux created a sufficiently strong

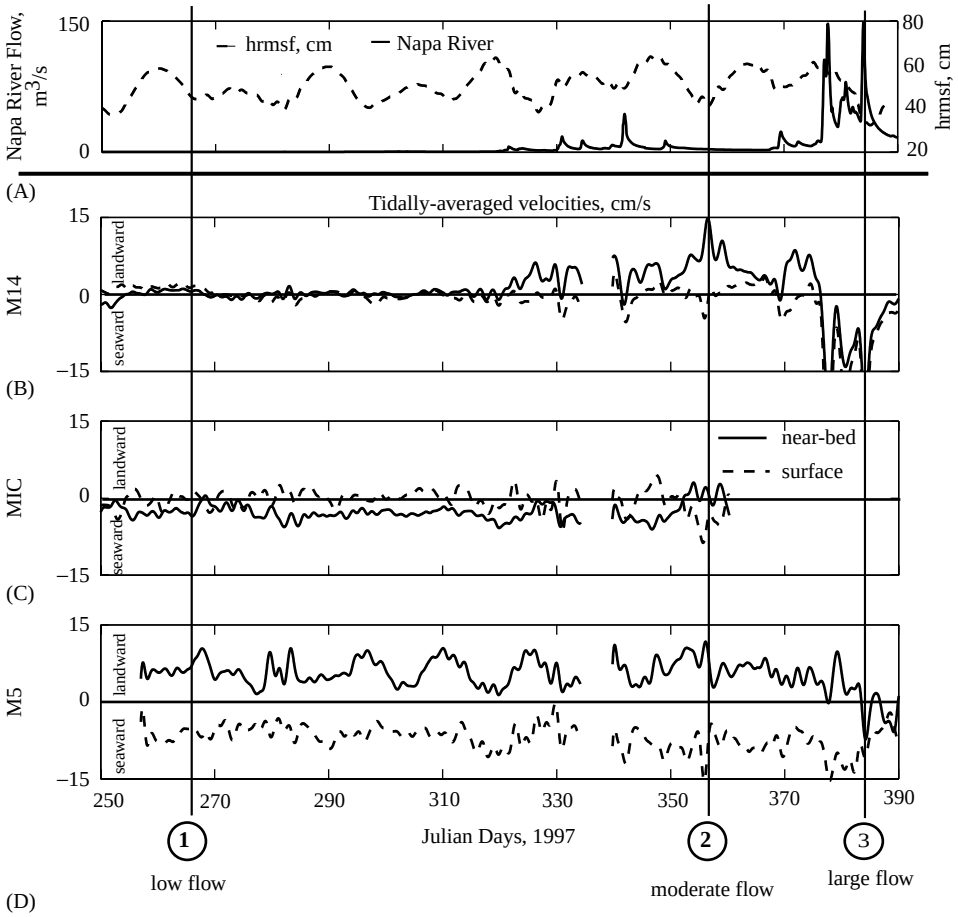

Fig. 7. Residual velocities: (A) discharge in the Napa River and hrmsf (=tidally averaged root mean square of the measured water level), and tidally averaged velocities from the top and bottom bins for sites; (B) M14; C, MIC; and D, M5. Profile lines 1, 2, and 3 refer to times of longitudinal plots in Fig. 8.

longitudinal density gradient at site M14 to produce a gravitational circulation residual current pattern (Figs. 7 and 8, time-period 2). As the freshwater inflow continued, the horizontal salinity gradient was finally pushed downstream to station MIC on day 355. This occurred during a neap tide, and a similar circulation pattern developed at MIC with upstream flow at the bottom and downstream at the surface. This circulation pattern lasted for approximately 8 days at site MIC producing a consistent flow pattern at all three sites.

Beyond Julian Day 380, the freshwater inflow increases and the salinity was temporarily washed out of Mare Island Strait (velocity record at site MIC nonrecoverable at that time). Then the residual flows throughout the strait became strictly barotropic (Figs. 7 and 8, time-period 3).

In summary, during periods of low freshwater inflow (time-period 1), a baroclinic convergence zone is created between sites M5 and MIC. However, during periods of increased freshwater inflows, an estuarine circulation pattern is established at sites M5, MIC, and M14 (time-period 2). During time periods of large, freshwater discharge, the residual velocities are downstream over the entire depth (time-period 3).

Tidally averaged suspended sediment fluxes from sites M14, MIC, and M5 are shown in Fig. 9 again with three representative time periods identified in

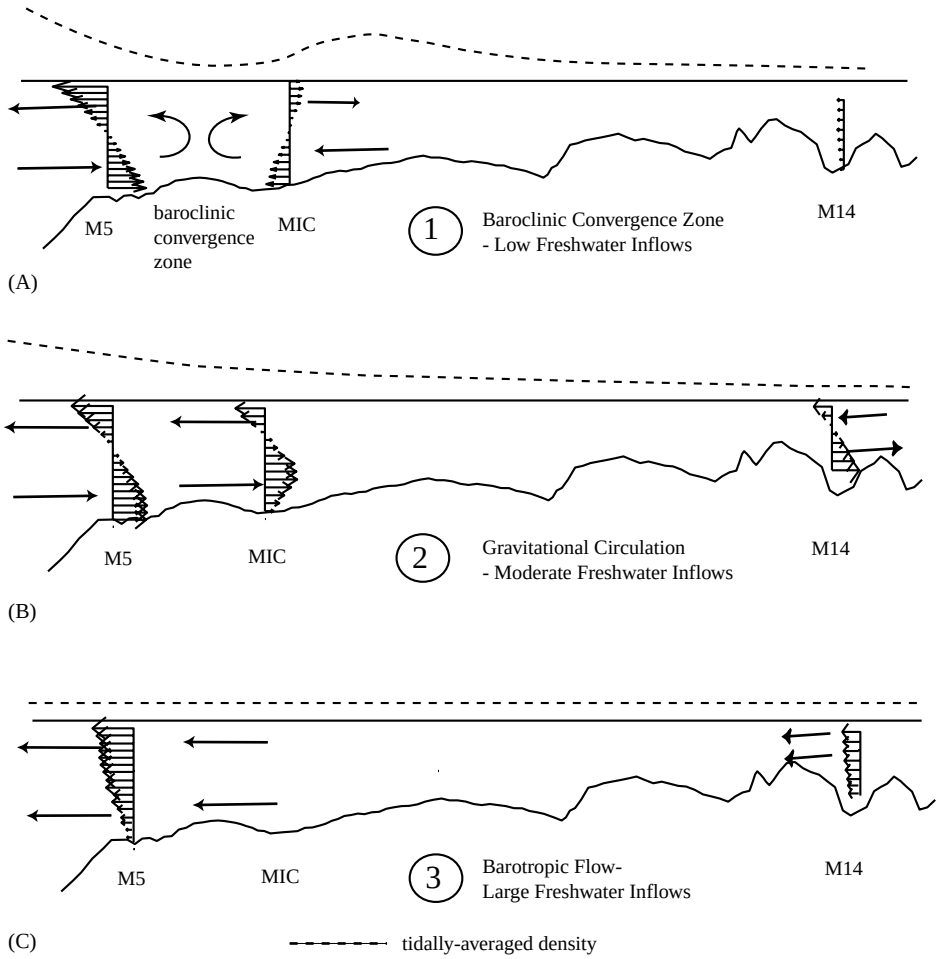

Fig. 8. Longitudinal profile of Napa River Bathymetry with vertical profiles of tidally averaged velocities and arrows showing residual circulation patterns for: (A) periods of very low freshwater inflows with baroclinic convergence zone; (B) increasing fresh water inflows with gravitational circulation; and (C) large freshwater inflows with barotropic flow. Longitudinal profiles 1, 2, and 3 refer to times in Fig. 7.

the figure. Measured time series of suspended sediment are non-continuous due to biological fouling and therefore the three representative time periods selected are different than in Fig. 7, however, the times represent similar flow magnitudes. For periods of low freshwater inflows (time-period 1) the flux of near bottom sediment is in the upstream direction at site M5 and in the downstream direction at site MIC. These converging sediment fluxes are attributed to the baroclinic convergence and will lead to enhanced deposition in Mare Island Strait. During periods of moderate freshwater discharge in the Napa River (time-period 2) the near-bed flux of sediment is upstream at all three sites responding to the estuarine circulation pattern. During high flow events (time-period 3) the sediment fluxes are downstream over the water column at all 3 sites, with peaks of sediment correlating to discharge peaks. These events occurred during barotropic flow.

5. Summary and conclusions

The monotonic increase in salinity from the head to the mouth of most estuaries creates a

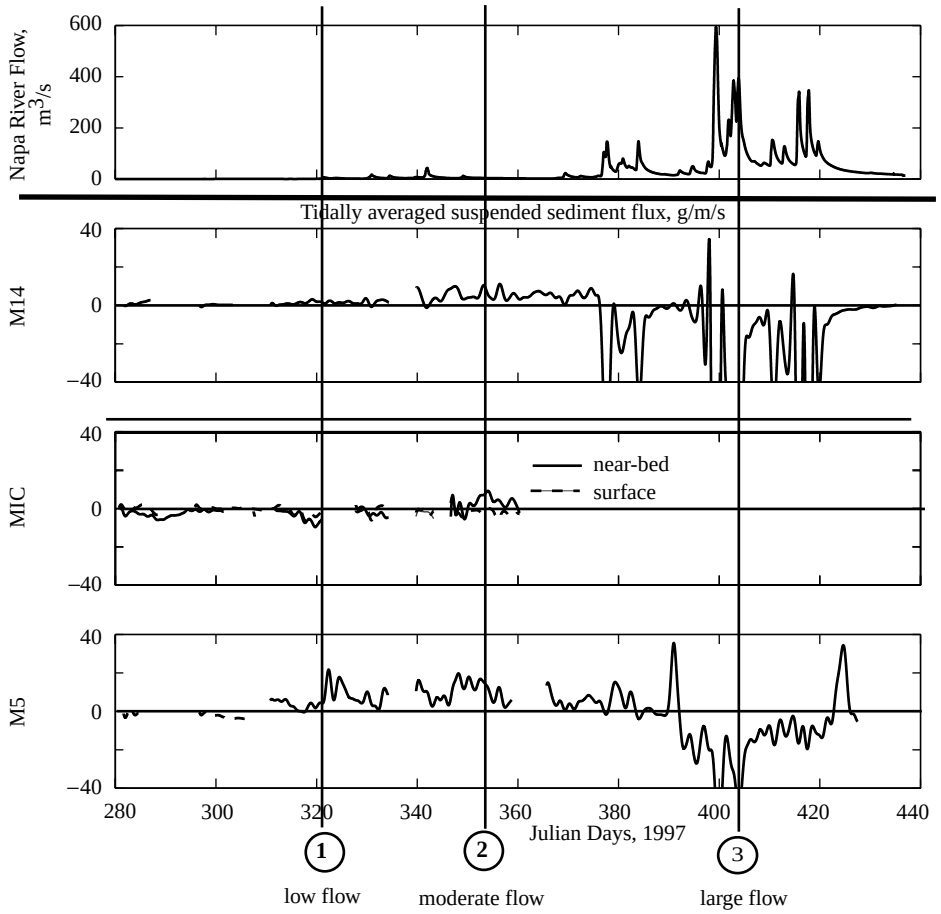

Fig. 9. Tidally averaged suspended sediment flux at sites: (A) M14; (B) MIC; and (C) M5.

residual flow pattern of estuarine circulation. However, physical processes can occur that alter the structure of the longitudinal density gradient, thus, creating different tidally averaged circulation patterns. The phasing of the currents at the junction of Mare Island and Carquinez Straits create a local salinity minimum in Mare Island Strait that alters the longitudinal density gradient. On a tidal time scale, the interaction of the baroclinic and barotropic pressure gradients affects the shear in the water column. On a tidally averaged time scale, the salinity minimum is a focus of converging baroclinic pressure gradients that drive a circulation pattern of converging near-bed velocities and diverging surface currents, termed a "baroclinic convergence zone". This convergence, together with a local supply of suspended sediment, probably account for the exceptional rates of sediment accumulation historically observed in Mare Island Strait.

Abstract: The present study experimentally assessed the uptake, loss, and resulting tissue distribution of As(V), Cd, Cr(III), Hg(II), and methylmercury (MeHg) in killifish (*Fundulus heteroclitus*) following aqueous exposure in water collected from 3 contaminated field sites—Baltimore Harbor and Elizabeth River (Chesapeake Bay), and Mare Island (San Francisco Bay)—using a radiotracer technique. Uptake rate constants ($L\,g^{-1}\,d^{-1}$) were highest for MeHg (0.370–0.781) and lowest for As (0.00028–0.00065). Loss rate constants (d^{-1}) were highest for As (0.046–0.096) and lowest for MeHg (0.006–0.009). Tissue distribution data showed that MeHg was redistributed around the body throughout the 9-d depuration period, and drinking may be an uptake mechanism for Cd from the aqueous phase in higher-salinity water. The kinetic parameters calculated in the present study were entered into a bioaccumulation model to calculate the predicted body burden of each metal at steady state and the percentage body burden attributable to dietary exposure on a site-specific basis. Calculated body burdens varied between field sites for all metals except Cr. The predicted values for Cd, Hg(II), and MeHg matched independent field data from contaminated estuaries, indicating that the model can account for the major processes governing metal concentration in killifish. The diet accounted for >97% of the body burden of Cd and MeHg and was the predominant exposure route for As and Cr. *Environ Toxicol Chem* 2014;33:89–101. © 2013 SETAC

Keywords: Metal uptake Bioavailability Metal accumulation Tissue distribution Biokinetic modeling

INTRODUCTION

Industrialized coastal estuaries have elevated levels of metals in sediment and water caused by anthropogenic activities, resulting in increased metal body burdens in estuarine organisms [1]. Methylmercury is of particular concern because it is highly toxic, can be biomagnified in aquatic food chains, and is found at elevated concentrations in a broad spectrum of marine and estuarine fish and shellfish that are regularly consumed as seafood [2], potentially posing a risk to human health.

Fish are exposed to metals through dietary and aqueous pathways, although studies have shown that diet is the dominant uptake route for most metals [3–5]. Various factors including prey choice and ingestion rate influence the assimilation efficiency (defined as the percentage of ingested metal that crosses the gut lining) and therefore dietary uptake of metal in fish; but the importance of the aqueous uptake pathway should not be overlooked. If the ingestion rate of the fish is low, the assimilation efficiency of ingested prey is low; or if the concentration of metal in the prey is low, then the aqueous phase could become an important uptake route. The bioavailability of aqueous metals to fish is predominantly influenced by the salinity and dissolved organic matter (DOM) concentration in the water. Salinity influences metal bioavailability as a result of chloro-complexation of the metal ion [6], whereas DOM can either decrease or enhance metal uptake into fish, depending on the composition of the DOM and the metal [7].

The distribution of metals in fish tissues following dietary and aqueous exposure remains poorly understood. Previous studies have attempted to characterize the tissue distribution of metals following uptake or after a depuration period [3,5–7], and these distributions are normally non–tissue-specific (e.g., head, viscera, and body). To provide a better understanding of the dynamics of metal redistribution between fish tissues, dissections need to be tissue-specific and carried out throughout the depuration period to enable calculations of metal efflux or influx rates for different tissues.

Killifish (*Fundulus heteroclitus*), a ubiquitous, small forage fish found in estuaries, bays, and salt marshes along the eastern seaboard of the United States from the Gulf of St. Lawrence to northeastern Florida [8], can be used as a model organism to investigate metal accumulation and tissue distribution. Killifish are a useful regional bioindicator of heavy metal contamination because they are euryhaline, have a limited swimming range, and show varying susceptibilities to aquatic contaminants [8].

To further understand the influence of salinity and dissolved organic carbon (DOC) on metal uptake and loss from the aqueous phase in natural waters and model metal bioaccumulation, we exposed killifish to 3 metals—Cd, Cr(III), and Hg (as Hg[II] and methylmercury [MeHg])—and 1 metalloid, As(V), in water collected from 3 contaminated field sites with varying salinity and DOC concentration: 2 in the Chesapeake Bay (Baltimore Harbor and Elizabeth River) and 1 in San Francisco Bay (Mare Island). The uptake and loss of each metal were monitored using gamma-emitting radioisotopes, and uptake rate constants (k_us) and loss rate constants (k_{ew}s) were calculated for each metal on a site-specific basis. The tissue distribution of each metal was determined at the end of depuration for all 3 field sites; however, to investigate how each metal is redistributed around the body over a 9-d period following aqueous exposure, fish in Baltimore Harbor were dissected regularly throughout depuration to calculate the efflux or influx rate constant for each tissue compartment and the corresponding biological half-life of each metal. Calculated kinetic parameters describing metal accumulation from water (k_u, k_{ew}; the present study) were entered into a bioaccumulation model [9], with the assimilation efficiency and loss rate constant after dietary

exposure (k_{ef}) calculated in a prior study [10], to determine the steady-state metal concentration in killifish and the primary uptake route for each metal at each field site.

All metals were chosen because they are on the list of US Environmental Protection Agency priority pollutants and are found at elevated concentrations in coastal waters, particularly those near large population centers and industrial activity. All of these metals are of environmental interest because of their potential impact on the health of aquatic ecosystems and the associated risk to humans from consuming contaminated seafood. Cadmium and Hg are known to chloro-complex, whereas As and Cr do not [11]. Cadmium and Hg are present as cations in solution, whereas As and Cr are present as oxyanions.

MATERIALS AND METHODS

Water and experimental conditions

Experiments were conducted using 0.2 μm sterile-filtered (Millipak 200; Millipore) water collected from 3 contaminated field sites: Baltimore Harbor (Baltimore, MD, USA; 39°12′25″N, 76°31′41″W), Elizabeth River (Norfolk, VA, USA; 36°12′32″N, 76°20′09″W), and Mare Island (Vallejo, CA, USA; 38°04′23″N, 122°14′91″W). Water was collected from a 2-m depth using a trace metal clean pump. Water parameters (salinity, chloride ion concentration, DOC concentration, and pH) are shown in Table 1. The chloride ion concentration was measured using a Dionex DX-500 ion chromatograph with an IonPac AS4A-SC anion-exchange column and sodium carbonate/bicarbonate eluent, and the DOC concentration was measured using a Shimadzu TOC-5000 total organic carbon analyzer. Filtered water from each field site was analyzed for background metal levels (concentration of metal in the water before addition of the radioisotope) by the Trace Element Analysis Core Laboratory at Dartmouth College (total Hg) and the Inorganic Analytical Core Laboratory at Rutgers University (As, Cd, and Cr) using inductively coupled plasma mass spectrometry (ICP-MS), and the results are shown in Table 1. All experiments were held at 18 ± 0.5 °C on a 14:10-h light:dark cycle.

Fish

Field-collected killifish, *F. heteroclitus* (Taylor River, Hampton, NH, USA; salinity = 25–30 ppt, mean wet wt = 1.95 g ± 0.35 standard deviation [SD]), purchased from Aquatic Research Organisms, were used in the present study. Fish were acclimated to experimental conditions for at least 2 wk prior to the start of experiments and fed a daily diet of bloodworms or brine shrimp and TetraCichlid cichlid flakes (TetraHolding). Prior to the start of experiments, fish were starved for 36 h to purge their gut of any remaining food, and the fish were not fed during the metal-uptake portion of the experiment; therefore, metal uptake was from only the aqueous phase.

Metal uptake, depuration, and tissue distribution from the aqueous phase

Radiolabeled water (250 mL) from each field site was poured into individual containers and left to equilibrate for several hours. Per 250 mL, each fish was exposed to 23 kBq to 38 kBq ^{73}As, 10 kBq to 14 kBq ^{109}Cd, 33 kBq to 38 kBq ^{51}Cr, 1.9 kBq to 9.6 kBq ^{203}Hg(II), and 1.1 kBq to 1.3 kBq MeHg. This equates to the addition of the following metal concentrations: 0.27 nM to 1.06 nM ^{73}As (Baltimore Harbor = 0.27 nM, Elizabeth River = 1.06 nM, Mare Island = 0.34 nM), 0.45 nM ^{109}Cd, 0.27 nM to 0.85 nM ^{51}Cr (Baltimore Harbor = 0.27 nM, Elizabeth River = 0.43 nM, Mare Island = 0.85 nM), 0.01 nM to 0.03 nM ^{203}Hg(II) (Baltimore Harbor and Elizabeth River = 0.01 nM, Mare Island = 0.03 nM), and 0.13 nM MeHg. Concentrations for each metal varied between field sites because of the radioactive decay of the radioisotopes between experiments. Methylmercury, ^{109}Cd, and ^{203}Hg(II) were single-labeled, whereas ^{73}As and ^{51}Cr were added together because the gamma emissions of these isotopes did not interfere with each other.

After radioisotope equilibration, 1 fish was added per container and uptake was monitored at regular intervals for 36 h to 37 h ($n = 8$ for Elizabeth River and Mare Island, $n = 25$ for Baltimore Harbor). This time period was chosen to allow sufficient time to radiolabel the fish while minimizing the risk of excessive metal loss from the fish throughout the uptake period. At each sample time throughout the uptake period, fish were removed from their container, rinsed twice with unlabeled site water to remove excess radioisotope adhering to the body surface, and radioassayed. A 1-mL water sample was also collected at each sample time and radioassayed to allow for calculations of concentration factors and uptake rate constants in the fish for each metal and field location. No fish showed adverse health effects (death, abnormal swimming behavior, excess mucus production, or not feeding during depuration) from the experimental procedure.

At the end of metal uptake, fish were radioassayed and returned to individual containers with 600 mL unlabeled water from the same field site, fed unlabeled bloodworms, and allowed to depurate for 9 d. To monitor metal loss, fish were regularly radioassayed for the first 2 d of depuration and then once a day for the remaining 7 d. Water was changed after 1 d and then every other day. At the end of the 9-d depuration period fish in Elizabeth River and Mare Island water were killed using tricaine methanesulfonate (MS-222); dissected into the head, gill, viscera, and body (skeleton, axial musculature [muscle], and skin); radioassayed; and dried at 60 °C for 48 h to calculate dry tissue weights. To investigate how the body distribution of each metal changed over 9 d following exposure to aqueous metals, 5 fish in Baltimore Harbor water were killed at the end of uptake and after 1 d, 3 d, 6 d, and 9 d of depuration. The head,

[a] For chloride ion concentration and DOC concentration, values represent means ± 1 standard deviation, $n = 3$.
BH = Baltimore Harbor; ER = Elizabeth River; MI = Mare Island; DOC = dissolved organic carbon; C_w = background metal concentration; MeHg = methylmercury.

gills, brain, eyes, viscera (excluding liver), liver, skeleton (including fins), muscle, and skin were dissected, radioassayed, and dried to obtain dry weights. Efflux or influx rates of metals in individual fish tissues were calculated by converting the mean radioactivity concentration in each fish tissue between day 1 and day 9 of depuration into percentage retained and conducting a linear regression analysis; the resulting slope was the efflux or influx rate.

One-way analysis of variance and Tukey post hoc tests were used to determine significant differences ($p < 0.05$ or $p < 0.01$) between kinetic parameters (k_u, k_{ew}) and field site. All statistical analyses were conducted using IBM SPSS statistics software (Ver 21).

Radioisotopes and radioanalyses

Microliter quantities of high–specific activity radioisotopes (1221–7844 kBq μg^{-1} ^{73}As, 814–1110 kBq μg^{-1} ^{109}Cd, 3071–6808 kBq μg^{-1} ^{51}Cr, 1369–15,318 kBq μg^{-1} ^{203}Hg[II], and 163–196 kBq μg^{-1} MeHg) were used in the present study. ^{73}Arsenic ($t_{½} = 80.3$ d, as As[V]) and ^{109}Cd ($t_{½} = 462.6$ d), both dissolved in 0.1 M HCl, were purchased from Los Alamos National Laboratory; ^{51}Cr ($t_{½} = 27.7$ d, as Cr[III], dissolved in 0.5 M HCl) was purchased from PerkinElmer; and ^{203}Hg ($t_{½} = 46.6$ d, as Hg[II], dissolved in 1 M HCl) was obtained from Georgia State University. Methylmercury ($CH_3{}^{203}Hg[II]$) was synthesized in our laboratory using a procedure described elsewhere [12] and held in deionized water. After adding the radioisotopes to experimental water, an equimolar concentration of sodium hydroxide was added to neutralize the acid, after which the pH was checked; it remained unchanged.

Killifish were radioassayed noninvasively in 30 mL non-radiolabeled site water using a Canberra deep-well NaI(Tl) gamma-detector for no longer than 5 min to reduce stress on the fish; this allows the same fish to be monitored throughout metal uptake and depuration, therefore reducing biological variability. The propagated counting errors were ≤5%, except for As and Cr where propagated counting errors could reach 25% because of low uptake of the radioisotopes. Water and dissected fish tissue were radioassayed for 5 min using an intercalibrated LKB Pharmacia-Wallac 1282-CompuGamma CS gamma-counter. All sample counts were corrected for background radioactivity and radioactive decay. The gamma-emissions of ^{109}Cd, ^{73}As, ^{203}Hg, and ^{51}Cr were detected at 22 keV, 53 keV, 279 keV, and 320 keV, respectively.

Modeling metal bioaccumulation in killifish

Metal bioaccumulation in killifish can be evaluated using a biokinetic model [9], which takes into account metal uptake and loss from aqueous and dietary sources and has been successfully tested using fish [3–5]. Under steady-state conditions

$$C_{ss} = [(k_u \times C_w)/(g + k_{ew})] + [(AE \times IR \times C_f)/(g + k_{ef})] \quad (1)$$

where C_{ss} is the steady-state concentration of metal in killifish ($\mu g\, g^{-1}$ dry wt), k_u is the uptake rate constant of metal from the dissolved phase ($L\, g^{-1}\, d^{-1}$), C_w is the background metal concentration in water ($\mu g\, L^{-1}$), g is the growth rate constant (d^{-1}), k_{ew} is the metal efflux rate constant after aqueous exposure (d^{-1}), AE is the assimilation efficiency of ingested metal in killifish (percentage as fraction), IR is the killifish ingestion rate ($g\, g^{-1}\, d^{-1}$), C_f is the metal concentration in prey ($\mu g\, g^{-1}$), and k_{ef} is the metal efflux rate constant after dietary exposure (d^{-1}).

Concentration factors were calculated by dividing the disintegrations per minute (dpm) per gram dry weight in fish by the dpm in 1 mL of water. Dry weight concentration factors can be converted to wet weight concentration factors by dividing by 4 (dry weight is approximately 25% of wet wt). Uptake rate constants of metal from the dissolved phase (k_u) were calculated as the slope of regressions for each metal and field site relating dpm per gram dry weight in fish divided by dpm in 1 L of water against time. For the model, k_u values were calculated between the 1-h and 13-h uptake time points for As, the 1-h and 25-h points for Cr, the 10.5-h and 37-h points for Hg(II), and the 1-h and 37-h points for Cd and MeHg. Efflux rate constants following aqueous exposure (k_{ew}) were calculated by fitting an exponential regression between the 2-d and 9-d depuration time points; the k_{ew} was the slope of the curve. For Baltimore Harbor, k_{ew}s were calculated only for fish that were killed at the end of 9 d.

In our model calculations, metal assimilation efficiency and k_{ef} values for killifish after feeding on amphipods in Baltimore Harbor water were taken from a prior study [10] and are as follows: assimilation efficiency, As = 9.4%, Cd = 4.5%, Cr = 0.2%, Hg(II) = 14%, MeHg = 92%; and k_{ef}, As = 0.287 d^{-1}, Cd = 0.064 d^{-1}, Hg(II) = 0.131 d^{-1}, MeHg = 0.008 d^{-1}. The Cr k_{ef} after feeding on amphipods was not determined because of near complete elimination of the radioisotope, so we applied a k_{ef} value for Cr in killifish after feeding on worms (0.064 d^{-1}) [10]. We applied an ingestion rate of 0.1 $g\, g^{-1}\, d^{-1}$ (dry wt) [13] and a growth rate of 0.005 d^{-1} [14].

Background metal concentrations in experimental waters (C_w) are shown in Table 1. The total Hg background values were 2.9 ng L^{-1} for Baltimore Harbor, 3.4 ng L^{-1} for Elizabeth River, and 2.7 ng L^{-1} for Mare Island; speciation of total Hg into Hg(II) and MeHg was determined assuming that 3% of Hg in marine waters is present as MeHg [15]. The C_f values for crustacean zooplankton prey (dry wt) were calculated by multiplying the C_w by the concentration factor of each metal in zooplankton; for Cr, the concentration factor was 6670 (assuming zooplankton dry wt is 15% of wet wt) [16]; and for As and Cd, the concentration factor was calculated by dividing the body burden of As and Cd in *Leptocheirus plumulosus* (0.85 $\mu g\, g^{-1}$ and 6.74 $\mu g\, g^{-1}$ dry wt, respectively) [17] by the C_w for Elizabeth River water, resulting in concentration factors of 615 for As and 32 000 for Cd. Inorganic Hg and MeHg zooplankton concentration factors (3820 and 366 700, respectively) were calculated using water and organism values from a prior study [15], assuming that 75% of Hg in crustacean zooplankton is present as MeHg [18].

To understand the relative importance of dietary and dissolved exposure routes, Equation 1 can be rearranged to calculate the percentage of C_{ss} that is attributed to dietary exposure (R)

$$R = ([(AE \times IR \times C_f)/(g + k_{ef})]/C_{ss}) \times 100 \quad (2)$$

To understand how long it takes for each metal to be excreted from the whole fish or individual tissue compartments after exposure to aqueous metal, the biological half-life ($tb_{½}$) can be calculated

$$tb_{1/2} = \ln 2/k_e \quad (3)$$

Assuming it takes 7 half-lives for >99% of the metal to be released from the whole fish or individual tissue compartments, the biological residence time for each metal can be calculated.

RESULTS

Metal uptake from the aqueous phase

Figure 1 shows the accumulation of As, Cd, Cr, Hg(II), and MeHg in killifish throughout the 37-h uptake period in experimental waters. To facilitate comparisons among metals, uptake over time is expressed as a dry weight concentration factor. For all metals and field sites, metal uptake was greatest during the first hour of exposure and then slowed throughout the remaining uptake period, except for Hg(II) in Mare Island water, which experienced the greatest uptake between 13 h and 37 h of exposure. While metal uptake slowed through the exposure period for most metals, concentration factors for Cd, Hg(II), and MeHg continued to slowly increase throughout the exposure period, whereas those for As and Cr began to approach steady state (except As in Mare Island water and Cr in Baltimore Harbor water). Cadmium, Cr, and MeHg accumulation was highest in Baltimore Harbor water, whereas As accumulation was highest in Elizabeth River water and Hg(II) accumulation was highest in Mare Island water at the end of the 37-h exposure period. When comparing the 2 Hg species, killifish in all 3 field-collected waters accumulated more MeHg than Hg(II) at the end of 37 h (Baltimore Harbor = 21.5 times, Elizabeth River = 15.4 times, and Mare Island = 2.5 times). Less than 1% of dissolved As, Cd, and Cr was removed from the water by the fish at the end of the 37-h exposure, whereas <28% of Hg(II) and 36% to 83% of MeHg was removed.

Throughout the uptake period concentration factors were highest for MeHg, followed by Hg(II), Cd, and Cr, with the lowest for As (Figure 1). Inorganic Hg and MeHg concentration factors were >1 throughout the uptake period, indicating that fish were more enriched in the metal than the experimental water, whereas As concentration factors were <1 for all field-collected waters. Figure 2 shows that Cd and MeHg accumulation had an inverse relationship with salinity, As accumulation increased with increasing salinity, and Cr accumulation showed no relationship with salinity. Inorganic Hg concentration factors were similar at 7.6 ppt (Baltimore Harbor) and 19.5 ppt

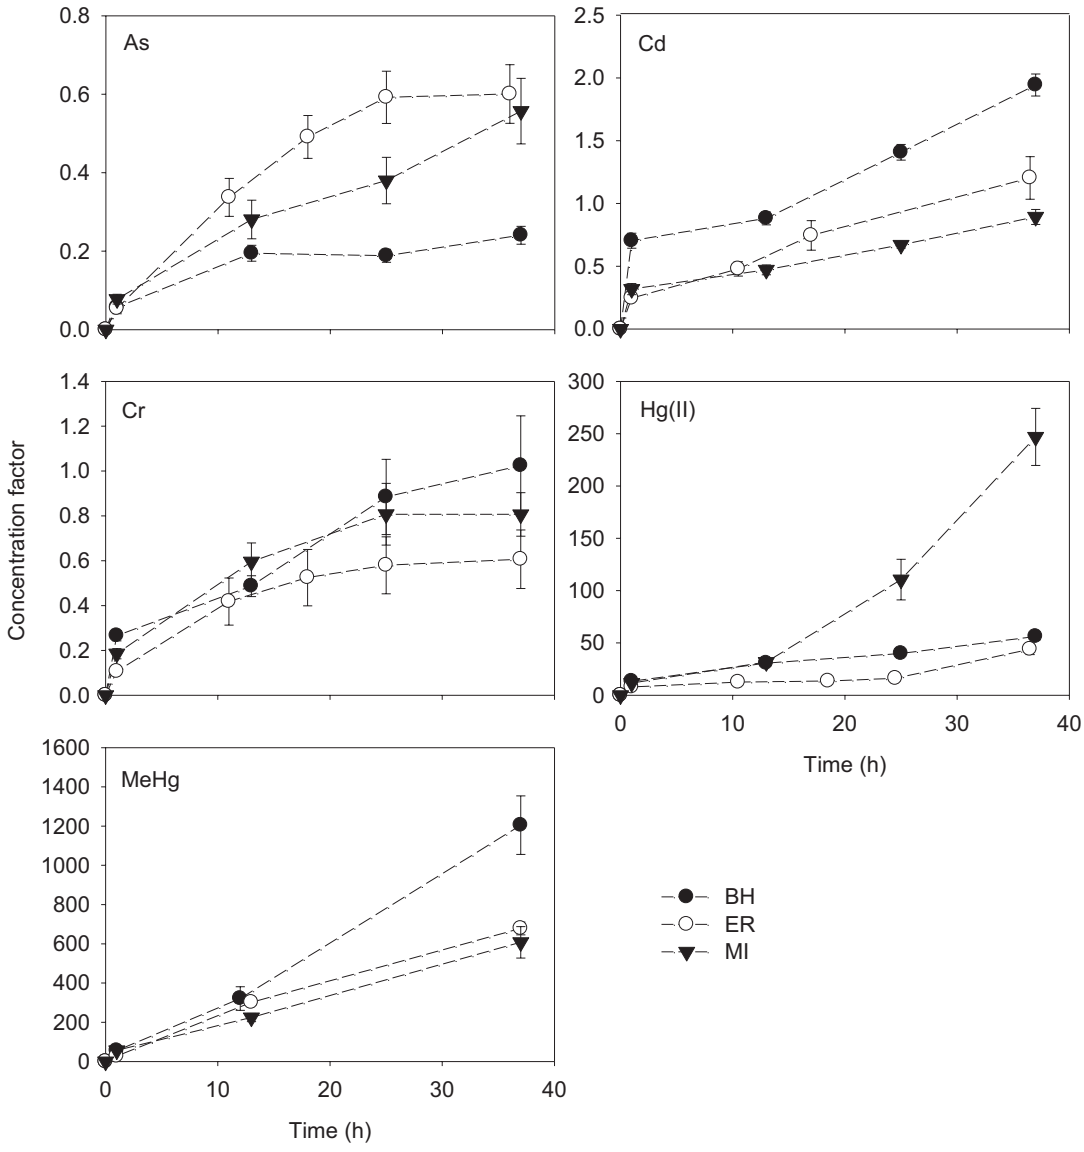

Figure 1. Accumulation of aqueous As, Cd, Cr, Hg(II), and methylmercury (MeHg) (as dry wt concentration factor) over a 37-h uptake period in killifish (*Fundulus heteroclitus*) in Baltimore Harbor (BH), Elizabeth River (ER), and Mare Island (MI) water. Values represent mean ± 1 standard error; $n = 8$ for Elizabeth River and Mare Island, $n = 25$ for Baltimore Harbor.

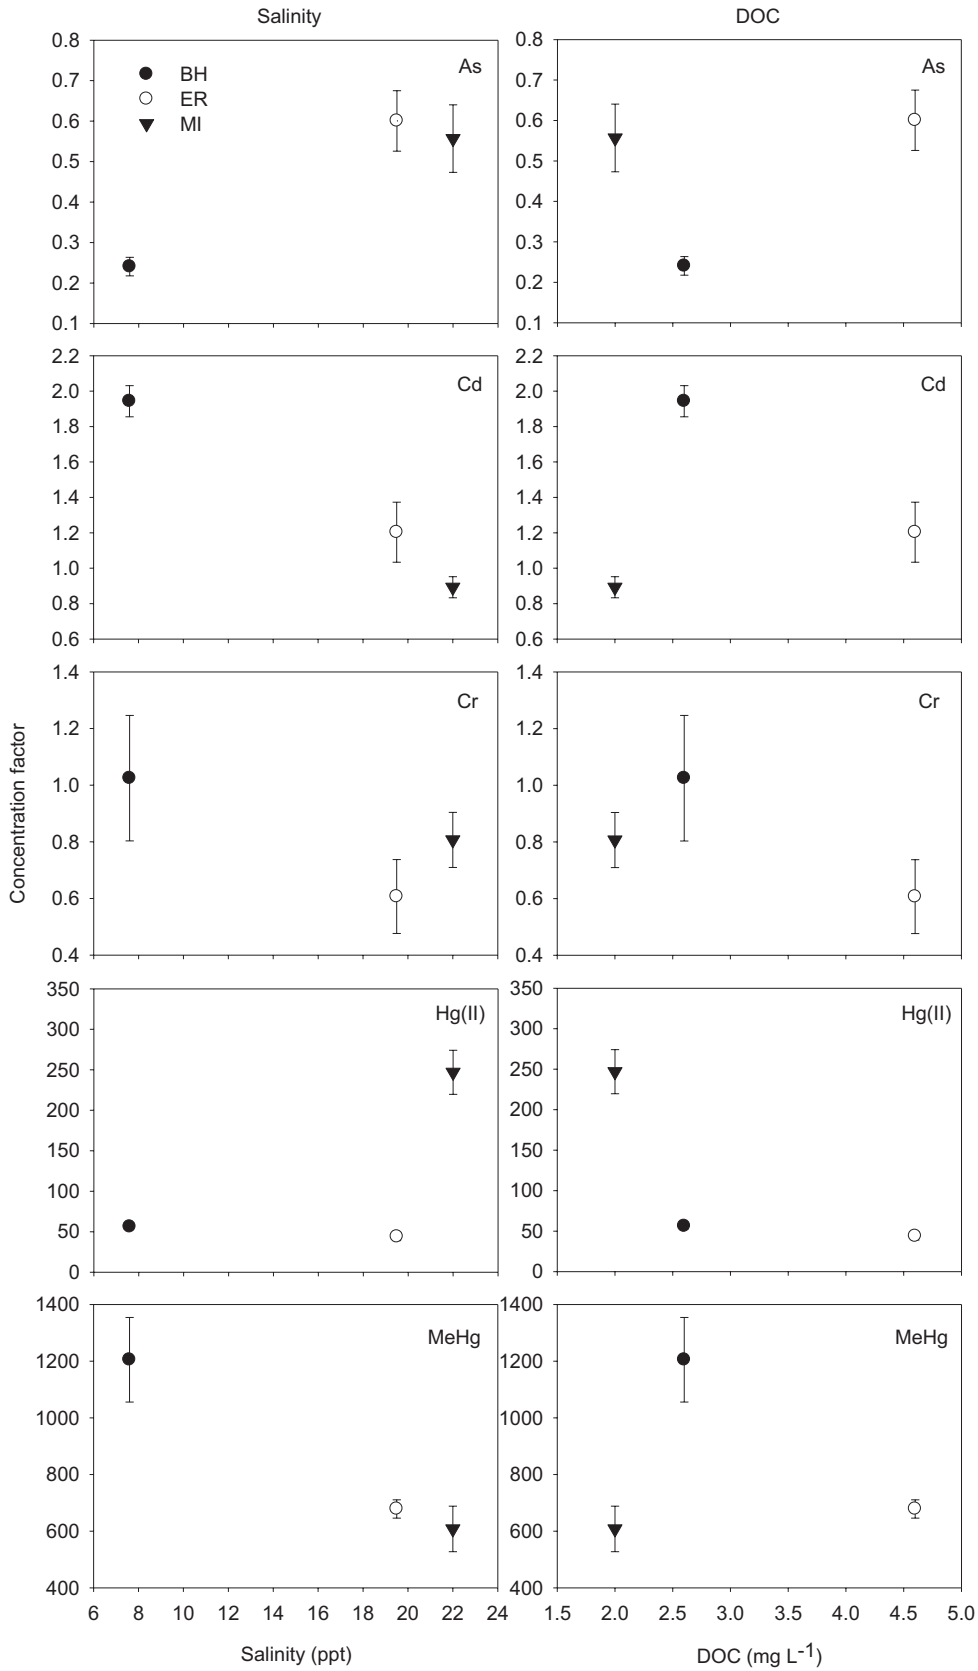

Figure 2. Metal concentration factors as a function of salinity and dissolved organic carbon (DOC) concentration in killifish (*Fundulus heteroclitus*) after 37-h exposure in Baltimore Harbor, Elizabeth River, and Mare Island water. Salinity and DOC concentration values are found in Table 1. Values represent mean ± 1 standard error; $n = 8$ for Elizabeth River and Mare Island, $n = 25$ for Baltimore Harbor. MeHg = methylmercury.

(Elizabeth River) (concentration factors = 40–44) and increased to 247 at 22 ppt. Of all the investigated metals, Hg(II) was the only one to show a relationship between metal accumulation and DOC concentration: as DOC concentration increased, Hg(II) accumulation decreased (Figure 2).

Table 2 shows the k_u ($L\,g^{-1}\,d^{-1}$) for each metal and field-collected water. Uptake rate constants were highest for MeHg (0.370–0.781), followed by Hg(II) (0.026–0.215), and lowest but comparable for Cd, Cr, and As (0.00039–0.00085, 0.00047–0.00063, and 0.00028–0.00065, respectively). The k_us did not vary significantly between field sites for Cr ($p > 0.05$) but did vary for As ($p < 0.01$; Baltimore Harbor vs Elizabeth River), Cd ($p < 0.01$; Baltimore Harbor vs Mare Island), Hg(II) ($p < 0.01$; Baltimore Harbor vs Mare Island, Elizabeth River vs Mare Island), and MeHg ($p < 0.05$; Baltimore Harbor vs Mare Island).

Metal retention and elimination after aqueous exposure

Figure 3 shows the loss of metals from killifish over 9 d following aqueous exposure in water collected from the 3 field sites. All metals in all field-collected waters showed the most rapid elimination of metal within the first several hours of depuration and a slower physiological turnover throughout the remaining 8 d. Efflux rate constants (d^{-1}) were highest for As and Cr (0.046–0.096 and 0.045–0.075, respectively) and lowest for MeHg (0.006–0.009) (Table 2). The k_{ew}s did not vary significantly between field sites for Cd and Cr ($p > 0.05$) but did vary for As ($p < 0.01$; Baltimore Harbor vs Elizabeth River), Hg(II) ($p < 0.01$, Baltimore Harbor vs Elizabeth River; $p < 0.05$, Baltimore Harbor vs Mare Island), and MeHg ($p < 0.05$; Baltimore Harbor vs Elizabeth River).

The biological half-lives ($tb_{½}$; d) of metals in whole fish following aqueous exposure were highest for MeHg (77–116) and lowest for Cr (9.2–15) and As (7.2–15) (Table 2). Assuming it takes 7 half-lives for all metal to be excreted from the killifish, the residence times are as follows: 539 d to 809 d for MeHg, 194 d to 323 d for Cd, 105 d to 211 d for Hg(II), 65 d to 108 d for Cr, and 51 d to 105 d for As.

Tissue distribution and radioactivity concentrations after aqueous exposure

Table 3 shows the tissue distribution, as a percentage of total body burden, at the end of 9-d depuration for each field location. Cadmium was predominantly associated with the gills (45%–60%); As, Hg(II), and MeHg were predominantly associated with the body (44–66%, 40–47%, and 57–58%, respectively); and Cr was split between the head (22–54%) and body (30–45%). Inorganic Hg and MeHg showed similar tissue distribution between the 3 field sites, whereas As, Cd, and Cr did not. In higher-salinity waters (Elizabeth River, Mare Island) the percentage of Cd associated with the gills was lower and the percentage of Cd associated with the viscera was higher than in lower-salinity water (Baltimore Harbor). The percentage of Cr associated with the head decreased and that associated with the viscera and body increased as the DOC concentration in the water increased (Elizabeth River > Baltimore Harbor > Mare Island). The percentage of As associated with the gills was greatest in the highest-DOC water (Elizabeth River) and that associated with the body decreased as DOC concentration increased. Radioactivity concentrations of each metal in fish were not calculated at the end of 9-d depuration for each field site because fish were exposed to varying radioactivity concentrations throughout uptake and therefore cannot be compared.

Table 4 shows the movement of metals between tissue compartments, as a percentage of total body burden, throughout the 9-d depuration period after exposure to aqueous metals in Baltimore Harbor water. Throughout depuration, Cr and Hg(II)

[a] Values represent means ± 1 standard error, $n = 8$ for Elizabeth River and Mare Island k_u and k_{ew}, $n = 25$ for Baltimore Harbor k_u, and $n = 5$ for Baltimore Harbor k_{ew}.

[b] $p < 0.01$ Baltimore Harbor versus Mare Island and Elizabeth River versus Mare Island.

[c] $p < 0.01$ Baltimore Harbor versus Elizabeth River and $p < 0.05$ Baltimore Harbor versus Mare Island.

* Statistically significant differences between field and kinetic parameters (k_u, k_{ew}) ($p < 0.05$).

** Statistically significant differences between field and kinetic parameters (k_u, k_{ew}) ($p < 0.01$).

k_u = uptake rate constant; k_{ew} = efflux rate constant; $tb_{½}$ = biological half-life; SE = standard error; BH = Baltimore Harbor; ER = Elizabeth River; MI = Mare Island; MeHg = methylmercury.

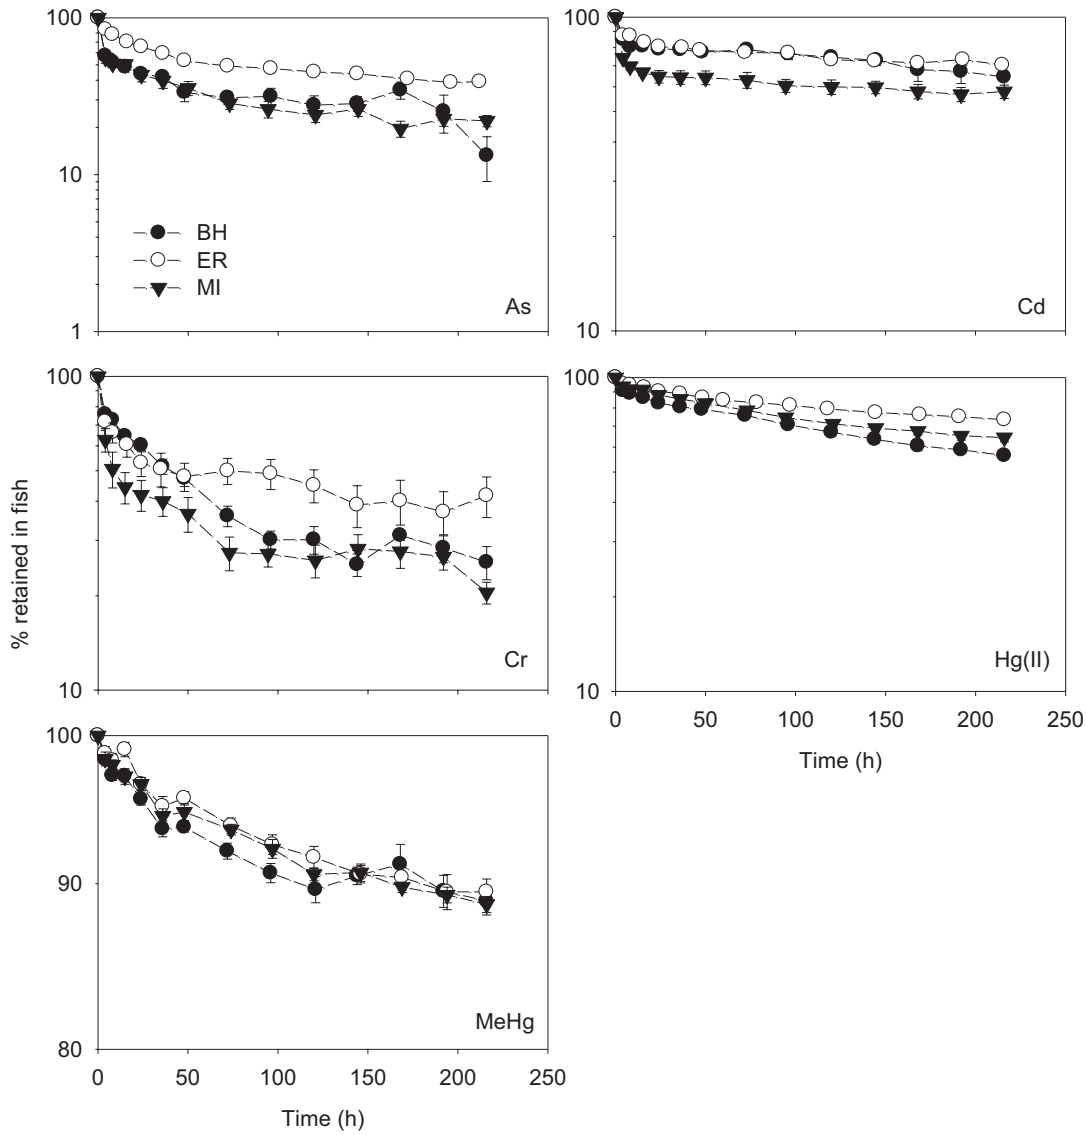

Figure 3. Loss of As, Cd, Cr, Hg(II), and methylmercury (MeHg) from killifish (*Fundulus heteroclitus*) over 9 d after aqueous exposure in Baltimore Harbor (BH), Elizabeth River (ER), and Mare Island (MI) water. Retention is shown as a percent of initial body burden after exposure. Values represent mean ± 1 standard error; $n = 8$ for Elizabeth River and Mare Island, $n = 5$ to 20 for Baltimore Harbor.

were predominantly associated with the head, Cd with the gills, and As with the muscle. The tissue distribution of MeHg changed throughout depuration; the percentage of MeHg associated with the head and gills decreased (25–19% and 23–4%, respectively), and that associated with the muscle increased (10–33%). Table 5 shows the radioactivity concentration on a weight-normalized basis in individual tissue compartments throughout depuration after exposure to aqueous metals in Baltimore Harbor water. Throughout depuration the highest concentration of Cd and Hg(II) was in the gills, whereas the highest concentration of Cr was in the gills and brain. The concentration of MeHg was highest in the gills, viscera, and liver, whereas As had a varied tissue distribution throughout depuration, which showed no consistent trends. Table 6 shows the rates of metal uptake or loss in each tissue compartment and the corresponding biological half-life. Arsenic had a high efflux rate and therefore a short biological half-life in the liver, whereas Cd, Cr, and Hg(II) were transferred into the liver over time. The gills and liver had the highest loss rate of MeHg, whereas MeHg was taken up over time into the brain, eyes, and muscle.

Modeling metal bioaccumulation in killifish

Model-predicted metal body burdens at steady-state (C_{ss}; ng g^{-1}; Table 7) were highest for Cd (396–508) and lowest for Cr (5.2–7.2) and Hg(II) (2.6–15.1). Chromium C_{ss} values did not vary between the 3 field sites, whereas the As, Cd, Hg(II), and MeHg values varied. The diet was the dominant source of Cd and MeHg to killifish at all field sites, accounting for >97% of accumulated metal, whereas a portion of As and Cr accumulation was attributed to aqueous exposure (13%–40% and 29%–40%, respectively). The importance of Hg(II) aqueous and dietary sources varied between field sites; the diet accounted for 43% of the Hg(II) C_{ss} for Baltimore Harbor but only 7% for Mare Island (Table 7).

DISCUSSION

Metal uptake from the aqueous phase

For all 3 field sites, the greatest accumulation of each metal was observed during the first hour of exposure as a result of the bioavailable metal binding to the most reactive site on the fish,

Table 3. Tissue distribution (as percentage of total body burden) of As, Cd, Cr, Hg(II), and MeHg in killifish after 9-d depuration following aqueous exposure in Baltimore Harbor, Elizabeth River, and Mare Island water[a]

[a] Values (means ± 1 standard error) represent the percentage of total body burden associated with each tissue compartment (head, gills, viscera, and body); $n = 5$ for Baltimore Harbor and $n = 8$ for Elizabeth River and Mare Island.
BH = Baltimore Harbor; ER = Elizabeth River; MI = Mare Island; MeHg = methylmercury.

presumably the gills. It is presumed that after the initial rapid uptake, the rate of metal accumulation decreased because of either saturation of the most reactive binding sites on the gill or possible internal regulation of the metal in the fish, as observed for As in Baltimore Harbor and Elizabeth River water and for Cr in Elizabeth River and Mare Island water. The difference in salinity between the 3 field sites most likely accounted for the difference in the concentration factor and k_u values calculated in the present study for most metals, whereas DOC concentration had less influence. Dissolved organic carbon can reduce metal bioavailability for fish, but the 3 field sites do not differ markedly in their DOC concentration range (2.0–4.6 mg L^{-1}), which could account for why no clear trend was observed between metal uptake and DOC concentration. The DOC concentration in each site water falls within the range of concentrations typically observed in estuarine waters [1]. It should be noted that the composition of the DOM presumably varies between field sites, but this was not characterized in the present study.

The experiments conducted in the present study were carried out in natural waters, and therefore, the interaction between salinity and DOC concentration could not be adequately assessed to understand the effect of each variable. While prior studies have investigated the influence of salinity and DOC concentration on metal uptake in killifish as separate variables [6,7], future experiments should include a full factorial design controlling for both salinity and DOC concentration to understand the effect of salinity on metal uptake at different DOC concentrations and vice versa.

Table 4. Metal partitioning (as percentage of total body burden) in killifish at the end of aqueous uptake (day 0) and after 1 d, 3 d, 6 d, and 9 d of depuration in Baltimore Harbor water[a]

[b] Units are kBq g^{-1} dry wt.

The low uptake of As in all 3 field-collected waters resulted in concentration factors <1, indicating the water was more enriched in As than the fish, consistent with earlier findings [6,7]. This could be attributed to both As(V) and the fish body surface being negatively charged and, therefore, repelling each other. Arsenic uptake appeared to reach steady state in killifish in Baltimore Harbor and Elizabeth River water by the end of the 36-h exposure. The high efflux rate (23% d^{-1}) of As from the liver calculated for killifish in Baltimore Harbor water (Table 6) indicates that As may be internally regulated, and therefore, part of the reason that steady-state conditions were reached was the rapid physiological turnover of As in the liver. Arsenic accumulation in killifish increased with increasing salinity; fish in Mare Island water (22 ppt) accumulated 2.3 times more As than fish in Baltimore Harbor water (7.6 ppt) by the end of the exposure period. Marine fish drink to osmoregulate, and drinking could be a possible uptake route for As; but this was not supported by the tissue-distribution data. The same relationship was observed in another laboratory study [6] and in a field study where fish collected from higher-salinity water had a higher body burden of As [19]. The k_u values calculated in the present study are comparable to those calculated in other laboratory studies [6,7].

	BH	241	97
	ER	263	99
	MI	210	99

[a] The C_{ss} values were calculated using background metal concentration values in Table 1, uptake rate constant and efflux rate constant values in Table 2, and assimilation efficiency, metal efflux rate constant, metal concentration in prey, ingestion rate, and growth rate constant values in *Materials and Methods*.
C_{ss} = steady-state concentration, dry weight; BH = Baltimore Harbor; ER = Elizabeth River; MI = Mare Island; MeHg = methylmercury.

Chromium was the only metal for which salinity and DOC concentration did not influence metal accumulation, as shown by the overlapping error bars in Figure 2. Like As, Cr also binds to oxygen and does not chloro-complex in seawater [11]. By the end of uptake, concentration factors were <1 in killifish in Elizabeth River and Mare Island water, indicating that the water was more enriched in Cr than the fish at those 2 field sites. Chromium(III) is particle-reactive and has low cell membrane permeability, which may account for the observed low uptake in all 3 field-collected waters. In comparison, Cr(VI) is much less particle-reactive than Cr(III) but has greater cell membrane permeability and therefore accumulates in aquatic organisms, as observed in mussels [20]. Chromium accumulation appeared to reach steady state in Elizabeth River and Mare Island water within the 37-h exposure period; unlike for As, there was not a high efflux rate of Cr from the liver; instead, the concentration of Cr in the liver increased over time. Another laboratory study also concluded that salinity had no influence on the uptake of Cr in fish [6]. Chromium accumulation was lowest in Elizabeth River water, which had the highest DOC concentration; although the 3 field sites have a narrow DOC concentration range, this finding conforms to another study which concluded that as DOM concentration increased from 0 mg L^{-1} to 5 mg L^{-1}, the uptake of Cr decreased [7].

Cadmium uptake showed an inverse relationship with salinity, similar to the findings of other studies [6,21]; concentration factors in killifish in Baltimore Harbor water were 2.2 times higher than those in killifish in Mare Island water. As salinity increases, Cd^{2+} binds to chloride, forming $CdCl_2$ and other chloro-complexes, which are less chemically reactive and therefore less bioavailable for uptake by killifish. The concentration of DOC did not influence Cd accumulation in killifish, supporting the finding of another study [7]. This could possibly be attributed to Cd having a lower binding affinity for DOC ($\log K_{Cd\text{-}DOC} = 7.4$) than for fish gills ($\log K_{Cd\text{-}gill} = 8.6$) [22]. The concentration factor and k_u values calculated in the present study are comparable to those from another study where Cd uptake was investigated as a function of salinity at 6 ppt, 12 ppt, and 25 ppt [6].

Like Cd, Hg(II) and MeHg chloro-complex in seawater. In freshwater, Hg binds to hydroxide (Hg is speciated as $Hg[OH]_2$ and MeHg as CH_3HgOH), whereas in seawater Hg(II) and MeHg bind to chloride, forming mercuric–chloride complexes ($HgCl_2$ and CH_3HgCl_2, respectively) [23]. As salinity increased, Hg(II) and MeHg behaved differently; at the end of uptake, the Hg(II) concentration factor was 5.6 times higher and the k_u value 7.2 times higher in Mare Island water than in Elizabeth River water, even though there was only a 2.5 ppt salinity difference between the 2 site waters. The reason for the sudden increase in Hg(II) uptake in Mare Island water after 12-h exposure is not apparent to us. This Hg(II)-uptake pattern was also observed in another study where Hg(II) accumulation in killifish was investigated as a function of humic acid concentration; in that study, the greatest rate of Hg(II) uptake was observed between 24 h and 47.5 h of exposure [7]. Furthermore, another laboratory-based study [6] showed a positive relationship between salinity and Hg(II) accumulation, whereas no clear trend was observed in the present study. The inverse relationship between Hg(II) uptake in killifish and DOC concentration was also observed in a prior study [6]. The Hg(II) k_u values in Baltimore Harbor and Elizabeth River water calculated in the present study are within the range of values calculated for freshwater, estuarine, and marine fish [3,5–7], although the k_u of Hg(II) in Mare Island water is higher than most values in other studies.

Methylmercury uptake showed an inverse relationship with salinity; killifish accumulated 2.0 times more MeHg in Baltimore Harbor water than in Mare Island water. In another study where MeHg accumulation in killifish was investigated as a function of salinity, a positive relationship was observed [6]. It should be noted that the prior study was strictly controlled, so salinity was the only variable, whereas the present study was conducted in natural waters. A field study investigating the concentration of Hg in largemouth bass (*Micropterus salmoides*) also found an inverse relationship with salinity [24]. Octanol–water partition coefficients (K_{OW}) calculated for Hg(II) and MeHg favor $HgCl_2$ and CH_3HgCl_2 as the most bioavailable species for uptake because of their greater lipophilicity and therefore cell membrane permeability [23]; as a result, Hg(II) and MeHg should be more readily taken up at higher salinities based on their K_{OW} values.

Metal retention and elimination after aqueous exposure

The rate of metal uptake in killifish and the resulting body burden from aqueous exposure are influenced by water chemistry and therefore varied between the 3 field sites. However, the loss of metals from killifish could be attributed to the physiological turnover rate of each metal within the fish. Apart from the higher As and Cr k_{ew} values in Baltimore Harbor water, there was little variability in the k_{ew} and therefore physiological turnover rate between the 3 field sites for each metal. This could possibly be attributed to the experiments being temperature-controlled; therefore, the killifish used in each experiment would have had the same routine metabolic rate.

Arsenic and Cr had the highest k_{ew} in all 3 field-collected waters, possibly accounting for As and Cr reaching steady state throughout uptake in Baltimore Harbor and Elizabeth River water and in Elizabeth River and Mare Island water, respectively. To our knowledge, this is the first study to calculate k_{ew} values

for fish after aqueous exposure to As, whereas our Cd, Cr, Hg(II), and MeHg k_{ew} values are within the range calculated in prior studies [3,5,25–27].

Tissue distribution of aqueous metals

Although the Cd k_u value decreased as salinity increased, there was an increase in the percentage of Cd associated with the viscera (presumably the intestine) in higher-salinity water (Elizabeth River, Mare Island). This can be attributed to marine fish drinking to osmoregulate, and drinking therefore is an uptake mechanism for Cd from the aqueous phase, as observed in prior studies where the tissue distribution of Cd was investigated as a function of salinity [6,21]. This finding indicates that the calculated Cd k_u value in Elizabeth River and Mare Island water is a result of aqueous uptake across the gut as well as the gill, whereas the calculated Cd k_u value in lower-salinity Baltimore Harbor water is predominantly a result of Cd uptake at the gill. A prior study has shown that Cd shares the same uptake pathway in the gill and gut as Ca^{2+} in fish [28]. The tissue distribution of As and Cr appeared to be influenced by DOC concentration, for reasons not apparent to us. Arsenic(V) is known to compete with PO_4 for uptake into cells, and the PO_4 transporter was recently identified in zebrafish [29]. It could be that Cr(III) is complexed to organic compounds, which are selected for by killifish and therefore taken up across the gills as observed in bivalves [30,31]; but to our knowledge, this is not known to be an uptake mechanism in fish. It should be noted, however, that very low radioactivity counts of As and Cr were detected in each tissue compartment, and this may account for some of the larger calculated standard error values. The similar tissue distribution of Hg(II) and MeHg between field sites indicates that once inside the body, Hg(II) and MeHg are redistributed around the body in the same way and are not influenced by salinity or DOC concentration. Both Hg species were predominantly associated with the body, presumably the muscle, because of their high binding affinity for sulfur.

To our knowledge, this is the first study to assess the body distribution of metals in fish throughout a several-day depuration period following aqueous exposure and the first study in which metal efflux and influx rates for individual tissue compartments were determined. Prior studies have focused on factors that influence the assimilation efficiency and k_u values of metals in fish, and the k_{ew} and k_{ef} values have received less attention. It is easier to understand what influences the calculated k_u and assimilation efficiency values because they result from uptake at essentially 1 site (gill and gut, respectively), although the calculated k_u value may be a result of aqueous uptake across the gut as well as the gill if drinking is an uptake mechanism. In comparison, the whole-fish k_{ew} and k_{ef} is essentially an integration of the efflux rate constants from different tissue compartments in fish, each with its own turnover rate. To date, efflux and influx rate constants in different tissue compartments have not been well described in animals, partially because it is difficult to do, but some exceptions exist [32]. A radiotracer technique can be used to overcome this issue and provide further insight into what determines whole k_{ew} and k_{ef} values, as determined in a prior study using fish following dietary exposure to MeHg [33]. However, it should be noted that between the metals examined, only 4 tissue compartments had calculated efflux rate constants that were significantly different from 0 ($p < 0.05$; Table 6); this can be attributed to the mean radioactivity concentration values being used in the regression analysis, so for each tissue compartment and metal only 4 data points were used. Furthermore, efflux rates from different tissue compartments may be a result of the transport of metal between individual tissue compartments and may not be responsible for the k_{ew} value calculated for the whole fish.

Cadmium and Hg(II) were not redistributed around the body throughout the 9-d depuration period. The large decrease in Cd and Hg(II) radioactivity concentrations in individual tissue compartments, especially the head, gills, and brain (48%, 47%, and 86% for Cd and 42%, 68%, and 72% for Hg[II], respectively) accounted for most of the metal loss observed from the whole fish and the resulting k_{ew} values. The high k_{ew} (7.5% d^{-1}) for Cr in killifish in Baltimore Harbor water is attributed to the 70% decrease in radioactivity concentration in the gills and the 39% decrease in the viscera. The lack of apparent trend in the tissue partitioning of As throughout depuration could be a result of low radioactivity counts in each tissue compartment. The loss of As from each tissue compartment, particularly the brain and liver, accounts for the highest k_{ew} value (9.6% d^{-1}) and shortest $tb_{½}$ of any metal in the whole fish. In comparison, MeHg was effectively redistributed around the body throughout depuration, presumably via the blood, instead of being released from the fish (except the liver), resulting in the low calculated k_{ew} value (0.6% d^{-1}).

For all metals the liver had an important role in the processing and excretion of metals, presumably via a biliary excretion route. We attempted to dissect the kidney in the present study to investigate renal excretion; however, the kidney is very small, and an accurate dry weight could not be determined. The influx rate of MeHg into the brain, eyes, and muscle indicated that MeHg accumulates in the sulfur-rich portion of the body (muscle) and can readily cross the blood–brain barrier in fish. A prior study also found that MeHg accumulates in the brain following dietary exposure [33], supporting the findings of the present study. For each metal, the calculated efflux rates for the skin (4.0–9.7% d^{-1}) were surprisingly high; although care was taken when dissecting the fish, a small portion of muscle tissue may have remained attached to the skin. However, the body surface of killifish is covered in scales, which can accumulate metals to high concentrations [34]; as a result, the calculated efflux rate constant may be a result of metals detaching from the scales.

Modeling metal bioaccumulation in killifish

When the aqueous kinetic parameters calculated in the present study were entered into the biokinetic model with the dietary kinetic parameters calculated in a previous study [10], the predicted body burden (C_{ss}) did not vary between the 3 field sites for Cr but did vary for As, Cd, Hg(II), and MeHg. Cadmium C_{ss} values were influenced by the salinity of the experimental waters; killifish exposed to Cd in Mare Island water had the lowest C_{ss} because of the low k_u compared to the other 2 field sites. The lower As C_{ss} calculated for killifish in Baltimore Harbor water is a result of fish in Baltimore Harbor water having a 1.5 to 2 times higher k_{ew} and therefore a faster physiological turnover of aqueous metal and a lower C_w compared with the other 2 field sites. Killifish in Mare Island water had a 3.5 to 5 times higher Hg(II) body burden because of the k_u value being 7.7 times higher in Mare Island fish compared with Baltimore Harbor and Elizabeth River fish. The MeHg C_{ss} value varied between field sites, with the lowest C_{ss} value found in the highest-salinity water (Mare Island) as a result of Mare Island having the lowest C_w and k_u values. To our knowledge, this is the first study to predict the concentration of As and Cr in fish at steady state.

No literature values could be found to compare our predicted values to field-collected fish at any of the 3 field sites. The

predicted Cd, Hg(II), and MeHg values calculated for killifish in the present study matched independent field data from other contaminated estuaries and partially enclosed bays, indicating that the model accounts for the major processes governing metal concentration in killifish and that metal parameters (k_u, assimilation efficiency, k_{ew}, k_{ef}) measured in laboratory experiments are applicable to natural waters. Our model-predicted Cd values are higher than those observed for field-collected killifish (*Fundulus parvipinnis*) in contaminated areas in southern California (200–300 ng g^{-1} dry wt) [35] but fall within the range of values observed for fish worldwide (0.04–15 840 ng g^{-1} dry weight) [1]. Our calculated MeHg values are within the range observed for field-collected killifish in a contaminated estuary in the Gulf of Maine (50–240 ng g^{-1} dry wt) [36] but higher than the total Hg value observed for killifish in contaminated bays on the south shore of Long Island, NY, USA (58–184 ng g^{-1} dry wt; J. Dutton and M.J. Record, Adelphi University, unpublished data). No As and Cr levels in field-collected killifish or other small forage fish were found in the literature. The killifish used in the present study were collected from a noncontaminated river; the background concentrations of metals in killifish, measured by ICP-MS (mean ± 1 SD, n =5) are as follows: As = 1332 ± 623 ng g^{-1}, Cd = 9.5 ± 1.6 ng g^{-1}, Cr = 1368 ± 715 ng g^{-1}, total Hg = 84 ± 15 ng g^{-1}. Our model-calculated Cd and Hg values for killifish in contaminated estuaries are much higher than those for pristine waters; however, our calculated As and Cr values are much lower. The latter can be attributed to ICP-MS analysis calculating total As and Cr concentrations in killifish, whereas the present study predicted the body burden of As(V) and Cr(III). Hexavalent Cr (Cr[VI]) is the dominant form of Cr in seawater [11], and although As is found as As(V) in seawater [1,11], in fish it is predominantly found as organic arsenobetaine, which is accumulated via the diet [37].

For Cd and MeHg dietary sources accounted for >97% of the metal body burden, as shown in other studies when fish were fed zooplankton prey [3–5,27]. The present study indicates that aqueous exposure can account for a significant portion of the Hg(II) body burden in killifish, especially in Mare Island water where aqueous accumulation of Hg(II) accounted for 93% of the C_{ss} value because of the higher k_u value. Our calculated Hg(II) values are lower than the findings of other studies using freshwater redear sunfish (46–60%) [3] and Atlantic silversides (>96%) [5]. Interspecific differences are presumably attributable to physiological differences between these fish. To our knowledge, this is the first study to calculate the relative importance of dietary and aqueous exposure routes on the body burden of As and Cr in fish, and for both metals the diet was the predominant exposure pathway.

Studies measuring the levels of metals in small field-caught fish are limited and in need of further pursuit because small forage fish, including killifish, are a conduit for the transfer of metals from lower trophic levels to their predators, including blue crab (*Callinectes sapidus*), bluefish (*Pomatomus saltatrix*), striped bass (*Morone saxatilis*), and dogfish (*Mustelus canis*) [38–40], which, if consumed, potentially provide a source of metals to humans. The present study and previous studies [3–5], provide important information to regulatory agencies that determine water-quality standards based on the ambient concentration of metals in the water and largely overlook the importance of the diet as a source of metals to fish. Although the diet is considered to be the dominant exposure pathway of most metals, our data combined with other literature values stress the importance of not ignoring the aqueous phase as a source of metals to fish.

Acknowledgment—We thank G. Cutter and the captain and crew of the *R/V Fay Slover* and the *R/V Questuary* for help collecting the water, A. Smirnov for the chloride ion analysis, D. Hirschberg for the DOC analysis, P. Field and B. Jackson for the ICP-MS analysis, and 2 anonymous reviewers for helpful comments on the manuscript. A National Pilot Study of Mercury Contamination of Aquatic Ecosystems along Multiple Gradients

By David P. Krabbenhoft, James G. Wiener, William G. Brumbaugh, Mark L. Olson, John F. DeWild, and Ty J. Sabin

ABSTRACT

Mercury (Hg) contamination of aquatic ecosystems is a global problem. However, databases for Hg in environmental samples at regional-to-national scales are few, especially for multi-media sampling that include determination of methylmercury (MeHg). A national scale pilot study to examine relations of total Hg (Hg_T) and MeHg in water, sediment and fish was conducted in the summer and fall of 1998. Samples were collected at 106 sites from 21 basins across the United States, including Alaska and Hawaii. The data showed wide ranges in concentrations, which were expected given the diverse array of environmental settings, water chemistry, and Hg loading represented by these sites. Wetland density was the single most important basin-scale factor controlling MeHg production. At low concentrations, total Hg in sediment may also influence MeHg production, but at high total Hg concentrations (>1,000 nanograms per gram; ng/g) in sediment there was little evidence of increasing MeHg production with increasing total Hg. An atmospheric Hg accumulation index was developed for differentiating areas where atmospheric Hg deposition was the dominant Hg source from areas with significant on-site sources. Four study basins along the east coast of the United States had the greatest methylation efficiency, as reflected by the MeHg/HgT ratio in sediments. Nationwide, sub-basins characterized as mixed agriculture and forest cover types had the highest methylation efficiency, whereas areas affected by mining had the lowest efficiency. This study represents a first step toward a national assessment of Hg contamination of aquatic ecosystems in the United States, however, additional data are needed to improve our resolution of the factors controlling MeHg production and bioaccumulation.

INTRODUCTION

Methylmercury is the most toxic and widespread contaminant affecting our Nation's aquatic ecosystems. Methylmercury contamination has prompted steadily increasing numbers of fish-consumption advisories in 40 states, now accounting for more than eighty percent of all such advisories in the Nation (1,782 advisories for mercury of 2,196 total advisories nationwide; U.S. Environmental Protection Agency, 1998). Eleven states have statewide advisories for Hg in fish from lakes and/or rivers, and five have statewide advisories for coastal waters. In addition, some tribal representatives report that adherence to fish-consumption advisories has adversely affected the social, economic, and cultural well being of certain Native American tribes (for example, Wheatley and others, 1997; Wheatley, 1997). Methylmercury readily crosses biological membranes, can accumulate to harmful concentrations in exposed organisms, and biomagnifies to concentrations of toxicological concern in aquatic food webs, posing a threat to humans (Grandjean and others, 1997) and an increasing, potentially severe threat to fish-eating wildlife (Heinz and Hoffman, 1998).

For most aquatic ecosystems, atmospheric deposition of inorganic Hg (about 0.3 to 30 micrograms per square meter per year; U.S. Environmental Protection Agency, 1997) is the primary source of contamination. Generally only a small fraction of this atmospheric Hg load to aquatic ecosystems exists as MeHg (Rudd, 1995). In addition, the masses of MeHg found in sedimentary and biological compartments of most

aquatic ecosystems cannot be accounted for by direct inputs of MeHg (Branfireun and others, 1998), and mass effluxes of MeHg from watersheds generally far exceed total inputs (Hurley and others, 1995). The bridge between the seemingly incongruent observations that inorganic Hg is the dominant form released to the environment, and MeHg is the dominant form of Hg found in edible fish (Bloom, 1992; Wiener and Spry, 1996) is the process of methylation. It is generally accepted that in natural settings mercury methylation is mediated through microbial sulfate reduction (Gilmour, 1991). Over the past 10 years, a great deal of scientific attention has been placed on trying to better understand mercury methylation. Yet, a complete understanding of the factors controlling methylation has remained elusive.

Management and regulatory responses to the growing mercury problem have been greatly impeded by a lack of information from a wide range of locations and environmental settings on the sources, transport, biogeochemical transformations, biological exposure, and toxicological consequences of mercury in the environment. Although there is a growing body of literature on mercury in the environment, to date there has not been a coordinated effort using consistent sampling and analytical methods conducted at the national scale. This paper presents the initial results of a pilot study to evaluate whether trends in Hg accumulation and MeHg production can be identified at national or regional scales across the United States. The study was designed so that a range of factors known to affect contamination levels, such as Hg loading rates, Hg source types, water chemistry, and land use and cover, could be evaluated.

THE USGS NATIONAL MERCURY PILOT STUDY

The National Mercury Pilot Study was conducted though the collaborative efforts of the Toxic Substances Hydrology program and the National Water Quality Assessment (NAWQA) program of the U.S. Geological Survey (USGS). The overall objective of this study is to identify ecosystem characteristics that favor the production and bioaccumulation of MeHg. Ultimately, we would like to be able to construct predictive models indicating environments of most concern for MeHg contamination, such as that depicted in figure 1. Ecosystems that have low methylation efficiency may exhibit low or moderate bioaccumulation even under high Hg loads, such as the Poplar Creek watershed, near Oak Ridge, Tennessee (Turner and others, 1993). On the other hand, significant bioaccumulation of methylmercury can result even when very low Hg loading rates exist if methylation efficiency is high, such as low-pH lakes in northern Wisconsin (Wiener and others, 1990; Lamborg, and others, 1995). Other ecosystems, such as newly constructed reservoirs, may experience a

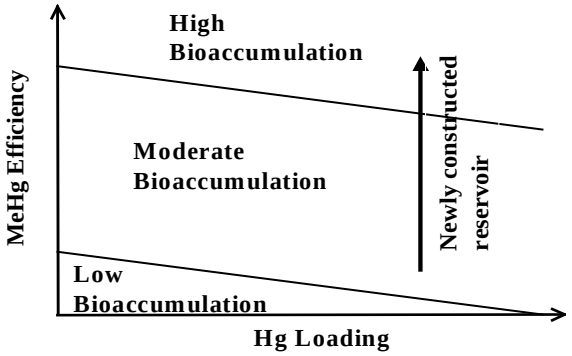

Figure 1. Hypothetical model for the relations between Hg loading, methylation efficiency and boaccumulation.

perturbation that increases methylation efficiency without increasing the mercury load (Bodaly and others, 1997). In this case, after flooding, the methylation efficiency of the reservoir would be expected to show a vertically upward trend across this conceptual model.

Regional and national scale fish surveys have been done in the past for mercury and other bioaccumulative contaminants. This is the only known study, however, in which national-scale, multi-media sampling (water, sediment, and fish) was conducted in concert with low-level Hg speciation analysis. Recent studies in Wisconsin have shown that several basin-scale factors influence the relative sensitivity of ecosystems to MeHg production (Hurley and others, 1995). These basin-scale factors include the relative abundance of wetlands (a site known to favor Hg methylation), soil types, and land use and cover. In Wisconsin, these factors serve as good

predictors of mercury methylation efficiency, Hg and MeHg yields, and levels of MeHg in water. We caution that when viewed from a national perspective, however, the variation in atmospheric Hg-deposition rates across Wisconsin are small (U.S. Environmental Protection Agency, 1997), point-source contributions were presumably few and moderate in strength, geologic sources were negligible, and the range of ecosystem types were limited. Thus, we can not reliably transfer these results to a national scale.

Study Design

The major characteristics of this study were its (1) national scope, (2) emphasis on multi-media sample collection (water, sediment, and predator fish), (3) consistent use of trace metal clean sampling methods, and (4) low-level Hg and MeHg analytical procedures. By collecting and analyzing all three media, much more can be ascertained about controls of Hg and MeHg partitioning, accumulation, bioconcentration, and methylation efficiency across the vast diversity of sites that comprise our Nation's freshwater ecosystems.

The NAWQA program has scientists located throughout the United States who are trained in the procedures for the collection of water, sediment and biological samples; this greatly facilitated field efforts for this study. An additional benefit of conducting the pilot study at NAWQA study basins is the substantial amount of ancillary information available to strengthen the interpretations of the data generated via this study.

Sampling was conducted from June to October, 1998 at multiple locations (3 to 8) in each of 21 NAWQA study basins (figure 2, table 1) for a total of 106 sampling sites. Nationally, these basins spanned the dominant east-to-west mercury deposition gradient (figure 3) and represented a wide range of environmental settings. Individual study basin teams were asked to choose sites spanning gradients of wetland density, surface water pH, sulfate (SO_4), total organic carbon (TOC), and suspected or known Hg loading. In most cases, the sites sampled were streams, and every attempt was made to sample during baseflow conditions. Several of the chosen basins had known point sources of mercury from mining activity, and were representative of very high mercury loading conditions.

Table 1. NAWQA study basins from which samples were collected for this study.

Abbrev.	Study Basin Name
ACAD	Acadian-Pontchartrain
ALMN	Allegheny and Monongahela Basins
COOK	Cook Inlet Basin
DELR	Delaware River Basin
GRSL	Great Salt Lake Basins
LINJ	Long Island and N. J. Coastal Drainages
LTEN	Lower Tennessee River Basin
MIAM	Great and Little Miami River Basins
MOBL	Mobile River and Tributaries
NECB	New England Coastal Basins
NROK	Northern Rockies Intermontane Basins
NVBR	Nevada Basin and Range
OAHU	Oahu Island
SACR	Sacramento Basin
SANA	Santa Ana Basin
SANT	Santee Basin and Coastal Drainages
SOFL	Southern Florida
TRIN	Trinity River Basin
UCOL	Upper Colorado River Basin
UIRB	Upper Illinois River Basin
YELL	Yellowstone Basin

Sampling Methods for Water, Sediment, and Fish

Aqueous Hg and MeHg samples were collected with trace-metal clean methods (Fitzgerald and Watras, 1989). All sample containers were Teflon (any use of trade, product, or firm names is for descriptive purposes only and does not imply endorsement by the U.S. Government), which had been rigorously cleaned in hot acid, partially filled with one percent HCl for storage, and then double bagged in Ziploc bags. Sampling crews wore plastic gloves, and executed clean-hands, dirty-hands techniques (Olson and DeWild, 1999) to remove the sample bottle from the two bags. Almost all of the sampling locations were streams, whereby grab samples were taken from the centroid of flow by submersing the bottle while wearing arm-length

gloves. Total-Hg (Hg_T) samples were acidified to one percent HCl by volume, while MeHg samples were immediately placed in a darkened cooler until they could be frozen.

Bed sediment samples were collected using the NAWQA program's trace-element sampling protocols (Shelton and Capel, 1994). Briefly, field personnel wore plastic gloves and used a clean Teflon or plastic scoop to collect the top few centimeters of sediment. Generally, samples were taken from multiple points (about 5 to 10) at each site, which were then pooled, homogenized, and then subsampled. A Teflon vial was used for the total Hg and MeHg subsample, while a second subsample was taken in a polypropylene vial and used for other analyses. Sediment samples were frozen as soon as possible.

Fish were collected by the most efficient means available, provided it did not jeopardize the specimen with regard to mercury contamination. Up to five individuals of a single, top-predator species were collected from each site. Field crews were asked to focus sampling efforts on largemouth bass of age 2-3 years, but in the absence of these fish to collect the most common predator species inhabiting the basin. If at all possible, the same species was collected from each sampling site within a study basin. Each fish was rinsed in stream water, measured for length and weight, placed in Ziploc bags, and frozen as soon as possible.

Anaytical Methods for Sediment and Water and Wetland Delineation

Details of the analytical procedures for Hg_T and MeHg in sediment and water are given in Olson and DeWild (1999) and Olson and others (1997). Samples collected for this study were shipped to the USGS Mercury Research Laboratory in Middleton, Wisconsin. Total mercury in aqueous samples was determined by cold vapor atomic fluorescence spectroscopy (CVAFS) following oxidation with BrCl at 50°C, reduction by $SnCl_2$, and purge and trap of the evolved Hg^0 onto gold-coated glass bead columns. Total mercury in sediments was determined with the same procedure, but samples were pre-digested with nitric and sulfuric acids in sealed Teflon bombs at 125°C. Methylmercury in sediment and water was analyzed with the distillation and aqueous phase ethylation method of Horvat et al. (1993), and detection by CVAFS. Analytical results for fish tissue samples were not available at the time of this paper, so the procedures are not given. Ancillary chemical parameters were determined by the following methods: pH was measured in the field with a calibrated probe; SO_4 by ion chromatography; DOC by a carbon analyzer that employs acidification and persulfate/UV oxidation; dry weight percent by drying wet sediment at 105°C; and loss on ignition (LOI) by heating dried sediment samples to 550°C.

A Geographic Information System (GIS) was used to quantify wetland areas within the study basins. Sampling locations for each study basin were plotted, and the sub-basin areas upstream of each point were delineated. Percent wetland area for each of the sub-basins was determined by overlaying a GIS coverage of the National Wetlands Inventory (Greg Allord, USGS, unpub. data, 1999).

RESULTS AND DISCUSSION

The study results are presented in three ways: across individual sites, among basins, and among site types.

All analytically determined parameters varied considerably within and among sites (table 2). This was expected given the extreme ranges in environmental settings (climate, geology, land use, and land cover), water chemistry, and Hg loading represented by this array of sampling sites. Generally, the Hg_T and MeHg concentrations in water and sediment were similar to the range of values from other recent freshwater studies that employed clean sampling and low-level Hg analysis. Very high concentrations of Hg_T and MeHg in water and sediment observed at the mining affected sites created a highly skewed distribution of concentration data. As a result, the mean values were much larger than their respective median values (table 2).

Overall, stronger correlations were observed between sediment MeHg and the

ancillary data (wetland density, pH, DOC and SO_4) than for aqueous MeHg results. This was likely due to the more transient nature of surface water samples compared to sediment, which tends to integrate site conditions over longer periods of time. Of the ancillary measurements, the strongest correlation was between sediment MeHg and percent wetland in the sub-basin (figure 4). Previous studies of MeHg production in boreal ecosystems also concluded that wetland density greatly influenced MeHg production (St. Louis and others, 1994; Hurley and others, 1995).

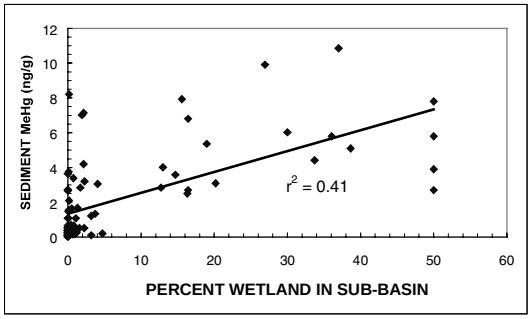

Figure 4. Sediment MeHg versus percent wetland in the sub-basins sampled during this study.

Similar positive correlations observed here suggest that these conclusions are valid over much broader geographical scales and ecosystem types. Sediment MeHg concentration also correlated positvely with LOI ($r^2 = 0.26$), which was used as a surrogate for organic carbon content of sediment. A subset of fifteen samples collected for this study and analyzed for organic carbon concentration showed a strong correlation with LOI ($r^2 = 0.97$). Negative correlations were observed between sediment MeHg and percent dry weight and surface water pH ($r^2 = 0.29$ and 0.15, respectively). The correlation results between MeHg and TOC was lower than expected ($r^2 = 0.18$), given that other studies have observed much stronger relations between these variables (Hurley and others, 1998). A more detailed analyses of the TOC quality from these various study basins may help to unravel the complexities of Hg-carbon interactions. Our observations suggest that mercury methylation is greatest for sub-basins with significant wetland density, organic sediments, and with low surface water pH.

One of the difficulties in analyzing Hg data from such differing ecosystems is the considerable variation in the measurable factors controlling important processes, such as methylation. For example, when we excluded the sites with mining impacts, a strong, positive correlation was observed between sediment MeHg and SO_4. When we included the data from the sulfate-rich mining sites, a weak, negative correlation was observed. At very high sulfate levels, methylation of mercury may not be limited by the availability of sulfate, or methylation can be inhibited by the abundance of sulfide (a by product of sulfate reduction) (Gilmour and others, 1998).

One important question concerning Hg bioaccumulation in aquatic ecosystems is whether Hg load drives methylation. The averaged, LOI-adjusted Hg_T and MeHg data for the 21 study basins suggest that Hg load (as reflected by Hg_T accumulation in sediment) has a logarithmic effect on methylation (figure 5). Methymercury production appears proporational to Hg_T concentrations at low sediment Hg_T levels; but at high Hg_T levels little additional MeHg is produced with additional Hg_T.

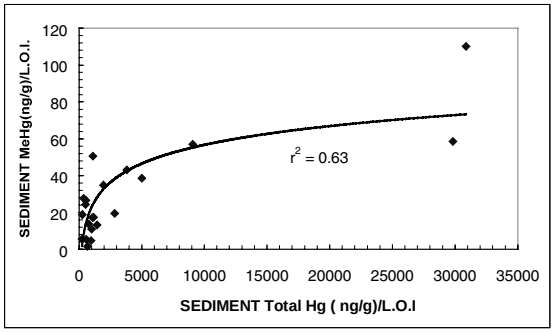

Figure 5. Average normalized (to LOI) sediment MeHg versus Hg_T for the 21 basins sampled for this study.

This finding is consistent with mercury methylation experiments on sediments, where a reduced methylation response to loading was observed when concentrations of $Hg_T > 1{,}000$ ng/g were used (Rudd and others, 1983). The two data points on the high end of the curve in figure 5 had Hg_T concentrations of about 1,000 ng/g (before normalizing to LOI).

The importance of atmospheric deposition relative other Hg sources within each

study basin was assessed by normalizing sediment Hg_T concentrations to estimated current atmospheric deposition rates for each study basin and LOI. In essence, this calculation produces an index of atmospheric Hg accumulation (AHA). High AHA values would be diagnostic of study basins having Hg sources other than atmospheric deposition, and low index values would suggest the atmosphere is the dominant Hg source for the basin. The AHA values for all 21 study basins are shown in table 3. Those study basins with the six highest AHA indices were heavily contaminated with metals from mining. Interestingly, the next highest AHA index value is for the Oahu study basin, which has no known mining contamination sites. One likely Hg source for Hawaii is the Kilauea volcano. Volcanoes are known to emit gaseous Hg vapors; however, quantitative estimates of Hg emissions and their impacts are scarce. Although not a precise estimate, this analysis suggests Hg from Kilauea is depositing on Oahu Island at a rate similar to loading from areas where mining activity is pervasive. After the Oahu study basin, the next highest AHA value was for the Yellowstone study basin. One likely Hg source for this study basin is the numerous hot springs that are known to have high mercury concentrations (Rytuba, 1997). The remaining study basins all had AHA values that were notably lower. Many of these study basins were heavily urbanized, yet the AHA values suggested that the atmosphere was the dominant Hg source for these areas. It should be noted that several of these areas have relatively high Hg_T concentrations in sediment, such as the New England Coastal Basins, but that apparently most of this mercury can be accounted for by high atmospheric deposition rates. Ecosystem effects from pending legislation to reduce atmospheric mercury emissions would likely be most effective in such areas. The Southern Florida study basin, which had the lowest AHA value, provides a calibration point for this index, given that recent studies have demonstrated that atmospheric deposition is the dominant source of mercury to the Everglades (Guentzel and others, 1995).

Methylation efficiency is a critical factor affecting the susceptibility of ecosystems to bioaccumulation. Actual methylation rate estimates would be expensive to perform on a national basis, but the $MeHg/Hg_T$ ratio in sediments and water provides a reasonable predictor of methylation efficiency (Gilmour and others, 1998). Table 3 lists the average MeHg concentration in sediments and the average $MeHg/Hg_T$ ratio for sediment and water for each study basin. Both of these measures identify the New England Coastal Basins, Santee Basin, Long Island and N. J. Coastal Drainages, and Southern Florida as systems having enhanced methylation efficiency. All of these areas have widespread advisories for high Hg concentrations in game fish.

Table 3. Summary data for the 21 study basins.

[3]Average value for the $MeHg/Hg_T$ ratio for sediment and water.

All of the study basins were heterogeneous with respect to land cover and use. For the purposes of this analysis, the sub-basins above each of the sampling sites were categorized into one of the five following broad classes: agriculture dominant (Ag); mixed agriculture and forest (A/F); background or reference site for the

study basin (Bkg); current or abandoned mining activity near sampling site (Mine); and urban or industrial activity near sampling site (Urb) (table 2). Total and methyl mercury concentrations in sediment and water differ significantly among these broad categories (table 4).

Table 4. Summary data for Hg_T and MeHg by land use/cover category.

Land use/cover (N)[1]	MeHg (ng/L)	Hg_T (ng/L)	MeHg (ng/g)	Hg_T (ng/g)
A/F (11)	0.48	5.59	2.73	34.07
Ag. (30)	0.15	10.76	1.20	73.34
Bkg (21)	0.13	3.43	2.10	104.9
Mine (14)	0.10	84.43	1.89	788.2
Urb. (30)	0.09	3.34	2.07	218.6

[1]Land use/cover definitions are found in table 2, N is the number of sampling sites falling each categories.

Sub-basins with mining operations present had the highest Hg_T concentrations in sediment and water, but MeHg levels were relatively low. Interestingly, sub-basins described as mixed agriculture and forest had the lowest average Hg_T concentration in sediment, yet the highest MeHg levels in sediment and water. Thus, the mixed agriculture and forest land type had the highest methylation efficiency, whereas mining and urban areas had the lowest (figure 6).

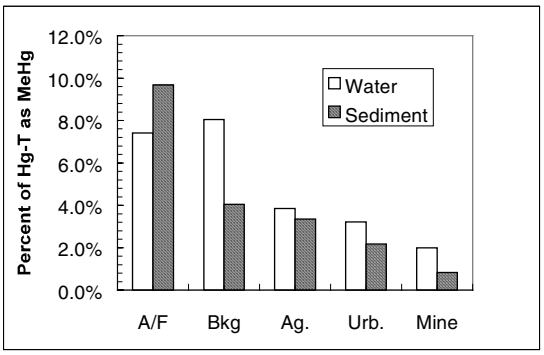

Figure 6. Average, normalized (to LOI) sediment MeHg versus Hg_T for the 21sub-basins sampled for this study.

SUMMARY

The concentrations of Hg_T and MeHg in sediment and water collected at 106 sites from 21 basins across the United States ranged widely. Variability in these data were expected, given the wide array of environmental settings, water chemistry, and Hg loading represented. Wetland density was found to be the most important basin-scale factor controlling MeHg production. By normalizing the sediment Hg_T and MeHg data to LOI, a logarithmic relation between Hg_T and MeHg was revealed. Methylmercury production appears proportional to Hg_T concentrations at low sediment Hg_T levels. At high Hg_T levels (<1,000 ng/g), however, little additional MeHg was evidently produced with increasing Hg_T. By normalizing the sediment Hg_T concentrations to LOI and the estimated atmospheric deposition rate for each study basin, a useful index (AHA) for assessing areas where atmospheric deposition is the dominant Hg source was obtained. Surprisingly, this index indicated that a significant Hg source other than atmospheric deposition exists for the Oahu study basin. Volcanic activity was a likely source of mercury in this basin. The New England Coastal Basins, Santee Basin, Long Island and N.J. Coastal Drainage, and Southern Florida showed the greatest methylation efficiency as reflected by the $MeHg/Hg_T$ ratio in sediments. That all of these sites had low AHA indices suggests that pending emission reductions might be especially effective in these areas. Sub-basins characterized as mixed agriculture and forested had the highest methylation efficiency, whereas areas affected by mining were the lowest. This study was designed as a "pilot" effort to test whether multi-media sampling for low-level Hg determinations could be effectively conducted. While the spatial coverage of sampling was good, the site density (106 sites nationally) is probably not adequate for making final conclusions about mercury contamination of aquatic ecosystems across the United States. More detailed sampling, including sampling for seasonal differences, across this same series of study basins is needed to provide a more thorough analysis of what controls Hg methylation, partitioning, and bioaccumulation at national scales.

ACKNOWLEDGMENTS

The authors are indebted to the NAWQA study-basin teams who participated in this study and demonstrated great diligence, commitment, and enthusiasm to the collection of the samples.

FOREWORD

This report describes the process of developing Fish Contaminant Goals and Advisory Tissue Levels for evaluating methylmercury, chlordane, DDTs, dieldrin, PCBs, selenium, and toxaphene, common contaminants in California sport fish. Fish provide unique nutritional benefits while also serving as a significant exposure pathway for several chemicals of concern. Fish Contaminant Goals (FCGs) are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs prevent consumers from being exposed to more than the daily RfD for non-carcinogens or to a risk level greater than $1x10^{-6}$ for carcinogens (not more than one additional cancer case in a population of 1,000,000 people consuming fish at the given consumption rate over a lifetime). FCGs are based solely on public health considerations without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption.

Advisory Tissue Levels (ATLs), while still conferring no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, were developed with the recognition that there are unique health benefits associated with fish consumption and that the advisory process should be expanded beyond a simple risk paradigm in order to best promote the overall health of the fish consumer. ATLs provide a number of recommended fish servings that correspond to the range of contaminant concentrations found in fish and are used to provide consumption advice to prevent consumers from being exposed to more than the average daily reference dose for non-carcinogens or to a risk level greater than $1x10^{-4}$ for carcinogens (not more than one additional cancer case in a population of 10,000 people consuming fish at the given consumption rate over a lifetime). ATLs are designed to encourage consumption of fish that can be eaten in quantities likely to provide significant health benefits, while discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be eaten in amounts recommended for improving overall health (eight ounces total, prior to cooking, per week). ATLs are one of the criteria that will be used by OEHHA for issuing fish consumption guidelines.

EXECUTIVE SUMMARY

Chemical contamination of fish is a global problem that has resulted in the issuance of fish consumption advisories in most states, including California. Although mercury contamination is a frequent basis for these advisories, polychlorinated biphenyls (PCBs) and chlorinated pesticides such as chlordane and dichlorodiphenyltrichloroethane (DDT) are also often implicated. In California, the Office of Environmental Health Hazard Assessment (OEHHA) is the agency solely responsible for evaluating the potential public health risks of chemical contaminants in sport fish and issuing state advisories, when appropriate. OEHHA is also consulted by other agencies interested in assessing the health risks of fish consumption during the process of developing water quality or clean-up "criteria." There are key differences between fish consumption advisories and other environmental risk criteria; advisories consider the significant benefits of fish consumption, while criteria may be strictly risk-based and may not take into account other factors.

In order to develop water quality criteria or fish consumption advisories, appropriate toxicity values for a chemical must be established. In this document, cancer and non-cancer health effects were evaluated for seven common contaminants found in California sport fish: chlordane, DDT and its metabolites (DDTs), dieldrin, mercury (as methylmercury), PCBs, selenium, and toxaphene. For each chemical, the toxicological literature was reviewed to establish an acceptable non-cancer reference dose (RfD; an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime) and/or a cancer slope factor (an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen).

Fish Contaminant Goals (FCGs) were then developed for these seven contaminants. FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs prevent consumers from being exposed to more than the daily RfD for non-carcinogens or to a risk level greater than $1x10^{-6}$ for carcinogens (not more than one additional cancer case in a population of 1,000,000 people consuming fish at the given consumption rate over a lifetime). FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption. FCGs were developed using an 8-ounce (227 g) serving size (prior to cooking; approximately six ounces after cooking) for adults who weigh 70 kg.

As a prelude to developing tissue-based values to be used for advisories, OEHHA reviewed the scientific literature on the benefits of fish and fish oil consumption. Although decreased incidence of coronary heart disease is perhaps the most recognized benefit of fish consumption, there is considerable evidence that other, particularly

inflammatory, disorders may also be mitigated or prevented by inclusion of fish in the diet. Additionally, maternal fish consumption is likely to provide cognitive benefits to the fetus. Following this review, OEHHA determined that there is a compelling body of evidence and general scientific consensus that eating fish at dietary levels that are easily achievable, but well above national average consumption rates, appears to promote significant health benefits, including decreased mortality. With the recognition that there are unique health benefits associated with fish consumption, it was concluded that the advisory process should be expanded beyond a simple risk paradigm, as is used in criteria development, in order to best promote the overall health of the fish consumer.

The first step in the advisory process, then, was to develop Advisory Tissue Levels (ATLs). ATLs were calculated using the same general formulas as those used to calculate FCGs, with some adjustments in order to incorporate the benefits of fish consumption. ATLs provide a number of recommended fish servings that correspond to the range of contaminant concentrations found in fish and are designed to prevent consumers from being exposed to more than the average daily reference dose for non-carcinogens or to a risk level greater than $1x10^{-4}$ for carcinogens (not more than one additional cancer case in a population of 10,000 people consuming fish at the given consumption rate over a lifetime). The use of ATLs still confers no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, while encouraging consumption of fish that can be eaten in quantities likely to provide significant health benefits and discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be recommended in amounts suggested for improving overall health (i.e., eight ounces total, prior to cooking, per week).

ATLs are used as part of the process to develop traditional health advisories (which focus on fish whose consumption should be avoided) as well as the newer "safe eating guidelines," which inform consumers of fish with low contaminant levels considered safe to eat frequently. ATLs should not be misinterpreted as static "bright lines" that others can use to duplicate state fish consumption advisories. ATLs are but one component of a complex process of data evaluation and interpretation used by OEHHA in the assessment and communication of fish consumption risks. The nature of the contaminant data or omega-3 fatty acid concentrations in a given species in a water body, as well as risk communication needs, may alter strict application of ATLs when developing site-specific advisories. OEHHA will use the guidelines set forth in this report as a framework, along with best professional judgment, to provide fish consumption guidance on an *ad hoc* basis that best combines the need for health protection and ease of communication for each site.

This document represents current knowledge of the toxicity of seven common fish contaminants and the overall benefits of fish consumption; FCGs and ATLs for individual chemicals may be revised, if necessary, as information becomes available. FCGs and ATLs may also be developed in the future for additional contaminants, as appropriate, using the same methodology.

INTRODUCTION

Fish consumption advisories have been issued in most states and cover approximately 35 percent and 24 percent of the country's total lake acreage and river miles, respectively (U.S. EPA, 2004a). Mercury contamination of fish, in particular, is a national problem that resulted in the issuance of 222 new advisories in 2003 alone (U.S. EPA, 2004a). Polychlorinated biphenyls (PCBs) and chlorinated pesticides such as chlordane and dichlorodiphenyltrichloroethane (DDT) are also a frequent basis for fish consumption advisories throughout the United States (U.S. EPA, 2004a). In California, the Office of Environmental Health Hazard Assessment (OEHHA) is the agency responsible for evaluating potential public health risks from chemical contamination of sport fish. This includes issuing state advisories, when appropriate, based on mandates in the California Health and Safety Code, Section 59009, to protect public health, and Section 59011, to advise local health authorities, and the California Water Code, Section 13177.5, to issue health advisories. OEHHA is also consulted by other agencies interested in assessing the health risks of fish consumption during the process of developing water quality or clean-up "criteria." There are key differences between fish consumption advisories and other environmental risk criteria; advisories consider the significant benefits of fish consumption, while criteria may be strictly risk-based and may not take into account other factors.

In order to develop advisories or criteria, appropriate toxicity values for a chemical must be established. In this document, cancer and non-cancer health effects were evaluated for seven common contaminants found in California sport fish: chlordane, DDT and its metabolites (DDTs), dieldrin, mercury (as methylmercury), PCBs, selenium, and toxaphene. For each chemical, the toxicological literature was reviewed to establish an acceptable non-cancer reference dose (RfD; an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime) and/or a cancer slope factor (an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen). Limited background information on the chemistry, environmental fate, metabolism, and typical exposure routes for each chemical is also provided.

Fish Contaminant Goals (FCGs) were then developed for these seven contaminants. FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption.

FCGs for non-cancer risk for non-nutrients were derived from the following basic equation:

$$\text{Tissue concentration} = \frac{(\text{Reference dose})(\text{Body weight})}{\text{Daily consumption rate}}$$

FCGs for cancer risk for non-nutrients were derived from the following basic equation:

$$\text{Tissue concentration} = \frac{(\text{Risk level})(\text{Body weight})}{(\text{Cancer slope factor})(\text{Daily consumption rate})}$$

Additional discussion and examples of FCG development can be found in the section "Equations used to calculate Fish Contaminant Goals."

As a prelude to developing tissue-based values to be used for advisories, OEHHA reviewed the scientific literature on the benefits of fish and fish oil consumption to determine to what degree the advisory process should be expanded beyond a simple risk paradigm, as is used in criteria development, in order to best promote the overall health of the fish consumer. Advisory Tissue Levels (ATLs), while still conferring no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, use the same general equations as those used to develop FCGs, with some adjustments to take into account benefits that are provided by fish consumption. ATLs were designed to encourage consumption of fish that can be eaten in quantities likely to provide significant health benefits, while discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be recommended in amounts suggested for improving overall health (i.e., eight ounces total, prior to cooking, per week).

This report provides critical toxicity values, FCGs and ATLs for seven common contaminants in California sport fish. Most fish advisories in the United States are issued for mercury, PCBs, chlordane, dioxins, and DDTs (U.S. EPA, 2005). OEHHA also included toxaphene and selenium in this document because of historic use in the state and natural occurrence, respectively. At this time, limited available analytical data for dioxins in fish throughout the state do not show widespread or high dioxin contamination. Several former point sources have been eliminated and subsequent concentrations in fish at associated sites were below a level of concern (Fan, 1994). Consequently, OEHHA did not develop an FCG or ATLs for dioxins at this time. However, FCGs and ATLs may be developed in the future for dioxins or other contaminants, as resources permit, using the same methodology. OEHHA staff is available for consultation on any fish contaminant of concern.

TOXICOLOGY AND CRITICAL TOXICITY VALUES FOR COMMON CONTAMINANTS IN CALIFORNIA SPORT FISH

CHLORDANE

CHLORDANE TOXICOLOGY

Chlordane is a chlorinated cyclodiene insecticide that was used in the United States beginning in 1948 for a variety of agricultural and structural pest control purposes (ATSDR, 1994; Ecobichon, 1991; Matsumura, 1985; U.S. EPA, 1997). Technical chlordane, the commercial mixture, is comprised of approximately 60 percent *cis* and *trans* chlordane isomers and about 40 percent other related compounds (e.g., *cis*-nonachlor, *trans*-nonachlor and oxychlordane) (U.S. EPA, 1997). As a result of their lipophilicity, low volatility and slow degradation rates, chlordane and other organochlorine pesticides are exceptionally persistent in the environment and are able to bioconcentrate and biomagnify throughout the food chain (Ecobichon, 1991). Bioconcentration factors (the quotient of the concentration of a chemical in an organism divided by the concentration of the chemical in the ambient water) for chlordane in various marine and freshwater fish, for example, have been reported as high as 3,000 to 37,800 (ATSDR, 1994; Fisher, 1999). Because of this, as well as concerns over human cancer risk and hazards to wildlife, the use of chlordane was severely restricted in the United States in 1978 and ultimately banned in 1988 (ATSDR, 1994; U.S. EPA, 2000). Chlordane remains a contaminant in many soils and waterways, however, with the most frequent source of human exposure being consumption of contaminated foods, especially fish (ATSDR, 1994). Saltwater and fresh water fish and shellfish, combined, account for approximately 95 percent of the total dietary exposure to chlordane (Dougherty et al., 2000).

Chlordane is readily absorbed by all exposure routes (ATSDR, 1994). Once absorbed, chlordane is rapidly distributed to the liver and kidneys, whereupon it undergoes transformation to a number of metabolites. Chlordane excretion is mainly through bile and breast milk (ATSDR, 1994). Chlordane that is not excreted is deposited in adipose tissue, primarily as the metabolites oxychlordane and heptachlor epoxide (ATSDR, 1994; U.S. EPA, 1997). The elimination half-life of chlordane in humans reported in different studies has ranged from 21to 88 days (Aldrich and Holmes, 1969; ATSDR, 1994; Curley and Garrettson, 1969; Olanoff et al., 1983).

The Agency for Toxic Substances and Disease Registry (ATSDR, 1994), U.S. Environmental Protection Agency (U.S. EPA, 1997), and OEHHA (1997) have extensively reviewed the toxicity of chlordane. Following acute oral exposures (14 days or less), chlordane is considered moderately to highly toxic to humans (U.S. EPA, 2000). The World Health Organization (WHO, 1984) estimated the acute human lethal dose to be between 25 and 50 mg/kg body weight. Acute poisoning symptoms include vomiting, diarrhea, seizures, anuria, ataxia, tremors, coma, and respiratory failure (ATSDR, 1994;

Curley and Garrettson, 1969; NIOSH, 1981, 2003; Olanoff et al., 1983), and can occur within 45 minutes of exposure (Grutsch and Khasawinah, 1991). The difference between the no-effect and the fatal serum levels in humans is small (approximately 3 to 5 times), indicating a steep dose-response curve (Grutsch and Khasawinah, 1991). Death is rare following acute oral poisoning, however, because the individual generally vomits, reducing the available dose (Grutsch and Khasawinah, 1991). Apparent recovery in non-fatal cases is rapid (Aldrich and Holmes, 1969; Curley and Garrettson, 1969; Grutsch and Khasawinah, 1991), although chemical hepatitis may develop subsequent to the acute phase (Olanoff et al., 1983). Acute chlordane toxicity in animals also results in neurotoxicity signs such as hyper-excitability, tremors, convulsions, hind limb paralysis and hypothermia (ATSDR, 1994; Grutsch and Khasawinah, 1991). Like other cyclodiene insecticides, the mechanism of neurotoxic action is believed to be inhibition of chloride transport, causing incomplete repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999).

Subchronic or chronic chlordane toxicity in humans has been difficult to quantify because of problems with dose determination and confounding exposures. Some humans living in chlordane-treated homes have developed hepatic and neurological signs such as jaundice and grand-mal seizures, respectively. The exact dose-response relationship has not been determined, however (ATSDR, 1994). In their review of the literature, Grutsch and Khasawinah (1991) reported that chronic, low-level chlordane exposure via inhalation, oral, or dermal routes has not been found to elicit signs or symptoms indicative of chlordane toxicity. ATSDR (1994) also noted that adverse health effects resulting from chlordane exposures have not been confirmed in studies of workers engaged in the manufacture of chlordane. More recent epidemiological studies, though, have indicated that chlordane may cause neurotoxicity following chronic exposures in humans (IRIS, 1998). In a cross-sectional study, Kilburn and Thornton (1995) found that neurobehavioral functions such as reaction times, verbal recall, and trail-making were impaired in 216 adults exposed to chlordane via inhalation compared to an unexposed referent population matched by age and educational level. However, effect levels could not be assigned because data on exposure, dose-response or potential co-exposure to other neurotoxicants were not available (U.S. EPA, 1997). In a subsequent study of nine chlordane-exposed patients seen consecutively for effects of chemical exposure, Kilburn (1997) noted that neurobehavioral functions such as balance, reaction times, verbal recall, and color discrimination were also diminished in the exposed group compared to a control population. Exposure dose was unknown and exposure duration ranged from 50 minutes to 18 years. Potential limitations associated with experimental design, including selection bias and an inadequately matched control population, severely limit interpretation of this study.

In rodent studies, the liver is clearly the target organ of chronic chlordane toxicity and hepatic necrosis has been deemed the critical effect (U.S. EPA, 1997). Khasawinah and Grutsch (1989a, 1989b) conducted the most extensive rat and mice toxicity studies available for chlordane, at similar dose-rates, which indicated that the mouse is more susceptible to the hepatotoxic effects of chlordane than is the rat (U.S. EPA, 1997).

Additional hepatic toxicity signs in mice included increased liver weights and elevated serum aspartate transferase (AST) and alanine transferase (ALT) levels (Khasawinah and Grutsch, 1989b).

Reproductive toxicity has been shown to occur following oral exposure to relatively high levels of chlordane in male mice. Balash et al. (1987) found that mature male mice orally gavaged with chlordane for 30 days had dose-related histological changes in seminiferous tubules. Similarly, Al-Omar et al. (2000) determined that mice gavaged with approximately 20 or 70 percent of the median lethal dose of chlordane suffered damage to testicular tissues, including decreased seminiferous tubule diameter, and reduced numbers of spermatogonia, spermatocytes and spermatids.

Developmental effects have also been reported in response to chlordane exposure in mice and rats (ATSDR, 1994). A series of neurobehavioral tests given to mice offspring following third-trimester fetal exposure to chlordane found depressed avoidance response acquisition and increased seizure threshold and exploratory activity, suggesting an effect on fetal brain (ATSDR, 1994; Al-Hachim and Al-Baken, 1973). Cassidy et al. (1994) showed that male and female rats exposed to low levels of chlordane *in utero* and during the early postnatal period (Day 4 of gestation through Day 21 of lactation) had gender-dependent alterations of sexually dimorphic functions and behaviors such as spatial abilities and auditory startle-evoked responses. Based on these results, the authors suggested that chlordane mimics and/or alters sex steroid concentrations and, thus, has a masculinizing effect on fetal and/or neonatal rats. In their review of the paper, however, U.S. EPA (1997) noted that dose-response relationships were inconsistent, as effects in high-dose animals were often similar to controls. Additionally, testosterone levels in males and females were not systematically related to the observed behavioral changes. U.S. EPA thus questioned the authors' interpretation of the study results and indicated that further research was necessary to confirm a relationship between these behavioral effects and low-dose chlordane exposure.

Immunological studies in mice indicated that *in utero* and neonatal treatment with chlordane suppressed cell-mediated immunity (Barnett et al., 1985a, 1985b; 1990a, 1990b; Blaylock et al., 1990; IRIS, 1998; Menna et al., 1985). Reported effects following such chlordane exposures included decreased fetal hematopoietic activity, delayed-type hypersensitivity-mediated pathology, and mixed lymphocyte reactivity. However, in some experiments, this suppression led to increased survival following influenza virus infection during young adulthood (Barnett et al., 1985a; Blaylock et al., 1990; Menna et al., 1985). More recent research has shown a variety of immunotoxic responses of rats following 28-day oral gavage of *cis*-nonachlor, *trans*-nonachlor and technical chlordane (Tryphonas et al., 2003). In those studies, *cis*- and *trans*-nonachlor were more likely to cause immunotoxic effects than technical chlordane, with these results more pronounced in females.

Oxychlordane, one of the principal metabolites of chlordane, is the second most common chlordane-related residue found in food, following *trans*-nonachlor (Bondy et al., 2003).

A series of twenty-eight-day feeding studies in female rats showed that oxychlordane caused weight loss and histopathological changes in the liver, thymus, and thyroid and produced signs of toxicity at doses approximately eight times lower than *cis*- or *trans*-nonachlor (Bondy et al., 2003). The authors suggested that exposure to oxychlordane may prove to be a more significant human health hazard than exposure to other chlordane compounds found in foods.

Information regarding the potential carcinogenicity of chlordane in humans is conflicting. A few studies have shown an association between chronic chlordane inhalation exposure in humans and the development of various blood dyscrasias, such as leukemia (reported in ATSDR, 1994; U.S. EPA, 1997). In contrast, Brown et al. (1990; 1993) failed to find a relationship between leukemia or multiple myeloma and chlordane inhalation exposure in adult men (U.S. EPA, 1997). A retrospective mortality study of workers in the chlordane manufacturing industry (Brown, 1992) indicated that workers exposed to chlordane and other organochlorines had lower than expected mortality from all causes as well as from all malignant neoplasms (ATSDR, 1994). Yet, in two case-control studies, Cantor et al. (1992) and Woods and Polissar (1989) found that non-Hodgkin's lymphoma patients were more likely to have had previous inhalation exposure to chlordane than healthy controls, although this association was only significant in the Cantor et al. study. U.S.EPA (1997) notes that there is no evidence to support the conclusion that oral exposure to chlordane from food or drinking water causes human carcinogenicity; however, the weight of evidence following high-level, long-term dermal or inhalation exposures does suggest that chlordane is likely a human carcinogen.

The International Agency for Research on Cancer (IARC) has listed chlordane as a possible human carcinogen, based on inadequate evidence in humans and sufficient evidence in experimental animals (IARC, 2001). U.S. EPA has classified chlordane as a likely human carcinogen, based on limited epidemiological evidence in humans, development of hepatocellular carcinomas in multiple strains of mice and liver toxicity in rats, and the structural resemblance of chlordane to other rodent hepatic carcinogens (IRIS, 1998; U.S. EPA, 1997). Chlordane is on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR CHLORDANE

A chronic reference dose (RfD) is an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime (including to sensitive population subgroups), expressed in units of mg/kg-day (IRIS, 1995). This estimate includes a factor to account for data uncertainty. The underlying assumption of an RfD is that, unlike most carcinogens, there is a threshold dose below which certain toxic effects will not occur. The RfD for a particular chemical is derived from review of relevant toxicological and epidemiological studies in animals and/or humans. These studies are used to determine a No-Observed-Adverse-Effect-Level (NOAEL; the highest dose at which no adverse effect is seen), a Lowest-Observed-Adverse-Effect-Level

(LOAEL; the lowest dose at which any adverse effect is seen), or a benchmark dose level (BMDL; a statistical lower confidence limit of a dose that produces a certain percent change in the risk of an adverse effect) (IRIS, 1995). Based on these values and the application of uncertainty factors to account for incomplete data and sensitive subgroups of the population, an RfD is then generated. Exposure to a level above the RfD does not mean that adverse effects will occur, only that the probability of adverse effects occurring has increased (IRIS, 1993).

Because chlordane dose-response data in humans are inadequate, the U.S. EPA RfD for this chemical was derived from animal data based on hepatic necrosis as the critical effect (IRIS, 1998; U.S. EPA, 1997). Although several studies have indicated that chronic chlordane exposure may also result in neurobehavioral or other neurotoxic effects, reliable dose-response information as well as data to support a plausible mode-of-action are not available for these endpoints (U.S. EPA, 1997). U.S. EPA thus chose Khasawinah and Grutsch (1989b) as the principal study for the RfD because of the clear dose-related incidence of hepatic effects, overall strength of the study, and comparatively low adverse effect level (IRIS, 1998; U.S. EPA, 1997). Newer chlordane toxicity studies published since the RfD was developed do not have sufficient data to determine acceptable exposure values and/or have not shown a lower adverse effect level.

Khasawinah and Grutsch (1989b) fed 80 ICR mice per sex per group 0, 1, 5, or 12.5 parts per million (ppm) dietary chlordane (estimated to be 0, 0.15, 0.75, and 1.875 mg/kg-day, respectively) for 104 weeks. Hepatocellular swelling was seen in both male and female mice at doses of 5 and 12.5 ppm dietary chlordane; incidence of hepatic necrosis was also significantly elevated at those dose levels, but only in male mice. Other hepatic effects, such as increased relative liver weights and alanine transferase activity, were seen at varying dose levels. The NOAEL and LOAEL values for this study were considered to be 1 and 5 ppm, respectively. To the NOAEL, U.S. EPA applied a 300-fold uncertainty factor (10 for interspecies extrapolation, 10 for intraspecies variation, and 3 for lack of a multigenerational reproductive study), leading to an RfD of $5x10^{-4}$ mg/kg-day (IRIS, 1998; U.S. EPA, 1997).

As required under Health and Safety Code Section 901(g), OEHHA developed a child-specific reference dose (chRD) for chlordane for the purpose of assessing risk at proposed or existing California school sites (OEHHA, 2005). The Cassidy et al. (1994) paper was selected as the most useful study for determination of a chRD, based on endocrine disruption in the developing offspring. Pregnant Sprague-Dawley rats were fed doses of 100, 500, or 5,000 ng/g technical chlordane from day 4 of gestation until day 21 of lactation. Offspring were dosed from postnatal day (PND) 22 to PND 80 and began behavioral testing on PND 76; serum testosterone was measured on PND 85. Body weights were significantly increased in the 500 ng/g dose group compared to controls for females only. Serum testosterone levels were significantly reduced in female offspring dosed with 500 and 5,000 ng/g, although not in a dose-dependent fashion. Male offspring showed only a slight, non-significant, reduction of serum testosterone in the highest (5,000 ng/g) exposure group. Following repeated testing in the Cincinnati water

maze, time to escape was significantly improved in female rat dosed with 100 and 500 ng/g chlordane compared to controls; male rats were not affected by treatment. Intromission latency was significantly reduced in 100 and 500 ng/g treated males; however, the high-dose group was similar to controls. Intromissions prior to ejaculation and total intromissions were significantly increased only in the 500 ng/g dose group. Latency to ejaculation was not different among groups. Open field activity was not affected by treatment in male or female offspring. In tests of reaction to auditory startle, only the maximum response parameter was significantly different from controls and only in the 100 ng/g dose group. OEHHA determined that the LOAEL from this study was 100 ng/g chlordane, based on disruption of sex hormone-mediated behaviors. To the LOAEL, OEHHA applied a 3000-fold uncertainty factor (10 for LOAEL to NOAEL, 10 for interspecies extrapolation, 10 for intraspecies variation, and 3 for inadequate database for hematotoxicity, immunotoxicity, neurotoxicity, and the lack of a valid developmental study), leading to an chRD of $3.3x10^{-5}$ mg/kg-day (OEHHA, 2005).

Although Cassidy et al. (1994) was the best study available to establish a chRD, there are significant limitations with the data as noted by U.S. EPA (1997). Nonetheless, OEHHA concludes that it is appropriate to use the chRD for developing a non-cancer FCG for chlordane. FCGs are, as noted, strictly risk-based and, thus, a study need not be eliminated from consideration solely on the basis of data strength. However, in setting an ATL, it is important to balance the risks and benefits of fish consumption (see the Advisory Tissue Level section, later in this document). For this reason, OEHHA has chosen to use the cancer risk basis for establishing the ATL for chlordane (see below), rather than non-cancer risk based on Cassidy et al. (1994), even though this results in a slightly higher ATL. Chlordane is well-established as a potential human carcinogen; thus, protection against the carcinogenic effects of chlordane is generally accepted by regulatory agencies. Additionally, the 3000-fold uncertainty factor incorporated into the Cassidy et al. study-based chRD should not be used to outweigh the certainty of benefits associated with fish consumption. In using the cancer basis for developing the ATL, OEHHA determines that there is still a large margin of safety (approximately 550- to 1,000-fold, over the range of exposures) for potential endocrine-disrupting health effects of chlordane that is adequate to protect children who would also receive the benefits from consuming fish. OEHHA similarly chose to use the cancer endpoint in developing a Public Health Goal (PHG) for chlordane in drinking water (OEHHA, 1997) although non-cancer health effects, based on the Cassidy study, would have resulted in a lower PHG. Thus, the chRD of $3.3x10^{-5}$ will be used to evaluate non-cancer risk for a chlordane FCG, but only cancer risk will be considered in the development of chlordane ATLs.

A cancer slope factor (CSF) is an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen and is expressed as $(mg/kg\text{-}day)^{-1}$ (U.S. EPA, 1989). The higher the CSF, the greater the estimated potency of a carcinogen. As is the case with noncancer endpoints, only animal data are available to quantify the carcinogenic risk of chlordane (U.S. EPA, 1997). In their 1998 cancer assessment, U.S. EPA combined the

results of five liver tumor data sets for male and female CD-1 and B6C3F1 mice and male ICR mice orally exposed to chlordane at doses from 5 to 64 ppm for a period of 78 to 104 weeks (IRDC, 1973; NCI, 1977; Khasawinah and Grutsch 1989b; U.S. EPA, 1997; IRIS, 1998). U.S. EPA used (body weight)$^{3/4}$ scaling and the linearized multistage model in Global 86 software to determine cancer potency. Individual slope factors for each of the data sets ranged from 0.114 to 0.858 (mg/kg-day)$^{-1}$; a geometric mean of these values was then calculated to derive an oral CSF for chlordane of 0.35 (mg/kg-day)$^{-1}$ (IRIS, 1998). At the time of completion of this cancer risk assessment, however, the 1996 Guidelines for Carcinogenic Risk Assessment were still in draft form (U.S. EPA, 1996). U.S. EPA noted that using the LED_{10} alternate method of low-dose extrapolation from the newer guidelines to calculate cancer potency would lead to a slope factor of 0.567 (mg/kg-day)$^{-1}$ (IRIS, 1998). These guidelines have since been finalized by U.S. EPA (U.S. EPA, 2005).

In the PHG for chlordane in drinking water developed by OEHHA, only the male and female CD-1 and B6C3F1 mice studies (IRDC, 1973; NCI, 1977) were used to determine a CSF; the male ICR mice study (Khasawinah and Grutsch,1989b) included in the U.S. EPA assessment (IRIS, 1998) was not used (OEHHA, 1997). An intercurrent mortality correction of approximately 2.4 was used to correct for less than lifetime duration of these four studies. OEHHA employed the methodology from the 1996 Guidelines for Carcinogenic Risk Assessment (U.S. EPA, 1996) to calculate CSFs for these studies. OEHHA's estimates were based on (body weight)$^{3/4}$ scaling and used Tox_Risk software to calculated the LED_{10} because, according to the author, this software had a greater ability to calculate lower bounds on doses in the observed range in the evaluated studies (OEHHA, 1997). OEHHA then calculated the geometric mean of the best fitting four data sets to determine a CSF of 1.3 (mg/kg-day)$^{-1}$. This CSF will be used to evaluate chlordane cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer value used to evaluate chlordane in fish for the development of FCGs will be **$3.3x10^{-5}$ mg/kd-day**. The cancer value used to evaluate chlordane in fish for the development of FCGs and ATLs will be **1.3 (mg/kg-day)$^{-1}$**.

DICHLORODIPHENYLTRICHLOROETHANE AND ITS METABOLITES (DDTs)

DDTs TOXICOLOGY

Dichlorodiphenyltrichloroethane (DDT) is a synthetic organochlorine insecticide once used throughout the world to control insects that transmit malaria, typhus, and other significant diseases (Crosby, 1998). First used in the United States in 1942, its registration was cancelled by U.S. EPA in 1973 after discovery of its environmental persistence, bioaccumulative properties, and induction of eggshell thinning in predatory species of birds (Hodgson et al., 1998). DDT is still used in some developing countries, however, because it is an effective and inexpensive method of vector control (ATSDR, 1994; Eicobichon, 1991). Humans are typically exposed to a mixture of DDT and its principal metabolites, DDD (tetrachlorodiphenylethane) and DDE (dichlorodiphenyl-dichloroethylene) (U.S. EPA, 2000), which are referred to collectively as total DDTs. U.S. EPA recommends that fish consumption limits be based on the sum of DDT, DDD, and DDE (i.e., total DDTs) (U.S. EPA, 2000).

DDTs are very lipid soluble and water insoluble, have relatively low volatility, and are chemically and biologically stable, which leads to their persistence in the environment and biomagnification by organisms (Ecobichon, 1991; Menzer, 1991; WHO, 1989). Bioconcentration factors as high as $1x10^6$ have been reported for DDTs in aquatic species (reported in Ecobichon, 1991). Because of their historical widespread use and chemical properties, DDTs are pervasive environmental contaminants (ATSDR, 2002).

Exposure of humans to DDTs occurs most commonly from food consumption, particularly meat, dairy products, poultry, and fish (ATSDR, 2002). Freshwater and saltwater fish, in fact, typically account for approximately 75 percent and 5 percent of the total dietary exposure to DDTs, respectively (Dougherty et al., 2000). DDTs are absorbed from the gastrointestinal tract following dietary exposure and are then distributed widely by the lymphatic system and blood before being stored primarily in high-lipid tissues such as fat, liver, kidney, and brain (ATSDR, 1994; 2002; U.S. EPA, 2000). Adipose storage of DDTs is considered protective as it lowers the concentration at the target organ (i.e., the brain) (Klaassen, 2001). DDTs are transferred across the placenta to the fetus (Saxena et al., 1981; Waliszewski et al., 2000; 2001) and easily cross the blood-brain barrier (ATSDR, 1994). Although the primary route of DDT excretion is urinary, lesser amounts are also excreted through feces and breast milk (ATSDR, 1994; 2002). Lactation is a significant means of maternal DDT decontamination (Waliszewski et al., 2001). The half-life of DDT in the body is 10-20 years (IRIS, 1996).

ATSDR (1994; 2002) has extensively reviewed the toxicity of DDT and related compounds. DDT has low acute toxicity with no confirmed human deaths reported solely from DDT exposure (ATSDR, 1994). Acute oral exposures to high levels of DDT primarily affect the nervous system in humans. DDT elicits adverse neurological effects

by inhibiting ion movement through neuronal membranes (ATSDR, 1994; 2002) and reducing the rate of depolarization, thereby intensifying the sensitivity of neurons to stimuli (Ecobichon, 2003). Symptoms have been reported to occur at doses of 5-10 mg/kg and above and include paresthesia, anxiety, irritability, vertigo, tremor, and convulsions, (ATSDR, 2002; Ecobichon, 1991; U.S. EPA, 2000). During an acute poisoning episode, tactile or auditory stimuli may induce repetitive tremors and seizures (Ecobichon, 2003).

Chronic oral exposures to moderate DDT levels have been reported to lead to anorexia and weight loss, anemia, tremors, muscular weakness, EEG changes, and anxiety in humans (Ecobichon, 1991). Similar to acute toxicity, the nervous system is considered a principal target following chronic exposure to this chemical (ATSDR, 2002). Subtle neurological deficits have been reported in humans following long-term chronic DDT exposure (van Wendel de Joode et al., 2001). Twenty-seven retired men, aged 55-70, with a history of occupational DDT exposure during the previous 41 years had exposure duration-related reduced neurobehavioral functioning and increased neuropsychological and psychiatric symptoms compared to a reference group. Performance on tests of verbal attention and visuomotor speed and sequencing were the most pronounced differences between groups. Exposure levels were not available.

A few studies have reported an association between plasma DDE levels and altered immune function in humans including lowered mitogen-induced lymphoproliferative activity, increased total lymphocytes, and either increased or decreased immunoglobulins (Vine et al., 2000, 2001; Cooper et al., 2004). Reproductive and developmental effects in humans such as alterations in the duration of lactation, maintenance of pregnancy, fertility, and length of gestation have also been associated with high levels of DDTs in blood and other body tissues (ATSDR, 2002; see, e.g., Gladen and Rogan, 1995; Longecker et al., 2001). Occasional and slight, but significant, decrements on the Bayley scales of infant development were seen in offspring at 6, 12 or 24 months of age corresponding to a ten-fold increase in maternal serum levels of *p,p*'-DDT, *o,p*'-DDT, or *p,p*'-DDE (Eskenazi et al., 2006).

While human epidemiological studies can only suggest a possible causal relationship between a chemical exposure and an adverse effect, animal studies using controlled exposures do demonstrate numerous toxic effects of DDT exposure. Similar to acute high-level DDT exposures in humans, relatively high long-term DDT exposure has been shown to lead to significant neurological signs in non-human primates. Six of 24 cynomolgus and rhesus monkeys given 20 mg/kg DDT for 130 months developed severe irreversible tremors requiring euthanasia during the first seven years of the study. Histological evidence of neurotoxicity was noted on necropsy (Takayama et al., 1999). Neurodevelopmental effects, most notably altered motor behavior in adult mice exposed prenatally, have also been reported in animals exposed to DDT (ATSDR, 2002; Eriksson et al., 1990a, 1990b, 1992).

Although there is no conclusive evidence that DDTs cause hepatic effects in humans (ATSDR, 2002), liver lesions have been shown to be the critical effect following chronic DDT exposure in rodent studies (IRIS, 1996). Laug et al. (1950), for example, found that weanling rats showed dose-related hepatic morphological changes at DDT doses of 5 ppm and above. DDT-induced hepatic effects have also been shown in hamsters, mice and dogs (IRIS, 1996). Fatty liver and histological signs of hepatotoxicity, including toxic hepatitis, coagulation necrosis, and focal liver necrosis, were seen in cynomolgus and rhesus monkeys dosed with 20 mg/kg DDT for 130 months and then followed for 25 years (Takayama et al., 1999).

Rodent studies have shown that DDTs in comparatively high doses have estrogenic properties that result in increased uterine weights and delayed vaginal opening (Clement and Okey, 1972), as well as antiandrogenic activity such as altered reproductive organ development and delayed puberty (Diel et al., 2000) (reported in ASTDR, 2002). Many animal studies have shown that DDTs are reproductive and developmental toxins. However, human studies have shown no clear link between exposure to environmental levels of DDTs and such effects. Intake of other estrogenic substances (as estrogen equivalents) from dietary bioflavonoids, for example, is estimated to be $4x10^7$ times higher than that from estrogenic pesticides (ATSDR, 2002; Safe, 1995).

Numerous epidemiological studies have attempted to determine whether DDTs cause cancer in humans, particularly those of the breast, pancreas, lymph system, prostate, and endometrium (reported in ATSDR, 2002). To date, these studies have not been sufficient to support a causal relationship between DDT exposure and the development of cancer in humans (ATSDR, 2002). However, the IARC has listed DDT as a possible human carcinogen, based on inadequate evidence of carcinogenicity in humans and sufficient evidence in experimental animals (development of liver tumors in several mouse and rat studies) (IARC, 1991). U.S. EPA classifies DDT as a probable human carcinogen, based on development of liver tumors in mice and rats (IRIS, 1996). OEHHA has administratively listed DDTs on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR DDTs

Because DDT dose-response data in humans are inadequate, the U.S.EPA RfD for this chemical was derived from animal data based on hepatic lesions as the critical effect (IRIS, 1996). U.S.EPA chose Laug et al. (1950) as the principal study for the RfD calculation because it had sufficient exposure duration, established the male rat as the most sensitive animal to DDT toxicity, used doses over the range of the dose-response curve, and provided both a NOAEL and LOAEL, including the lowest LOAEL determined for this chemical (IRIS, 1996).

Laug et al. (1950) fed male and female weanling rats diets containing 0, 1, 5, 10 or 50 ppm commercial DDT for 15-27 weeks. No gross signs of toxicity were apparent.

Histological evaluation of liver and kidneys showed centrilobular hepatic cell enlargement at doses of 5 ppm and above, particularly in male rats. The authors concluded that "the difference observed between the control and 5 ppm animals represents the smallest detectable morphologic effects of DDT, based on extensive observations of rat liver as affected by a variety of chemicals" (Laug et al., 1950; IRIS; 1996). The NOAEL and LOAEL values for this study were considered to be 1 and 5 ppm dietary DDT, respectively (IRIS, 1996). To the NOAEL (corresponding to 0.05 mg/kg-day), U.S. EPA applied a 100-fold uncertainty factor (10 for interspecies conversion and 10 to protect sensitive human subpopulations), leading to an RfD of $5x10^{-4}$ mg/kg-day (IRIS, 1996).

ATSDR has developed a minimal risk level (MRL) for DDTs based on neurodevelopmental effects in mice reported by Eriksson and colleagues (ATSDR, 2002; Eriksson and Nordberg, 1986; Eriksson et al., 1990a, 1990b, 1993; Johansson et al., 1995, 1996; Talts et al., 1998). Male suckling mice given a single oral dose of 0.5 mg/kg body weight DDT during the peak period of rapid brain growth (10 days of age) showed increased spontaneous motor activity when subjected to behavioral testing as 4-month old adults, indicating a disruption of habituation (Ericksson et al., 1990a, 1990b, 1992). Similar effects were not seen when exposures occurred either before (3 days of age) or after (19 days of age) this period (Ericksson et al., 1992). These studies identified a LOAEL of 0.5 mg/kg-day, to which ATSDR applied a 1000-fold uncertainty factor (10 for use of a LOAEL, and 10 each for animal to human extrapolation and intrahuman variability). The resulting MRL is identical to the U.S. EPA RfD based on hepatic effects ($5x10^{-4}$ mg/kg-day), which will be used to evaluate DDT non-cancer risk for OEHHA fish consumption guidelines.

Although studies to assess carcinogenicity in humans have been inadequate and conflicting, DDT has been shown to cause benign and malignant tumors in multiple animal studies and is structurally related to other known animal carcinogens such as DDD, DDE, dicofol, and chlorobenzilate (IRIS, 1996). In their 1991 cancer assessment, U.S. EPA combined the results of six liver tumor data sets for male and female CF-1 mice, male BABL/C mice, male MRC Porton rats, and male and female Wistar rats (Turusov et al., 1973; Terracini et al., 1973; Thorpe and Walker, 1973; Tomatis and Turusov, 1975; Cabral et al., 1982; and Rossi et al., 1977) given doses from 2 to 500 ppm in lifetime feeding studies. Individual slope factors from each of the data sets ranged from 0.082 to 1.04 $(mg/kg\text{-}day)^{-1}$; a geometric mean of these values was then calculated to derive an oral CSF for DDT of 0.34 $(mg/kg\text{-}day)^{-1}$. This oral slope factor will be used to evaluate DDT cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer and cancer critical values used to evaluate DDT in fish for the development of consumption guidelines will be **$5x10^{-4}$ mg/kg-day and 0.34 $(mg/kg\text{-}day)^{-1}$**, respectively.

DIELDRIN

DIELDRIN TOXICOLOGY

Dieldrin is a chlorinated cyclodiene insecticide widely used in the United States from the 1950s to 1970 on crops such as corn and cotton and as a termiticide in subsequent years, until its registration was canceled by U.S. EPA in 1989 (ATSDR, 2002; Stevenson et al., 1999; WHO, 1989). As a result of their low volatility, slow degradation rates and lipophilicity, dieldrin and other organochlorine pesticides resist degradation in the environment and are able to bioconcentrate and biomagnify throughout the terrestrial and aquatic food chain (ATSDR, 2002; Ecobichon, 1991). For example, bioconcentration factors of 12,500 and 13,300 have been found for dieldrin in guppies and sculpins, respectively (Fisher, 1999). Dieldrin is extremely persistent (Matsumura, 1985) and, as such, is still found in the environment, particularly in soil, sediment, and animal fat (ATSDR, 2002).

Diet is the main source of dieldrin exposure in most individuals, with foods such as dairy and meat products, fish, garden fruits, and root vegetables providing the largest dietary contribution (ATSDR, 2002; WHO, 1989). Currently, approximately 90 percent of dietary dieldrin exposure is derived from saltwater and freshwater fish, combined (Dougherty et al., 2000). Dieldrin levels in fish are most commonly associated with areas of corn production (ATSDR, 2002). Following oral exposure, dieldrin is absorbed from the gastrointestinal tract and rapidly distributed through the lymphatic system to various body tissues before being stored largely in adipose tissue and bone marrow (ATSDR, 2002; de Vlieger et al., 1968; Morgan and Roan, 1970; Scheele, 1998). Body burdens are positively correlated with total body fat (ATSDR, 2002; Hunter and Robinson, 1967; 1968). Dieldrin is transferred across the placenta to the fetus where it is widely distributed to fetal organs (Curley et al., 1969). During labor, levels in extracted lipids of fetal blood are higher than in maternal blood (ATSDR, 2002; Polishuk et al., 1977; WHO, 1989). Dieldrin also crosses the blood brain barrier (WHO, 1989). The primary route of dieldrin excretion is through feces via the bile (ATSDR, 2002; Richardson and Robinson, 1971; WHO, 1989), although dieldrin is also excreted in breast milk (ATSDR, 2002; Schecter et al., 1989; Stevens et al., 1993). Breast milk dieldrin levels have been reported to be significantly lower in vegetarians whose diets do not contain animal products compared to U.S. population means, even though breast milk lipid levels were similar between groups (Hergenrather et al., 1981). The biological half-life of dieldrin is approximately one year (WHO, 1989).

ATSDR (2002) and WHO (1989) have extensively reviewed the toxicity of dieldrin. Similar to other chlorinated cyclodienes, dieldrin has relatively high acute toxicity following oral or inhalation exposures compared to most organochlorine pesticides with signs and symptoms including dizziness, vomiting, motor hyperexcitability, and convulsions that generally appear within 20 minutes to 24 hours post-exposure (Ecobichon, 1991; 2003; Klassen and Watkins, 1999; WHO, 1989). The nervous system is the most sensitive target organ following acute and chronic oral exposures in humans

(ATSDR, 2002); adverse neurological effects, including electroencephalographic abnormalities, have been reported in workers occupationally exposed to dieldrin (Hoogendam et al., 1962; 1965). The mechanism of neurotoxic action is believed to be inhibition of chloride transport, resulting in only partial repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999). In animals, initial signs of single-dose dieldrin intoxication are irritability and tremor prior to tonic-clonic convulsions; these may occur as little as one hour after exposure (WHO, 1989). The adult human lethal dose is estimated to be five g (WHO, 1989). The single dose oral LD_{50} for dieldrin in the rat is approximately 37 to 46 mg/kg (ATSDR, 2002). Interspecies variation in susceptibility to acute dieldrin toxicity is significant, with toxicity inversely correlated with species total body fat content (Geyer et al., 1993).

Dieldrin may affect the endocrine system in humans. An epidemiological study of blood organochlorine levels found that dieldrin concentrations were inversely correlated with T4 levels in hypothyroid women (Rathore et al., 2002). Correlational studies such as this, however, cannot prove a causal relationship between exposure and adverse effect.

There is no clear evidence that dieldrin causes hepatotoxicity in humans; however, in rodent studies, the liver is the target organ of chronic dieldrin toxicity and liver lesions are considered to be the critical effect (IRIS, 1990). Liver histopathological changes in rats and increased liver weights and liver-to-body weight ratios in rats and dogs were found in response to varying levels of dieldrin exposure for two years (Walker et al., 1969). Hepatomegaly and histopathological evidence of liver damage were also seen in mice exposed to 10 ppm dietary dieldrin for two years (Thorpe and Walker, 1973). Kitselman (1953) showed that dieldrin-induced gross and histopathological liver changes in dogs were reversible after dieldrin was removed from the diet. In a six-year study of monkeys fed 0.01 to 5.0 ppm dietary dieldrin, hepatic microsomal cytochrome P-450 levels were significantly increased in a dose-dependent fashion at doses of 0.1 ppm and above (approximately 25 to 30 µg/kg body weight per day or greater). Other hepatic variables such as liver weights and alkaline phosphatase, glucose-6-phosphatase, and succinic dehydrogenase activities were not affected by treatment, with the exception of slightly increased microsomal protein contents at the highest doses (Wright et al., 1978).

Several studies have indicated that fertility, litter size, and maternal behavior may be adversely affected following dieldrin exposure in rodents (Harr et al., 1970; Good and Ware, 1969; Virgo and Bellward, 1975; Treon and Cleveland, 1955). A small reproductive study in male and female dogs found delayed estrus, decreased libido, lack of mammary function, and increased stillbirths in animals exposed to 0.15 or 0.30 mg/kg-day dieldrin (Deichmann et al., 1971; reported in ATSDR, 2002). Teratogenesis was not observed in offspring of rats and mice fed graded doses of dieldrin during the period of organogenesis; however, fetotoxicity, as evidenced by an increase in the number of supernumerary ribs and decreased numbers of caudal ossification centers, was seen in doses that also caused signs of maternal toxicity (Chernoff et al., 1975).

Dieldrin has been shown to exert neurobehavioral effects in animals. Following a low dose (0.5, 1.5, or 4.5 mg/kg) acute exposure, a dose-related decrement in adaptive capacity to an uncontrollable stressor was seen in adult mice (Carlson and Rosellini, 1987). In a small study, 0.1 mg/kg-day dieldrin for 55 days impaired learning acquisition in monkeys while 0.01 mg/kg-day did not (Smith et al., 1976). Neurodevelopmental changes such as cerebral edema, internal and external hydrocephalus, and focal neuronal degeneration were seen in rat pups whose dams were exposed to 0.004-0.008 mg/kg-day dieldrin during gestation (ATSDR, 2002; Harr et al., 1970). However, inadequacies of study design and statistical analyses limit interpretation of these results (ATSDR, 2002).

Mouse studies have shown that dieldrin may cause immunosuppression, as evidenced by increased lethality of various viruses (ATSDR, 2002). For example, Krzystyniak et al. (1985) found that a single oral dose of 18 or 30 mg/kg dieldrin in mice significantly reduced the mean day of death following exposure to a lethal dose of mouse hepatitis virus 3 (MHV3). Mice fed 1 or 5 ppm dietary dieldrin for 10 weeks (corresponding to doses as low as 0.13 mg/kg/day; ATSDR, 2002) had reduced survival times when infected with *Plasmodium berghei* or *Leishmania tropica* (Loose, 1982).

Whether dieldrin can cause cancer in human populations is controversial. Several long-term epidemiological studies of workers in pesticide manufacturing plants have not found higher cancer mortality rates related to occupational dieldrin exposure in workers compared to controls (Amoateng-Adjepong et al., 1995; Ribbens, 1985; Swaen et al., 2002). Although Quintana et al. (2004) found that cadaver adipose tissue dieldrin levels were positively associated with risk of non-Hodgkin's lymphoma, according to the authors, lack of data on confounding variables in cases and controls or exposure level or duration hamper interpretation of these results. On the other hand, Cantor et al. (2003) did not see an association between pre-diagnostic serum dieldrin levels and risk of non-Hodgkin's lymphoma in matched controls. IARC has listed dieldrin as not classifiable as to its carcinogenicity, based on inadequate evidence of carcinogenicity in humans and limited evidence of carcinogenicity in animals (IARC, 1987). In contrast, U.S.EPA lists dieldrin as a probable human carcinogen, based on development of benign liver tumors and hepatocarcinomas in multiple strains of mice (IRIS, 1993) and OEHHA has administratively listed dieldrin on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR DIELDRIN

Data for determining NOAEL or LOAEL values for dieldrin in humans are inadequate; thus, U.S. EPA derived an RfD for this chemical based on animal studies. In contrast to humans, where neurotoxicity appears to be the most sensitive endpoint for acute and chronic toxicity, hepatic lesions are the chronic critical effect reported in animals (IRIS, 1990). U.S. EPA chose Walker et al. (1969) as the principal study for the RfD because it supported the critical effect and was a comparatively comprehensive chronic toxicity assessment (IRIS, 1990). Although minimal neurotoxic effects were also seen in this

study, they occurred at a 10-fold higher dose level than did the hepatotoxic effects (ATSDR, 2002) and were thus not used in deriving a reference dose.

Walker et al. (1969) fed five-week-old male and female CFE rats diets containing 0, 0.1, 1.0, and 10.0 ppm dieldrin for two years. Body weights, feed intake, hematology, clinical chemistry, and mortality were unaffected by treatment. High-dose animals showed irritability and occasional tremors and convulsions during the course of the study. One- and 10 ppm-treated female rats had increased absolute and relative liver weights compared to controls. Hepatic parenchymal cell changes indicative of organochlorine exposure were found in some 10 ppm-treated male and female rats. U.S. EPA identified 0.1 and 1.0 ppm, respectively, as the NOAEL and LOAEL values for this study (IRIS, 1990). To the NOAEL (corresponding to 0.005 mg/kg-day), U.S. EPA applied a 100-fold uncertainty factor (10 for interspecies conversion and 10 to protect sensitive humans), leading to an RfD of $5x10^{-5}$ mg/kg-day (IRIS, 1990). ATSDR (2002) has developed a chronic oral minimum risk level (MRL) of $5x10^{-5}$ mg/kg-day, also based on the Walker et al. (1969) study, which is identical to the U.S. EPA RfD. This RfD will be used to evaluate dieldrin non-cancer risk for OEHHA fish consumption guidelines.

Studies to assess the carcinogenicity of dieldrin in humans are inadequate; however, dieldrin has been shown to cause cancer in multiple mouse strains (see caveats noted above) and is structurally related to other known rodent carcinogens (e.g., aldrin, chlordane, heptachlor, and heptachlor epoxide) (IRIS, 1993). U.S. EPA combined the results of 13 liver carcinoma data sets for male and female C3H and CF1 mice, and male B63F1, C57B1/6J, and C3H/H3 mice to determine carcinogenicity for this chemical. Individual slope factors for each of the data sets ranged from 7.1 to 55 $(mg/kg\text{-}day)^{-1}$. A geometric mean of those values was used to set an oral slope factor for dieldrin of 16 $(mg/kg\text{-}day)^{-1}$ (IRIS, 1993). This oral slope factor will be used to evaluate dieldrin cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer and cancer critical values used to evaluate dieldrin in fish for the development of consumption guidelines will be **$5x10^{-5}$ mg/kg-day and 16 $(mg/kg\text{-}day)^{-1}$**, respectively.

METHYLMERCURY

METHYLMERCURY TOXICOLOGY

Mercury is a metal found naturally in rocks, soil, air, and water that can be concentrated to high levels in the aquatic food chain by a combination of natural processes and human activities (ATSDR, 1999). The toxicity of mercury to humans is greatly dependent on its chemical form (elemental, inorganic, or organic) and route of exposure (oral, dermal, or inhalation). Methylmercury (an organic form) is highly toxic and can pose a variety of human health risks (NAS/NRC, 2000). Of the total amount of mercury found in fish muscle tissue, methylmercury comprises more than 95 percent (ATSDR, 1999; Bloom, 1992). Because analysis of total mercury is less expensive than that for methylmercury, total mercury is usually analyzed for most fish studies and assumed to be 100 percent methylmercury for the purposes of risk assessment.

In general, mercury concentrations in fish and other biota are dependent on the mercury level of the environment, which can vary based on differences in pH, redox potential, temperature, alkalinity, buffering capacity, suspended sediment load, and geomorphology of individual water bodies (Andren and Nriagu, 1979; Berlin, 1986; WHO, 1989). Other factors also affect the accumulation of mercury in fish tissue, including fish diet, species and age (as inferred from length) (WHO, 1989; 1990). Fish at the highest trophic levels (i.e., predatory fish) generally have the highest levels of mercury. Additionally, because of the long biological half-life of methylmercury in fish (approximately 2 years), tissue concentrations in fish increase with increased duration of exposure (Krehl, 1972; Stopford and Goldwater, 1975; Tollefson and Cordle, 1986). As a result, tissue methylmercury concentrations are expected to increase with increasing age and length within a given species, particularly in piscivorous fish.

Fish consumption is the major route of exposure to methylmercury in the United States (ATSDR, 1999). As noted above, almost all fish contain detectable levels of methylmercury, which, when ingested, is almost completely absorbed from the gastrointestinal tract (Aberg et al., 1969; Myers et al., 2000). Once absorbed, methylmercury is distributed throughout the body, reaching the largest concentration in kidneys. Its ability to cross the placenta as well as the blood-brain barrier allows methylmercury to accumulate in the brain and fetus, which are known to be especially sensitive to the toxic effects of this chemical (ATSDR, 1999). In the body, methylmercury is slowly converted to inorganic mercury and excreted predominantly by the fecal (biliary) pathway. Methylmercury is also excreted in breast milk (ATSDR, 1999). The biological half-life of methylmercury is approximately 44-74 days in humans (Aberg, 1969; Smith et al., 1994), meaning that it takes approximately 44-74 days for one-half of a single ingested dose of methylmercury to be eliminated from the body.

Human toxicity of methylmercury has been well studied following several epidemics of human poisoning resulting from consumption of highly contaminated fish (Japan) or seed grain (Iraq, Guatemala, and Pakistan) (Elhassani, 1982-83). The first recorded mass

methylmercury poisoning occurred in the 1950s and 1960s in Minamata, Japan, following the consumption of fish contaminated by industrial pollution (Marsh, 1987). The resulting illness was manifested largely by neurological signs and symptoms such as loss of sensation in the hands and feet, loss of gait coordination, slurred speech, sensory deficits including blindness, and mental disturbances (Bakir et al., 1973; Marsh, 1987). This syndrome was subsequently named Minamata Disease. A second outbreak of methylmercury poisoning occurred in Niigata, Japan, in the mid-1960s. In that case, contaminated fish were also the source of illness (Marsh, 1987). In all, more than 2,000 cases of methylmercury poisoning were reported in Japan, including more than 900 deaths (Mishima, 1992).

The largest outbreak of methylmercury poisoning occurred in Iraq in 1971-1972 and resulted from consumption of bread made from seed grain treated with a methylmercury fungicide (Bakir et al., 1973). This epidemic occurred over a relatively short term (several months) compared to the Japanese outbreak. The mean methylmercury concentration of wheat flour samples was found to be 9.1 micrograms per gram (μg/g). Over 6,500 people were hospitalized, with 459 fatalities. Signs and symptoms of methylmercury toxicity were similar to those reported in the Japanese epidemic. Review of data collected during and subsequent to the Japan and Iraq outbreaks identified the critical target of methylmercury as the nervous system and the most sensitive subpopulation as the developing organism (U.S. EPA, 1997). During critical periods of prenatal and postnatal structural and functional development, the fetus and children are especially susceptible to the toxic effects of methylmercury (ATSDR, 1999; IRIS, 1995). When maternal methylmercury consumption is very high, as happened in Japan and Iraq, significant methylmercury toxicity can occur to the fetus during pregnancy, with only very mild or even in the absence of symptoms in the mother. In those cases, symptoms in children were often not recognized until development of cerebral palsy and/or mental retardation many months after birth (Harada, 1978; Marsh et al., 1980; Marsh et al., 1987; Matsumoto et al., 1964; Snyder, 1971).

IARC has listed methylmercury compounds as possible human carcinogens, based on inadequate data in humans and limited evidence in experimental animals (increased incidence of tumors in mice exposed to methylmercury chloride) (IARC, 1993). U.S. EPA has also listed methylmercury as a possible human carcinogen (IRIS, 2001). OEHHA has administratively listed methylmercury compounds on the Proposition 65 list of chemicals known to the State of California to cause cancer. No estimate of the increased cancer risk from lifetime exposure to a chemical has been developed for methylmercury.

DERIVATION OF REFERENCE DOSES FOR METHYLMERCURY

The first U.S. EPA RfD for methylmercury was developed in 1985 and set at $3x10^{-4}$ mg/kg-day (U.S. EPA, 1997). This RfD was based, in part, on a WHO report summarizing data obtained from several early epidemiological studies on the Iraqi and Japanese methylmercury poisoning outbreaks (WHO, 1976). WHO found that the

earliest symptoms of methylmercury intoxication (paresthesias) were reported in adults at blood and hair concentrations ranging from 200-500 µg/L and 50-125 µg/g, respectively. In cases where ingested mercury dose could be estimated (based, for example, on mercury concentration in contaminated bread and number of loaves consumed daily), an empirical correlation between blood and/or hair mercury concentrations and onset of symptoms was obtained. From these studies, WHO determined that methylmercury exposure equivalent to long-term daily intake of 3-7 µg/kg body weight in adults was associated with an approximately 5 percent prevalence of paresthesias (WHO, 1976). U.S. EPA further cited a study by Clarkson et al. (1976) to support the range of blood mercury concentrations at which paresthesias were first observed in sensitive members of the adult population. This study found that a small percentage of Iraqi adults exposed to methylmercury-treated seed grain developed paresthesias at blood levels ranging from 240 to 480 µg/L. The low end of this range was considered to be a LOAEL and was estimated to be equivalent to a dosage of 3 µg/kg-day. U.S. EPA applied a 10-fold uncertainty factor to the LOAEL to reach what was expected to be the NOAEL. Because the LOAEL was observed in sensitive individuals in the population after chronic exposure, additional uncertainty factors were not considered necessary for exposed adults (U.S. EPA, 1997).

Although this RfD was derived based on effects in adults, even at that time researchers were aware that the fetus might be more sensitive to methylmercury (WHO, 1976). It was not until 1995, however, that U.S. EPA had sufficient data from Marsh et al. (1987) and Seafood Safety (1991) to develop an oral RfD based on methylmercury exposures during the prenatal stage of development (IRIS, 1995). Marsh et al. (1987) collected and summarized data from 81 mother and child pairs where the child had been exposed to methylmercury *in utero* during the Iraqi epidemic. Maximum mercury concentrations in maternal hair during gestation were correlated with clinical signs in the offspring such as cerebral palsy, altered muscle tone and deep tendon reflexes, and delayed developmental milestones that were observed over a period of several years after the poisoning. Clinical effects incidence tables included in the critique of the risk assessment for methylmercury conducted by the U.S. Food and Drug Administration (FDA) (Seafood Safety, 1991) provided dose-response data for a benchmark dose approach to the RfD, rather than the previously used NOAEL/LOAEL method. The BMDL was based on a maternal hair mercury concentration of 11 ppm. From that, an average blood mercury concentration of 44 µg/L was estimated based on a hair: blood concentration ratio of 250:1. Blood mercury concentration was, in turn, used to calculate a daily oral dose of 1.1 µg/kg-day, using an equation that assumed steady-state conditions and first-order kinetics for mercury. An uncertainty factor of 10 was applied to this dose to account for variability in the biological half-life of methylmercury, the lack of a two-generation reproductive study and insufficient data on the effects of exposure duration on developmental neurotoxicity and adult paresthesia. The oral RfD was then calculated to be $1x10^{-4}$ mg/kg-day, to protect against developmental neurological abnormalities in infants (IRIS, 1995). This fetal RfD was deemed protective of infants and sensitive adults.

The two previous RfDs for methylmercury were developed using data from high-dose poisoning events. Recently, the National Academy of Sciences (NSA) was directed to provide scientific guidance to U.S. EPA on the development of a new RfD for methylmercury (NAS/NRC, 2000). Three large prospective epidemiological studies were evaluated in an attempt to provide more precise dose-response estimates for methylmercury at chronic low-dose exposures, such as might be expected to occur in the United States. The three studies were conducted in the Seychelles Islands (Davidson et al., 1995, 1998), the Faroe Islands (Grandjean et al., 1997, 1998, 1999), and New Zealand (Kjellstrom et al., 1986, 1989). The residents of these areas were selected for study because their diets rely heavily on consumption of fish and marine mammals, which provide a continual source of methylmercury exposure (NAS/NRC, 2000).

Although estimated prenatal methylmercury exposures were similar among the three studies, subtle neurobehavioral effects in children, such as problems with attention, fine-motor function, and verbal memory, were found to be associated with maternal methylmercury dose in the Faroe Islands and New Zealand studies, but not in the Seychelle Islands study. The reasons for this discrepancy were unclear; however, it may have resulted from differences in sources of exposure (marine mammals and/or fish), differences in exposure pattern, differences in neurobehavioral tests administered and age at testing, the effects of confounding variables, or issues of statistical analysis (NRC/NAS, 2000). The NAS report supported the current U.S. EPA RfD of $1x10^{-4}$ mg/kg-day for fetuses, but suggested that it should be based on the Faroe Islands study rather than Iraqi data.

U.S. EPA recently published a new RfD document that arrives at the same numerical RfD as the previous fetal RfD, using data from all three recent epidemiological studies while placing emphasis on the Faroe Island data (IRIS, 2001). In order to develop an RfD, U.S. EPA used several test scores from the Faroes data, rather than a single measure for the critical endpoint as is customary (IRIS, 2001). U.S. EPA developed BMDLs utilizing test scores for several different neuropsychological effects mentioned above with cord blood as the biomarker for mercury exposure. The BMDLs for different neuropsychological effects in the Faroes study ranged from 46-79 µg mercury/liter blood. U.S. EPA then chose a one-compartment model for conversion of cord blood to ingested maternal dose, which resulted in estimated maternal mercury exposures of 0.857-1.472 µg/kg-day (IRIS, 2001). An uncertainty factor of ten was applied to the oral doses corresponding to the range of BMDLs to account for interindividual toxicokinetic variability in ingested dose estimation from cord-blood mercury levels and pharmacodynamic variability and uncertainty, leading to an RfD of $1x10^{-4}$ mg/kg-day (IRIS, 2001). In support of this RfD, U.S. EPA found that benchmark dose analysis of several neuropsychological endpoints from the Faroe Island and New Zealand studies, as well as an integrative analysis of all three epidemiological studies, converged on an RfD of $1x10^{-4}$ mg/kg-day (IRIS, 2001). U.S. EPA (IRIS, 2001) now considers this RfD to be protective for all populations. However, in their joint Federal Advisory for Mercury in Fish, U.S. EPA and U.S. FDA only apply this RfD to women who are pregnant or might become pregnant, nursing mothers, and young children (U.S. EPA, 2004).

OEHHA finds that there is convincing evidence that the fetus is more sensitive than adults to the neurotoxic and subtle neuropsychological effects of methylmercury. As noted previously, during the Japanese and Iraqi methylmercury poisoning outbreaks, significant neurological toxicity occurred to the fetus even in the absence of symptoms in the mother. In later epidemiological studies at lower exposure levels (e.g., in the Faroe Islands), these differences in maternal and fetal susceptibility to methylmercury toxicity were also observed. Recent evidence has shown that the nervous system continues to develop through adolescence (see, for example, Giedd et al., 1999; Paus et al., 1999; Rice and Barone, 2000). As such, it is likely that exposure to a neurotoxic agent during this time may damage neural structure and function (Adams et al., 2000), which may not become evident for many years (Rice and Barone, 2000). Thus, OEHHA considers the RfD based on subtle neuropsychological effects following fetal exposure to be the best estimate of a protective daily exposure level for women aged 18 to 45 years and children aged 1 to17 years.

In an effort to address the risks of methylmercury contamination in different populations, two separate RfDs will be used to assess risk for different population groups. OEHHA has formerly used a separate methylmercury RfD for sensitive populations to formulate advisories for methylmercury contamination of sport fish (Stratton et al., 1987). Additionally, the majority of states issue separate consumption advice for sensitive (e.g., children) and general population groups**.** OEHHA chooses to use both the current and previous U.S. EPA RfDs to evaluate methylmercury non-cancer risk for fish consumption guidelines for two distinct population groups. In OEHHA advisories, the current RfD of $1x10^{-4}$ mg/kg-day, based on effects in infants, will be used for women 18 to 45 years and children aged 1 to17 years. The previous RfD of $3x10^{-4}$ mg/kg-day, based on effects in adults, will be used for women over 45 years and men.

In summary, the non-cancer critical values used to evaluate methylmercury in fish for development of consumption guidelines will be **$1x10^{-4}$ mg/kg-day** for women aged 18 to 45 years and children aged 1 to 17 years, and **$3x10^{-4}$ mg/kg-day**, for women over 45 years and men.

POLYCHLORINATED BIPHENYLS (PCBs)

PCBs TOXICOLOGY

Polychlorinated biphenyls (PCBs) are a class of synthetic persistent lipophilic organic chemicals containing complex mixtures of biphenyls that are chlorinated to varying degrees (ATSDR, 2000; U.S. EPA, 2000a). The chemical formula for PCBs is $C_{12}H_{10-n}Cl_n$, where n equals the number of chlorine atoms ranging from one to ten (WHO, 1993). PCBs were manufactured in the United States from about 1930 to 1977 for use as coolants in electrical transformers and capacitors, and as hydraulic fluids, lubricating and cutting oils, and plasticizers (ATSDR, 2000; Erickson, 2001). Although there are 209 possible individual chlorinated biphenyl compounds (known as congeners), only approximately 130 are found in commercial products (U.S. EPA, 2000a; WHO, 1993). In the United States, PCBs were generally sold as mixtures of congeners under the trade name Aroclor (ATSDR, 2000; Nessel and Gallo, 1992).

PCBs primarily enter the environment as a result of accidental spills and leaks from products containing Aroclor mixtures and are redistributed among environmental compartments by volatilization and runoff (ATSDR, 2000). Because of their lipophilicity and slow degradation rates, PCBs are very resistant to degradation in the environment (ATSDR, 2000). PCBs are found chiefly in soil, sediment, and fatty biological tissue, where they accumulate and biomagnify in the food chain (Dekoning and Karmaus, 2000; Menzer, 1991; Moser and McLachlan, 2001). Bioconcentration factors of some congeners are reported to reach as high as $1x10^7$ in fish (Erickson, 2001). PCB residue levels in fish are affected by sediment characteristics (e.g., organic carbon content), fish species and lipid content, and trophic structure of the food chain (Eisler, 1996).

The composition of Aroclor mixtures in the environment will change over time as individual PCB congeners undergo differential partitioning, degradation, and biotransformation. This process, referred to as “weathering,” results in differential persistence and bioaccumulation, which changes the PCB pattern found in environmental samples from the original pattern in technical Aroclor mixtures (Erickson, 2001). As a rule, the environmental persistence of PCBs increases with the degree of chlorination (Menzer, 1991). As a result of improved methods and equipment, PCBs in environmental samples can be quantified as congeners and congener patterns can be related to potential sources and to the technical Aroclor mixture they most closely resemble (Newman, et al., 1998).

Saltwater and fresh water fish and shellfish, combined, account for a significant portion of the total dietary exposure to PCBs (Dougherty et al., 2000). In a study comparing frequent and infrequent Great Lakes sport fish consumers, lifetime sport fish consumption was found to be the best predictor of PCB body burdens (Hanrahan et al., 1999). Fishers who consume fish from PCB-contaminated waters have been found to have serum PCB levels several times those of the general population and similar to individuals occupationally exposed to PCBs (Kreiss, 1985).

Absorption of PCBs following oral exposure occurs via passive diffusion and ranges from approximately 75 percent to more than 90 percent (U.S. EPA, 2000a), depending on congener and the diffusion gradient between PCB concentration in the gut contents and serum lipids (Juan et al., 2002; ATSDR, 2000). Once absorbed, PCBs are distributed throughout the body, accumulating primarily in lipid-rich tissues such as liver, adipose tissue, skin, and breast milk (U.S. EPA, 2000a). More than 95 percent of most PCB congeners are absorbed from breast milk (Dahl et al., 1995; McLachlan, 1993). PCBs are also transferred across the placenta to the fetus (ATSDR, 2000; DeKoning and Karmaus, 2000). Excretion of PCBs occurs primarily through the feces and urine as well as breast milk of lactating women (ATSDR, 2000; Moser and McLachlan, 2001). Net absorption (absorption from the gastrointestinal tract minus excretion) is significantly influenced by blood lipid levels, congener body burden (ATSDR, 2000; Schlummer et al., 1998), and body mass index (Juan et al., 2002). Although various studies have shown substantial disparities in estimated half-lives of PCBs (less than one year to greater than 10 years), the best evidence suggests that the majority of PCB congeners found in an occupational setting have half-lives in the human body from one to six years (Shirai and Kissel, 1996; Wolff et al., 1982).

The toxicity of PCBs following occupational exposure has been known since 1936 when the development of chloracne (a severe form of acne) in PCB-exposed workers resulted in the establishment of a workplace threshold limit value for these compounds (Erickson, 2001). Occupational exposure has also been reported to result in ocular effects such as Meibomian gland hypersecretion, swollen eyelids, and abnormal conjunctival pigmentation (ATSDR, 2000). Incidents of purported widespread PCB poisonings occurred in Japan in 1968 ("Yusho") and Taiwan in 1979 ("Yu-Cheng") following consumption of PCB-contaminated rice oil (WHO, 1993). Signs and symptoms in affected persons were primarily ocular and dermatological; edema, alterations in blood chemistry values, and various respiratory, immunological, reproductive, developmental, and neurological disturbances were also seen (ATSDR, 2000; WHO, 1993). Although the clinical syndrome was originally thought to have resulted solely from PCB toxicity, ensuing investigations determined that the co-contaminants polychlorinated dibenzofurans (PCDFs) were the primary causal factors in Yusho and Yu-Cheng diseases (Ikeda, 1996; Kunita et al., 1984; Schantz, 1996; Wilson, 1987; Yao et al., 2002). In a sample of Yusho rice oil, for example, 2,3,4,7,8-pentaCDF was found to contribute the majority (58 percent) of the total toxic equivalents (TEQ), while PCB-126 was the second most abundant contributor to total TEQ (16 percent) (Yao et al., 2002). It is possible, however, that some signs and symptoms in the Yusho and Yu-Cheng poisonings resulted from non-*Ah* receptor mediated mechanisms of PCB toxicity.

Numerous epidemiological studies since that time have attempted to determine whether PCBs pose a human health risk at levels currently found in the environment. Many authors have subsequently reported an association between oral environmental PCB exposures and cancer as well as various adverse neurological, reproductive, and developmental effects (ATSDR, 2000). In particular, several observational cohort studies have found one or more neurodevelopmental deficits in children exposed to PCBs *in*

utero and/or postnatally (see descriptions in Winneke et al., 1998; 2002); however, results have differed with respect to the type and persistence of effects as well as the matrix (e.g., cord blood or breast milk) used to indicate exposure (Winneke et al., 1998). For example, Jacobson et al. (1992) and Jacobson and Jacobson (1996) noted that children exposed to PCBs prenatally through maternal consumption of contaminated Great Lakes fish had poorer performance on cognitive tests for visual, verbal and memory abilities at four years of age, and lowered verbal and full-scale IQ at age eleven compared to children with lower intrauterine PCB exposures. In similarly exposed infants, Gladen et al. (1988) found decreases in psychomotor scores at twelve months as well as delays in motor maturation up to 24 months (Rogan and Gladen, 1991), but no changes in mental scores. These effects were no longer observed at 3-5 years of age (Gladen and Rogan, 1991). Schantz et al. (1999) found no effect on visual-motor coordination or hand steadiness in a population of adults over 50 years of age exposed to PCBs and other contaminants through long-term consumption of large amounts of Great Lakes fish compared to those who consumed little or no Great Lakes fish. However, the same population showed a decrease in verbal memory in one of two standardized tests of memory and learning compared to controls (Schantz et al., 2001). No effects were seen on executive or visual-spatial function. In a study comparing women who had consumed more than 40 pounds of Great Lakes fish over their lifetimes with women who had never consumed Great Lakes fish, Stewart et al. (2000) found a significant linear relationship between highly chlorinated (C17-C19) PCB congeners in cord blood and decreased habituation and autonomic scores in the Neonatal Behavioral Assessment Scale. In a European cohort, Winneke et al. (1998) found the sum of PCBs 138, 153, and 180 in breast milk to be negatively associated with cognitive development, but not motor development or recognition memory in seven-month-old infants. These outcomes were not related to cord plasma PCBs. Neurological effects have also been observed in infants, children, and adults following PCB poisonings (ATSDR, 2000).

Recent data indicate that typical environmental levels of PCBs might affect the developing immune system in humans (Weisglas-Kuperus et al., 2000). Prenatal PCB exposure was positively associated with number of lymphocytes, T cells, and $CD3^{+}CD8^{+}$ (cytotoxic), $CD4^{+}$ $CD45RO^{+}$ (memory), $TcR\alpha\beta^{+}$, and $CD3^{+}$HLA-DR^{+} (activated) T cells and negatively associated with antibody levels to mumps and rubella in 42 month-old children. Current plasma PCB levels were positively associated with prevalence of chicken pox and recurrent middle ear infections, while negatively associated with prevalence of allergic reactions. Increased duration of breast feeding counteracted the negative effects of postnatal PCB exposure (Weisglas-Kuperus et al., 2000).

Human studies have shown inconsistent results with respect to adverse reproductive effects following PCB exposures (ATSDR, 2000). Menstrual cycles were slightly shorter and female fecundity was reduced in women consuming PCB-contaminated Great Lakes fish (Buck et al., 2000; Mendola et al. 1997). However, other studies have shown no adverse reproductive effects in women consuming high-PCB fish when examining endpoints such as increased time-to-pregnancy or risk of spontaneous fetal death (Buck et al., 1997; Courval et al., 1999; Mendola et al., 1995), although there was a small

association between sport-caught fish consumption and conception delay for men (Courval et al., 1999). Results of human studies on potential developmental effects of PCB exposure have also been mixed (ATSDR, 2000). Maternal PCB exposure via fish consumption has been reported to have a negative, positive, or no association with birth weight, head circumference, or gestation age (see, for example, Buck et al., 2003; Dar et al., 1992; Jacobson et al. 1990a, 1990b; Lonky et al., 1996; Rylander et al., 1995; Smith, 1984; ATSDR, 2000).

Most human epidemiological studies examining adverse effects of PCB exposure have been confounded by concomitant exposure to the trace contaminants PCDFs or other workplace chemicals such as solvents, benzene, and lead (Erickson, 2001; Persky, 2001), or have had other serious design or reporting flaws (Swanson et al., 1995). In fact, in a systematic critical evaluation of 72 occupational or environmental PCB exposure studies conducted prior to 1995, Swanson et al. (1995) found that only five of the occupational studies and none of the environmental studies provided either positive or suggestive evidence of a causal relationship between PCB exposure and adverse effects in humans. Most studies were deemed inconclusive. This is particularly true in studies of fish-eating populations as fish are often contaminated with multiple organochlorines and other neurological, developmental or reproductive toxins (Seegal, 1996; 1999). Although human epidemiological studies are quite limited in their ability to prove a causal relationship between PCB exposure and disease (Seegal, 1996), animal studies using controlled exposures to specific Aroclor mixtures do clearly demonstrate adverse effects on the hepatic, hematological, gastrointestinal, immunological, neurological, endocrine, and reproductive systems following oral PCB exposure (ATSDR, 2000). To date, the most sensitive effects of PCB toxicity have been identified in monkeys, including clinical signs showing developmental effects such as ocular exudate, inflamed Meibomian glands, and distorted growth of fingernails and toenails, as well as immunological effects such as decreased antibody response to sheep erythrocytes (IRIS, 1996). Studies showing specific effects are discussed in more detail below.

As has been the case with various non-cancer endpoints, epidemiological research in humans has also found an association between exposure to PCBs and mortality rates from cancers of the liver, gall bladder, biliary tract, and brain, as well as non-Hodgkin's lymphoma and malignant melanoma (see Cogliano, 1998 and ATDSR, 2000, for discussion). Additionally, male Yusho victims were noted to have an increase in mortality from liver cancer when compared to national death rates (Kuratsune et al., 1987); however, this may have resulted from PCDF contamination (Cogliano, 2001). While epidemiological studies cannot prove a causal relationship between exposure and health effects as noted above, numerous experimental investigations in rodents have clearly shown the ability of various commercial Aroclor mixtures to cause cancerous or pre-cancerous hepatic and gastrointestinal lesions (see Cogliano et al., 1998 and ATSDR, 2000, for discussion). IARC has listed PCBs as probable human carcinogens, based on limited evidence of hepatobiliary cancer in humans and sufficient evidence of malignant liver neoplasms in rodents (IARC, 1987). U.S. EPA also designates PCBs as probable human carcinogens based on tumors found in female mice exposed to Aroclors 1260,

1254, 1242, and 1016 and also in male rats exposed to Aroclor 1260 (IRIS, 1997). Based on these actions, OEHHA has administratively listed PCBs on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR PCBs

Studies to identify an RfD or CSF for PCBs have been conducted with the specific Aroclor mixtures that were prevalent as commercial products during the period that Aroclors were actively manufactured and used. However, as noted above, PCBs found in fish or other environmental media have undergone weathering that can selectively increase or decrease individual congeners, possibly increasing the overall toxicity of the mixture (Cogliano, 2001). U.S. EPA has adopted an approach that matches the expected environmental persistence and toxicity of congeners to the congener profile and toxicity of different Aroclors (Cogliano, 2001). Fish consumption is considered an exposure of high risk and persistence, so recommended health effects values are based on the cancer and non-cancer toxicities of Aroclors 1260 and 1254, which show the greatest toxicity and content of environmentally persistent chlorines (U.S. EPA, 1996).

Because PCB dose-response data for non-cancer endpoints in humans are inadequate, the U.S. EPA RfD for these compounds has been derived from animal data. The RfD for Aroclor 1254 of $2x10^{-5}$ mg/kg-day (IRIS, 1996) is based on a series of studies in adult female Rhesus monkeys (Arnold et al., 1993a, 1993b; Tryphonas et al., 1989, 1991a, 1991b) that were treated for 23 to 55 months. The critical effects noted in treated adults were ocular exudate, inflamed Meibomian (tarsal) glands, distorted fingernail and toenail growth, as well as a decreased antibody response to sheep erythrocytes, all of which occurred at the lowest tested dose of 0.005 mg/kg-day (IRIS, 1996). To this LOAEL, an uncertainty factor of three hundred (ten for sensitive individuals, three for extrapolation from rhesus monkey to humans, a partial factor[1] for the use of a minimal LOAEL [i.e., the effects were not severe], and three to convert from subchronic to chronic) was applied to develop the RfD (IRIS, 1996). OEHHA also used the LOAEL from Arnold et al. (1993a, 1993b) and a three hundred-fold uncertainty factor (ten for interindividual variability, ten for interspecies variation and three for mild and reversible effects at the LOAEL) to account for immunological effects of PCBs to derive a PHG (the concentration of a chemical in drinking water determined to present no significant risk to human health when consumed over a lifetime) (Avalos and Brodberg, 2004). Results of continuing studies in which these treated females were mated to untreated males have been published (Arnold et al. 1995; 1997) since the U.S. EPA derived its RfD. These studies present findings on effects on female reproduction and developmental effects in infants following intrauterine and post-parturition exposures (22 weeks via breast milk). Arnold et al. (1995) showed decreased conception rates at 0.02 mg/kg-day and above, but not at 0.005 mg/kg-day. Developmental effects such as inflammation or enlargement of the Meibomian (tarsal) glands, nail lesions and gum recession, as well as a decrease in

[1] IRIS did not stipulate what the "partial factor" was; however, by deduction, it must have been three.

titers to IgM sheep red blood cells and a dose-related decrease in head circumference were seen in infant rhesus monkeys whose mothers were exposed to 0.005 mg/kg-day Aroclor 1254. Studies with other Aroclor compounds (e.g., Aroclor 1016) have shown developmental and neurological effects in monkeys at slightly higher doses with minor morphological effects occurring at levels where no or minimal neurobehavioral effects were manifested (e.g., Shantz et al., 1989). Although the current RfD is derived from a LOAEL from a study in adult monkeys, similar morphological effects in offspring were reported at the same exposure level. Since morphological effects have been found to occur at or below the exposure levels causing developmental neurobehavioral effects (Schantz et al., 1989), the RfD is also expected to be protective of the developing fetus. This RfD of $2x10^{-5}$ mg/kg-day will be used to evaluate PCB non-cancer risk for OEHHA fish consumption guidelines.

Human cancer dose-response data for PCBs are also inadequate and, thus, the PCB CSF has been generated based on animal studies. Because of the differential ability of different PCB mixtures to cause cancer, U.S. EPA developed a range of CSFs based on Aroclors 1016, 1242, 1254, and 1260. These Aroclors include the range of typical congeners found in various environmental media such as water and fish (IRIS, 1997). For food chain exposure, such as fish consumption, where environmental processes increase risk, a "high-risk" cancer slope factor of 2.0 $(mg/kg\text{-}day)^{-1}$ is used based on the carcinogenic potential of Aroclors 1254 and 1260 (U.S. EPA, 1996). This value was derived from a study of male and female rats (Brunner et al., 1996; Norback and Weltman, 1985). A significant, dose-related increase in the number of liver adenomas or carcinomas was found in female rats exposed to all Aroclors and in male rats exposed to Aroclor 1260 (IRIS, 1997). Aroclors 1254 and 1260 are the most frequently detected Aroclors sampled in California fish (Brodberg and Pollock, 1999; LACSD, 2000). The CSF of 2.0 $(mg/kg\text{-}day)^{-1}$ will be used to evaluate PCB cancer risk for OEHHA fish consumption guidelines.

For fish consumption advisories, cancer and non-cancer health effects values are applied to the sum of detected Aroclors (generally 1248, 1254, and 1260) or a sum of congeners in fish tissue, as recommended by U.S. EPA (2000b).

In summary, the non-cancer and cancer critical values used to evaluate PCBs in fish for the development of consumption guidelines will be **$2x10^{-5}$ mg/kg-day** and **2.0 $(mg/kg\text{-}day)^{-1}$**, respectively.

SELENIUM

SELENIUM TOXICOLOGY

Selenium is a metalloid found naturally, but highly variably, throughout the environment (ATSDR, 1999; Reilly, 1996). Although toxic at relatively low levels, selenium is also a required nutrient that functions to protect against oxidative stress, regulate thyroid hormones, and in vitamin C metabolism (IOM, 2000). The current Recommended Dietary Allowance (RDA) for selenium is 55 µg/day for the general adult population, 60 µg/day for pregnant women, and 70 µg/day during lactation (IOM, 2000). Selenium is found in a variety of inorganic and organic forms (Haygarth, 1994); however, in animal tissues, most selenium occurs as the amino acids selenomethionine or selenocysteine (IOM, 2000). Fish and other food samples are analyzed for total selenium content, as nutritional and toxicity values have not been developed for specific chemical forms of the element.

Selenium is dispersed naturally in the environment by weathering of selenium-containing rocks and volcanic eruptions (ATSDR, 2003). Human activities can significantly redistribute environmental selenium; fossil fuel processing and combustion as well as irrigation of seleniferous soils are important origins of localized selenium contamination (Lemly, 1997). Because of the inherent variability in soil selenium concentrations, human and animal selenium exposures can fluctuate quite dramatically by geographic locale. Human selenium intakes in different regions of China known for endemic deficiency and toxicosis, for example, have been shown to range from seven to 38,000 µg/day, respectively (Levander, 1987).

Environmental conditions (e.g., pH and oxidation-reduction potential) dictate the chemical form in which selenium will be found, which, in turn, determines the biological fate of the element (ATSDR, 2003). Water and air selenium levels are generally low except in isolated areas; humans are exposed to selenium primarily through food. Cereals, grains, and forage crops are the largest contributors of selenium to the diet (ATSDR, 2003), although fish also can be a relatively rich source of the element (USDA, 2004). Freshwater fish in the United States have been found to contain a mean concentration of 0.56 ppm selenium, wet weight (May, 1981); however, in areas of California where high-selenium irrigation drainage water contaminated nearby waterways, selenium concentrations in whole body carp were reported up to 60 ppm (Fan, 1988). Brazil nuts, on average, contain the highest selenium concentration of any common food, ranging from 0.03 to 512 ppm, wet weight, depending on geographic location (Chang et al., 1995). Six to eight nuts (one ounce) typically supply approximately ten times (544 µg) the RDA for this nutrient (USDA, 2004).

Following ingestion, most forms of dietary selenium are well absorbed from the gastrointestinal tract (ATSDR, 2003; Barceloux, 1999; Thomson, 1998). Once absorbed, selenium is distributed to many tissues, reaching the highest concentrations in liver and kidney; selenium also crosses the placenta and is found in breast milk (ASTDR, 2003).

Excretion occurs primarily through urine and, to a lesser extent, feces. In cases of excess consumption, selenium is excreted in the breath and sweat as garlic-odored dimethylselenide (IOM, 2000; Klaassen and Watkins, 1999). The half-life of selenomethionine in the human body is 234 days (Klaassen and Watkins, 1999).

The toxicity of selenium was recognized many years before its role as an essential nutrient was discovered in the 1950s by Schwarz and Foltz (1957). Franke and Potter (1935) were the first to prove that selenium was the plant constituent responsible for signs of toxicosis such as hair and hoof loss reported in livestock grazing on the plains of Nebraska and South Dakota (Combs and Combs, 1986). Since that time, selenium toxicity has been well reviewed by many authors (e.g., ATSDR, 2003; Combs and Combs, 1986; Reilly, 1996; Barceloux, 1999; Schrauzer, 2000, 2003) and has been found to be dependent on chemical form and solubility (Klaassen and Watkins, 1999).

Acute, sometimes fatal, selenium toxicity only rarely has been reported in humans and has generally been the result of self-medication, accidental, suicidal, or occupational exposures (Civil and McDonald, 1978; Sioris et al., 1980; Gasmi et al., 1997; Schellmann et al., 1986). Gastrointestinal and neurological signs and symptoms, as well as hair and nail loss, predominate the clinical presentation (Combs and Combs, 1986). At least one case of acute selenium intoxication from a natural source has been noted in the literature. A 54-year-old Venezuelan man suffered anxiety, chills, diarrhea, fever, anorexia, and weakness after consuming 70 to 80 "Coco de Mono" (*Lecythis ollaria*) almonds. Eight days after consuming the nuts, he suffered extensive loss of scalp and body hair (Kerdel-Vegal, 1964). Subsequent studies identified the pharmacologically active agent as selenocystathionine (Aronow and Kerdel-Vegas, 1965; Kerdel-Vegas et al., 1965). Acute selenium poisoning was also reported in five individuals who consumed sodium selenate intended for use as a turkey diet supplement (dose not provided). Symptoms and signs, which resolved within 24 hours, included nausea, vomiting, diarrhea, abdominal pain, chills, and tremors (Sioris et al., 1980). Acute to sub-acute selenium toxicosis occurred in 13 individuals who consumed an improperly formulated over-the-counter selenium supplement (FDA Drug Bulletin, 1984; Jensen et al., 1984; Helzlsouer et al., 1984). Analysis of several tablets revealed that the selenium content was 182 times higher than labeled (approximately 27-30 mg per tablet, in the form of sodium selenate and elemental selenium). Estimates of ingested selenium dose ranged from 27 to 2310 mg (from a single tablet to 77 tablets taken over a 2 ½ month period). Signs and symptoms of toxicity included nausea, abdominal cramps, nail and hair changes (including total hair loss), peripheral neuropathy, garlic breath odor, fatigue, and irritability.

Chronic selenium toxicosis in humans has been well characterized as a result of endemic disease occurring in a seleniferous region of China (Yang et al., 1983, 1989a, 1989b). Excessive selenium intakes (a mean of 4,990 µg/day, versus 116 µg/day in a selenium adequate area) resulted from consumption of high-selenium corn and vegetables during a drought period. Affected individuals suffered nail and hair loss, dermal swelling, erythema and ulcerations, as well as paresthesias. Hair selenium levels were approximately 100 times higher than those found in selenium adequate areas (Yang et al.,

1983). Chronic human selenium toxicity as a consequence of environmental exposures has not been reported in the United States, although ranchers in a seleniferous area of South Dakota were found to consume as much as 724 µg selenium per day (Longnecker et al., 1991).

Although high levels of selenium have been shown to be teratogenic in birds (Ohlendorf, 1986; 1988), there is no evidence that selenium induces terata in humans or other mammals (ATSDR, 2003). Other developmental effects following *in utero* selenium exposure in mammals have only been conclusively demonstrated at doses that cause frank maternal toxicity (Willhite, 1993; ATSDR, 2003).

IARC and U.S. EPA have listed selenium compounds as not classifiable as to their carcinogenicity in humans because of inadequate evidence of carcinogenicity in humans or animals (IARC, 1975; IRIS, 1993). Selenium sulfide, an industrial chemical not present in food, is considered a probable human carcinogen by U.S. EPA (IRIS, 1993) and is listed by OEHHA on the Proposition 65 list of carcinogens.

DERIVATION OF A REFERENCE DOSE FOR SELENIUM

The current U.S. EPA RfD for selenium and selenium compounds was developed in 1991 and set at $5x10^{-3}$ mg/kg-day (IRIS, 1991), corresponding to 350 µg/day for a 70-kg adult or approximately six-fold higher than the RDA for the general adult population. This RfD was based on an epidemiological study of approximately 400 people residing in a seleniferous region of China noted above. Overt signs of clinical selenosis (e.g., garlic breath odor, nail changes, hair and nail loss, decreased hemoglobin, skin lesions, mottled teeth, and central nervous system effects) were reported at whole blood concentrations of 1.35 mg/L, corresponding to a daily selenium intake of 1.261 mg (Yang et al., 1989b; IRIS, 1991). A blood selenium level of 1.0 mg/L (equivalent to an intake of 0.853 mg selenium/day) did not elicit signs of selenium toxicity. Thus, a chronic oral NOAEL and LOAEL of 0.853 and 1.261 mg/day, respectively, were determined from this study and converted to a body weight basis using the average Chinese adult body weight of 55 kg (IRIS, 1991). U.S. EPA also cited a year-long study of individuals from high-selenium areas of South Dakota and Wyoming in support of the RfD (see above, Longnecker et al. 1991). Individuals consuming as much as 0.724 mg Se/day in these regions did not show signs or symptoms associated with selenium toxicity, thus confirming the NOAEL from the Yang et al. (1989b) study. To account for sensitive individuals, U.S. EPA applied a three-fold uncertainty factor to the NOAEL (0.015 mg/kg-day) to derive an RfD of $5x10^{-3}$ mg/kg-day. Because a similar NOAEL was observed in two moderate-sized populations exposed over a lifetime, a full 10-fold uncertainty factor was not considered necessary (IRIS, 1991). ATSDR (2003) also has developed a chronic oral MRL of $5x10^{-3}$ mg/kg-day, based on a follow-up study by Yang and Zhou (1994) that reexamined five individuals included in the original Yang et al. (1989b) paper. This study confirmed the original NOAEL used by U.S. EPA to set the RfD. OEHHA will use this RfD to evaluate selenium non-cancer risk for fish consumption guidelines.

In summary, the non-cancer critical value used to evaluate selenium in fish for the development of consumption guidelines will be **$5x10^{-3}$ mg/kg-day**.

TOXAPHENE

TOXAPHENE TOXICOLOGY

Toxaphene (camphechlor) is an organochlorine insecticide consisting of a mixture of over 670 chlorinated terpenes (ATSDR, 1996; U.S. EPA, 2000). The average chemical formula for toxaphene and related toxaphene-like pesticides is $C_{10}H_{10}C1_8$ (WHO, 1984; ATSDR, 1996; de Geus, 1999). Toxaphene was first produced in 1945, primarily as an insecticidal agent for cotton, but also for parasite control in livestock and to kill unwanted fish species in various water bodies (DHHS, 2002; de Geus, 1999). Once the most heavily used pesticide in the United States (Ribick et al., 1982), U.S. EPA restricted most applications of toxaphene in 1982 and banned it completely in 1990 (DHHS, 2002).

Because of its extensive use, volatility, and resistance to degradation, toxaphene is distributed throughout various environmental matrices worldwide, particularly in freshwater and marine fish (Alder, 1997; ATSDR, 1996; de Geus, 1999). Bioconcentration factors of persistent toxaphene congeners in fish and shellfish have been reported to reach as high as $3.5x10^6$ (Geyer et al., 1999). Biomagnification also occurs in the aquatic food chain (ATSDR, 1996). Fish toxaphene levels have been shown to be positively correlated with fish age and fat content (Alder, 1997). Similar to the case with PCBs, the composition of the toxaphene "technical" mixture is altered in the environment as a result of differential degradation of individual congeners (Stern et al., 1992). The number of congeners decreases with increasing trophic level; approximately twenty, eight and two primary congeners have been found in fish, marine mammals, and humans, respectively (Calciu et al., 1997).

Toxaphene is known to be absorbed from all absorption routes, although dermal absorption is comparatively low (ATSDR, 1996; WHO, 1984). Once absorbed, toxaphene is distributed primarily to fat, but also to liver, bone, kidney, brain, heart, muscle, lung, spleen, adrenal gland, and testis (ATSDR, 1996). Rat studies have shown that only a small percent of a maternal toxaphene dose is transferred to the fetus (Pollock and Hillstrand, 1982); however, toxaphene has been found in human breast milk, particularly in women residing in the Arctic region where dietary organochlorine levels can be very high (Dewailly et al., 1993; Chan and Yeboah, 2000; Newsome and Ryan, 1999; Walker et al., 2003; Vaz and Blomkvist, 1985). Breast milk from Inuit women in northern Quebec, for example, has been reported to contain toxaphene concentrations as high as 294 ng/g on a lipid weight basis (Newsome and Ryan, 1999; Stern et al., 1992). Toxaphene is excreted in both urine and feces with the majority of absorbed toxaphene undergoing metabolic transformation (ASTDR, 1996). The excretion half-life of radiolabeled toxaphene has been shown to be approximately nine days in rodents, with about twice as much excreted in feces as in urine over this time period (ATSDR, 1996). Even though the pesticide has been banned for many years, significant toxaphene residues have recently been found in adipose tissue of children in western Europe (Witt and Niessen, 2000).

The toxicity of toxaphene has been well reviewed by several authors (e.g., ASTDR, 1996; Pollock and Kilgore, 1978; WHO, 1984; Saleh, 1991). Like other cyclodiene insecticides, the mechanism of neurotoxic action is believed to be inhibition of chloride transport, resulting in only partial repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999). Following acute oral toxaphene intoxication in humans, signs and symptoms of central nervous system stimulation are seen such as hypersalivation, restlessness, muscle tremors, and convulsions (U.S. EPA, 1987). Signs often begin within two hours of ingestion; fatal doses generally cause death by respiratory failure within 24 hours (McGee et al., 1952; Wells and Milhorn, 1983). The human acute lethal dose has been estimated to range from 21-100 mg/kg body weight (U.S. EPA, 1987) or about 2 to 7 grams for an adult (WHO, 1984). In addition to nervous system and respiratory effects mentioned above, heart dilation, kidney swelling, and elevated liver enzymes have also been reported in humans following acute toxaphene ingestion (ATSDR, 1996; McGee et al., 1952; Wells and Milhorn, 1983).

In animals, neurological effects similar to those reported in humans have been reported following acute toxaphene toxicity (ATSDR, 1996). Intermediate or chronic toxaphene exposures in various animal species have been shown to cause hepatic and renal effects including increased liver and kidney weights, hepatic enzyme induction, and degenerative histopathological changes in both organs (ATSDR, 1996). Protein deficiency may significantly increase acute toxaphene toxicity (Boyd and Taylor, 1971).

Toxaphene has not been shown to cause reproductive harm in animals at levels that do not also cause parental toxicity. For example, decreased fetal weights, fetal death, or increased incidence of encephaloceles were reported in rats and mice exposed to toxaphene during the period of organogenesis, but only at doses that also caused maternal toxicity and death (Chernoff and Carver, 1976). In a three-generation study, rats fed 0, 25 or 100 ppm toxaphene showed no adverse effects on reproductive outcomes such as litter size, pup survival or weanling body weights; however, liver cytoplasmic vacuolization was seen in the majority of adults at the 100 ppm dose (Kennedy et al., 1973). Similarly, while dietary toxaphene concentrations of 20 ppm and above caused increased liver weights as well as histopathological changes in liver, thyroid and kidney in adults rats during a reproductive study, there were no effects on fertility, litter size, pup weight, or other indices of gestation or survival in rats fed dietary concentrations up to 500 ppm toxaphene (0.38 mg/kg-day) (Chu et al., 1988).

Developmental effects have been reported following toxaphene exposure in rats. Olson et al. (1980) found that juvenile rats exposed to 0.05 mg/kg-day toxaphene in the pre- and postnatal periods had decreased swimming and righting ability compared to controls, although differences in swimming ability between groups had disappeared by postnatal day 16. Time to master righting reflex was also prolonged in offspring of rats exposed to 6 mg/kg-day from gestation day 7 until parturition (Crowder et al., 1980).

A few studies have found immunotoxic effects resulting from toxaphene exposure. Adult mice fed 100 or 200 ppm dietary toxaphene for eight weeks showed a dose-dependent decrease in antibody response to bovine serum albumin (Allen et al., 1983). Liver-to-body weight ratios were also increased at both dose levels and histopathological changes were noted in livers. Immunological effects were more pronounced in offspring exposed *in utero* or during lactation (Allen et al., 1983). An immunotoxicity study in cynomolgus monkeys is described below (Tryphonas et al., 2001). *In vitro* human studies have confirmed that neutrophils are a significant immunologic target of toxaphene toxicity (Gauthier et al., 2001).

There are no data available to evaluate the carcinogenicity of toxaphene in humans; however, toxaphene has been found to be a liver carcinogen in mice and to cause thyroid cancer in rats (Litton Bionetics, 1978; Reuber, 1979; NCI, 1979). IARC has listed toxaphene as a possible human carcinogen, based on inadequate data in humans and sufficient evidence in experimental animals (IARC, 2001). U.S. EPA lists toxaphene as a probable human carcinogen, based on no data in humans and sufficient evidence of carcinogenicity in experimental animals (IRIS, 1991). OEHHA has administratively listed toxaphene on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR TOXAPHENE

U.S. EPA has not developed an RfD for toxaphene. However, in 2003, OEHHA published a PHG for toxaphene in drinking water, selecting a study by Chu et al. (1986) to determine the NOAEL for non-cancer effects (OEHHA, 2003). Rats fed diets containing 20 to 500 ppm toxaphene (corresponding to approximately 0.35 to 63 mg/kg-day) had biologically significant histopathological changes in liver, thyroid, and kidney at doses of approximately 1.8 mg/kg-day and above. Liver-to-body weight ratios and hepatic mixed function oxidase activities were also increased at the highest dose level. The NOAEL and LOAEL values in this study were determined to be 0.35 and 1.8 mg/kg-day, respectively. To the NOAEL, an uncertainty factor of 1000 (10 for interspecies extrapolation, 10 for sensitive individuals, and 10 for extrapolation from subchronic to chronic) can be applied to develop a reference dose of 3.5×10^{-4} mg/kg-day.

A more recent study in cynomolgus monkeys by Tryphonas et al. (2001) can also be used to support the RfD for toxaphene. Monkeys were fed 0, 0.1, 0.4, or 0.8 mg/kg-day toxaphene for 75 weeks. Doses of 0.4 and 0.8 mg/kg-day significantly reduced humoral immunity in female monkeys, as evidenced by decreased primary and secondary immune response to sheep erythrocytes. The NOAEL of 0.1 mg/kg-day in this study was similar to that derived by Chu (Chu et al., 1986). As the Chu et al. study produced the highest NOAEL below the lowest LOAEL, it will be used to set the reference dose to evaluate toxaphene non-cancer risk for fish consumption guidelines.

Human dose-response data for cancer are also inadequate; thus, the toxaphene CSF has been generated from animal studies. Two long-term rodent carcinogenicity assays have been published for toxaphene (Litton Bionetics, 1978; NCI, 1979). In their 1991 carcinogenicity assessment, U.S. EPA chose the Litton Bionetics study for determination of the toxaphene cancer slope factor. A significantly increased incidence of hepatocellular carcinomas was found in male B6C3F1 mice at a dietary dose of 50 ppm. Using a linearized multistage model, U.S. EPA determined the oral CSF for toxaphene in this study to be 1.1 $(mg/kg\text{-}day)^{-1}$ (IRIS, 1991). OEHHA (2003) employed a CSF of 1.2 $(mg/kg\text{-}day)^{-1}$ in their toxaphene PHG, using the same data set as U.S. EPA but making slightly different assumptions regarding the conversion of dietary toxaphene concentrations to mg/kg body weight doses. For the purpose of evaluating cancer risk for fish consumption guidelines, the CSF of 1.2 $(mg/kg\text{-}day)^{-1}$ will be used.

In summary, the non-cancer and cancer critical values used to evaluate toxaphene in fish for the development of consumption guidelines will be **$3.5x10^{-4}$ mg/kg-day** and **1.2 $(mg/kg\text{-}day)^{-1}$**, respectively.

FISH CONTAMINANT GOALS FOR CHLORDANE, DDTs, DIELDRIN, METHYLMERCURY, PCBs, SELENIUM, AND TOXAPHENE

As is also the case for air, drinking water, or any other food, the ultimate goal of agencies responsible for the protection of public health is for fish to be devoid of biological or chemical contamination. FCGs can be derived for chemicals found in fish, comparable to PHGs for drinking water (Health and Safety Code, Section 116365). FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs were developed for chlordane, DDTs, dieldrin, methylmercury, PCBs, selenium, and toxaphene. FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, feasibility, the counterbalancing benefits of fish consumption, or alternative risks of other protein sources that may be consumed in place of fish.

FCGs can be found in Table 1. OEHHA used the following assumptions in the development of FCGs for fish contaminants. Agencies developing fish tissue-based criteria may choose to alter one or more of these assumptions in order to meet their own specific goals or requirements:

Body Weight:

The default value for adult body weight for these calculations was assumed to be 70 kg, which is recommended in most risk assessment guidelines. While, at one time, 70 kg was the approximate combined average weight for adult males and females in the United States, it is now significantly less than the average weight for both adult females and males in this country (about 75 and 87 kg, respectively) (Ogden et al., 2004). The use of a lower default body weight for risk assessment calculations results in lower allowable contaminant concentrations in fish.

Serving Size and Consumption Rate:

Serving size assumptions vary considerably. The American Heart Association (AHA) recommends eating fish at least two times a week (AHA, 2006), and considers a single serving size to be four ounces (113.5 g) of fish prior to cooking (corresponding to three ounces [85 g] of cooked fish). The Institute of Medicine (IOM) also considers serving size to be three ounces of cooked fish, based on the National Health and Nutrition Examination Survey (NHANES) 1999-2002 data showing three ounces to be the average daily consumption rate for people who eat fish (IOM, 2007). In their 2006 food pyramid, the U.S. Department of Agriculture recommends five to six ounces, *total*, of meat, poultry, fish, dried beans or peas, eggs, nuts, and seeds *per day* for adult women and men,

suggesting that the typical serving size of a single animal protein source in a given day is three to four ounces (USDA, 2006). In contrast, U.S. EPA assumed a serving size of eight ounces of fish, prior to cooking, in their fish advisory guidance document (U.S. EPA, 2000b), as did both U.S. EPA and FDA in their joint national advisory for mercury in fish (U.S. EPA, 2004c). While OEHHA contemplated reducing serving sizes to four ounces, prior to cooking, to align with federal nutrition, IOM and AHA guidelines, focus groups interviewed by the California Department of Public Health indicated that sport fishers typically consume significantly larger portion sizes. Thus, an 8-ounce serving size was retained for use in fish advisories. OEHHA considers it to be a reasonable goal to provide recreational fish that, at a minimum, are safe to eat at the AHA recommended consumption rate for adults of at least eight ounces of fish per week, prior to cooking (an average of 32 g/day) and that this is an appropriate consumption rate for development of an FCG. Because of their smaller body weights, children will be advised to eat approximately one-half as much fish (in either quantity or frequency) as are women aged 18 to 45 years.

Hazard Quotient:

Standard risk assessment guidelines generally recommend limiting non-cancer exposures to no more than the RfD, which results in a hazard quotient (HQ; the ratio of exposure to the RfD) that does not exceed 1. FCGs were set using a maximum HQ of 1 at the consumption rate of 32 g/day.

Risk Level:

FCGs were developed using a maximum cancer risk level (RL) of $1x10^{-6}$, estimating that, at a given consumption rate, not more than one additional cancer case would be expected in a population of one million people consuming fish over a lifetime. This risk level is at the lower end of the acceptable range of risks ($1x10^{-4}$ to $1x10^{-6}$) used by U.S. EPA in regulatory criteria for drinking water (Fed. Reg., 1998) and is provided as an example of an acceptable risk level in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories (U.S. EPA, 2000a,b). FCGs were set using a maximum RL of $1x10^{-6}$ at the consumption rate of 32 g/day.

Exposure Duration and Averaging Time:

For carcinogenic chemicals, the exposure duration and averaging time was assumed to be 30 years over a 70 year lifespan, based on the 95th percentile of U.S. residence time (U.S. EPA, 1997). This may be modified in cases where a carcinogenic contaminant is widespread throughout state water bodies and the source is relatively ubiquitous.

Cooking Reduction Factor:

OEHHA strongly recommends to all consumers that they skin and thoroughly cook their fish prior to eating. Skinning and cooking remove or reduce a variety of chemical and

biological hazards. FCGs take into account organochlorine contaminant loss during the cooking process. The concentration of PCBs and other organic contaminants in fish are generally reduced by at least 30 percent, depending on cooking method (Anderson et al., 1993; Sherer and Price, 1993; Santerre, 2000; Wilson et al., 1998; Zabik et al., 1996). As such, a cooking reduction factor of 0.7 was included in the FCG equation for organic compounds (allowing for 70 percent of the contaminant to remain after cooking). Although fish analytical data are generally provided to OEHHA as skin-off fillets, when contaminant levels are determined using skin-on fillets, a cooking and skinning reduction factor of 0.5 is used to account for organic chemical losses of approximately 50 percent that occur during both processes combined (Anderson et al., 1993). Mercury and selenium concentrations in fish are not reduced by cooking or cleaning techniques and, thus, no reduction factor has been applied for these chemicals.

Nutrients:

Unlike the case for other fish contaminants listed above, selenium is a required nutrient and fish are a major dietary source of selenium. Thus, it should be ensured that the FCGs for selenium do not unduly limit sport fish as a potential source of selenium and that they also take into account additional dietary exposures to this element. As reported above, the current RDA for selenium is 55 µg/day for the general adult population, 60 µg/day for pregnant women, and 70 µg/day during lactation (IOM, 2000). Data from NHANES III show that the mean selenium intake for all individuals from diet alone is 113.7 µg/day, while the mean intake from diet plus supplements is 116 µg/day (IOM, 2000). This indicates that most individuals in the United States easily meet their nutritional needs for selenium and do not consume selenium supplements. Thus, the mean selenium intake from diet alone (114 µg/day; IOM, 2000) will be used as the background dietary selenium consumption rate for developing FCGs for selenium. As in all cases of supplement intake, consumers who take selenium supplements should take them with caution and under the advisement of their physician.

Use/Application of FCGs:

OEHHA has developed FCGs, using standard exposure factors and a consumption rate of eight ounces prior to cooking (six ounces after cooking), to provide a starting point to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. Any agency using FCGs provided in this report to establish fish tissue-based criteria for their own purposes must accept the assumptions described herein.

Table 1. Fish Contaminant Goals (FCGs) for Selected Fish Contaminants Based on Cancer and Non-Cancer Risk* Using an 8-Ounce/Week (prior to cooking) Consumption Rate (32 g/day)**	
	FCGs (ppb, wet weight)
Contaminant Cancer Slope Factor $(mg/kg/day)^{-1}$	
Chlordane (1.3)	**5.6**
DDTs (0.34)	**21**
Dieldrin (16)	**0.46**
PCBs (2)	**3.6**
Toxaphene (1.2)	**6.1**
Contaminant Reference Dose (mg/kg-day)	
Chlordane ($3.3x10^{-5}$)	100
DDTs ($5x10^{-4}$)	1600
Dieldrin ($5x10^{-5}$)	160
Methylmercury ($1x10^{-4}$)[S]	**220**
PCBs ($2x10^{-5}$)	63
Selenium ($5x10^{-3}$)	**7400**
Toxaphene ($3.5x10^{-4}$)	1100

*The most health protective Fish Contaminant Goal for each chemical (cancer slope factor- versus reference dose-derived) for each meal category is bolded.
**g/day represents the average amount of fish consumed daily, distributed over a 7-day period, using an 8-ounce serving size, prior to cooking.
[S]Fish Contaminant Goal for sensitive populations (i.e., women aged 18 to 45 years and children aged 1 to 17 years.)

Tabled values are rounded based on laboratory reporting of three significant digits in results, where the third reported digit is uncertain (estimated). Tabled values are rounded to the second digit, which is certain. When data are compared to this table they should also first be rounded to the second significant digit as in this table.

EQUATIONS USED TO CALCULATE FISH CONTAMINANT GOALS

The following general equations were used to calculate Fish Contaminant Goals for chemicals at the consumption rates listed in Table 1, using an 8-ounce (prior to cooking) serving size. Separate equations are used for carcinogenic effects, non-carcinogenic effects, and nutrients with non-carcinogenic effects.

The following general equation can be used to calculate Fish Contaminant Goals (in µg/kg) at which the consumption exposure from a chemical with a ***carcinogenic*** effect is equal to the risk level for that chemical at any consumption level:

$$\text{Tissue concentration (ppb)} = \frac{\text{(Risk Level)(kg BW)(1000 µg/mg)}}{\text{[CSF (mg/kg/day)}^{-1}\text{] (CR kg/day)(ED/AT)(CRF)}}$$

As an example, for dieldrin, the Fish Contaminant Goal using a risk level of $1x10^{-6}$ and a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{(1x10^{-6})(70\text{ kg})(1000\text{ µg/mg})}{[16\text{ (mg/kg/day)}^{-1}](0.032\text{ kg/day})(30/70)(0.7)} = 0.46\text{ ppb}$$

The following general equation can be used to calculate Fish Contaminant Goals (in µg/kg) at which the consumption exposure from a chemical with a ***non-carcinogenic effect*** is equal to the reference level for that chemical at any consumption level:

$$\text{Tissue concentration (ppb)} = \frac{\text{(RfD mg/kg-day)(kg BW)(1000 µg/mg)}}{\text{(CR kg/day)(CRF)}}$$

As an example, for mercury, the Fish Contaminant Goal using a consumption rate of one, 8-ounce serving per week (32.0 g/day) for women aged 18 to 45 years and children aged 1 to 17 years would be calculated as follows:

$$\frac{(1x10^{-4}\text{ mg/kg-day})(70\text{ kg BW})(1000\text{ µg/mg})}{(0.032\text{ kg/day})(1)} = 219\text{ ppb}$$

The following general equation can be used to calculate the Fish Contaminant Goals (in mg/kg) at which consumption exposure from a ***nutrient with a non-carcinogenic effect*** is equal to the reference level for that chemical at any consumption level:

Tissue Concentration (ppb) =

$$\frac{\text{[(RfD mg/kg-day)(kg BW) – mg/day Background Dietary Level](1000 µg/mg)}}{\text{(CR kg/day)}}$$

As an example, for selenium, the Fish Contaminant Goal using a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{[(5\times10^{-3}\ \text{mg/kg-day})(70\ \text{kg}) - 0.114\ \text{mg/day}](1000\ \mu\text{g/mg})}{0.032\ \text{kg/day}} = 7{,}375\ \text{ppb}$$

Where,
Risk Level = 1×10^{-6}
BW = Body weight of consumer (70 kg default)
CSF = Cancer Slope Factor
CR = Consumption Rate as the daily amount of fish consumed
CRF = Cooking Reduction Factor (0.7 for organic contaminants in skin-off fillet)
ED/AT = Exposure Duration/Averaging Time (30 yr exposure/70 yr lifetime)
RfD = Chemical specific reference dose or other reference level

POTENTIAL BENEFITS OF FISH CONSUMPTION

Fish consumption advice is generally provided to the public from disparate arms of the biomedical community: physicians and nutritionists, who focus on the health benefits of eating fish, and toxicologists, who concentrate on the risks from exposure to contaminants that may be found in fish. The conflicting messages that often result likely confuse the consumer, who may then ignore recommendations to limit consumption of contaminated fish or, alternatively, avoid eating fish altogether (see, e.g., Oken et al., 2003). Only recently has there been a more focused attempt to craft unified guidance that addresses benefits and risks of fish consumption, although beneficial aspects are generally only discussed qualitatively.

With the discovery in the 1970s that, despite their high fat diet, Greenlandic Eskimos were virtually devoid of ischemic heart disease and diabetes mellitus, came the earliest recognition that fatty acids found in fish and marine mammals may have particular benefits to human health (Bang and Dyerberg, 1972; Dyerberg et al., 1975; Bang et al., 1976; Dyerberg et al., 1978; Dyerberg and Bang, 1979; Bang et al., 1980). The diet and blood lipid profile of the Eskimos were found to be very high in omega-3 fatty acids and very low in omega-6 fatty acids, in direct contrast to a typical "Western" diet in which the reverse is true (Dyerberg et al., 1975; Bang et al., 1980).

Omega-3 fatty acids, such as α-linolenic acid, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are long-chain polyunsaturated fatty acids (PUFAs) with the first double bond inserted at the *third* carbon atom from the methyl end, while omega-6 fatty acids, such as linoleic acid, γ-linolenic acid and arachidonic acid, have the first double bond inserted at the *sixth* carbon atom from the methyl end (IOM, 2005). Fatty acids are designated by their number of carbon atoms, followed by the number of double bonds and the placement of the first double bond. For example, linoleic acid is denoted as 18:2n-6 because it has 18 carbons and two double bonds, with the first double bond located six carbons from the methyl end (the "n" or "omega" position). α-Linolenic (18:3n-3) and linoleic acids cannot be synthesized by humans and are thus required in the diet (IOM, 2005). α-Linolenic acid's only known function is as the precursor to the very long chain PUFAs EPA (20:5n-3) and DHA (22:6n-3), omega-3 fatty acids that are also consumed directly from fish (IOM, 2005). Because the conversion of α-linolenic acid to EPA and DHA is so inefficient (estimated at less than 5 percent) (Wang et al., 2006), and DHA and EPA levels are so low in other foods, fish or fish oil consumption is by far the most important dietary source of these fatty acids (Marszalek and Lodish, 2005). DHA serves as an important structural lipid in nervous tissue, spermatozoa, and the retina, and may be retroconverted to EPA; linoleic acid (18:2n-6), the most common dietary PUFA, is the precursor to arachidonic acid (20:4n-6) (IOM, 2005; Kris-Etherton et al., 2000). Arachidonic acid is also consumed directly from dietary sources such as meat, egg yolk and dairy (Calder, 2006; Richardson, 2006).

Once dietary omega-3 and omega-6 fatty acid precursors are converted *in vivo* to EPA or arachidonic acid, respectively, they can then be metabolized to produce different

eicosanoids, including various prostaglandins, thromboxanes, and leukotrienes, which, in turn, have contravening physiological actions (Robinson and Stone, 2006; Calder, 2006). The omega-3 derived eicosanoids, such as thromboxane A_3 and B_3, prostaglandins PGI_3 and PGE_3, and leukotriene B_5, induce vasodilation, inhibit arrhythmia, decrease platelet aggregation, and are anti-inflammatory. In contrast, eicosanoids derived from omega-6 fatty acids, such as thromboxane A_2 and B_2, prostaglandins PGI_2 and PGE_2, and leukotriene B_4, cause vasoconstriction, are pro-arrhythmic, and increase platelet aggregation and inflammation (Robinson and Stone, 2006; Simopoulos, 1999; DeFilippis and Sperling, 2006). A proper ratio of dietary omega-6 to omega-3 fatty acids is thus imperative to protect health (Simopoulos, 1999; 2002), particularly since high dietary omega-6 levels inhibit the *in vivo* conversion of α-linolenic acid to DHA and EPA (Kris-Etherton et al., 2000). Similarly, high dietary omega-3 fatty acid levels reduce the formation of 2-series eicosanoids from arachidonic acid (IOM, 2005). It has been speculated that conflicting results in clinical trials on the benefits of dietary omega-3 fatty acids may have resulted from failure to take into account background dietary omega-6 fatty acid consumption, high levels of which may inhibit the production of anti-aggregatory eicosanoids and thus undermine the effectiveness of omega-3 fatty acids in disease prevention (Hibbeln et al., 2006).

Humans evolved consuming a diet that was largely equivalent in omega-6 and omega-3 fatty acids. In the 1960s, however, a dramatic shift in the level and composition of dietary fat occurred following the recommendation that saturated fats in the diet be replaced with vegetable oils, such as corn oil and safflower oil, which contain omega-6 to omega-3 ratios greater than 60:1 (Simopoulos, 2001). At the same time, the proportion of farm-raised to wild fish consumption increased (DeFilippis and Sperling, 2006). Farm-raised fish, like farm-raised cows, pigs, and chickens, are often fed diets rich in omega-6 fatty acids and many have tissue omega-6 to omega-3 ratios considerably higher than wild fish of the same species (Hamilton et al., 2005; DeFilippis and Sperling, 2006; Kris-Etherton et al., 2002; Foran et al., 2005; Marszalek and Lodish, 2005). The typical "Western" diet has been estimated to have an omega-6 to omega-3 ratio of 10:1 to 20:1 (Simopoulos, 2003), with a total omega-3 fatty acid consumption of approximately 1.6 g/day (Johnson and Schaefer, 2006). Of that, mean consumption of EPA + DHA is about 0.1 g/day (IOM, 2007). In NHANES 1999-2002, all age/sex population groups were reported to consume an average of less than 0.2 g/day EPA + DHA (IOM, 2007).

Since the Greenlandic Eskimo studies in the 1970s, an explosion of research has examined potential health benefits of fish consumption, with a particular emphasis on omega-3 fatty acids. In 1996, the AHA published their first statement on fish consumption, fish oils, lipids, and coronary heart disease (Stone, 1996). While considering it "premature" at that time to recommend the use of fish oil supplements for the prevention of cardiovascular disease by the general public, the AHA did nonetheless recognize that consumption of marine sources of omega-3 fatty acids seemed "reasonable" because of the low content of saturated fat in fish compared to other meat products and the potential for cardiovascular benefits that might be borne out by future research (Stone, 1996). Subsequently, the most recent AHA statement on the subject

(Kris-Etherton et al., 2002) was strengthened significantly from its original version, as additional research since 1996 has provided even more compelling evidence of the benefits of fish and fish oil consumption.

Currently, the AHA recommends that *individuals without documented coronary heart disease* "eat a variety of (preferably fatty) fish at least twice a week," *individuals with documented coronary heart disease* "consume about 1 g of EPA + DHA per day, preferably from fatty fish (EPA + DHA from capsule form could be considered in consultation with the physician)," and *individuals who need to reduce triglycerides* should consume "two to four grams of EPA + DHA per day provided as capsules under a physician's care" (AHA, 2006). The AHA considers a serving size to be four ounces of fish prior to cooking, or three ounces after cooking, one-half of the serving size typically assumed in fish consumption advisories. The WHO also recommends consumption of 1-2 servings of fish per week (to provide 200-500 mg of EPA + DHA per serving) to protect against coronary heart disease and ischemic stroke (WHO, 2003), while the 2005 Dietary Guidelines Advisory Committee (DGAC) Report concludes that "consumption of two servings (approximately eight ounces) per week of fish high in EPA and DHA is associated with reduced risk of both sudden death and CHD (coronary heart disease) death in adults." The Committee further states that "to benefit from the potential cardioprotective effects of EPA and DHA, the weekly consumption of two serving of fish, particularly fish rich in EPA and DHA, is suggested" (DGAC, 2005). In their report assessing the risks and benefits of fish consumption, the Scientific Advisory Committee on Nutrition (SACN) of the Food Standards Agency and Department of Health in the United Kingdom recommends that all individuals, including pregnant women, "eat at least two portions of fish per week, of which one should be oily," providing approximately 450 mg/day long chain omega-3 fatty acids (SACN, 2004; see also IOM, 2007, for additional discussion).

Presented below is a brief summary of many of the potential benefits of fish or fish oil consumption, given the current state of scientific knowledge. This review is not intended as an exhaustive evaluation of the merits and weaknesses of the vast number of articles on this subject, but merely to be illustrative of significant, and generally recent, research or review articles in the field. Many studies are observational, as is also commonly the case with human toxicity studies on fish contaminants, and cannot prove cause and effect relationships with certainty. Even randomized controlled trials (RCTs), the gold standard of human medical experimentation, may suffer in the case of fish or fish oil studies from the inability to blind the subject to the treatment. Although current scientific consensus recommends fish consumption as a likely way to prevent specific chronic disease conditions, it is unclear to what extent potential benefits from fish or fish oil consumption listed below may be realized through the following mechanisms: increased consumption of omega-3 fatty acids, decreased dietary omega-6 to omega-3 fatty acid ratio (as generally occurs to a lesser extent with fish oil supplementation and to a greater extent with fish consumption), simple replacement of other high fat dietary protein sources with fish, or other nutritive or non-nutritive factors that may covary with fish consumption

(e.g., an overall healthy lifestyle). Many of these issues are discussed in the recent IOM report on balancing the risks and benefits of seafood consumption (IOM, 2007).

Cardiovascular Disease and Total Mortality:

The most thoroughly evaluated potential beneficial effect of fish or fish oil consumption has been on the prevention and treatment of cardiovascular disease. In a recent meta-analysis, Hooper et al. (2006) concluded that evidence to date does not support the position that short or long chain omega-3 fatty acids have a clear effect on this condition. Numerous researchers criticized this review, however, particularly with respect to inappropriate pooling of study participants, outcomes, and marine- and plant-based omega-3 fatty acids, as well as the inclusion of a "methodologically poor" study, which, in and of itself, "changed the conclusion of the meta-analysis from clear benefit to no benefit" (Deckelbaum and Akabas, 2006; Geleijnse et al., 2006; He and Song, 2006; Twisselmann, 2006; von Schacky et al., 2006). A subsequent systematic review of the literature addressed some of these shortcomings (Deckelbaum and Akabas, 2006). After evaluating 46 studies meeting strict selection criteria, Wang et al. (2006) found that omega-3 fatty acids from fish or fish oil supplements, but not α-linolenic acid, appeared to reduce the risk of all-cause mortality, cardiac and sudden death, and stroke. Because RCTs on the effects of omega-3 fatty acids in individuals already suffering from cardiovascular disease (secondary prevention) have been conducted, the strength of the evidence for that outcome is greater than that for prevention of cardiovascular disease in healthy individuals (primary prevention), for which only cohort studies are available (Wang et al., 2006). Mozaffarian and Rimm (2006) also reported that evidence generated from pooling published prospective or randomized primary and secondary prevention trials indicated that consumption of 250 to 500 mg/d of EPA + DHA reduced the relative risk of coronary heart disease death by 36 percent compared to little or no EPA + DHA intake. Additional intake did not appear to confer additional benefits; risk reduction was most closely linked to consumption of fatty fish, not lean fish. Other recent meta-analyses or systematic literature reviews have supported the conclusion that omega-3 fatty acid consumption has a significant beneficial effect on cardiovascular disease (He et al., 2004a; Bucher et al., 2002; Jacobson, 2006; Whelton et al., 2004; Konig et al., 2005; Harper et al., 2005).

Several studies have suggested that mercury may attenuate cardioprotective effects of omega-3 fatty acids in fish (e.g., Salonen et al., 1995; Rissanen et al., 2000; Guallar et al., 2002; Virtanen et al., 2005), particularly in Finnish men, although at least one study did not find such an association (Yoshizawa et al., 2002). Current evidence suggests that fish or fish oils provide more health benefits to those individuals who also have low methylmercury body burdens (IOM, 2007).

Stroke:

Early research on the potentially protective effects of omega-3 fatty acid and/or fish consumption and stroke showed conflicting results (see, for example, Gillum et al., 1996;

Keli et al., 1994; Orencia et al., 1996). This may have occurred, in part, because of a failure to differentiate ischemic and hemorrhagic strokes in study populations (He et al., 2004b), which are caused by opposing mechanisms. A recent meta-analysis of nine cohorts suggested that fish consumption and ischemic stroke were inversely related, with the possibility that as few as one to three fish meals a month might significantly reduce the incidence of this disorder (He et al., 2004b). In a study of 79,839 women, Iso et al. (2001) found that risk of thrombotic infarction was decreased 48 percent for women who ate fish two to four times per week compared to those who ate fish less than once per month. In another analysis of published studies, Bouzan et al. (2005) found that any fish consumption provided significant reduction in stroke risk compared to no fish consumption. The authors noted that an incremental increase in fish consumption may reduce stroke risk even further. In a review of the literature, Wang et al. (2006) found that studies on the effect of marine-based omega-3 fatty acids on stroke were not consistent, but suggested a possible role of fish or fish oils in the prevention of stroke.

Cognitive Function:

Brain tissue is highly enriched in DHA, which is considered essential for the functional development of neural tissues. Much of DHA and other long chain PUFA content of fetal brain is obtained from the maternal blood supply, as *in vivo* synthesis from shorter chain PUFAs is minimal during this period (Cheruku et al., 2002; Marszalek and Lodish, 2005; Uauy and Dangour, 2006). Studies have suggested that fish consumption by the mother during pregnancy or by the young child may improve several neurological outcomes during early development (Mozaffarian and Rim, 2006). Language and social skills, for example, were higher in 6- and 12-month-old infants who ate fish once or more per week compared to those who rarely or never ate fish (Daniels et al., 2004). Maternal fish intake was also positively associated with infant cognitive scores in this study. Sleep-state patterns indicative of greater cognitive maturity were seen in infants whose mothers had higher plasma phospholipid DHA levels compared to those whose mothers had lower plasma phospholipid DHA levels (Cheruku et al., 2002). Oken et al. (2005) showed that infant cognitive scores were positively correlated with fish consumption, but inversely related to maternal hair mercury concentrations. Scores were highest among infants whose mothers had hair mercury concentrations of 1.2 ppm or less and consumed two or more fish meals per week. Conversely, scores were lowest among infants whose mothers had hair mercury concentrations greater than 1.2 ppm and ate two or fewer fish meals per week. Hibbeln et al. (2007) found that, after adjusting for 28 potentially confounding variables, the risk of suboptimal scores for verbal intelligence, prosocial behavior, fine motor, communication, and social development in children six months to eight years old was greater when maternal fish consumption was less than 340 g per week compared to when maternal fish consumption was greater than 340 g per week.

Several studies have shown that DHA levels are reduced in brain and plasma of patients with Alzheimer disease (AD) or other forms of dementia (Johnson and Schaefer, 2006). Potential mechanisms by which these fatty acids may modify the risk for dementia include the prevention or reduction of atherosclerosis, thrombosis, and inflammation

(Barberger-Gateau et al., 2002). In one of the first studies to investigate the potential relationship between fish consumption and dementia, Kalmijn et al. (1997) found that the incident risk of developing all forms of dementia was reduced 60 percent in people 55 years or older who consumed 18.5 or more g/day of fish compared to those consuming 3.0 or fewer g/day fish. The risk for developing AD without cerebrovascular disease in these respective populations was reduced 70 percent. Similarly, Morris et al. (2003) found that people who ate fish at least once per week reduced their risk of incident AD by 60 percent compared to those who rarely or never ate fish. In a subsequent study using the same population group, fish consumption was also found to be significantly inversely related to expected cognitive decline in individuals 65 years and older over a six year period (Morris et al., 2005). Fatty fish consumption and EPA + DHA consumption were also inversely related to mild cognitive decline in a cross-sectional study of middle-aged males and females (Kalmijn et al., 2004). Huang et al. (2005) specifically showed that fatty fish consumption, but not consumption of lean or fried fish, decreased the risk of dementia in a dose-dependent fashion in individuals who did not carry the *APOE* ε4 allele (a risk factor for AD). Fatty fish consumption more than twice per week decreased the risk of incident dementia and AD by 28 and 41 percent, respectively, compared to those eating fish less than once per month. Using a more accurate estimate of omega-3 fatty acid exposure, Heude et al. (2003) found that omega-3 fatty acid concentration and omega-3 to omega-6 ratio of erythrocyte membranes was inversely related to cognitive decline in 63-74 year-old men and women over a four year period.

Although omega-3 fatty acids are often considered the physiologically active agents responsible for positive health effects of fish, some research indicates that other components may have benefits as well. For example, fish, but not omega-3 fatty acid, consumption was inversely associated with a reduced rate of cognitive deterioration over a six-year period in a study of 6,158 males and females, aged 65 or older (Morris et al., 2005). Consumers who ate fish once a week or more maintained the mental status of a person three to four years younger compared to those who ate fish less than once a week.

Preliminary studies have found that omega-3 fatty acids mitigate symptoms in some children with attention-deficit/hyperactivity disorder; however, other studies have not supported these results (Richardson, 2006; Young and Conquer, 2005). Additionally, several epidemiological studies and intervention trials have shown that fish or omega-3 fatty acid consumption may be useful for the prevention or treatment of depression or other mood disorders, which may reflect the well-recognized link between depression and cardiovascular disease (see Parker et al., 2006; Nemets et al., 2006). Numerous authors have reported decreased blood omega-3 fatty acid levels in patients with psychiatric disorders (Tiemeier et al., 2003; Peet and Stokes, 2005; Sublette et al., 2006; Young and Conquer, 2005; Richardson, 2006). Additional research is needed to elucidate the potential role of fish or fish oils in the treatment of neuropsychiatric disorders (Parker et al., 2006; Richardson, 2006; Young and Conquer, 2005).

Visual Function:

DHA is found in very high concentrations in the retina and has a functional role in visual development (Connor et al., 1992; Neuringer, 2000; Cho et al., 2001; Uauy and Dangour, 2006; Johnson and Schaefer, 2006). As noted above, fetal DHA is largely obtained through the maternal blood supply and, postnatally, through breast milk (Marszalek and Lodish, 2005). The degree to which DHA supplementation of infant formulas is necessary or beneficial is not known (Mozaffarian and Rimm, 2006), although the evidence supporting its benefit for preterm infants is more persuasive than it is for term infants (Heird and Lapillonne, 2005; Cheatham et al., 2006). A recent meta-analysis of 14 controlled trials of DHA supplementation of infant formulas showed a strong positive relationship between DHA dose and visual acuity measurements in four-month-old infants (Uauy et al., 2003). Some studies show that the relationship between low dietary omega-3 fatty acids and slowed development of visual acuity may be transitory; however, long-term sequelae of early visual impairments that may occur with low-DHA diets have not been studied and could be significant (Neuringer, 2000).

Numerous studies have also shown that fish and/or omega-3 fatty acid consumption provides benefits to the aging eye and may protect against retinal pathologies associated with ischemia, light, oxygen, inflammation, and age (SanGiovanni and Chew, 2005). Age-related macular degeneration (AMD) is the primary cause of visual disability and blindness in older Americans (Chua et al. 2006; Seddon et al., 2006). In a cross-sectional population-based study, Smith et al. (2000) reported that individuals consuming fish more than once per week were at significantly lower risk of developing late AMD than individuals consuming fish less than once per month. Similarly, in two large prospective cohort studies, fish consumption was inversely related to AMD development; consumption of four or more servings per week reduced the risk of AMD 35 percent compared to eating fish three or fewer times per week. DHA consumption had a smaller, but still significant, inverse relation with AMD development, indicating that substances in fish other than fatty acids may also decrease AMD risk (Cho et al., 2001). In prospective cohort and case control studies, Seddon et al. (2001; 2003; 2006) showed that the risk for development and progression of AMD was significantly reduced or slowed, respectively, with increasing fish or omega-3 fatty acid consumption. In two of the three studies, however, this relationship existed only if consumption of linoleic acid was also low, indicating that the omega-6 to omega-3 ratio may be an important component to the protective effect of omega-3 fatty acids in the development and progression of this disease (Seddon et al., 2006). Chua et al. (2006) found that weekly fish consumption reduced the 5-year incidence of early AMD about 40 percent, while eating fish three times per week or more reduced the 5-year incidence of late AMD about 75 percent. In a review of published studies, Hodge et al. (2006) found that, while there is evidence to suggest that omega-3 fatty acids may play a role in prevention of AMD, variability among studies and the lack of a RCT prevent clinical conclusions from being drawn.

Inflammatory Diseases:

The effect of omega-3 fatty acids on inflammation and inflammatory diseases has been recently reviewed (Ariza-Ariza et al., 1998; Calder, 2006; Cleland et al., 2005; Simopoulos, 2002). Omega-3 fatty acids have been theorized to be useful as anti-inflammatory agents because they generate anti-inflammatory mediators, decrease production of arachidonic acid-derived pro-inflammatory eicosanoids, and modify the expression of inflammatory genes (Calder, 2006). Research has strongly supported the role of long-chain omega-3 fatty acids in the treatment of rheumatoid arthritis (Calder, 2006), including the reduced need for traditional non-steroidal anti-inflammatory drugs (NSAIDS) in patients taking sufficient doses of fish oils (Ariza-Ariza et al., 1998; Cleland, 2005; 2006). However, the data are less robust for the use of long chain omega-3 fatty acids in the treatment of other inflammatory diseases, such as inflammatory bowel disease or asthma, and additional clinical trials are recommended to further define their potential role in the treatment of these conditions (Calder, 2006). Currently, the effective dose for anti-inflammatory effect in rheumatoid arthritis is estimated to be 2.7 g/day EPA + DHA (Cleland, 2005), a dose not easily obtainable through fish consumption alone. It is recommended that this dose not be achieved through the use of cod liver oil supplementation because of the high vitamin A concentration of this product (Cleland, 2005). The shorter chain α-linolenic acid has not been shown to possess anti-inflammatory properties at practical intakes (Calder, 2006).

CONSIDERATION OF THE RISKS AND BENEFITS OF FISH CONSUMPTION

Since the recognition in the 1960s and 1970s that dietary fish might play a significant role in both health and disease, a vast number of studies have been conducted on the benefits and risks of fish consumption. As noted above, though, these areas of research are typically evaluated independently. Risk assessments on contaminants found in fish are occasionally published in the peer-reviewed literature (e.g., Hites et al., 2004; Mahaffey et al., 2004; Knobeloch et al., 2006); a recent risk assessment of organic contaminants in wild and farmed salmon (Hites et al., 2004) sparked intense controversy over whether the known benefits of fish consumption had been adequately considered in comparison to the relatively small lifetime cancer risks associated with organochlorine compounds (Stokstad, 2004; Rembold, 2004; Tuomisto et al., 2004; Lund et al., 2004; Foran et al., 2006; Willett, 2005; 2006). Recently, a few authors have published risk-benefit analyses for fish consumption that considered one or more contaminants and incorporated a quantitative estimate of benefit (Anderson and Wiener, 1995; Foran et al. 2005; Cohen et al., 2005; Gochfeld and Burger, 2005; Ponce et al., 2000; Sidhu, 2003). Using one method of calculating the combined risks and benefits of fish consumption, for example, Foran et al. (2005) found that consumption of farmed salmon was estimated to prevent nearly 300 times more cardiac-related deaths than it potentially caused from PCB-associated cancer. In most assessments, the comparative risks of alternate foods are not taken into account. Other sources of animal protein that may be consumed in place of fish, such as beef, pork, or chicken, also contain undesirable components (e.g., PCBs, dioxins, saturated fat, and hormone or antibiotic residues) whose risk has not been characterized or estimated in a fashion similar to that of fish.

As early as 1986, OEHHA held a workshop on balancing the risks and benefits of fish consumption (CDHS, 1988). In more recent years, OEHHA, and similar agencies from other states, have incorporated benefit statements into their fish consumption advisories that assure the public that fish should be part of a healthy diet. In a technical memorandum describing the derivation of a noncommercial fish consumption recommendation for women who may become pregnant, pregnant women, nursing mothers, and young children, U.S. EPA and FDA noted that their advice "balances the risk from mercury with the benefits of fish" (U.S. EPA, 2004).

Conclusions:

OEHHA determines that there is a significant body of evidence and general scientific consensus that eating fish at dietary levels that are easily achievable, but well above national average consumption rates, appears to promote significant health benefits, including decreased mortality**.** As is the case with all foods, fish contain constituents that may be harmful when consumed in unrestricted quantities. However, because of the unique health benefits associated with fish consumption, the advisory process should be

expanded beyond a simple risk paradigm in order to best promote the overall health of the fish consumer.

ADVISORY TISSUE LEVELS FOR CHLORDANE, DDTs, DIELDRIN, METHYLMERCURY, PCBs, SELENIUM, AND TOXAPHENE

To include the benefits of fish consumption in the advisory process, ATLs were calculated for each of the contaminants for which FCGs were derived. In comparison to FCGs, which were based on a single meal frequency, ATLs were calculated for several meal frequency categories that are used to provide advice to the consumer that balances the benefits and risks of fish consumption. This yields a range of corresponding contaminant concentrations in fish within categories as shown in Table 2. ATLs were calculated using the same general formulas as those used to calculate FCGs, with some adjustments in order to incorporate the benefits of fish consumption. Because benefits are integrated differently into ATL equations for cancer and non-cancer risk, these methods are discussed separately. All factors and assumptions not specifically addressed are the same as those used to develop FCGs.

Cancer Risk:

$$\text{Tissue concentration (ppb)} = \frac{\text{(Risk Level)(kg BW)(1000 µg/mg)}}{\text{[CSF (mg/kg/day)}^{-1}\text{] (CR kg/day)(ED/AT)(CRF)}}$$

Risk Level:

For FCGs, the maximum risk level was set at $1x10^{-6}$, estimating that, at the given consumption rate, not more than one additional cancer case would be expected in a population of one million people consuming fish over a lifetime. OEHHA acknowledges that, while it should be a goal to maintain a risk level of $1x10^{-6}$ for fish and other foods, the counterbalancing nutritional benefits of foods, particularly the unique benefits of fish, must be considered. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued through fish consumption.

Thus, OEHHA concludes that, for the purposes of developing fish consumption advisories, ATLs should be calculated using a maximum risk level of $1x10^{-4}$, estimating that, at the given consumption rate, not more than one additional cancer case would be expected in a population of 10,000 people consuming fish over a lifetime. This risk level is within the acceptable range of risks ($1x10^{-4}$ to $1x10^{-6}$) used by U.S. EPA in regulatory criteria for drinking water (Fed. Reg., 1998) and is provided as an example of a maximum acceptable risk level in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories (U.S. EPA, 2000a). OEHHA considers that a maximum risk level of $1x10^{-4}$ appropriately balances the cancer risk associated with fish consumption with the numerous known health benefits that can be accrued from eating fish. Because each meal frequency category encompasses a range of fish

contaminant levels (see consumption rate discussion and ATL table below), fishers, over time, will be exposed to a range of risk levels as they catch and eat different fish. Thus, when the *maximum* risk level is set at $1x10^{-4}$ for each meal frequency category, the actual *average* cancer risk for fish consumers over their lifetime is less than $1x10^{-4}$ (ranging from approximately $5x10^{-5}$ to $1x10^{-4}$), when consumption advisories are based on carcinogens detected in fish.

Consumption Rate (CR):

FCGs were calculated using a single consumption rate (32 g/day, or a single serving of eight ounces of fish, prior to cooking, per week) aligning with the AHA's minimum recommended fish consumption rate for adults and exceeding the typical consumption rate for the vast majority of sport fishers (see, for example, SFEI, 2000). This consumption rate is also used to begin issuing fish consumption advisories that are based on cancer risk using the ATLs and other considerations. Because OEHHA also considers it important to offer advice for the small segment of fishers who choose to consume fish more frequently than one 8-ounce serving per week, ATLs for two and three 8-ounce servings per week, prior to cooking (64 and 96 g/day, respectively), were also calculated based on cancer risk.

Example Calculation:

Using a risk level of $1x10^{-4}$, the slope factor for each chemical, and consumption rates of 32, 64, and 96 g of fish/day in the above equation will yield three numbers that are the cutoff values for one, two, and three servings per week, respectively, for cancer risk.

As an example, for dieldrin, the ATL using a risk level of $1x10^{-4}$ and a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{(1x10^{-4})(70\text{ kg})(1000\ \mu g/mg)}{[16\ (mg/kg/day)^{-1}](0.032\text{ kg/day})(30/70)(0.7)} = 46\text{ ppb}$$

Thus, fish containing 46 ppb dieldrin, or less, can be consumed in the amount of at least one, 8-ounce serving per week.

Non-Cancer Risk:

$$\text{Tissue concentration (ppb)} = \frac{(\text{RfD mg/kg-day})(\text{kg BW})(1000\ \mu g/mg)}{(\text{CR kg/day})(\text{CRF})}$$

Hazard Quotient and Consumption Rate:

For FCGs, the maximum HQ was set at 1, indicating that the *maximum* exposure (based on CR in the equation) is equivalent to the RfD. In order to balance the risks and benefits

of fish consumption when considering non-cancer risk, however, OEHHA determined that the *average* exposure should be equivalent to the RfD. With the ATLs, each meal frequency category (one, two and three servings per week) encompasses a range of fish contaminant levels, as noted above. Thus, fishers over time will be exposed to a range of HQs as they catch and eat different fish. When the *maximum* HQ for each meal consumption frequency is set at 1, using the maximum consumption rate in the equation (32, 64, and 96 g/day for one, two, and three servings per week, respectively) to set the cutoff for each meal frequency leads to an actual *average* HQ for fish consumers, over a multiple week basis, of less than 1. This is because the majority of fish caught in each meal frequency category will have a lower contaminant level than the maximum contaminant level used to set the cutoff. However, if the cutoffs are adjusted slightly so that the *average* rather than the maximum HQ is 1, over a multiple week basis, and an acceptable maximum HQ is still maintained, fishers who follow the advice will be able to consume a greater amount of fish and consequently enjoy a higher level of health benefits without incurring significant non-cancer risks from contaminants in fish.

U.S. EPA adjusted a meal frequency cutoff to establish its national advisory for mercury of one serving per week of sport fish from untested water bodies. They combined several meal categories (two, three and four servings per month), as do many states, in order to balance the risks and benefits of fish consumption and simplify communication (U.S. EPA, 2004). U.S. EPA used the contaminant concentration that would otherwise be associated with a recommendation of two servings per month as the cutoff for the one serving per week advice. Although this results in an HQ higher than 1 for some fish that fall into the 1 serving per week category, this advice is still health protective because, on average, fishers will be consuming fish with lower mercury levels than those used to establish the one serving per week cutoff.

OEHHA incorporated an "average HQ" concept into the ATLs by modifying the fish consumption rate used in the ATL equation. As explained above, one, 8-ounce serving of fish per week is equivalent to a consumption rate of 32 g/day. Consumption of two servings of fish per month would be equivalent to 0.5 servings per week, or 16 g/day. Following the example of U.S. EPA in their national advisory (see above), OEHHA also used a 16 g/d consumption rate to calculate the cutoff for the one serving per week category when considering non-cancer risk for the ATLs. As can be seen in the sample calculation below, this allows for greater consumption of fish (and a better balancing of risks and benefits) than if a consumption rate of 32 g/day were used. In a similar fashion, OEHHA used a consumption rate of 48 g/day (approximately 1.5 servings per week) to compute the ATLs for the two servings per week category for non-cancer risk. A consumption rate of 96 g/day was used, as it was for cancer risk, to determine the ATLs for three servings per week. As a consequence of making these adjustments, the *average* HQ, over the entire range of potential exposures, is approximately 1. OEHHA considers this average HQ appropriate to balance the risk and benefits of fish consumption when considering non-cancer risk.

Example Calculation:

Using the RfD for each chemical, and consumption rates of 16, 48, and 96 g/day, in the above equation will yield three numbers that are the cutoff values for one, two, and three servings per week, respectively, for non-cancer risk.

As an example, for mercury, the ATL for one, 8-ounce serving per week for women aged 18-45 years would be calculated as follows:

$$\frac{(1\times10^{-4}\ \text{mg/kg-day})(70\ \text{kg BW})(1000\ \mu\text{g/mg})}{(0.016\ \text{kg/day})(1)} = 440\ \text{ppb}$$

Thus, fish containing 440 ppb mercury, or less, can be consumed in the amount of at least one, 8-ounce serving per week.

Final ATL Calculations:

For each chemical, ATLs were calculated separately for cancer and non-cancer risk, if appropriate, for consumption frequency categories of one, two, and three 8-ounce servings per week. Values for cancer and non-cancer risk were then compared to determine whether the cancer or non-cancer value was the most health-protective. For all chemicals except DDTs, either cancer or non-cancer risk determined the ATL for each consumption frequency category. For DDTs, consumption advice for one serving per week was based on cancer risk, while consumption advice for two and three servings per week was based on non-cancer risk.

OTHER CONSIDERATIONS USED IN THE DEVELOPMENT OF FISH CONSUMPTION ADVISORIES AND SAFE EATING GUIDELINES

ATLs are used as part of the process to develop traditional health advisories (which focus on fish whose consumption should be restricted or avoided altogether) as well as the newer "safe eating guidelines," which inform consumers of fish with low contaminant levels considered safe to eat frequently. Other factors, including the following, will also be used by OEHHA to develop advisories and safe eating guidelines, as appropriate.

Omega-3 Fatty Acid Levels:

The fatty acid content of fish is highly variable within and among species; fish diet, sex, age, and reproductive status, as well as location and season all affect the total concentration and composition of tissue fat (Nettleton, 1995). At the present time, omega-3 fatty acids levels are not available specifically for California sport fish, although applicable national averages have been published for some species. If acceptable surrogate or actual omega-3 fatty acid data exist for California sport fish, this information may be used to alter fish consumption advice. For example, OEHHA may recommend higher consumption of fish with high omega-3 levels than fish with identical levels of contaminants but lower omega-3 levels.

Contaminant Data:

Once the consumption frequency categories and ATLs are established, the data must then be carefully examined to determine what contaminant values will be compared to the ATLs. Fish contaminant data collected from a water body are often highly variable, reflecting environmental factors such as seasonal effects and localized sources or sediment methylation processes. Evaluating these data prior to developing site-specific (water body) or regional consumption advice is a complex process that may involve one or more approaches. The most common and simplest method of interpreting fish contaminant data collected from a site is to calculate a value of central tendency such as the geometric mean, arithmetic mean, median or mode. OEHHA often uses the arithmetic mean for developing safe eating guidelines; however, each of these measurements is helpful in interpreting the distribution of the data. Another method of interpreting a data set is to examine the regression line between species length and chemical contaminant level. Consumption guidance can then be tailored to different fish size classes or to the predicted contaminant concentration of the most typical length of fish consumed, provided adequate creel data are available to make this determination. This method is most useful for contaminants, such as mercury, where the concentration is largely dependent on fish size in specific fish species.

After careful selection of an appropriate contaminant concentration for each species at a site (e.g., an arithmetic mean, mode or a regression analysis), that value or values can then be compared to the range of concentrations presented in the ATL table (Table 2).

Risk Communication:

After thorough evaluation of fish contaminant data for a site and comparison of appropriate contaminant values to the ATLs, OEHHA may determine that strict adherence to established consumption frequency categories results in consumption advice that is too complex for the fisher to follow, particular for large water bodies. In these cases, OEHHA may make minor adjustments to recommended consumption limits for a species in order to best facilitate communication. For example, if contaminant levels in a species vary along a discreet coastal region, OEHHA may choose the most restrictive or most common advice for that species for the entire region, depending on circumstances and communication considerations. Additionally, in safe eating guidelines, fishers who do not skin or cook their fish may be advised to consume less fish than guidelines recommend for their population group, if organochlorine contaminants are present in quantities that affect consumption guidelines. Skinning and cooking do not reduce methylmercury concentrations in fish tissue. Serving sizes are based on fish consumption by an average 160 pound person. Individuals weighing less than 160 pounds will be encouraged to eat proportionately smaller amounts. As noted previously, because of their smaller body weights, children will be advised to eat approximately one-half as much fish (in either quantity or frequency) as are women of childbearing age.

Conclusions:

The ATLs described in this report should not be misinterpreted as static “bright lines” that others can use to duplicate state fish consumption advisories. As noted, ATLs are but one component of a complex process of data evaluation and interpretation used by OEHHA in the assessment and communication of fish consumption risks. The nature of the contaminant data or omega-3 fatty acid concentrations in a given species in a water body, as well as risk communication needs, may alter strict application of ATLs when developing site-specific advisories. For example, OEHHA may recommend that consumers eat fish containing low levels of omega-3 fatty acids less often than the ATL table would suggest based solely on contaminant concentrations. OEHHA will use the guidelines set forth in this report as a framework, along with best professional judgment, to provide fish consumption guidance on an *ad hoc* basis that best combines the needs for health protection and ease of communication for each site.

Table 2. Advisory Tissue Levels (ATLs) for Selected Fish Contaminants Based on Cancer or Non-Cancer Risk Using an 8-Ounce Serving Size (Prior to Cooking) (ppb, wet weight)				
Contaminant	**Three 8-ounce Servings* a Week**	**Two 8-ounce Servings* a Week**	**One 8-ounce Servings* a Week**	**No Consumption**
Chlordane[c]	≤190	>190-280	>280-560	>560
DDTs[nc**]	≤520	>520-1,000	>1,000-2,100	>2,100
Dieldrin[c]	≤15	>15-23	>23-46	>46
Methylmercury (Women aged 18-45 years and children aged 1-17 years)[nc]	≤70	>70-150	>150-440	>440
Methylmercury (Women over 45 years and men)[nc]	≤220	>220-440	>440-1,310	>1,310
PCBs[nc]	≤21	>21-42	>42-120	>120
Selenium[nc]	≤2500	>2500-4,900	>4,900-15,000	>15,000
Toxaphene[c]	≤200	>200-300	>300-610	>610

[c]ATLs are based on cancer risk
[nc]ATLs are based on non-cancer risk
*Serving sizes are based on an average 160 pound person. Individuals weighing less than 160 pounds should eat proportionately smaller amounts (for example, individuals weighing 80 pounds should eat one 4-ounce serving a week when the table recommends eating one 8-ounce serving a week).
**ATLS for DDTs are based on non-cancer risk for two and three servings per week and cancer risk for one serving per week.

Tabled values are rounded based on laboratory reporting of three significant digits in results, where the third reported digit is uncertain (estimated). Tabled values are rounded to the second digit, which is certain. When data are compared to this table they should also first be rounded to the second significant digit as in this table.

APPENDIX 1: RESPONSE TO COMMENTS

Comments and Responses to the Original Draft Document:
Development of Guidance Tissue Levels and Screening Values for Common Contaminants in California Sport Fish:
Chlordane, DDTs, Dieldrin, Methylmercury, PCBs, Selenium, and Toxaphene.

Commenter 1:
Sheila Hamilton
General Manager
Big Bear Municipal Water District
P.O. Box 2863
Big Bear Lake, CA 92315

Comment 1.1
Because the final guidance tissue levels and screening values will, no doubt, play a significant role in future regulatory decisions throughout the state, we urge OEHHA to be more specific on the proper and improper use of these proposed thresholds. For example, the State Water Resources Control Board recently misinterpreted OEHHA's screening values (SVs) as thresholds defining impaired water quality. The report does not caution against using the screening values as informal Water Quality Objectives or Maximum Contaminant Levels.

Response 1.1
OEHHA has reconsidered the usefulness of establishing SVs as part of our protocol to develop fish consumption recommendations and determined that the SVs should be removed from the final document. We are providing Fish Contaminant Goals that can be used as a starting point for agencies to develop fish tissue-based criteria. Agencies that require screening criteria for mandated activities may still seek OEHHA's advice for their development. Any screening criteria employ numerous assumptions, particularly the consumption rate and risk level, and may be targeted to different population groups. These issues must be considered and agreed upon as relevant to the purpose of the criteria prior to their development and use by any agency.

Comment 1.2
The draft document was developed using a wide variety of assumptions. We recommend that these assumptions be summarized in a single table.

Response 1.2
The assumptions are explained carefully and individually in the text where they are used, which is considered most appropriate.

Comment 1.3
Table 1 shows a range of recommended GTLs that vary in relation to the average amount of fish consumed in a month. The presentation should be expanded to show how changes in other key assumptions will cause the GTL or SV to increase or decrease.

Response 1.3
While Fish Contaminant Goals (FCGs) and GTLs (now the Advisory Tissue Levels, or ATLs) will change if the assumptions change, the assumptions made by OEHHA in development of this document are fairly standard in risk assessment and have been clearly described in the document. As OEHHA is responsible for issuing sport fish consumption guidelines in the state of California, there is no reason to present alternative assumptions that will not be used to issue fish consumption advice.

Comment 1.4:
We recommend that OEHHA develop a simple spreadsheet tool, based on the equations shown on page 39-40 (now page 43-44) of the draft report, that allow end users to modify the underlying assumption and graph the range of recommended values. With minor modifications, that tool could be adapted for general use by other state agencies.

Response 1.4:
As noted previously, it is OEHHA's mandate to issue health advisories for sport fish consumption in the State of California. As such, OEHHA is the only "end user" of the GTLs (now ATLs), although the ATLs may be used by counties to issue interim advice in consultation with OEHHA. The sole purpose of releasing the document was to improve transparency of the fish advisory process, not to provide other agencies with a tool to provide their own fish consumption advice to the public. To prevent such confusion in the future, OEHHA will rename the final document: Development of Fish Contaminant Goals and Advisory Tissue Levels for Common Contaminants in California Sport Fish: Chlordane, DDTs, Dieldrin, Methylmercury, PCBs, selenium, and toxaphene. OEHHA recognizes that use of the word "guidance" in Guidance Tissue Level has led some to think that this is a "guidance document" to be used by other agencies in developing their own advisories. We are making the change to correct this misinterpretation.

Comment 1.5:
The draft document does not describe what constitutes "sufficient fish tissue data" (p. 2) nor does it provide an explanation as to how to perform the highly-specialized risk analyses recommended.

Response 1.5:
The GTL (now ATL) document is not intended as a guidance document to be used by other agencies (see response to comments above) to develop their own advisories. OEHHA performs the risk analyses; recommendations provided to other agencies responsible for data collection and analyses are provided in another document (Gassel and Brodberg, 2006; General Protocol for Sport Fish Sampling and Analysis). Because each water body is unique, agencies should consult OEHHA prior to collecting fish from

California water bodies so that OEHHA can direct sampling and analysis to collect data sufficient to adequately estimate human health risks. The discussion of sampling and analysis has been removed from the document.

Comment 1.6:
We are concerned that OEHHA elected to make very large adjustments to the estimated reference dose to account for various "uncertainty factors." The published GTLs and SVs should be presented with and without such adjustments so that it is clear to other state agencies that a safety factor has already been applied. Otherwise, it is likely that other agencies will incorrectly assume that the GTL or SV represents the No-Observed-Effect-Threshold and seek to add on their own safety factors. It would be useful to explain that the magnitude of adjustment applied was somewhat arbitrary. Higher or lower multipliers may be equally well justified.

Response 1.6:

Uncertainty factors (UFs) are always included in the development of an RfD. After evaluating the original toxicity data, toxicologists apply uncertainty factors to the point of departure value (e.g., the NOAEL or LOAEL), taking into account any deficiencies in the data (such as short-term exposure, the use of an animal model, or lack of a reproductive study) in order to arrive at the RfD. UFs are not arbitrary but are routinely and rather consistently applied using accepted risk assessment principles. With the exception of toxaphene and chlordane, the UFs and RfDs used for each chemical in this document were originally developed by U.S. EPA and are in general use by the risk assessment community. After reviewing the most current literature, OEHHA has chosen to maintain these RfDs. Again, other agencies should not attempt to modify OEHHA advisories by manipulating any of the parameters used by OEHHA in developing the advisories.

Comment 1.7:
It is unclear if OEHHA considered the published recommendation of other federal agencies (e.g., FDA's less restrictive "Action Levels") and, if so, why those recommendations were rejected. Nor is it clear why OEHHA declined to use EPA's more stringent recommendations.

Response 1.7:

OEHHA conducted a thorough evaluation of federal and other state's methods of providing fish consumption recommendations and selected methods that appropriately balanced benefits and risks. FDA action levels are not appropriate for setting sport fish consumption guidelines. In their guidance document, U.S. EPA does not propose a single, specific method of providing fish consumption recommendations but, instead, illustrates one possible scenario using only the RfD and a risk level of 1×10^{-5}. The U.S. EPA acknowledges that states and tribes may modify this method in multiple ways to make it more or less conservative as they see fit. Examples of RLs from 10^{-4} to 10^{-7} are also included in their guidance document. OEHHA uses the most up-to-date data and

methodology and considers sensitive populations. OEHHA's advisories are within the range of guidance provided by U.S. EPA but, in several cases, are more conservative.

Comment 2.1
Clarification of the reduction factor for organic chemicals for skinning of fillets is needed. You have applied a reduction factor to your GTL calculations that assumes people consume fish as skin-off fillets. Since you assume a 30% reduction due to contaminant loss during cooking and you assume a 50% loss due to cooking and skinning combined, skinning alone appears to account for about a 20% reduction in contaminants in your calculations. This reduction factor for skinning should be explicitly stated.

Response 2.1
Data on the contaminant reduction achieved by various trimming and cooking techniques are variable. It is known that removing the skin and associated fat as well as cooking remove a significant amount of organic contaminants. The general cooking reduction factors of 50% and 30% are typical values that have been generated with experiments using either skin-on or skin-off fillets, respectively. Therefore, there is no explicit reduction factor for skinning alone. The 30% and 50% reduction factors are used, for example, by the Protocol for a Uniform Great Lakes Sport Fish Consumption Advisory and by other states in their fish consumption advisories.

Comment 2.2
Incorporating an assumption that people eat skin-off fillets results in GTLs that are not adequately health protective for a significant number of people. In a survey of San Francisco Bay anglers (SFEI 2001), DHS found that significant numbers of anglers report eating the skin of fish. Specifically, we found that 21% of striped bass consumers and 38% of white croaker consumers reported eating the skin more than half of the time. Generally, among anglers who reported eating skin, there were more non-white anglers, particularly African Americans and Asians. Thus, using a skin-off fillet as the default to develop GTLs for organic chemicals will disproportionately affect these groups.

Response 2.2
OEHHA recommends fish preparation methods, such as skinning, that allow anglers to safely eat more fish. In order to protect anglers who choose not to follow these guidelines, however, OEHHA may provide separate advice, as part of risk

communication, to fishers who do not skin or otherwise trim fish or cook it by methods recommended to reduce contaminant levels when guidance is based on chlorinated hydrocarbon contaminants.

Comment 2.3
The draft document states that "if fishers choose not to follow this advice and cook fish as skin-on fillets, they should reduce their consumption by approximately one-fourth…to achieve and equivalent exposure." From a practical perspective, it does not make sense to base the GTLs on a consumption pattern that people "should" follow, rather than what they already do. The GTLs should not assume that a significant proportion of people will take additional measures in order for the advisory to be adequately health protective. Furthermore, advisory messages need to be as simple as possible. Adding another qualifier to the advisory message (e.g., this advice will only be health protective if you remove the skin) complicates the message.

Response 2.3
Based on the study cited, the majority of anglers *do* skin fish, whether doing this of their own accord or following recommendations that OEHHA provides. OEHHA does not issue consumption and cleaning/cooking advice only to protect the most exposed individual but makes recommendations that all fishers can choose to follow – or not – to lower their exposure to contaminants. Fishers who do not follow advice to skin and/or cook their fish also may not follow advice to limit fish consumption. In the case of mercury, separate advice is provided for two populations groups so that less sensitive individuals (women beyond childbearing age and men) do not have their fish consumption unduly restricted by the needs of the other group (women of childbearing age and children). So it should be with cooking and cleaning methods, i.e., the majority of fishers who do consume/prepare fish in the safest manner should be offered advice that allows them to consume the most fish safely while fishers who choose to eat the skin or prepare fish in a way that does not reduce contaminant loads should be offered separate advice tailored to their needs. This is particularly important in the case of subsistence fishers, for example, where unwarranted fish consumption restrictions may impose an economic burden. The draft report recommended that fishers who do not follow advice to skin fish should reduce their consumption by approximately one-fourth. However, newer data indicate that the amount of contaminants found in skin may be more variable (and ultimately higher) that previously thought. In some cases, fish that could be eaten once or twice a week without skin will fall into the "do not consume" category with skin. For additional consideration in the final report and in future advisories for chlorinated hydrocarbons, OEHHA will consider site- or species-specific advice to reduce consumption if fishers do not cook or clean their fish in the safest manner.

Comment 2.4
Additionally, the decision to use skin-off fillets for scaled fish is not consistent with U.S. EPA guidance for fish advisories. U.S. EPA recommends that contaminant concentrations be measured using skin-on fillets for scaled fish species and skinless fillets for scaleless fish species (e.g., catfish).

Response 2.4
Historically, fish monitoring programs in California have analyzed skinless fillets of fish. See response 2.3 for further discussion. Analyzing skin-on fillets actually dilutes the measured mercury concentrations, making the advice less conservative. As mercury is the predominant fish contaminant in California, OEHHA recommends measuring contaminant concentrations in skin-off fillets.

Comment 2.5
On page 39, a correction to the example equation for dieldrin is needed; 1000 µg/kg should be 1000 µg/mg.

Response 2.5
Corrected. The mistake was the result of a typographical error. Calculated values were correct in the original version.

Comment 3.1
A major component of the EPA Institutional Controls Program for the Palos Verdes Shelf site is educating the public on the current state sport fish consumption guidelines. The current state fish advisory for DDTs uses an excess cancer risk of 10^{-5}. The proposed GTLs use a 10^{-4} level. The GTLs guidance cites that other states (e.g., Georgia and West Virginia) use the risk level of 10^{-4} in fish consumption advisories. However, these states have not used a risk level of 10^{-5} before, while California has been using 10^{-5} cancer risk endpoint for at least 15 years. No rationale for this change is provided.

Response 3.1
The rationale for the current protocol was discussed in the draft document. The 10^{-5} risk level was not consistently used for all chemicals in the Southern California sport fish consumption guidelines and has not been the basis for other advisories. Over the last 15 years, a tremendous amount of data has been published on the benefits of fish consumption – information that was not available when the 10^{-5} risk level was initially used. As scientific knowledge and protocols continue to expand or develop, our understanding of the risk and benefits of fish consumption have increased. The revised document has greatly expanded the discussion of the benefits of fish consumption and the reasoning behind the choice of the 10^{-4} risk level. In their fish advisory guidance document, U.S. EPA allows states to choose risk levels ranging from 10^{-4} to 10^{-7}. OEHHA concludes that, while it should be a goal to maintain a risk level of $1x10^{-6}$, when considering the counterbalancing benefits of fish consumption, a risk level of $1x10^{-4}$ is

appropriate. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption.

Comment 3.2
The draft GTLs are consistent with the FDA cancer risk level used for establishing tolerance levels in fish. However, the underlying assumptions used in the FDA methodology were not intended to be protective of recreational, ethnic, and subsistence fishers who typically consume larger quantities of fish than the general population and often harvest the fish and shellfish they consume from the same local water bodies repeatedly over many years, such as in the case for PV Shelf. The EPA national guidance states that "the FDA action levels and tolerances are indicators of chemical residue levels in fish and shellfish typically purchased in supermarkets or fish markets that sell products that are harvested from a wide geographic area, including imported fish and shellfish products."

Response 3.2
The reference to the FDA tolerance level for PCBs has been removed.

Comment 3.3
Using a cooking reduction of 30% in volume of fish consumed would increase the allowable contaminant intake in the screening value. Using this factor is inconsistent with the EPA national guidance for fish advisories. In addition, the assumption of skin-off fillet is not protective of sensitive populations such as ethnic populations who often eat whole fish, and fish stew and/or soup.

Response 3.3
Appendix C in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories, Vol. 2, discusses dose modifications that may be used to adjust for food preparation and cooking. Various surveys in California have shown that the majority of fishers eat skin-off, cooked fish. OEHHA will provide differential advice for those that prepare and cook fish in the safest manner as well as those that do not (see 2.3 above).

Comment 3.4
For chlordane, DDT and PCBs, the noncancer endpoint is not protective of effects for children. The 10^{-5} indirectly provides protection to these sensitive populations as the 10^{-5} value is the more conservative value. However, the use of 10^{-4} risk level does not provide this indirect buffer.

Response 3.4
OEHHA is not aware of any compelling evidence that children have increased susceptibility to DDTs that is not accounted for by the current RfD. OEHHA is currently assessing whether children may have increased susceptibility to PCBs under our SB 25 toxic air contaminants program. RfDs are generated taking into account the most

sensitive population; in particular, the RfD for PCBs is deemed protective of neurodevelopmental effects in fetuses and children as those occurred at a higher dose than the critical effect. The RfDs for DDTs and PCBs have uncertainty factors of 100 and 300, respectively, which should offer ample protection should additional adverse effects of these contaminants be determined later. If new research allows development of a childhood-specific RfD, like that for mercury or chlordane, OEHHA will reevaluate fish consumption guidelines at that time.

Comment 3.5
The draft GTLs guidance states that "Even if fishers fish the same location for 70 years, their exposure to such chemicals will undoubtedly decline significantly over this period" due to decline in levels in the environment. When the duration of exposure increases, even if there is a decline in contaminant levels, it is possible that the increase in the exposure time outweighs the decline in contaminant levels. At this time, we have not fully evaluated the existing and current data to corroborate the assumption that the levels of these contaminants are declining in the environment.

Response 3.5
The assumption of a 30 year exposure from fish consumption for a particular water body is a reasonable high-end health protective assumption for assessing risk from carcinogens, given current knowledge about population mobility from various studies. This assumption may need further consideration for bioaccumulating, carcinogenic contaminants ubiquitously present in water bodies.

Commenter 4
Mark Gold, D. Env.
Director
Kirsten James, MESM
Staff Scientist
Heal the Bay

Santa Monica, CA 90401

Comment 4.1
OEHHA should decrease the allowed cancer risk level in calculating GTLs and SVs to maintain the 10^{-5} end point for carcinogens to adequately protect sensitive subpopulations such as ethnic subsistence fishers, pregnant women and children. The lines of reasoning provided by OEHHA for the 10^{-4} risk level are not sufficient to justify the increase in allowed cancer risk. The FDA methodology used to calculate their level of acceptable risk cited in the draft report assumes that the population consumes a smaller number of fish from multiple sources; in this case, the draft report calculations are intended to protect people who consume fish from *local* water bodies. Finally, the draft report implies that consuming a certain amount of fish may be more important than avoiding contaminant exposure. Not only does this conclusion appear to be outside the purview of OEHHA, it is not well justified in the draft report. In sum, there is no appropriate

rationale provided in the Draft Report to justify the change to a less protective endpoint. OEHHA should use an allowed cancer risk level of 10^{-5} in calculating GTLs and SVs to be sufficiently protective of human health particularly under circumstances that occur in California. This lower value would serve as a "buffer" for other non-conservative assumptions relied upon by OEHHA as discussed below.

Reponse 4.1
OEHHA has removed the SVs from the draft report; see additional discussion below. Instead, OEHHA has provided Fish Contaminant Goals (FCGs) that maintain very conservative assumptions and may be used by other agencies as a starting point for developing fish tissue-based criteria.

The reference to the FDA tolerance limit for PCBs has been removed.

OEHHA (formerly of the Department of Health Services) has discussed balancing the risk and benefits of fish consumption since as early as 1986 (California Department of Health Services. Balancing the scales: Weighing the benefits and risks of fish consumption. Proceedings of a workshop held in Concord, California, October 20, 1988.). With the vast amount of data that has become available on the benefits of fish consumption in the last few years, OEHHA determined that this section should be significantly expanded in the final report. OEHHA believes that using a 10^{-4} risk level best balances known health benefits with cancer risks of fish consumption. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption.

Comment 4.2
OEHHA should ensure that GTLs and SVs are protective of the entire population including several sensitive subpopulations. The GTLs and SVs are not protective of certain highly relevant population groups, including children, pregnant women, and ethnic subsistence fishers. For example, the authors make various assumptions about the consumer in developing the GTLs and SVs, such as assuming a body weight of 160 pounds and a normal meal size of 6 ounces after cooking. While these assumptions are accounted for somewhat in the Draft Report by including recommendations to adjust the amount of fish consumed based on the weight of the consumer, OEHHA is also proposing to base the screening values upon the same characteristics of an average adult, thus failing to account for other routinely exposed groups of the population. In addition, under this assumption, OEHHA appears to recommend that children under 40 pounds should not eat any fish at all and kids under 80 pounds should not eat a tuna fish sandwich (based on a 2 oz serving size). This is not realistic. There is ample evidence that children in California consume local fish regularly and often, and thus are exposed to these contaminants. To adequately protect all consumers, OEHHA should use a much more conservative (lower) body weight in calculating the GTLs and SVs.

Response 4.2
The assumption of a 70 kg adult body weight is standard risk assessment protocol and six ounces after cooking is considered a standard fish meal size. Because there is a strong positive correlation between food consumption and body weight, particularly when averaged over a lifetime as the risks and hazards are, most risk assessments simply assume the concomitantly reduced consumption rate for lower body weights rather than stating it explicitly. In the final document, simplified instructions will be added to reduce meal sizes proportionately to body weight. Additionally, 70 kg is currently well below the average adult body weight for males and females, making the use of this default value a conservative assumption.

Comment 4.3
The cooking reduction factor of 30 percent and skin-on reduction factor of 20 percent should be removed from the calculations of GTLs and SVs. The GTL calculations also incorporate a cooking reduction factor of 30 percent and a skin-on reduction factor of 20 percent based on a theory that the process of heating the fish will break down organic contaminants and most consumers do not eat skin-on fish. This may be appropriate under some circumstances, but not in *all* cases. First, the specific method of cooking may determine the extent of breakdown of these organic constituents. For instance, searing the fish or cooking the fish in a stew may lead to a reduction in organic contaminants that is much lower than 30 percent. Second, methylmercury will not likely breakdown during the cooking process. Third, ethnic subsistence fishermen are put at additional risk under this assumption because they often use the whole fish (not a fillet) with skin-on. For instance, a fish consumption study found that of Asian anglers surveyed, 50 percent consume the whole fish. In fact, white croaker, a popular fish in Asian communities, is *rarely* eaten as a fillet. Thus, as just one example, Asian populations are not properly protected using these reduction factor assumptions. And again, while the draft report recommends reducing consumption if skin-on fillets are used, the screening values do not take this variable into account. Plainly, the reduction factors increase the allowable contaminated fish consumption in the screening values and will lead to fewer fish advisories and thus less protection for all groups of consumers. OEHHA should remove the 30 percent cooking reduction factor and 20 percent skin-on reduction factor in calculating the GTLs and SVs.

Response 4.3
See response to comments 2.2, 2.3, and 3.3. As noted in the draft document, the cooking and skinning reduction factors are not applied to mercury data. Mercury analysis of skin-off fillets provides more conservative fish consumption advice than analysis of skin-on fillets would (see response 2.4).

Comment 4.4
OEHHA should consider the policy implications of the draft report. There are additional water quality policy issues tied to the finalization of this draft report. Currently, California's Clean Water Act 303(d) list relies heavily on OEHHA Screening Values to determine fish tissue impairment. In fact, the *Water Quality Control Policy for*

Developing California's Clean Water Act 303(d) List ("Listing Policy") specifies that evaluation guidelines for protection from the consumption of fish and shellfish published by OEHHA can be used in evaluating fish tissue data for 303(d) listing and de-listing purposes. (Listing Policy at 20.) As a result, various listings and delistings in the Draft 2006 303(d) List are based upon the current OEHHA SVs or "benchmarks." In addition, the Listing Policy specifies that a waterbody "…shall be placed on the section 303(d) list if a health advisory against the consumption of edible resident organisms, or a shellfish harvesting ban has been issued by the Office of Environmental Health Hazard Assessment (OEHHA)." (Listing Policy at 5.) Further, numeric targets in certain TMDLs are derived from these screening values.

As discussed above, the Draft Report uses a risk level of 10^{-4}. In contrast, water quality standards, such as CTR standards, were set using the 10^{-6} risk level. Thus, there may be conflict between the protection offered through the Clean Water Act and policy decisions based upon the GTLs and SVs that are calculated using the 10^{-4} risk levels. In addition, the SVs included in the Draft Report are as much as 6 times higher than the 1999 OEHHA SVs. This may result in many inappropriate de-listings from the 303(d) list, resulting, in turn, in a failure to address the underlying problem at the source. Given the seriousness of the risks here, this is entirely inappropriate.

Response 4.4
As noted above, the SVs have been removed from the final document. Fish Contaminant Goals (FCGs), developed in this final report, use a 10^{-6} risk level. Agencies can use these values as a starting point to develop fish tissue-based criteria. GTLs (now ATLs) are not regulatory standards. OEHHA does not determine policies developed by other state programs. However, if other state programs choose to consider or use values that OEHHA has developed for some other purpose, then it is advisable that they consult with OEHHA to avoid any misuse or misinterpretation. (See response 1.1).

Comment 4.5
In general, OEHHA will be taking a step backward in terms of protecting public health if it adopts the non-conservative assumptions proposed in this Draft Report. As discussed above, there are major implications for sensitive subpopulations – particularly children and ethnic Asian subpopulations. An allowable cancer risk level of one in 10,000 is just not acceptable given these variable consumption patterns and practices. Therefore, we *strongly* urge OEHHA to maintain the 10^{-5} endpoint, as well as to use more conservative assumptions in calculating the GTLs and SVs.

Response 4.5
OEHHA has addressed the "non-conservative" assumptions in prior responses to comments. OEHHA has determined that highly conservative assumptions, as used in traditional risk assessment paradigms, are not protective of overall health when considering fish consumption. However, in response to comments regarding the cooking reduction factor, separate advice may be tailored to those who do not cook or clean according to OEHHA recommendations. OEHHA maintains that using a 10^{-4} risk level

best balances the cancer risks and benefits (health and economic) of sport fish consumption as well as the risks of alternate protein sources that might be consumed in place of sport fish. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption. OEHHA does not agree with the premise that "sensitive subpopulations" are not accounted for in the advisory process. All consumers who follow the advice are equally protected based on known sensitivities. When there is compelling evidence that women or children are more susceptible to a contaminant (e.g., mercury), the advisories provide separate advice for their protection.

Commenter 5
Joseph P. Skorupa, Ph.D.
Clean Water Act Biologist
Environmental Contaminants Branch
Division of Environmental Quality
U.S. Fish and Wildlife Service
4401 N. Fairfax Drive, Rm. 322
Arlington, VA 22203

Comment 5.1
This is a wonderfully well done report that should be viewed as "state of the art" in its niche.

Comment 5.2
"Avians" is not an accepted noun.

Response 5.2
Changed "avians" to birds.

Comment 5.3
It would be helpful to provide the reference dose as µg/day, in addition to mg/kg-day, to facilitate comparison to the RDA.

Response 5.3
Additional units included.

Comment 5.4
Is the advice for reducing consumption by approximately one-fourth for skin-on fillets really applicable to selenium?

Response 5.4
Language altered to indicate that, of the chemicals evaluated, reduction of contaminant levels by cooking and skinning is only applicable to chlorinated hydrocarbons, rather than "organics" as stated.

Comment 5.5
The equations presented on page 39 result in calculated outcomes expressed on a ppm (mg/kg) basis, yet the summary table of outcomes, Table 1, presents everything on a ppb basis. It would be an improvement to make the equations and outcomes table internally consistent.

Response 5.5
The equations include mg/kg units because the reference doses and cancer slope factors are presented in those units. Conversion factors were included in the equations to change the outcome units to ppb (µg/kg), to coincide with the most convenient way of expressing fish contaminant levels as presented in Table 1 and Table 2.

Comment 5.6
The selenium screening value is expressed on a wet weight basis. Many historic fish tissue databases are expressed on a dry weight basis without corresponding percent moistures and, thus, there is no way to convert the values to a wet weight basis. EPAs new tissue-based chronic criterion value for selenium will be issued on a dry weight basis. It would be useful to provide a conversion to dry weight basis for a range of fish species.

Response 5.6
Screening values have been eliminated from the document. However, fish collected for human health assessments must be based on wet weight analysis; dry weight data for individual or composite fish samples are not consistently available. OEHHA will leave developing national conversion factors for multiple species to other agencies.

Olympia, WA 94504

Comment 6.1
Overall the document read well and its purpose was clearly stated. Calculations of GTLs and screening level values were checked and consistent with our calculations. Appropriate studies are cited to support your selection of toxicity criteria.

Comment 6.2
Within the introduction, it may be useful to give subheadings to the sections dealing with the development of screening level values and for establishing GTLs. A brief description of the equation for deriving GTLs for cancer endpoints similar to the noncancer equation would be useful. The differences in the two equations could be explained, briefly describing the differences in averaging times used in the two calculations.

Response 6.2
An equation for deriving GTLs (now ATLs) for cancer endpoints was included. The SVs are no longer included in the final document.

Comment 6.3
Within the introduction, it would be helpful to list major data sources and give a brief description of the programs that they are collected under. Fish tissue collection and analysis is often conducted for reasons other than to evaluate human health concerns. Therefore, the adequacy of the database should first be determined.

Response 6.3
This information is outside the scope of this document. It is presented in the Health Advisory and Safe Eating Guidelines for each water body. Recommendations for sampling are included in the report "General Protocol for Sport Fish Sampling and Analysis," by Gassel and Brodberg, 2006.

Comment 6.4
A summary table should be included with the contaminants of concern and their corresponding cancer and noncancer values separate from the GTL calculated concentrations.

Response 6.4
Cancer and noncancer values are presented in at least two places in the document, including Table 1. OEHHA feels that including another separate table of these values is not necessary, given that they are clearly presented in the toxicology profiles and in the derivation of the ATLs.

Comment 6.5
A brief discussion on the consumption rate used to establish screening level values. What are they based on and what populations do they protect or not protect?

Response 6.5
The screening values have been removed from the final document.

Comment 6.6
The discussion of the Guidance Tissue Levels for the various contaminants is easy to follow and provides appropriate background on use of various parameters considered.

Comment 6.7
Consider graphing contaminant meal recommendations with contaminant concentrations.

Response 6.7
Graphs were presented by the commenter as another way of looking at GTLs (now ATLs). We didn't find that these added to the clarity or usefulness of the document.

Comment 6.8
We find that people often get hung up on the numbers such as GTLs but are unaware that these values are generally a starting point in determining what the recommended meal limits should be. Left out of the discussion is the risk management and risk communication aspects in evaluating fish.

Response 6.8
OEHHA agrees that the ATLs are just a starting point for developing fish consumption guidelines. We have attempted to strengthen the language in the document to make that point. A brief discussion of risk communication has been added to the document, but risk communication details are developed as part of individual safe eating guidelines for specific water bodies.

DEVELOPMENT OF FISH CONTAMINANT GOALS AND ADVISORY TISSUE LEVELS FOR COMMON CONTAMINANTS IN CALIFORNIA SPORT FISH:

CHLORDANE, DDTs, DIELDRIN, METHYLMERCURY, PCBs, SELENIUM, AND TOXAPHENE

FOREWORD

This report describes the process of developing Fish Contaminant Goals and Advisory Tissue Levels for evaluating methylmercury, chlordane, DDTs, dieldrin, PCBs, selenium, and toxaphene, common contaminants in California sport fish. Fish provide unique nutritional benefits while also serving as a significant exposure pathway for several chemicals of concern. Fish Contaminant Goals (FCGs) are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs prevent consumers from being exposed to more than the daily RfD for non-carcinogens or to a risk level greater than $1x10^{-6}$ for carcinogens (not more than one additional cancer case in a population of 1,000,000 people consuming fish at the given consumption rate over a lifetime). FCGs are based solely on public health considerations without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption.

Advisory Tissue Levels (ATLs), while still conferring no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, were developed with the recognition that there are unique health benefits associated with fish consumption and that the advisory process should be expanded beyond a simple risk paradigm in order to best promote the overall health of the fish consumer. ATLs provide a number of recommended fish servings that correspond to the range of contaminant concentrations found in fish and are used to provide consumption advice to prevent consumers from being exposed to more than the average daily reference dose for non-carcinogens or to a risk level greater than $1x10^{-4}$ for carcinogens (not more than one additional cancer case in a population of 10,000 people consuming fish at the given consumption rate over a lifetime). ATLs are designed to encourage consumption of fish that can be eaten in quantities likely to provide significant health benefits, while discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be eaten in amounts recommended for improving overall health (eight ounces total, prior to cooking, per week). ATLs are one of the criteria that will be used by OEHHA for issuing fish consumption guidelines.

EXECUTIVE SUMMARY

Chemical contamination of fish is a global problem that has resulted in the issuance of fish consumption advisories in most states, including California. Although mercury contamination is a frequent basis for these advisories, polychlorinated biphenyls (PCBs) and chlorinated pesticides such as chlordane and dichlorodiphenyltrichloroethane (DDT) are also often implicated. In California, the Office of Environmental Health Hazard Assessment (OEHHA) is the agency solely responsible for evaluating the potential public health risks of chemical contaminants in sport fish and issuing state advisories, when appropriate. OEHHA is also consulted by other agencies interested in assessing the health risks of fish consumption during the process of developing water quality or clean-up "criteria." There are key differences between fish consumption advisories and other environmental risk criteria; advisories consider the significant benefits of fish consumption, while criteria may be strictly risk-based and may not take into account other factors.

In order to develop water quality criteria or fish consumption advisories, appropriate toxicity values for a chemical must be established. In this document, cancer and non-cancer health effects were evaluated for seven common contaminants found in California sport fish: chlordane, DDT and its metabolites (DDTs), dieldrin, mercury (as methylmercury), PCBs, selenium, and toxaphene. For each chemical, the toxicological literature was reviewed to establish an acceptable non-cancer reference dose (RfD; an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime) and/or a cancer slope factor (an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen).

Fish Contaminant Goals (FCGs) were then developed for these seven contaminants. FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs prevent consumers from being exposed to more than the daily RfD for non-carcinogens or to a risk level greater than $1x10^{-6}$ for carcinogens (not more than one additional cancer case in a population of 1,000,000 people consuming fish at the given consumption rate over a lifetime). FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption. FCGs were developed using an 8-ounce (227 g) serving size (prior to cooking; approximately six ounces after cooking) for adults who weigh 70 kg.

As a prelude to developing tissue-based values to be used for advisories, OEHHA reviewed the scientific literature on the benefits of fish and fish oil consumption. Although decreased incidence of coronary heart disease is perhaps the most recognized benefit of fish consumption, there is considerable evidence that other, particularly

inflammatory, disorders may also be mitigated or prevented by inclusion of fish in the diet. Additionally, maternal fish consumption is likely to provide cognitive benefits to the fetus. Following this review, OEHHA determined that there is a compelling body of evidence and general scientific consensus that eating fish at dietary levels that are easily achievable, but well above national average consumption rates, appears to promote significant health benefits, including decreased mortality. With the recognition that there are unique health benefits associated with fish consumption, it was concluded that the advisory process should be expanded beyond a simple risk paradigm, as is used in criteria development, in order to best promote the overall health of the fish consumer.

The first step in the advisory process, then, was to develop Advisory Tissue Levels (ATLs). ATLs were calculated using the same general formulas as those used to calculate FCGs, with some adjustments in order to incorporate the benefits of fish consumption. ATLs provide a number of recommended fish servings that correspond to the range of contaminant concentrations found in fish and are designed to prevent consumers from being exposed to more than the average daily reference dose for non-carcinogens or to a risk level greater than $1x10^{-4}$ for carcinogens (not more than one additional cancer case in a population of 10,000 people consuming fish at the given consumption rate over a lifetime). The use of ATLs still confers no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, while encouraging consumption of fish that can be eaten in quantities likely to provide significant health benefits and discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be recommended in amounts suggested for improving overall health (i.e., eight ounces total, prior to cooking, per week).

ATLs are used as part of the process to develop traditional health advisories (which focus on fish whose consumption should be avoided) as well as the newer "safe eating guidelines," which inform consumers of fish with low contaminant levels considered safe to eat frequently. ATLs should not be misinterpreted as static "bright lines" that others can use to duplicate state fish consumption advisories. ATLs are but one component of a complex process of data evaluation and interpretation used by OEHHA in the assessment and communication of fish consumption risks. The nature of the contaminant data or omega-3 fatty acid concentrations in a given species in a water body, as well as risk communication needs, may alter strict application of ATLs when developing site-specific advisories. OEHHA will use the guidelines set forth in this report as a framework, along with best professional judgment, to provide fish consumption guidance on an *ad hoc* basis that best combines the need for health protection and ease of communication for each site.

This document represents current knowledge of the toxicity of seven common fish contaminants and the overall benefits of fish consumption; FCGs and ATLs for individual chemicals may be revised, if necessary, as information becomes available. FCGs and ATLs may also be developed in the future for additional contaminants, as appropriate, using the same methodology.

INTRODUCTION

Fish consumption advisories have been issued in most states and cover approximately 35 percent and 24 percent of the country's total lake acreage and river miles, respectively (U.S. EPA, 2004a). Mercury contamination of fish, in particular, is a national problem that resulted in the issuance of 222 new advisories in 2003 alone (U.S. EPA, 2004a). Polychlorinated biphenyls (PCBs) and chlorinated pesticides such as chlordane and dichlorodiphenyltrichloroethane (DDT) are also a frequent basis for fish consumption advisories throughout the United States (U.S. EPA, 2004a). In California, the Office of Environmental Health Hazard Assessment (OEHHA) is the agency responsible for evaluating potential public health risks from chemical contamination of sport fish. This includes issuing state advisories, when appropriate, based on mandates in the California Health and Safety Code, Section 59009, to protect public health, and Section 59011, to advise local health authorities, and the California Water Code, Section 13177.5, to issue health advisories. OEHHA is also consulted by other agencies interested in assessing the health risks of fish consumption during the process of developing water quality or clean-up "criteria." There are key differences between fish consumption advisories and other environmental risk criteria; advisories consider the significant benefits of fish consumption, while criteria may be strictly risk-based and may not take into account other factors.

In order to develop advisories or criteria, appropriate toxicity values for a chemical must be established. In this document, cancer and non-cancer health effects were evaluated for seven common contaminants found in California sport fish: chlordane, DDT and its metabolites (DDTs), dieldrin, mercury (as methylmercury), PCBs, selenium, and toxaphene. For each chemical, the toxicological literature was reviewed to establish an acceptable non-cancer reference dose (RfD; an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime) and/or a cancer slope factor (an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen). Limited background information on the chemistry, environmental fate, metabolism, and typical exposure routes for each chemical is also provided.

Fish Contaminant Goals (FCGs) were then developed for these seven contaminants. FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, technical feasibility, or the counterbalancing benefits of fish consumption.

FCGs for non-cancer risk for non-nutrients were derived from the following basic equation:

$$\text{Tissue concentration} = \frac{(\text{Reference dose})(\text{Body weight})}{\text{Daily consumption rate}}$$

FCGs for cancer risk for non-nutrients were derived from the following basic equation:

$$\text{Tissue concentration} = \frac{(\text{Risk level})(\text{Body weight})}{(\text{Cancer slope factor})(\text{Daily consumption rate})}$$

Additional discussion and examples of FCG development can be found in the section "Equations used to calculate Fish Contaminant Goals."

As a prelude to developing tissue-based values to be used for advisories, OEHHA reviewed the scientific literature on the benefits of fish and fish oil consumption to determine to what degree the advisory process should be expanded beyond a simple risk paradigm, as is used in criteria development, in order to best promote the overall health of the fish consumer. Advisory Tissue Levels (ATLs), while still conferring no significant health risk to individuals consuming sport fish in the quantities shown over a lifetime, use the same general equations as those used to develop FCGs, with some adjustments to take into account benefits that are provided by fish consumption. ATLs were designed to encourage consumption of fish that can be eaten in quantities likely to provide significant health benefits, while discouraging consumption of fish that, because of contaminant concentrations, should not be eaten or cannot be recommended in amounts suggested for improving overall health (i.e., eight ounces total, prior to cooking, per week).

This report provides critical toxicity values, FCGs and ATLs for seven common contaminants in California sport fish. Most fish advisories in the United States are issued for mercury, PCBs, chlordane, dioxins, and DDTs (U.S. EPA, 2005). OEHHA also included toxaphene and selenium in this document because of historic use in the state and natural occurrence, respectively. At this time, limited available analytical data for dioxins in fish throughout the state do not show widespread or high dioxin contamination. Several former point sources have been eliminated and subsequent concentrations in fish at associated sites were below a level of concern (Fan, 1994). Consequently, OEHHA did not develop an FCG or ATLs for dioxins at this time. However, FCGs and ATLs may be developed in the future for dioxins or other contaminants, as resources permit, using the same methodology. OEHHA staff is available for consultation on any fish contaminant of concern.

TOXICOLOGY AND CRITICAL TOXICITY VALUES FOR COMMON CONTAMINANTS IN CALIFORNIA SPORT FISH

CHLORDANE

CHLORDANE TOXICOLOGY

Chlordane is a chlorinated cyclodiene insecticide that was used in the United States beginning in 1948 for a variety of agricultural and structural pest control purposes (ATSDR, 1994; Ecobichon, 1991; Matsumura, 1985; U.S. EPA, 1997). Technical chlordane, the commercial mixture, is comprised of approximately 60 percent *cis* and *trans* chlordane isomers and about 40 percent other related compounds (e.g., *cis*-nonachlor, *trans*-nonachlor and oxychlordane) (U.S. EPA, 1997). As a result of their lipophilicity, low volatility and slow degradation rates, chlordane and other organochlorine pesticides are exceptionally persistent in the environment and are able to bioconcentrate and biomagnify throughout the food chain (Ecobichon, 1991). Bioconcentration factors (the quotient of the concentration of a chemical in an organism divided by the concentration of the chemical in the ambient water) for chlordane in various marine and freshwater fish, for example, have been reported as high as 3,000 to 37,800 (ATSDR, 1994; Fisher, 1999). Because of this, as well as concerns over human cancer risk and hazards to wildlife, the use of chlordane was severely restricted in the United States in 1978 and ultimately banned in 1988 (ATSDR, 1994; U.S. EPA, 2000). Chlordane remains a contaminant in many soils and waterways, however, with the most frequent source of human exposure being consumption of contaminated foods, especially fish (ATSDR, 1994). Saltwater and fresh water fish and shellfish, combined, account for approximately 95 percent of the total dietary exposure to chlordane (Dougherty et al., 2000).

Chlordane is readily absorbed by all exposure routes (ATSDR, 1994). Once absorbed, chlordane is rapidly distributed to the liver and kidneys, whereupon it undergoes transformation to a number of metabolites. Chlordane excretion is mainly through bile and breast milk (ATSDR, 1994). Chlordane that is not excreted is deposited in adipose tissue, primarily as the metabolites oxychlordane and heptachlor epoxide (ATSDR, 1994; U.S. EPA, 1997). The elimination half-life of chlordane in humans reported in different studies has ranged from 21to 88 days (Aldrich and Holmes, 1969; ATSDR, 1994; Curley and Garrettson, 1969; Olanoff et al., 1983).

The Agency for Toxic Substances and Disease Registry (ATSDR, 1994), U.S. Environmental Protection Agency (U.S. EPA, 1997), and OEHHA (1997) have extensively reviewed the toxicity of chlordane. Following acute oral exposures (14 days or less), chlordane is considered moderately to highly toxic to humans (U.S. EPA, 2000). The World Health Organization (WHO, 1984) estimated the acute human lethal dose to be between 25 and 50 mg/kg body weight. Acute poisoning symptoms include vomiting, diarrhea, seizures, anuria, ataxia, tremors, coma, and respiratory failure (ATSDR, 1994;

Curley and Garrettson, 1969; NIOSH, 1981, 2003; Olanoff et al., 1983), and can occur within 45 minutes of exposure (Grutsch and Khasawinah, 1991). The difference between the no-effect and the fatal serum levels in humans is small (approximately 3 to 5 times), indicating a steep dose-response curve (Grutsch and Khasawinah, 1991). Death is rare following acute oral poisoning, however, because the individual generally vomits, reducing the available dose (Grutsch and Khasawinah, 1991). Apparent recovery in non-fatal cases is rapid (Aldrich and Holmes, 1969; Curley and Garrettson, 1969; Grutsch and Khasawinah, 1991), although chemical hepatitis may develop subsequent to the acute phase (Olanoff et al., 1983). Acute chlordane toxicity in animals also results in neurotoxicity signs such as hyper-excitability, tremors, convulsions, hind limb paralysis and hypothermia (ATSDR, 1994; Grutsch and Khasawinah, 1991). Like other cyclodiene insecticides, the mechanism of neurotoxic action is believed to be inhibition of chloride transport, causing incomplete repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999).

Subchronic or chronic chlordane toxicity in humans has been difficult to quantify because of problems with dose determination and confounding exposures. Some humans living in chlordane-treated homes have developed hepatic and neurological signs such as jaundice and grand-mal seizures, respectively. The exact dose-response relationship has not been determined, however (ATSDR, 1994). In their review of the literature, Grutsch and Khasawinah (1991) reported that chronic, low-level chlordane exposure via inhalation, oral, or dermal routes has not been found to elicit signs or symptoms indicative of chlordane toxicity. ATSDR (1994) also noted that adverse health effects resulting from chlordane exposures have not been confirmed in studies of workers engaged in the manufacture of chlordane. More recent epidemiological studies, though, have indicated that chlordane may cause neurotoxicity following chronic exposures in humans (IRIS, 1998). In a cross-sectional study, Kilburn and Thornton (1995) found that neurobehavioral functions such as reaction times, verbal recall, and trail-making were impaired in 216 adults exposed to chlordane via inhalation compared to an unexposed referent population matched by age and educational level. However, effect levels could not be assigned because data on exposure, dose-response or potential co-exposure to other neurotoxicants were not available (U.S. EPA, 1997). In a subsequent study of nine chlordane-exposed patients seen consecutively for effects of chemical exposure, Kilburn (1997) noted that neurobehavioral functions such as balance, reaction times, verbal recall, and color discrimination were also diminished in the exposed group compared to a control population. Exposure dose was unknown and exposure duration ranged from 50 minutes to 18 years. Potential limitations associated with experimental design, including selection bias and an inadequately matched control population, severely limit interpretation of this study.

In rodent studies, the liver is clearly the target organ of chronic chlordane toxicity and hepatic necrosis has been deemed the critical effect (U.S. EPA, 1997). Khasawinah and Grutsch (1989a, 1989b) conducted the most extensive rat and mice toxicity studies available for chlordane, at similar dose-rates, which indicated that the mouse is more susceptible to the hepatotoxic effects of chlordane than is the rat (U.S. EPA, 1997).

Additional hepatic toxicity signs in mice included increased liver weights and elevated serum aspartate transferase (AST) and alanine transferase (ALT) levels (Khasawinah and Grutsch, 1989b).

Reproductive toxicity has been shown to occur following oral exposure to relatively high levels of chlordane in male mice. Balash et al. (1987) found that mature male mice orally gavaged with chlordane for 30 days had dose-related histological changes in seminiferous tubules. Similarly, Al-Omar et al. (2000) determined that mice gavaged with approximately 20 or 70 percent of the median lethal dose of chlordane suffered damage to testicular tissues, including decreased seminiferous tubule diameter, and reduced numbers of spermatogonia, spermatocytes and spermatids.

Developmental effects have also been reported in response to chlordane exposure in mice and rats (ATSDR, 1994). A series of neurobehavioral tests given to mice offspring following third-trimester fetal exposure to chlordane found depressed avoidance response acquisition and increased seizure threshold and exploratory activity, suggesting an effect on fetal brain (ATSDR, 1994; Al-Hachim and Al-Baken, 1973). Cassidy et al. (1994) showed that male and female rats exposed to low levels of chlordane *in utero* and during the early postnatal period (Day 4 of gestation through Day 21 of lactation) had gender-dependent alterations of sexually dimorphic functions and behaviors such as spatial abilities and auditory startle-evoked responses. Based on these results, the authors suggested that chlordane mimics and/or alters sex steroid concentrations and, thus, has a masculinizing effect on fetal and/or neonatal rats. In their review of the paper, however, U.S. EPA (1997) noted that dose-response relationships were inconsistent, as effects in high-dose animals were often similar to controls. Additionally, testosterone levels in males and females were not systematically related to the observed behavioral changes. U.S. EPA thus questioned the authors' interpretation of the study results and indicated that further research was necessary to confirm a relationship between these behavioral effects and low-dose chlordane exposure.

Immunological studies in mice indicated that *in utero* and neonatal treatment with chlordane suppressed cell-mediated immunity (Barnett et al., 1985a, 1985b; 1990a, 1990b; Blaylock et al., 1990; IRIS, 1998; Menna et al., 1985). Reported effects following such chlordane exposures included decreased fetal hematopoietic activity, delayed-type hypersensitivity-mediated pathology, and mixed lymphocyte reactivity. However, in some experiments, this suppression led to increased survival following influenza virus infection during young adulthood (Barnett et al., 1985a; Blaylock et al., 1990; Menna et al., 1985). More recent research has shown a variety of immunotoxic responses of rats following 28-day oral gavage of *cis*-nonachlor, *trans*-nonachlor and technical chlordane (Tryphonas et al., 2003). In those studies, *cis*- and *trans*-nonachlor were more likely to cause immunotoxic effects than technical chlordane, with these results more pronounced in females.

Oxychlordane, one of the principal metabolites of chlordane, is the second most common chlordane-related residue found in food, following *trans*-nonachlor (Bondy et al., 2003).

A series of twenty-eight-day feeding studies in female rats showed that oxychlordane caused weight loss and histopathological changes in the liver, thymus, and thyroid and produced signs of toxicity at doses approximately eight times lower than *cis*- or *trans*-nonachlor (Bondy et al., 2003). The authors suggested that exposure to oxychlordane may prove to be a more significant human health hazard than exposure to other chlordane compounds found in foods.

Information regarding the potential carcinogenicity of chlordane in humans is conflicting. A few studies have shown an association between chronic chlordane inhalation exposure in humans and the development of various blood dyscrasias, such as leukemia (reported in ATSDR, 1994; U.S. EPA, 1997). In contrast, Brown et al. (1990; 1993) failed to find a relationship between leukemia or multiple myeloma and chlordane inhalation exposure in adult men (U.S. EPA, 1997). A retrospective mortality study of workers in the chlordane manufacturing industry (Brown, 1992) indicated that workers exposed to chlordane and other organochlorines had lower than expected mortality from all causes as well as from all malignant neoplasms (ATSDR, 1994). Yet, in two case-control studies, Cantor et al. (1992) and Woods and Polissar (1989) found that non-Hodgkin's lymphoma patients were more likely to have had previous inhalation exposure to chlordane than healthy controls, although this association was only significant in the Cantor et al. study. U.S.EPA (1997) notes that there is no evidence to support the conclusion that oral exposure to chlordane from food or drinking water causes human carcinogenicity; however, the weight of evidence following high-level, long-term dermal or inhalation exposures does suggest that chlordane is likely a human carcinogen.

The International Agency for Research on Cancer (IARC) has listed chlordane as a possible human carcinogen, based on inadequate evidence in humans and sufficient evidence in experimental animals (IARC, 2001). U.S. EPA has classified chlordane as a likely human carcinogen, based on limited epidemiological evidence in humans, development of hepatocellular carcinomas in multiple strains of mice and liver toxicity in rats, and the structural resemblance of chlordane to other rodent hepatic carcinogens (IRIS, 1998; U.S. EPA, 1997). Chlordane is on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR CHLORDANE

A chronic reference dose (RfD) is an estimate of daily human exposure to a chemical that is likely to be without significant risk of adverse effects during a lifetime (including to sensitive population subgroups), expressed in units of mg/kg-day (IRIS, 1995). This estimate includes a factor to account for data uncertainty. The underlying assumption of an RfD is that, unlike most carcinogens, there is a threshold dose below which certain toxic effects will not occur. The RfD for a particular chemical is derived from review of relevant toxicological and epidemiological studies in animals and/or humans. These studies are used to determine a No-Observed-Adverse-Effect-Level (NOAEL; the highest dose at which no adverse effect is seen), a Lowest-Observed-Adverse-Effect-Level

(LOAEL; the lowest dose at which any adverse effect is seen), or a benchmark dose level (BMDL; a statistical lower confidence limit of a dose that produces a certain percent change in the risk of an adverse effect) (IRIS, 1995). Based on these values and the application of uncertainty factors to account for incomplete data and sensitive subgroups of the population, an RfD is then generated. Exposure to a level above the RfD does not mean that adverse effects will occur, only that the probability of adverse effects occurring has increased (IRIS, 1993).

Because chlordane dose-response data in humans are inadequate, the U.S. EPA RfD for this chemical was derived from animal data based on hepatic necrosis as the critical effect (IRIS, 1998; U.S. EPA, 1997). Although several studies have indicated that chronic chlordane exposure may also result in neurobehavioral or other neurotoxic effects, reliable dose-response information as well as data to support a plausible mode-of-action are not available for these endpoints (U.S. EPA, 1997). U.S. EPA thus chose Khasawinah and Grutsch (1989b) as the principal study for the RfD because of the clear dose-related incidence of hepatic effects, overall strength of the study, and comparatively low adverse effect level (IRIS, 1998; U.S. EPA, 1997). Newer chlordane toxicity studies published since the RfD was developed do not have sufficient data to determine acceptable exposure values and/or have not shown a lower adverse effect level.

Khasawinah and Grutsch (1989b) fed 80 ICR mice per sex per group 0, 1, 5, or 12.5 parts per million (ppm) dietary chlordane (estimated to be 0, 0.15, 0.75, and 1.875 mg/kg-day, respectively) for 104 weeks. Hepatocellular swelling was seen in both male and female mice at doses of 5 and 12.5 ppm dietary chlordane; incidence of hepatic necrosis was also significantly elevated at those dose levels, but only in male mice. Other hepatic effects, such as increased relative liver weights and alanine transferase activity, were seen at varying dose levels. The NOAEL and LOAEL values for this study were considered to be 1 and 5 ppm, respectively. To the NOAEL, U.S. EPA applied a 300-fold uncertainty factor (10 for interspecies extrapolation, 10 for intraspecies variation, and 3 for lack of a multigenerational reproductive study), leading to an RfD of $5x10^{-4}$ mg/kg-day (IRIS, 1998; U.S. EPA, 1997).

As required under Health and Safety Code Section 901(g), OEHHA developed a child-specific reference dose (chRD) for chlordane for the purpose of assessing risk at proposed or existing California school sites (OEHHA, 2005). The Cassidy et al. (1994) paper was selected as the most useful study for determination of a chRD, based on endocrine disruption in the developing offspring. Pregnant Sprague-Dawley rats were fed doses of 100, 500, or 5,000 ng/g technical chlordane from day 4 of gestation until day 21 of lactation. Offspring were dosed from postnatal day (PND) 22 to PND 80 and began behavioral testing on PND 76; serum testosterone was measured on PND 85. Body weights were significantly increased in the 500 ng/g dose group compared to controls for females only. Serum testosterone levels were significantly reduced in female offspring dosed with 500 and 5,000 ng/g, although not in a dose-dependent fashion. Male offspring showed only a slight, non-significant, reduction of serum testosterone in the highest (5,000 ng/g) exposure group. Following repeated testing in the Cincinnati water

maze, time to escape was significantly improved in female rat dosed with 100 and 500 ng/g chlordane compared to controls; male rats were not affected by treatment. Intromission latency was significantly reduced in 100 and 500 ng/g treated males; however, the high-dose group was similar to controls. Intromissions prior to ejaculation and total intromissions were significantly increased only in the 500 ng/g dose group. Latency to ejaculation was not different among groups. Open field activity was not affected by treatment in male or female offspring. In tests of reaction to auditory startle, only the maximum response parameter was significantly different from controls and only in the 100 ng/g dose group. OEHHA determined that the LOAEL from this study was 100 ng/g chlordane, based on disruption of sex hormone-mediated behaviors. To the LOAEL, OEHHA applied a 3000-fold uncertainty factor (10 for LOAEL to NOAEL, 10 for interspecies extrapolation, 10 for intraspecies variation, and 3 for inadequate database for hematotoxicity, immunotoxicity, neurotoxicity, and the lack of a valid developmental study), leading to an chRD of $3.3x10^{-5}$ mg/kg-day (OEHHA, 2005).

Although Cassidy et al. (1994) was the best study available to establish a chRD, there are significant limitations with the data as noted by U.S. EPA (1997). Nonetheless, OEHHA concludes that it is appropriate to use the chRD for developing a non-cancer FCG for chlordane. FCGs are, as noted, strictly risk-based and, thus, a study need not be eliminated from consideration solely on the basis of data strength. However, in setting an ATL, it is important to balance the risks and benefits of fish consumption (see the Advisory Tissue Level section, later in this document). For this reason, OEHHA has chosen to use the cancer risk basis for establishing the ATL for chlordane (see below), rather than non-cancer risk based on Cassidy et al. (1994), even though this results in a slightly higher ATL. Chlordane is well-established as a potential human carcinogen; thus, protection against the carcinogenic effects of chlordane is generally accepted by regulatory agencies. Additionally, the 3000-fold uncertainty factor incorporated into the Cassidy et al. study-based chRD should not be used to outweigh the certainty of benefits associated with fish consumption. In using the cancer basis for developing the ATL, OEHHA determines that there is still a large margin of safety (approximately 550- to 1,000-fold, over the range of exposures) for potential endocrine-disrupting health effects of chlordane that is adequate to protect children who would also receive the benefits from consuming fish. OEHHA similarly chose to use the cancer endpoint in developing a Public Health Goal (PHG) for chlordane in drinking water (OEHHA, 1997) although non-cancer health effects, based on the Cassidy study, would have resulted in a lower PHG. Thus, the chRD of $3.3x10^{-5}$ will be used to evaluate non-cancer risk for a chlordane FCG, but only cancer risk will be considered in the development of chlordane ATLs.

A cancer slope factor (CSF) is an upper-bound estimate of the probability that an individual will develop cancer over a lifetime as a consequence of exposure to a given dose of a specific carcinogen and is expressed as $(mg/kg\text{-}day)^{-1}$ (U.S. EPA, 1989). The higher the CSF, the greater the estimated potency of a carcinogen. As is the case with noncancer endpoints, only animal data are available to quantify the carcinogenic risk of chlordane (U.S. EPA, 1997). In their 1998 cancer assessment, U.S. EPA combined the

results of five liver tumor data sets for male and female CD-1 and B6C3F1 mice and male ICR mice orally exposed to chlordane at doses from 5 to 64 ppm for a period of 78 to 104 weeks (IRDC, 1973; NCI, 1977; Khasawinah and Grutsch 1989b; U.S. EPA, 1997; IRIS, 1998). U.S. EPA used (body weight)$^{3/4}$ scaling and the linearized multistage model in Global 86 software to determine cancer potency. Individual slope factors for each of the data sets ranged from 0.114 to 0.858 (mg/kg-day)$^{-1}$; a geometric mean of these values was then calculated to derive an oral CSF for chlordane of 0.35 (mg/kg-day)$^{-1}$ (IRIS, 1998). At the time of completion of this cancer risk assessment, however, the 1996 Guidelines for Carcinogenic Risk Assessment were still in draft form (U.S. EPA, 1996). U.S. EPA noted that using the LED_{10} alternate method of low-dose extrapolation from the newer guidelines to calculate cancer potency would lead to a slope factor of 0.567 (mg/kg-day)$^{-1}$ (IRIS, 1998). These guidelines have since been finalized by U.S. EPA (U.S. EPA, 2005).

In the PHG for chlordane in drinking water developed by OEHHA, only the male and female CD-1 and B6C3F1 mice studies (IRDC, 1973; NCI, 1977) were used to determine a CSF; the male ICR mice study (Khasawinah and Grutsch,1989b) included in the U.S. EPA assessment (IRIS, 1998) was not used (OEHHA, 1997). An intercurrent mortality correction of approximately 2.4 was used to correct for less than lifetime duration of these four studies. OEHHA employed the methodology from the 1996 Guidelines for Carcinogenic Risk Assessment (U.S. EPA, 1996) to calculate CSFs for these studies. OEHHA's estimates were based on (body weight)$^{3/4}$ scaling and used Tox_Risk software to calculated the LED_{10} because, according to the author, this software had a greater ability to calculate lower bounds on doses in the observed range in the evaluated studies (OEHHA, 1997). OEHHA then calculated the geometric mean of the best fitting four data sets to determine a CSF of 1.3 (mg/kg-day)$^{-1}$. This CSF will be used to evaluate chlordane cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer value used to evaluate chlordane in fish for the development of FCGs will be **$3.3x10^{-5}$ mg/kd-day**. The cancer value used to evaluate chlordane in fish for the development of FCGs and ATLs will be **1.3 (mg/kg-day)$^{-1}$**.

DICHLORODIPHENYLTRICHLOROETHANE AND ITS METABOLITES (DDTs)

DDTs TOXICOLOGY

Dichlorodiphenyltrichloroethane (DDT) is a synthetic organochlorine insecticide once used throughout the world to control insects that transmit malaria, typhus, and other significant diseases (Crosby, 1998). First used in the United States in 1942, its registration was cancelled by U.S. EPA in 1973 after discovery of its environmental persistence, bioaccumulative properties, and induction of eggshell thinning in predatory species of birds (Hodgson et al., 1998). DDT is still used in some developing countries, however, because it is an effective and inexpensive method of vector control (ATSDR, 1994; Eicobichon, 1991). Humans are typically exposed to a mixture of DDT and its principal metabolites, DDD (tetrachlorodiphenylethane) and DDE (dichlorodiphenyl-dichloroethylene) (U.S. EPA, 2000), which are referred to collectively as total DDTs. U.S. EPA recommends that fish consumption limits be based on the sum of DDT, DDD, and DDE (i.e., total DDTs) (U.S. EPA, 2000).

DDTs are very lipid soluble and water insoluble, have relatively low volatility, and are chemically and biologically stable, which leads to their persistence in the environment and biomagnification by organisms (Ecobichon, 1991; Menzer, 1991; WHO, 1989). Bioconcentration factors as high as $1x10^6$ have been reported for DDTs in aquatic species (reported in Ecobichon, 1991). Because of their historical widespread use and chemical properties, DDTs are pervasive environmental contaminants (ATSDR, 2002).

Exposure of humans to DDTs occurs most commonly from food consumption, particularly meat, dairy products, poultry, and fish (ATSDR, 2002). Freshwater and saltwater fish, in fact, typically account for approximately 75 percent and 5 percent of the total dietary exposure to DDTs, respectively (Dougherty et al., 2000). DDTs are absorbed from the gastrointestinal tract following dietary exposure and are then distributed widely by the lymphatic system and blood before being stored primarily in high-lipid tissues such as fat, liver, kidney, and brain (ATSDR, 1994; 2002; U.S. EPA, 2000). Adipose storage of DDTs is considered protective as it lowers the concentration at the target organ (i.e., the brain) (Klaassen, 2001). DDTs are transferred across the placenta to the fetus (Saxena et al., 1981; Waliszewski et al., 2000; 2001) and easily cross the blood-brain barrier (ATSDR, 1994). Although the primary route of DDT excretion is urinary, lesser amounts are also excreted through feces and breast milk (ATSDR, 1994; 2002). Lactation is a significant means of maternal DDT decontamination (Waliszewski et al., 2001). The half-life of DDT in the body is 10-20 years (IRIS, 1996).

ATSDR (1994; 2002) has extensively reviewed the toxicity of DDT and related compounds. DDT has low acute toxicity with no confirmed human deaths reported solely from DDT exposure (ATSDR, 1994). Acute oral exposures to high levels of DDT primarily affect the nervous system in humans. DDT elicits adverse neurological effects

by inhibiting ion movement through neuronal membranes (ATSDR, 1994; 2002) and reducing the rate of depolarization, thereby intensifying the sensitivity of neurons to stimuli (Ecobichon, 2003). Symptoms have been reported to occur at doses of 5-10 mg/kg and above and include paresthesia, anxiety, irritability, vertigo, tremor, and convulsions, (ATSDR, 2002; Ecobichon, 1991; U.S. EPA, 2000). During an acute poisoning episode, tactile or auditory stimuli may induce repetitive tremors and seizures (Ecobichon, 2003).

Chronic oral exposures to moderate DDT levels have been reported to lead to anorexia and weight loss, anemia, tremors, muscular weakness, EEG changes, and anxiety in humans (Ecobichon, 1991). Similar to acute toxicity, the nervous system is considered a principal target following chronic exposure to this chemical (ATSDR, 2002). Subtle neurological deficits have been reported in humans following long-term chronic DDT exposure (van Wendel de Joode et al., 2001). Twenty-seven retired men, aged 55-70, with a history of occupational DDT exposure during the previous 41 years had exposure duration-related reduced neurobehavioral functioning and increased neuropsychological and psychiatric symptoms compared to a reference group. Performance on tests of verbal attention and visuomotor speed and sequencing were the most pronounced differences between groups. Exposure levels were not available.

A few studies have reported an association between plasma DDE levels and altered immune function in humans including lowered mitogen-induced lymphoproliferative activity, increased total lymphocytes, and either increased or decreased immunoglobulins (Vine et al., 2000, 2001; Cooper et al., 2004). Reproductive and developmental effects in humans such as alterations in the duration of lactation, maintenance of pregnancy, fertility, and length of gestation have also been associated with high levels of DDTs in blood and other body tissues (ATSDR, 2002; see, e.g., Gladen and Rogan, 1995; Longecker et al., 2001). Occasional and slight, but significant, decrements on the Bayley scales of infant development were seen in offspring at 6, 12 or 24 months of age corresponding to a ten-fold increase in maternal serum levels of *p,p*'-DDT, *o,p*'-DDT, or *p,p*'-DDE (Eskenazi et al., 2006).

While human epidemiological studies can only suggest a possible causal relationship between a chemical exposure and an adverse effect, animal studies using controlled exposures do demonstrate numerous toxic effects of DDT exposure. Similar to acute high-level DDT exposures in humans, relatively high long-term DDT exposure has been shown to lead to significant neurological signs in non-human primates. Six of 24 cynomolgus and rhesus monkeys given 20 mg/kg DDT for 130 months developed severe irreversible tremors requiring euthanasia during the first seven years of the study. Histological evidence of neurotoxicity was noted on necropsy (Takayama et al., 1999). Neurodevelopmental effects, most notably altered motor behavior in adult mice exposed prenatally, have also been reported in animals exposed to DDT (ATSDR, 2002; Eriksson et al., 1990a, 1990b, 1992).

Although there is no conclusive evidence that DDTs cause hepatic effects in humans (ATSDR, 2002), liver lesions have been shown to be the critical effect following chronic DDT exposure in rodent studies (IRIS, 1996). Laug et al. (1950), for example, found that weanling rats showed dose-related hepatic morphological changes at DDT doses of 5 ppm and above. DDT-induced hepatic effects have also been shown in hamsters, mice and dogs (IRIS, 1996). Fatty liver and histological signs of hepatotoxicity, including toxic hepatitis, coagulation necrosis, and focal liver necrosis, were seen in cynomolgus and rhesus monkeys dosed with 20 mg/kg DDT for 130 months and then followed for 25 years (Takayama et al., 1999).

Rodent studies have shown that DDTs in comparatively high doses have estrogenic properties that result in increased uterine weights and delayed vaginal opening (Clement and Okey, 1972), as well as antiandrogenic activity such as altered reproductive organ development and delayed puberty (Diel et al., 2000) (reported in ASTDR, 2002). Many animal studies have shown that DDTs are reproductive and developmental toxins. However, human studies have shown no clear link between exposure to environmental levels of DDTs and such effects. Intake of other estrogenic substances (as estrogen equivalents) from dietary bioflavonoids, for example, is estimated to be $4x10^7$ times higher than that from estrogenic pesticides (ATSDR, 2002; Safe, 1995).

Numerous epidemiological studies have attempted to determine whether DDTs cause cancer in humans, particularly those of the breast, pancreas, lymph system, prostate, and endometrium (reported in ATSDR, 2002). To date, these studies have not been sufficient to support a causal relationship between DDT exposure and the development of cancer in humans (ATSDR, 2002). However, the IARC has listed DDT as a possible human carcinogen, based on inadequate evidence of carcinogenicity in humans and sufficient evidence in experimental animals (development of liver tumors in several mouse and rat studies) (IARC, 1991). U.S. EPA classifies DDT as a probable human carcinogen, based on development of liver tumors in mice and rats (IRIS, 1996). OEHHA has administratively listed DDTs on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR DDTs

Because DDT dose-response data in humans are inadequate, the U.S.EPA RfD for this chemical was derived from animal data based on hepatic lesions as the critical effect (IRIS, 1996). U.S.EPA chose Laug et al. (1950) as the principal study for the RfD calculation because it had sufficient exposure duration, established the male rat as the most sensitive animal to DDT toxicity, used doses over the range of the dose-response curve, and provided both a NOAEL and LOAEL, including the lowest LOAEL determined for this chemical (IRIS, 1996).

Laug et al. (1950) fed male and female weanling rats diets containing 0, 1, 5, 10 or 50 ppm commercial DDT for 15-27 weeks. No gross signs of toxicity were apparent.

Histological evaluation of liver and kidneys showed centrilobular hepatic cell enlargement at doses of 5 ppm and above, particularly in male rats. The authors concluded that "the difference observed between the control and 5 ppm animals represents the smallest detectable morphologic effects of DDT, based on extensive observations of rat liver as affected by a variety of chemicals" (Laug et al., 1950; IRIS; 1996). The NOAEL and LOAEL values for this study were considered to be 1 and 5 ppm dietary DDT, respectively (IRIS, 1996). To the NOAEL (corresponding to 0.05 mg/kg-day), U.S. EPA applied a 100-fold uncertainty factor (10 for interspecies conversion and 10 to protect sensitive human subpopulations), leading to an RfD of $5x10^{-4}$ mg/kg-day (IRIS, 1996).

ATSDR has developed a minimal risk level (MRL) for DDTs based on neurodevelopmental effects in mice reported by Eriksson and colleagues (ATSDR, 2002; Eriksson and Nordberg, 1986; Eriksson et al., 1990a, 1990b, 1993; Johansson et al., 1995, 1996; Talts et al., 1998). Male suckling mice given a single oral dose of 0.5 mg/kg body weight DDT during the peak period of rapid brain growth (10 days of age) showed increased spontaneous motor activity when subjected to behavioral testing as 4-month old adults, indicating a disruption of habituation (Ericksson et al., 1990a, 1990b, 1992). Similar effects were not seen when exposures occurred either before (3 days of age) or after (19 days of age) this period (Ericksson et al., 1992). These studies identified a LOAEL of 0.5 mg/kg-day, to which ATSDR applied a 1000-fold uncertainty factor (10 for use of a LOAEL, and 10 each for animal to human extrapolation and intrahuman variability). The resulting MRL is identical to the U.S. EPA RfD based on hepatic effects ($5x10^{-4}$ mg/kg-day), which will be used to evaluate DDT non-cancer risk for OEHHA fish consumption guidelines.

Although studies to assess carcinogenicity in humans have been inadequate and conflicting, DDT has been shown to cause benign and malignant tumors in multiple animal studies and is structurally related to other known animal carcinogens such as DDD, DDE, dicofol, and chlorobenzilate (IRIS, 1996). In their 1991 cancer assessment, U.S. EPA combined the results of six liver tumor data sets for male and female CF-1 mice, male BABL/C mice, male MRC Porton rats, and male and female Wistar rats (Turusov et al., 1973; Terracini et al., 1973; Thorpe and Walker, 1973; Tomatis and Turusov, 1975; Cabral et al., 1982; and Rossi et al., 1977) given doses from 2 to 500 ppm in lifetime feeding studies. Individual slope factors from each of the data sets ranged from 0.082 to 1.04 $(mg/kg\text{-}day)^{-1}$; a geometric mean of these values was then calculated to derive an oral CSF for DDT of 0.34 $(mg/kg\text{-}day)^{-1}$. This oral slope factor will be used to evaluate DDT cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer and cancer critical values used to evaluate DDT in fish for the development of consumption guidelines will be **$5x10^{-4}$ mg/kg-day and 0.34 $(mg/kg\text{-}day)^{-1}$**, respectively.

DIELDRIN

DIELDRIN TOXICOLOGY

Dieldrin is a chlorinated cyclodiene insecticide widely used in the United States from the 1950s to 1970 on crops such as corn and cotton and as a termiticide in subsequent years, until its registration was canceled by U.S. EPA in 1989 (ATSDR, 2002; Stevenson et al., 1999; WHO, 1989). As a result of their low volatility, slow degradation rates and lipophilicity, dieldrin and other organochlorine pesticides resist degradation in the environment and are able to bioconcentrate and biomagnify throughout the terrestrial and aquatic food chain (ATSDR, 2002; Ecobichon, 1991). For example, bioconcentration factors of 12,500 and 13,300 have been found for dieldrin in guppies and sculpins, respectively (Fisher, 1999). Dieldrin is extremely persistent (Matsumura, 1985) and, as such, is still found in the environment, particularly in soil, sediment, and animal fat (ATSDR, 2002).

Diet is the main source of dieldrin exposure in most individuals, with foods such as dairy and meat products, fish, garden fruits, and root vegetables providing the largest dietary contribution (ATSDR, 2002; WHO, 1989). Currently, approximately 90 percent of dietary dieldrin exposure is derived from saltwater and freshwater fish, combined (Dougherty et al., 2000). Dieldrin levels in fish are most commonly associated with areas of corn production (ATSDR, 2002). Following oral exposure, dieldrin is absorbed from the gastrointestinal tract and rapidly distributed through the lymphatic system to various body tissues before being stored largely in adipose tissue and bone marrow (ATSDR, 2002; de Vlieger et al., 1968; Morgan and Roan, 1970; Scheele, 1998). Body burdens are positively correlated with total body fat (ATSDR, 2002; Hunter and Robinson, 1967; 1968). Dieldrin is transferred across the placenta to the fetus where it is widely distributed to fetal organs (Curley et al., 1969). During labor, levels in extracted lipids of fetal blood are higher than in maternal blood (ATSDR, 2002; Polishuk et al., 1977; WHO, 1989). Dieldrin also crosses the blood brain barrier (WHO, 1989). The primary route of dieldrin excretion is through feces via the bile (ATSDR, 2002; Richardson and Robinson, 1971; WHO, 1989), although dieldrin is also excreted in breast milk (ATSDR, 2002; Schecter et al., 1989; Stevens et al., 1993). Breast milk dieldrin levels have been reported to be significantly lower in vegetarians whose diets do not contain animal products compared to U.S. population means, even though breast milk lipid levels were similar between groups (Hergenrather et al., 1981). The biological half-life of dieldrin is approximately one year (WHO, 1989).

ATSDR (2002) and WHO (1989) have extensively reviewed the toxicity of dieldrin. Similar to other chlorinated cyclodienes, dieldrin has relatively high acute toxicity following oral or inhalation exposures compared to most organochlorine pesticides with signs and symptoms including dizziness, vomiting, motor hyperexcitability, and convulsions that generally appear within 20 minutes to 24 hours post-exposure (Ecobichon, 1991; 2003; Klassen and Watkins, 1999; WHO, 1989). The nervous system is the most sensitive target organ following acute and chronic oral exposures in humans

(ATSDR, 2002); adverse neurological effects, including electroencephalographic abnormalities, have been reported in workers occupationally exposed to dieldrin (Hoogendam et al., 1962; 1965). The mechanism of neurotoxic action is believed to be inhibition of chloride transport, resulting in only partial repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999). In animals, initial signs of single-dose dieldrin intoxication are irritability and tremor prior to tonic-clonic convulsions; these may occur as little as one hour after exposure (WHO, 1989). The adult human lethal dose is estimated to be five g (WHO, 1989). The single dose oral LD_{50} for dieldrin in the rat is approximately 37 to 46 mg/kg (ATSDR, 2002). Interspecies variation in susceptibility to acute dieldrin toxicity is significant, with toxicity inversely correlated with species total body fat content (Geyer et al., 1993).

Dieldrin may affect the endocrine system in humans. An epidemiological study of blood organochlorine levels found that dieldrin concentrations were inversely correlated with T4 levels in hypothyroid women (Rathore et al., 2002). Correlational studies such as this, however, cannot prove a causal relationship between exposure and adverse effect.

There is no clear evidence that dieldrin causes hepatotoxicity in humans; however, in rodent studies, the liver is the target organ of chronic dieldrin toxicity and liver lesions are considered to be the critical effect (IRIS, 1990). Liver histopathological changes in rats and increased liver weights and liver-to-body weight ratios in rats and dogs were found in response to varying levels of dieldrin exposure for two years (Walker et al., 1969). Hepatomegaly and histopathological evidence of liver damage were also seen in mice exposed to 10 ppm dietary dieldrin for two years (Thorpe and Walker, 1973). Kitselman (1953) showed that dieldrin-induced gross and histopathological liver changes in dogs were reversible after dieldrin was removed from the diet. In a six-year study of monkeys fed 0.01 to 5.0 ppm dietary dieldrin, hepatic microsomal cytochrome P-450 levels were significantly increased in a dose-dependent fashion at doses of 0.1 ppm and above (approximately 25 to 30 µg/kg body weight per day or greater). Other hepatic variables such as liver weights and alkaline phosphatase, glucose-6-phosphatase, and succinic dehydrogenase activities were not affected by treatment, with the exception of slightly increased microsomal protein contents at the highest doses (Wright et al., 1978).

Several studies have indicated that fertility, litter size, and maternal behavior may be adversely affected following dieldrin exposure in rodents (Harr et al., 1970; Good and Ware, 1969; Virgo and Bellward, 1975; Treon and Cleveland, 1955). A small reproductive study in male and female dogs found delayed estrus, decreased libido, lack of mammary function, and increased stillbirths in animals exposed to 0.15 or 0.30 mg/kg-day dieldrin (Deichmann et al., 1971; reported in ATSDR, 2002). Teratogenesis was not observed in offspring of rats and mice fed graded doses of dieldrin during the period of organogenesis; however, fetotoxicity, as evidenced by an increase in the number of supernumerary ribs and decreased numbers of caudal ossification centers, was seen in doses that also caused signs of maternal toxicity (Chernoff et al., 1975).

Dieldrin has been shown to exert neurobehavioral effects in animals. Following a low dose (0.5, 1.5, or 4.5 mg/kg) acute exposure, a dose-related decrement in adaptive capacity to an uncontrollable stressor was seen in adult mice (Carlson and Rosellini, 1987). In a small study, 0.1 mg/kg-day dieldrin for 55 days impaired learning acquisition in monkeys while 0.01 mg/kg-day did not (Smith et al., 1976). Neurodevelopmental changes such as cerebral edema, internal and external hydrocephalus, and focal neuronal degeneration were seen in rat pups whose dams were exposed to 0.004-0.008 mg/kg-day dieldrin during gestation (ATSDR, 2002; Harr et al., 1970). However, inadequacies of study design and statistical analyses limit interpretation of these results (ATSDR, 2002).

Mouse studies have shown that dieldrin may cause immunosuppression, as evidenced by increased lethality of various viruses (ATSDR, 2002). For example, Krzystyniak et al. (1985) found that a single oral dose of 18 or 30 mg/kg dieldrin in mice significantly reduced the mean day of death following exposure to a lethal dose of mouse hepatitis virus 3 (MHV3). Mice fed 1 or 5 ppm dietary dieldrin for 10 weeks (corresponding to doses as low as 0.13 mg/kg/day; ATSDR, 2002) had reduced survival times when infected with *Plasmodium berghei* or *Leishmania tropica* (Loose, 1982).

Whether dieldrin can cause cancer in human populations is controversial. Several long-term epidemiological studies of workers in pesticide manufacturing plants have not found higher cancer mortality rates related to occupational dieldrin exposure in workers compared to controls (Amoateng-Adjepong et al., 1995; Ribbens, 1985; Swaen et al., 2002). Although Quintana et al. (2004) found that cadaver adipose tissue dieldrin levels were positively associated with risk of non-Hodgkin's lymphoma, according to the authors, lack of data on confounding variables in cases and controls or exposure level or duration hamper interpretation of these results. On the other hand, Cantor et al. (2003) did not see an association between pre-diagnostic serum dieldrin levels and risk of non-Hodgkin's lymphoma in matched controls. IARC has listed dieldrin as not classifiable as to its carcinogenicity, based on inadequate evidence of carcinogenicity in humans and limited evidence of carcinogenicity in animals (IARC, 1987). In contrast, U.S.EPA lists dieldrin as a probable human carcinogen, based on development of benign liver tumors and hepatocarcinomas in multiple strains of mice (IRIS, 1993) and OEHHA has administratively listed dieldrin on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR DIELDRIN

Data for determining NOAEL or LOAEL values for dieldrin in humans are inadequate; thus, U.S. EPA derived an RfD for this chemical based on animal studies. In contrast to humans, where neurotoxicity appears to be the most sensitive endpoint for acute and chronic toxicity, hepatic lesions are the chronic critical effect reported in animals (IRIS, 1990). U.S. EPA chose Walker et al. (1969) as the principal study for the RfD because it supported the critical effect and was a comparatively comprehensive chronic toxicity assessment (IRIS, 1990). Although minimal neurotoxic effects were also seen in this

study, they occurred at a 10-fold higher dose level than did the hepatotoxic effects (ATSDR, 2002) and were thus not used in deriving a reference dose.

Walker et al. (1969) fed five-week-old male and female CFE rats diets containing 0, 0.1, 1.0, and 10.0 ppm dieldrin for two years. Body weights, feed intake, hematology, clinical chemistry, and mortality were unaffected by treatment. High-dose animals showed irritability and occasional tremors and convulsions during the course of the study. One- and 10 ppm-treated female rats had increased absolute and relative liver weights compared to controls. Hepatic parenchymal cell changes indicative of organochlorine exposure were found in some 10 ppm-treated male and female rats. U.S. EPA identified 0.1 and 1.0 ppm, respectively, as the NOAEL and LOAEL values for this study (IRIS, 1990). To the NOAEL (corresponding to 0.005 mg/kg-day), U.S. EPA applied a 100-fold uncertainty factor (10 for interspecies conversion and 10 to protect sensitive humans), leading to an RfD of $5x10^{-5}$ mg/kg-day (IRIS, 1990). ATSDR (2002) has developed a chronic oral minimum risk level (MRL) of $5x10^{-5}$ mg/kg-day, also based on the Walker et al. (1969) study, which is identical to the U.S. EPA RfD. This RfD will be used to evaluate dieldrin non-cancer risk for OEHHA fish consumption guidelines.

Studies to assess the carcinogenicity of dieldrin in humans are inadequate; however, dieldrin has been shown to cause cancer in multiple mouse strains (see caveats noted above) and is structurally related to other known rodent carcinogens (e.g., aldrin, chlordane, heptachlor, and heptachlor epoxide) (IRIS, 1993). U.S. EPA combined the results of 13 liver carcinoma data sets for male and female C3H and CF1 mice, and male B63F1, C57B1/6J, and C3H/H3 mice to determine carcinogenicity for this chemical. Individual slope factors for each of the data sets ranged from 7.1 to 55 $(mg/kg\text{-}day)^{-1}$. A geometric mean of those values was used to set an oral slope factor for dieldrin of 16 $(mg/kg\text{-}day)^{-1}$ (IRIS, 1993). This oral slope factor will be used to evaluate dieldrin cancer risk for OEHHA fish consumption guidelines.

In summary, the non-cancer and cancer critical values used to evaluate dieldrin in fish for the development of consumption guidelines will be **$5x10^{-5}$ mg/kg-day and 16 $(mg/kg\text{-}day)^{-1}$**, respectively.

METHYLMERCURY

METHYLMERCURY TOXICOLOGY

Mercury is a metal found naturally in rocks, soil, air, and water that can be concentrated to high levels in the aquatic food chain by a combination of natural processes and human activities (ATSDR, 1999). The toxicity of mercury to humans is greatly dependent on its chemical form (elemental, inorganic, or organic) and route of exposure (oral, dermal, or inhalation). Methylmercury (an organic form) is highly toxic and can pose a variety of human health risks (NAS/NRC, 2000). Of the total amount of mercury found in fish muscle tissue, methylmercury comprises more than 95 percent (ATSDR, 1999; Bloom, 1992). Because analysis of total mercury is less expensive than that for methylmercury, total mercury is usually analyzed for most fish studies and assumed to be 100 percent methylmercury for the purposes of risk assessment.

In general, mercury concentrations in fish and other biota are dependent on the mercury level of the environment, which can vary based on differences in pH, redox potential, temperature, alkalinity, buffering capacity, suspended sediment load, and geomorphology of individual water bodies (Andren and Nriagu, 1979; Berlin, 1986; WHO, 1989). Other factors also affect the accumulation of mercury in fish tissue, including fish diet, species and age (as inferred from length) (WHO, 1989; 1990). Fish at the highest trophic levels (i.e., predatory fish) generally have the highest levels of mercury. Additionally, because of the long biological half-life of methylmercury in fish (approximately 2 years), tissue concentrations in fish increase with increased duration of exposure (Krehl, 1972; Stopford and Goldwater, 1975; Tollefson and Cordle, 1986). As a result, tissue methylmercury concentrations are expected to increase with increasing age and length within a given species, particularly in piscivorous fish.

Fish consumption is the major route of exposure to methylmercury in the United States (ATSDR, 1999). As noted above, almost all fish contain detectable levels of methylmercury, which, when ingested, is almost completely absorbed from the gastrointestinal tract (Aberg et al., 1969; Myers et al., 2000). Once absorbed, methylmercury is distributed throughout the body, reaching the largest concentration in kidneys. Its ability to cross the placenta as well as the blood-brain barrier allows methylmercury to accumulate in the brain and fetus, which are known to be especially sensitive to the toxic effects of this chemical (ATSDR, 1999). In the body, methylmercury is slowly converted to inorganic mercury and excreted predominantly by the fecal (biliary) pathway. Methylmercury is also excreted in breast milk (ATSDR, 1999). The biological half-life of methylmercury is approximately 44-74 days in humans (Aberg, 1969; Smith et al., 1994), meaning that it takes approximately 44-74 days for one-half of a single ingested dose of methylmercury to be eliminated from the body.

Human toxicity of methylmercury has been well studied following several epidemics of human poisoning resulting from consumption of highly contaminated fish (Japan) or seed grain (Iraq, Guatemala, and Pakistan) (Elhassani, 1982-83). The first recorded mass

methylmercury poisoning occurred in the 1950s and 1960s in Minamata, Japan, following the consumption of fish contaminated by industrial pollution (Marsh, 1987). The resulting illness was manifested largely by neurological signs and symptoms such as loss of sensation in the hands and feet, loss of gait coordination, slurred speech, sensory deficits including blindness, and mental disturbances (Bakir et al., 1973; Marsh, 1987). This syndrome was subsequently named Minamata Disease. A second outbreak of methylmercury poisoning occurred in Niigata, Japan, in the mid-1960s. In that case, contaminated fish were also the source of illness (Marsh, 1987). In all, more than 2,000 cases of methylmercury poisoning were reported in Japan, including more than 900 deaths (Mishima, 1992).

The largest outbreak of methylmercury poisoning occurred in Iraq in 1971-1972 and resulted from consumption of bread made from seed grain treated with a methylmercury fungicide (Bakir et al., 1973). This epidemic occurred over a relatively short term (several months) compared to the Japanese outbreak. The mean methylmercury concentration of wheat flour samples was found to be 9.1 micrograms per gram (μg/g). Over 6,500 people were hospitalized, with 459 fatalities. Signs and symptoms of methylmercury toxicity were similar to those reported in the Japanese epidemic. Review of data collected during and subsequent to the Japan and Iraq outbreaks identified the critical target of methylmercury as the nervous system and the most sensitive subpopulation as the developing organism (U.S. EPA, 1997). During critical periods of prenatal and postnatal structural and functional development, the fetus and children are especially susceptible to the toxic effects of methylmercury (ATSDR, 1999; IRIS, 1995). When maternal methylmercury consumption is very high, as happened in Japan and Iraq, significant methylmercury toxicity can occur to the fetus during pregnancy, with only very mild or even in the absence of symptoms in the mother. In those cases, symptoms in children were often not recognized until development of cerebral palsy and/or mental retardation many months after birth (Harada, 1978; Marsh et al., 1980; Marsh et al., 1987; Matsumoto et al., 1964; Snyder, 1971).

IARC has listed methylmercury compounds as possible human carcinogens, based on inadequate data in humans and limited evidence in experimental animals (increased incidence of tumors in mice exposed to methylmercury chloride) (IARC, 1993). U.S. EPA has also listed methylmercury as a possible human carcinogen (IRIS, 2001). OEHHA has administratively listed methylmercury compounds on the Proposition 65 list of chemicals known to the State of California to cause cancer. No estimate of the increased cancer risk from lifetime exposure to a chemical has been developed for methylmercury.

DERIVATION OF REFERENCE DOSES FOR METHYLMERCURY

The first U.S. EPA RfD for methylmercury was developed in 1985 and set at $3x10^{-4}$ mg/kg-day (U.S. EPA, 1997). This RfD was based, in part, on a WHO report summarizing data obtained from several early epidemiological studies on the Iraqi and Japanese methylmercury poisoning outbreaks (WHO, 1976). WHO found that the

earliest symptoms of methylmercury intoxication (paresthesias) were reported in adults at blood and hair concentrations ranging from 200-500 µg/L and 50-125 µg/g, respectively. In cases where ingested mercury dose could be estimated (based, for example, on mercury concentration in contaminated bread and number of loaves consumed daily), an empirical correlation between blood and/or hair mercury concentrations and onset of symptoms was obtained. From these studies, WHO determined that methylmercury exposure equivalent to long-term daily intake of 3-7 µg/kg body weight in adults was associated with an approximately 5 percent prevalence of paresthesias (WHO, 1976). U.S. EPA further cited a study by Clarkson et al. (1976) to support the range of blood mercury concentrations at which paresthesias were first observed in sensitive members of the adult population. This study found that a small percentage of Iraqi adults exposed to methylmercury-treated seed grain developed paresthesias at blood levels ranging from 240 to 480 µg/L. The low end of this range was considered to be a LOAEL and was estimated to be equivalent to a dosage of 3 µg/kg-day. U.S. EPA applied a 10-fold uncertainty factor to the LOAEL to reach what was expected to be the NOAEL. Because the LOAEL was observed in sensitive individuals in the population after chronic exposure, additional uncertainty factors were not considered necessary for exposed adults (U.S. EPA, 1997).

Although this RfD was derived based on effects in adults, even at that time researchers were aware that the fetus might be more sensitive to methylmercury (WHO, 1976). It was not until 1995, however, that U.S. EPA had sufficient data from Marsh et al. (1987) and Seafood Safety (1991) to develop an oral RfD based on methylmercury exposures during the prenatal stage of development (IRIS, 1995). Marsh et al. (1987) collected and summarized data from 81 mother and child pairs where the child had been exposed to methylmercury *in utero* during the Iraqi epidemic. Maximum mercury concentrations in maternal hair during gestation were correlated with clinical signs in the offspring such as cerebral palsy, altered muscle tone and deep tendon reflexes, and delayed developmental milestones that were observed over a period of several years after the poisoning. Clinical effects incidence tables included in the critique of the risk assessment for methylmercury conducted by the U.S. Food and Drug Administration (FDA) (Seafood Safety, 1991) provided dose-response data for a benchmark dose approach to the RfD, rather than the previously used NOAEL/LOAEL method. The BMDL was based on a maternal hair mercury concentration of 11 ppm. From that, an average blood mercury concentration of 44 µg/L was estimated based on a hair: blood concentration ratio of 250:1. Blood mercury concentration was, in turn, used to calculate a daily oral dose of 1.1 µg/kg-day, using an equation that assumed steady-state conditions and first-order kinetics for mercury. An uncertainty factor of 10 was applied to this dose to account for variability in the biological half-life of methylmercury, the lack of a two-generation reproductive study and insufficient data on the effects of exposure duration on developmental neurotoxicity and adult paresthesia. The oral RfD was then calculated to be $1x10^{-4}$ mg/kg-day, to protect against developmental neurological abnormalities in infants (IRIS, 1995). This fetal RfD was deemed protective of infants and sensitive adults.

The two previous RfDs for methylmercury were developed using data from high-dose poisoning events. Recently, the National Academy of Sciences (NSA) was directed to provide scientific guidance to U.S. EPA on the development of a new RfD for methylmercury (NAS/NRC, 2000). Three large prospective epidemiological studies were evaluated in an attempt to provide more precise dose-response estimates for methylmercury at chronic low-dose exposures, such as might be expected to occur in the United States. The three studies were conducted in the Seychelles Islands (Davidson et al., 1995, 1998), the Faroe Islands (Grandjean et al., 1997, 1998, 1999), and New Zealand (Kjellstrom et al., 1986, 1989). The residents of these areas were selected for study because their diets rely heavily on consumption of fish and marine mammals, which provide a continual source of methylmercury exposure (NAS/NRC, 2000).

Although estimated prenatal methylmercury exposures were similar among the three studies, subtle neurobehavioral effects in children, such as problems with attention, fine-motor function, and verbal memory, were found to be associated with maternal methylmercury dose in the Faroe Islands and New Zealand studies, but not in the Seychelle Islands study. The reasons for this discrepancy were unclear; however, it may have resulted from differences in sources of exposure (marine mammals and/or fish), differences in exposure pattern, differences in neurobehavioral tests administered and age at testing, the effects of confounding variables, or issues of statistical analysis (NRC/NAS, 2000). The NAS report supported the current U.S. EPA RfD of $1x10^{-4}$ mg/kg-day for fetuses, but suggested that it should be based on the Faroe Islands study rather than Iraqi data.

U.S. EPA recently published a new RfD document that arrives at the same numerical RfD as the previous fetal RfD, using data from all three recent epidemiological studies while placing emphasis on the Faroe Island data (IRIS, 2001). In order to develop an RfD, U.S. EPA used several test scores from the Faroes data, rather than a single measure for the critical endpoint as is customary (IRIS, 2001). U.S. EPA developed BMDLs utilizing test scores for several different neuropsychological effects mentioned above with cord blood as the biomarker for mercury exposure. The BMDLs for different neuropsychological effects in the Faroes study ranged from 46-79 µg mercury/liter blood. U.S. EPA then chose a one-compartment model for conversion of cord blood to ingested maternal dose, which resulted in estimated maternal mercury exposures of 0.857-1.472 µg/kg-day (IRIS, 2001). An uncertainty factor of ten was applied to the oral doses corresponding to the range of BMDLs to account for interindividual toxicokinetic variability in ingested dose estimation from cord-blood mercury levels and pharmacodynamic variability and uncertainty, leading to an RfD of $1x10^{-4}$ mg/kg-day (IRIS, 2001). In support of this RfD, U.S. EPA found that benchmark dose analysis of several neuropsychological endpoints from the Faroe Island and New Zealand studies, as well as an integrative analysis of all three epidemiological studies, converged on an RfD of $1x10^{-4}$ mg/kg-day (IRIS, 2001). U.S. EPA (IRIS, 2001) now considers this RfD to be protective for all populations. However, in their joint Federal Advisory for Mercury in Fish, U.S. EPA and U.S. FDA only apply this RfD to women who are pregnant or might become pregnant, nursing mothers, and young children (U.S. EPA, 2004).

OEHHA finds that there is convincing evidence that the fetus is more sensitive than adults to the neurotoxic and subtle neuropsychological effects of methylmercury. As noted previously, during the Japanese and Iraqi methylmercury poisoning outbreaks, significant neurological toxicity occurred to the fetus even in the absence of symptoms in the mother. In later epidemiological studies at lower exposure levels (e.g., in the Faroe Islands), these differences in maternal and fetal susceptibility to methylmercury toxicity were also observed. Recent evidence has shown that the nervous system continues to develop through adolescence (see, for example, Giedd et al., 1999; Paus et al., 1999; Rice and Barone, 2000). As such, it is likely that exposure to a neurotoxic agent during this time may damage neural structure and function (Adams et al., 2000), which may not become evident for many years (Rice and Barone, 2000). Thus, OEHHA considers the RfD based on subtle neuropsychological effects following fetal exposure to be the best estimate of a protective daily exposure level for women aged 18 to 45 years and children aged 1 to17 years.

In an effort to address the risks of methylmercury contamination in different populations, two separate RfDs will be used to assess risk for different population groups. OEHHA has formerly used a separate methylmercury RfD for sensitive populations to formulate advisories for methylmercury contamination of sport fish (Stratton et al., 1987). Additionally, the majority of states issue separate consumption advice for sensitive (e.g., children) and general population groups**.** OEHHA chooses to use both the current and previous U.S. EPA RfDs to evaluate methylmercury non-cancer risk for fish consumption guidelines for two distinct population groups. In OEHHA advisories, the current RfD of $1x10^{-4}$ mg/kg-day, based on effects in infants, will be used for women 18 to 45 years and children aged 1 to17 years. The previous RfD of $3x10^{-4}$ mg/kg-day, based on effects in adults, will be used for women over 45 years and men.

In summary, the non-cancer critical values used to evaluate methylmercury in fish for development of consumption guidelines will be **$1x10^{-4}$ mg/kg-day** for women aged 18 to 45 years and children aged 1 to 17 years, and **$3x10^{-4}$ mg/kg-day**, for women over 45 years and men.

POLYCHLORINATED BIPHENYLS (PCBs)

PCBs TOXICOLOGY

Polychlorinated biphenyls (PCBs) are a class of synthetic persistent lipophilic organic chemicals containing complex mixtures of biphenyls that are chlorinated to varying degrees (ATSDR, 2000; U.S. EPA, 2000a). The chemical formula for PCBs is $C_{12}H_{10-n}Cl_n$, where n equals the number of chlorine atoms ranging from one to ten (WHO, 1993). PCBs were manufactured in the United States from about 1930 to 1977 for use as coolants in electrical transformers and capacitors, and as hydraulic fluids, lubricating and cutting oils, and plasticizers (ATSDR, 2000; Erickson, 2001). Although there are 209 possible individual chlorinated biphenyl compounds (known as congeners), only approximately 130 are found in commercial products (U.S. EPA, 2000a; WHO, 1993). In the United States, PCBs were generally sold as mixtures of congeners under the trade name Aroclor (ATSDR, 2000; Nessel and Gallo, 1992).

PCBs primarily enter the environment as a result of accidental spills and leaks from products containing Aroclor mixtures and are redistributed among environmental compartments by volatilization and runoff (ATSDR, 2000). Because of their lipophilicity and slow degradation rates, PCBs are very resistant to degradation in the environment (ATSDR, 2000). PCBs are found chiefly in soil, sediment, and fatty biological tissue, where they accumulate and biomagnify in the food chain (Dekoning and Karmaus, 2000; Menzer, 1991; Moser and McLachlan, 2001). Bioconcentration factors of some congeners are reported to reach as high as $1x10^7$ in fish (Erickson, 2001). PCB residue levels in fish are affected by sediment characteristics (e.g., organic carbon content), fish species and lipid content, and trophic structure of the food chain (Eisler, 1996).

The composition of Aroclor mixtures in the environment will change over time as individual PCB congeners undergo differential partitioning, degradation, and biotransformation. This process, referred to as “weathering,” results in differential persistence and bioaccumulation, which changes the PCB pattern found in environmental samples from the original pattern in technical Aroclor mixtures (Erickson, 2001). As a rule, the environmental persistence of PCBs increases with the degree of chlorination (Menzer, 1991). As a result of improved methods and equipment, PCBs in environmental samples can be quantified as congeners and congener patterns can be related to potential sources and to the technical Aroclor mixture they most closely resemble (Newman, et al., 1998).

Saltwater and fresh water fish and shellfish, combined, account for a significant portion of the total dietary exposure to PCBs (Dougherty et al., 2000). In a study comparing frequent and infrequent Great Lakes sport fish consumers, lifetime sport fish consumption was found to be the best predictor of PCB body burdens (Hanrahan et al., 1999). Fishers who consume fish from PCB-contaminated waters have been found to have serum PCB levels several times those of the general population and similar to individuals occupationally exposed to PCBs (Kreiss, 1985).

Absorption of PCBs following oral exposure occurs via passive diffusion and ranges from approximately 75 percent to more than 90 percent (U.S. EPA, 2000a), depending on congener and the diffusion gradient between PCB concentration in the gut contents and serum lipids (Juan et al., 2002; ATSDR, 2000). Once absorbed, PCBs are distributed throughout the body, accumulating primarily in lipid-rich tissues such as liver, adipose tissue, skin, and breast milk (U.S. EPA, 2000a). More than 95 percent of most PCB congeners are absorbed from breast milk (Dahl et al., 1995; McLachlan, 1993). PCBs are also transferred across the placenta to the fetus (ATSDR, 2000; DeKoning and Karmaus, 2000). Excretion of PCBs occurs primarily through the feces and urine as well as breast milk of lactating women (ATSDR, 2000; Moser and McLachlan, 2001). Net absorption (absorption from the gastrointestinal tract minus excretion) is significantly influenced by blood lipid levels, congener body burden (ATSDR, 2000; Schlummer et al., 1998), and body mass index (Juan et al., 2002). Although various studies have shown substantial disparities in estimated half-lives of PCBs (less than one year to greater than 10 years), the best evidence suggests that the majority of PCB congeners found in an occupational setting have half-lives in the human body from one to six years (Shirai and Kissel, 1996; Wolff et al., 1982).

The toxicity of PCBs following occupational exposure has been known since 1936 when the development of chloracne (a severe form of acne) in PCB-exposed workers resulted in the establishment of a workplace threshold limit value for these compounds (Erickson, 2001). Occupational exposure has also been reported to result in ocular effects such as Meibomian gland hypersecretion, swollen eyelids, and abnormal conjunctival pigmentation (ATSDR, 2000). Incidents of purported widespread PCB poisonings occurred in Japan in 1968 ("Yusho") and Taiwan in 1979 ("Yu-Cheng") following consumption of PCB-contaminated rice oil (WHO, 1993). Signs and symptoms in affected persons were primarily ocular and dermatological; edema, alterations in blood chemistry values, and various respiratory, immunological, reproductive, developmental, and neurological disturbances were also seen (ATSDR, 2000; WHO, 1993). Although the clinical syndrome was originally thought to have resulted solely from PCB toxicity, ensuing investigations determined that the co-contaminants polychlorinated dibenzofurans (PCDFs) were the primary causal factors in Yusho and Yu-Cheng diseases (Ikeda, 1996; Kunita et al., 1984; Schantz, 1996; Wilson, 1987; Yao et al., 2002). In a sample of Yusho rice oil, for example, 2,3,4,7,8-pentaCDF was found to contribute the majority (58 percent) of the total toxic equivalents (TEQ), while PCB-126 was the second most abundant contributor to total TEQ (16 percent) (Yao et al., 2002). It is possible, however, that some signs and symptoms in the Yusho and Yu-Cheng poisonings resulted from non-*Ah* receptor mediated mechanisms of PCB toxicity.

Numerous epidemiological studies since that time have attempted to determine whether PCBs pose a human health risk at levels currently found in the environment. Many authors have subsequently reported an association between oral environmental PCB exposures and cancer as well as various adverse neurological, reproductive, and developmental effects (ATSDR, 2000). In particular, several observational cohort studies have found one or more neurodevelopmental deficits in children exposed to PCBs *in*

utero and/or postnatally (see descriptions in Winneke et al., 1998; 2002); however, results have differed with respect to the type and persistence of effects as well as the matrix (e.g., cord blood or breast milk) used to indicate exposure (Winneke et al., 1998). For example, Jacobson et al. (1992) and Jacobson and Jacobson (1996) noted that children exposed to PCBs prenatally through maternal consumption of contaminated Great Lakes fish had poorer performance on cognitive tests for visual, verbal and memory abilities at four years of age, and lowered verbal and full-scale IQ at age eleven compared to children with lower intrauterine PCB exposures. In similarly exposed infants, Gladen et al. (1988) found decreases in psychomotor scores at twelve months as well as delays in motor maturation up to 24 months (Rogan and Gladen, 1991), but no changes in mental scores. These effects were no longer observed at 3-5 years of age (Gladen and Rogan, 1991). Schantz et al. (1999) found no effect on visual-motor coordination or hand steadiness in a population of adults over 50 years of age exposed to PCBs and other contaminants through long-term consumption of large amounts of Great Lakes fish compared to those who consumed little or no Great Lakes fish. However, the same population showed a decrease in verbal memory in one of two standardized tests of memory and learning compared to controls (Schantz et al., 2001). No effects were seen on executive or visual-spatial function. In a study comparing women who had consumed more than 40 pounds of Great Lakes fish over their lifetimes with women who had never consumed Great Lakes fish, Stewart et al. (2000) found a significant linear relationship between highly chlorinated (C17-C19) PCB congeners in cord blood and decreased habituation and autonomic scores in the Neonatal Behavioral Assessment Scale. In a European cohort, Winneke et al. (1998) found the sum of PCBs 138, 153, and 180 in breast milk to be negatively associated with cognitive development, but not motor development or recognition memory in seven-month-old infants. These outcomes were not related to cord plasma PCBs. Neurological effects have also been observed in infants, children, and adults following PCB poisonings (ATSDR, 2000).

Recent data indicate that typical environmental levels of PCBs might affect the developing immune system in humans (Weisglas-Kuperus et al., 2000). Prenatal PCB exposure was positively associated with number of lymphocytes, T cells, and $CD3^{+}CD8^{+}$ (cytotoxic), $CD4^{+}$ $CD45RO^{+}$ (memory), $TcR\alpha\beta^{+}$, and $CD3^{+}$HLA-DR^{+} (activated) T cells and negatively associated with antibody levels to mumps and rubella in 42 month-old children. Current plasma PCB levels were positively associated with prevalence of chicken pox and recurrent middle ear infections, while negatively associated with prevalence of allergic reactions. Increased duration of breast feeding counteracted the negative effects of postnatal PCB exposure (Weisglas-Kuperus et al., 2000).

Human studies have shown inconsistent results with respect to adverse reproductive effects following PCB exposures (ATSDR, 2000). Menstrual cycles were slightly shorter and female fecundity was reduced in women consuming PCB-contaminated Great Lakes fish (Buck et al., 2000; Mendola et al. 1997). However, other studies have shown no adverse reproductive effects in women consuming high-PCB fish when examining endpoints such as increased time-to-pregnancy or risk of spontaneous fetal death (Buck et al., 1997; Courval et al., 1999; Mendola et al., 1995), although there was a small

association between sport-caught fish consumption and conception delay for men (Courval et al., 1999). Results of human studies on potential developmental effects of PCB exposure have also been mixed (ATSDR, 2000). Maternal PCB exposure via fish consumption has been reported to have a negative, positive, or no association with birth weight, head circumference, or gestation age (see, for example, Buck et al., 2003; Dar et al., 1992; Jacobson et al. 1990a, 1990b; Lonky et al., 1996; Rylander et al., 1995; Smith, 1984; ATSDR, 2000).

Most human epidemiological studies examining adverse effects of PCB exposure have been confounded by concomitant exposure to the trace contaminants PCDFs or other workplace chemicals such as solvents, benzene, and lead (Erickson, 2001; Persky, 2001), or have had other serious design or reporting flaws (Swanson et al., 1995). In fact, in a systematic critical evaluation of 72 occupational or environmental PCB exposure studies conducted prior to 1995, Swanson et al. (1995) found that only five of the occupational studies and none of the environmental studies provided either positive or suggestive evidence of a causal relationship between PCB exposure and adverse effects in humans. Most studies were deemed inconclusive. This is particularly true in studies of fish-eating populations as fish are often contaminated with multiple organochlorines and other neurological, developmental or reproductive toxins (Seegal, 1996; 1999). Although human epidemiological studies are quite limited in their ability to prove a causal relationship between PCB exposure and disease (Seegal, 1996), animal studies using controlled exposures to specific Aroclor mixtures do clearly demonstrate adverse effects on the hepatic, hematological, gastrointestinal, immunological, neurological, endocrine, and reproductive systems following oral PCB exposure (ATSDR, 2000). To date, the most sensitive effects of PCB toxicity have been identified in monkeys, including clinical signs showing developmental effects such as ocular exudate, inflamed Meibomian glands, and distorted growth of fingernails and toenails, as well as immunological effects such as decreased antibody response to sheep erythrocytes (IRIS, 1996). Studies showing specific effects are discussed in more detail below.

As has been the case with various non-cancer endpoints, epidemiological research in humans has also found an association between exposure to PCBs and mortality rates from cancers of the liver, gall bladder, biliary tract, and brain, as well as non-Hodgkin's lymphoma and malignant melanoma (see Cogliano, 1998 and ATDSR, 2000, for discussion). Additionally, male Yusho victims were noted to have an increase in mortality from liver cancer when compared to national death rates (Kuratsune et al., 1987); however, this may have resulted from PCDF contamination (Cogliano, 2001). While epidemiological studies cannot prove a causal relationship between exposure and health effects as noted above, numerous experimental investigations in rodents have clearly shown the ability of various commercial Aroclor mixtures to cause cancerous or pre-cancerous hepatic and gastrointestinal lesions (see Cogliano et al., 1998 and ATSDR, 2000, for discussion). IARC has listed PCBs as probable human carcinogens, based on limited evidence of hepatobiliary cancer in humans and sufficient evidence of malignant liver neoplasms in rodents (IARC, 1987). U.S. EPA also designates PCBs as probable human carcinogens based on tumors found in female mice exposed to Aroclors 1260,

1254, 1242, and 1016 and also in male rats exposed to Aroclor 1260 (IRIS, 1997). Based on these actions, OEHHA has administratively listed PCBs on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR PCBs

Studies to identify an RfD or CSF for PCBs have been conducted with the specific Aroclor mixtures that were prevalent as commercial products during the period that Aroclors were actively manufactured and used. However, as noted above, PCBs found in fish or other environmental media have undergone weathering that can selectively increase or decrease individual congeners, possibly increasing the overall toxicity of the mixture (Cogliano, 2001). U.S. EPA has adopted an approach that matches the expected environmental persistence and toxicity of congeners to the congener profile and toxicity of different Aroclors (Cogliano, 2001). Fish consumption is considered an exposure of high risk and persistence, so recommended health effects values are based on the cancer and non-cancer toxicities of Aroclors 1260 and 1254, which show the greatest toxicity and content of environmentally persistent chlorines (U.S. EPA, 1996).

Because PCB dose-response data for non-cancer endpoints in humans are inadequate, the U.S. EPA RfD for these compounds has been derived from animal data. The RfD for Aroclor 1254 of $2x10^{-5}$ mg/kg-day (IRIS, 1996) is based on a series of studies in adult female Rhesus monkeys (Arnold et al., 1993a, 1993b; Tryphonas et al., 1989, 1991a, 1991b) that were treated for 23 to 55 months. The critical effects noted in treated adults were ocular exudate, inflamed Meibomian (tarsal) glands, distorted fingernail and toenail growth, as well as a decreased antibody response to sheep erythrocytes, all of which occurred at the lowest tested dose of 0.005 mg/kg-day (IRIS, 1996). To this LOAEL, an uncertainty factor of three hundred (ten for sensitive individuals, three for extrapolation from rhesus monkey to humans, a partial factor[1] for the use of a minimal LOAEL [i.e., the effects were not severe], and three to convert from subchronic to chronic) was applied to develop the RfD (IRIS, 1996). OEHHA also used the LOAEL from Arnold et al. (1993a, 1993b) and a three hundred-fold uncertainty factor (ten for interindividual variability, ten for interspecies variation and three for mild and reversible effects at the LOAEL) to account for immunological effects of PCBs to derive a PHG (the concentration of a chemical in drinking water determined to present no significant risk to human health when consumed over a lifetime) (Avalos and Brodberg, 2004). Results of continuing studies in which these treated females were mated to untreated males have been published (Arnold et al. 1995; 1997) since the U.S. EPA derived its RfD. These studies present findings on effects on female reproduction and developmental effects in infants following intrauterine and post-parturition exposures (22 weeks via breast milk). Arnold et al. (1995) showed decreased conception rates at 0.02 mg/kg-day and above, but not at 0.005 mg/kg-day. Developmental effects such as inflammation or enlargement of the Meibomian (tarsal) glands, nail lesions and gum recession, as well as a decrease in

[1] IRIS did not stipulate what the "partial factor" was; however, by deduction, it must have been three.

titers to IgM sheep red blood cells and a dose-related decrease in head circumference were seen in infant rhesus monkeys whose mothers were exposed to 0.005 mg/kg-day Aroclor 1254. Studies with other Aroclor compounds (e.g., Aroclor 1016) have shown developmental and neurological effects in monkeys at slightly higher doses with minor morphological effects occurring at levels where no or minimal neurobehavioral effects were manifested (e.g., Shantz et al., 1989). Although the current RfD is derived from a LOAEL from a study in adult monkeys, similar morphological effects in offspring were reported at the same exposure level. Since morphological effects have been found to occur at or below the exposure levels causing developmental neurobehavioral effects (Schantz et al., 1989), the RfD is also expected to be protective of the developing fetus. This RfD of $2x10^{-5}$ mg/kg-day will be used to evaluate PCB non-cancer risk for OEHHA fish consumption guidelines.

Human cancer dose-response data for PCBs are also inadequate and, thus, the PCB CSF has been generated based on animal studies. Because of the differential ability of different PCB mixtures to cause cancer, U.S. EPA developed a range of CSFs based on Aroclors 1016, 1242, 1254, and 1260. These Aroclors include the range of typical congeners found in various environmental media such as water and fish (IRIS, 1997). For food chain exposure, such as fish consumption, where environmental processes increase risk, a "high-risk" cancer slope factor of 2.0 $(mg/kg\text{-}day)^{-1}$ is used based on the carcinogenic potential of Aroclors 1254 and 1260 (U.S. EPA, 1996). This value was derived from a study of male and female rats (Brunner et al., 1996; Norback and Weltman, 1985). A significant, dose-related increase in the number of liver adenomas or carcinomas was found in female rats exposed to all Aroclors and in male rats exposed to Aroclor 1260 (IRIS, 1997). Aroclors 1254 and 1260 are the most frequently detected Aroclors sampled in California fish (Brodberg and Pollock, 1999; LACSD, 2000). The CSF of 2.0 $(mg/kg\text{-}day)^{-1}$ will be used to evaluate PCB cancer risk for OEHHA fish consumption guidelines.

For fish consumption advisories, cancer and non-cancer health effects values are applied to the sum of detected Aroclors (generally 1248, 1254, and 1260) or a sum of congeners in fish tissue, as recommended by U.S. EPA (2000b).

In summary, the non-cancer and cancer critical values used to evaluate PCBs in fish for the development of consumption guidelines will be **$2x10^{-5}$ mg/kg-day** and **2.0 $(mg/kg\text{-}day)^{-1}$**, respectively.

SELENIUM

SELENIUM TOXICOLOGY

Selenium is a metalloid found naturally, but highly variably, throughout the environment (ATSDR, 1999; Reilly, 1996). Although toxic at relatively low levels, selenium is also a required nutrient that functions to protect against oxidative stress, regulate thyroid hormones, and in vitamin C metabolism (IOM, 2000). The current Recommended Dietary Allowance (RDA) for selenium is 55 µg/day for the general adult population, 60 µg/day for pregnant women, and 70 µg/day during lactation (IOM, 2000). Selenium is found in a variety of inorganic and organic forms (Haygarth, 1994); however, in animal tissues, most selenium occurs as the amino acids selenomethionine or selenocysteine (IOM, 2000). Fish and other food samples are analyzed for total selenium content, as nutritional and toxicity values have not been developed for specific chemical forms of the element.

Selenium is dispersed naturally in the environment by weathering of selenium-containing rocks and volcanic eruptions (ATSDR, 2003). Human activities can significantly redistribute environmental selenium; fossil fuel processing and combustion as well as irrigation of seleniferous soils are important origins of localized selenium contamination (Lemly, 1997). Because of the inherent variability in soil selenium concentrations, human and animal selenium exposures can fluctuate quite dramatically by geographic locale. Human selenium intakes in different regions of China known for endemic deficiency and toxicosis, for example, have been shown to range from seven to 38,000 µg/day, respectively (Levander, 1987).

Environmental conditions (e.g., pH and oxidation-reduction potential) dictate the chemical form in which selenium will be found, which, in turn, determines the biological fate of the element (ATSDR, 2003). Water and air selenium levels are generally low except in isolated areas; humans are exposed to selenium primarily through food. Cereals, grains, and forage crops are the largest contributors of selenium to the diet (ATSDR, 2003), although fish also can be a relatively rich source of the element (USDA, 2004). Freshwater fish in the United States have been found to contain a mean concentration of 0.56 ppm selenium, wet weight (May, 1981); however, in areas of California where high-selenium irrigation drainage water contaminated nearby waterways, selenium concentrations in whole body carp were reported up to 60 ppm (Fan, 1988). Brazil nuts, on average, contain the highest selenium concentration of any common food, ranging from 0.03 to 512 ppm, wet weight, depending on geographic location (Chang et al., 1995). Six to eight nuts (one ounce) typically supply approximately ten times (544 µg) the RDA for this nutrient (USDA, 2004).

Following ingestion, most forms of dietary selenium are well absorbed from the gastrointestinal tract (ATSDR, 2003; Barceloux, 1999; Thomson, 1998). Once absorbed, selenium is distributed to many tissues, reaching the highest concentrations in liver and kidney; selenium also crosses the placenta and is found in breast milk (ASTDR, 2003).

Excretion occurs primarily through urine and, to a lesser extent, feces. In cases of excess consumption, selenium is excreted in the breath and sweat as garlic-odored dimethylselenide (IOM, 2000; Klaassen and Watkins, 1999). The half-life of selenomethionine in the human body is 234 days (Klaassen and Watkins, 1999).

The toxicity of selenium was recognized many years before its role as an essential nutrient was discovered in the 1950s by Schwarz and Foltz (1957). Franke and Potter (1935) were the first to prove that selenium was the plant constituent responsible for signs of toxicosis such as hair and hoof loss reported in livestock grazing on the plains of Nebraska and South Dakota (Combs and Combs, 1986). Since that time, selenium toxicity has been well reviewed by many authors (e.g., ATSDR, 2003; Combs and Combs, 1986; Reilly, 1996; Barceloux, 1999; Schrauzer, 2000, 2003) and has been found to be dependent on chemical form and solubility (Klaassen and Watkins, 1999).

Acute, sometimes fatal, selenium toxicity only rarely has been reported in humans and has generally been the result of self-medication, accidental, suicidal, or occupational exposures (Civil and McDonald, 1978; Sioris et al., 1980; Gasmi et al., 1997; Schellmann et al., 1986). Gastrointestinal and neurological signs and symptoms, as well as hair and nail loss, predominate the clinical presentation (Combs and Combs, 1986). At least one case of acute selenium intoxication from a natural source has been noted in the literature. A 54-year-old Venezuelan man suffered anxiety, chills, diarrhea, fever, anorexia, and weakness after consuming 70 to 80 "Coco de Mono" (*Lecythis ollaria*) almonds. Eight days after consuming the nuts, he suffered extensive loss of scalp and body hair (Kerdel-Vegal, 1964). Subsequent studies identified the pharmacologically active agent as selenocystathionine (Aronow and Kerdel-Vegas, 1965; Kerdel-Vegas et al., 1965). Acute selenium poisoning was also reported in five individuals who consumed sodium selenate intended for use as a turkey diet supplement (dose not provided). Symptoms and signs, which resolved within 24 hours, included nausea, vomiting, diarrhea, abdominal pain, chills, and tremors (Sioris et al., 1980). Acute to sub-acute selenium toxicosis occurred in 13 individuals who consumed an improperly formulated over-the-counter selenium supplement (FDA Drug Bulletin, 1984; Jensen et al., 1984; Helzlsouer et al., 1984). Analysis of several tablets revealed that the selenium content was 182 times higher than labeled (approximately 27-30 mg per tablet, in the form of sodium selenate and elemental selenium). Estimates of ingested selenium dose ranged from 27 to 2310 mg (from a single tablet to 77 tablets taken over a 2 ½ month period). Signs and symptoms of toxicity included nausea, abdominal cramps, nail and hair changes (including total hair loss), peripheral neuropathy, garlic breath odor, fatigue, and irritability.

Chronic selenium toxicosis in humans has been well characterized as a result of endemic disease occurring in a seleniferous region of China (Yang et al., 1983, 1989a, 1989b). Excessive selenium intakes (a mean of 4,990 µg/day, versus 116 µg/day in a selenium adequate area) resulted from consumption of high-selenium corn and vegetables during a drought period. Affected individuals suffered nail and hair loss, dermal swelling, erythema and ulcerations, as well as paresthesias. Hair selenium levels were approximately 100 times higher than those found in selenium adequate areas (Yang et al.,

1983). Chronic human selenium toxicity as a consequence of environmental exposures has not been reported in the United States, although ranchers in a seleniferous area of South Dakota were found to consume as much as 724 µg selenium per day (Longnecker et al., 1991).

Although high levels of selenium have been shown to be teratogenic in birds (Ohlendorf, 1986; 1988), there is no evidence that selenium induces terata in humans or other mammals (ATSDR, 2003). Other developmental effects following *in utero* selenium exposure in mammals have only been conclusively demonstrated at doses that cause frank maternal toxicity (Willhite, 1993; ATSDR, 2003).

IARC and U.S. EPA have listed selenium compounds as not classifiable as to their carcinogenicity in humans because of inadequate evidence of carcinogenicity in humans or animals (IARC, 1975; IRIS, 1993). Selenium sulfide, an industrial chemical not present in food, is considered a probable human carcinogen by U.S. EPA (IRIS, 1993) and is listed by OEHHA on the Proposition 65 list of carcinogens.

DERIVATION OF A REFERENCE DOSE FOR SELENIUM

The current U.S. EPA RfD for selenium and selenium compounds was developed in 1991 and set at $5x10^{-3}$ mg/kg-day (IRIS, 1991), corresponding to 350 µg/day for a 70-kg adult or approximately six-fold higher than the RDA for the general adult population. This RfD was based on an epidemiological study of approximately 400 people residing in a seleniferous region of China noted above. Overt signs of clinical selenosis (e.g., garlic breath odor, nail changes, hair and nail loss, decreased hemoglobin, skin lesions, mottled teeth, and central nervous system effects) were reported at whole blood concentrations of 1.35 mg/L, corresponding to a daily selenium intake of 1.261 mg (Yang et al., 1989b; IRIS, 1991). A blood selenium level of 1.0 mg/L (equivalent to an intake of 0.853 mg selenium/day) did not elicit signs of selenium toxicity. Thus, a chronic oral NOAEL and LOAEL of 0.853 and 1.261 mg/day, respectively, were determined from this study and converted to a body weight basis using the average Chinese adult body weight of 55 kg (IRIS, 1991). U.S. EPA also cited a year-long study of individuals from high-selenium areas of South Dakota and Wyoming in support of the RfD (see above, Longnecker et al. 1991). Individuals consuming as much as 0.724 mg Se/day in these regions did not show signs or symptoms associated with selenium toxicity, thus confirming the NOAEL from the Yang et al. (1989b) study. To account for sensitive individuals, U.S. EPA applied a three-fold uncertainty factor to the NOAEL (0.015 mg/kg-day) to derive an RfD of $5x10^{-3}$ mg/kg-day. Because a similar NOAEL was observed in two moderate-sized populations exposed over a lifetime, a full 10-fold uncertainty factor was not considered necessary (IRIS, 1991). ATSDR (2003) also has developed a chronic oral MRL of $5x10^{-3}$ mg/kg-day, based on a follow-up study by Yang and Zhou (1994) that reexamined five individuals included in the original Yang et al. (1989b) paper. This study confirmed the original NOAEL used by U.S. EPA to set the RfD. OEHHA will use this RfD to evaluate selenium non-cancer risk for fish consumption guidelines.

In summary, the non-cancer critical value used to evaluate selenium in fish for the development of consumption guidelines will be **$5x10^{-3}$ mg/kg-day**.

TOXAPHENE

TOXAPHENE TOXICOLOGY

Toxaphene (camphechlor) is an organochlorine insecticide consisting of a mixture of over 670 chlorinated terpenes (ATSDR, 1996; U.S. EPA, 2000). The average chemical formula for toxaphene and related toxaphene-like pesticides is $C_{10}H_{10}C1_8$ (WHO, 1984; ATSDR, 1996; de Geus, 1999). Toxaphene was first produced in 1945, primarily as an insecticidal agent for cotton, but also for parasite control in livestock and to kill unwanted fish species in various water bodies (DHHS, 2002; de Geus, 1999). Once the most heavily used pesticide in the United States (Ribick et al., 1982), U.S. EPA restricted most applications of toxaphene in 1982 and banned it completely in 1990 (DHHS, 2002).

Because of its extensive use, volatility, and resistance to degradation, toxaphene is distributed throughout various environmental matrices worldwide, particularly in freshwater and marine fish (Alder, 1997; ATSDR, 1996; de Geus, 1999). Bioconcentration factors of persistent toxaphene congeners in fish and shellfish have been reported to reach as high as $3.5x10^6$ (Geyer et al., 1999). Biomagnification also occurs in the aquatic food chain (ATSDR, 1996). Fish toxaphene levels have been shown to be positively correlated with fish age and fat content (Alder, 1997). Similar to the case with PCBs, the composition of the toxaphene "technical" mixture is altered in the environment as a result of differential degradation of individual congeners (Stern et al., 1992). The number of congeners decreases with increasing trophic level; approximately twenty, eight and two primary congeners have been found in fish, marine mammals, and humans, respectively (Calciu et al., 1997).

Toxaphene is known to be absorbed from all absorption routes, although dermal absorption is comparatively low (ATSDR, 1996; WHO, 1984). Once absorbed, toxaphene is distributed primarily to fat, but also to liver, bone, kidney, brain, heart, muscle, lung, spleen, adrenal gland, and testis (ATSDR, 1996). Rat studies have shown that only a small percent of a maternal toxaphene dose is transferred to the fetus (Pollock and Hillstrand, 1982); however, toxaphene has been found in human breast milk, particularly in women residing in the Arctic region where dietary organochlorine levels can be very high (Dewailly et al., 1993; Chan and Yeboah, 2000; Newsome and Ryan, 1999; Walker et al., 2003; Vaz and Blomkvist, 1985). Breast milk from Inuit women in northern Quebec, for example, has been reported to contain toxaphene concentrations as high as 294 ng/g on a lipid weight basis (Newsome and Ryan, 1999; Stern et al., 1992). Toxaphene is excreted in both urine and feces with the majority of absorbed toxaphene undergoing metabolic transformation (ASTDR, 1996). The excretion half-life of radiolabeled toxaphene has been shown to be approximately nine days in rodents, with about twice as much excreted in feces as in urine over this time period (ATSDR, 1996). Even though the pesticide has been banned for many years, significant toxaphene residues have recently been found in adipose tissue of children in western Europe (Witt and Niessen, 2000).

The toxicity of toxaphene has been well reviewed by several authors (e.g., ASTDR, 1996; Pollock and Kilgore, 1978; WHO, 1984; Saleh, 1991). Like other cyclodiene insecticides, the mechanism of neurotoxic action is believed to be inhibition of chloride transport, resulting in only partial repolarization of neurons and uncontrolled central nervous system stimulation (Ecobichon, 2003; Klassen and Watkins, 1999). Following acute oral toxaphene intoxication in humans, signs and symptoms of central nervous system stimulation are seen such as hypersalivation, restlessness, muscle tremors, and convulsions (U.S. EPA, 1987). Signs often begin within two hours of ingestion; fatal doses generally cause death by respiratory failure within 24 hours (McGee et al., 1952; Wells and Milhorn, 1983). The human acute lethal dose has been estimated to range from 21-100 mg/kg body weight (U.S. EPA, 1987) or about 2 to 7 grams for an adult (WHO, 1984). In addition to nervous system and respiratory effects mentioned above, heart dilation, kidney swelling, and elevated liver enzymes have also been reported in humans following acute toxaphene ingestion (ATSDR, 1996; McGee et al., 1952; Wells and Milhorn, 1983).

In animals, neurological effects similar to those reported in humans have been reported following acute toxaphene toxicity (ATSDR, 1996). Intermediate or chronic toxaphene exposures in various animal species have been shown to cause hepatic and renal effects including increased liver and kidney weights, hepatic enzyme induction, and degenerative histopathological changes in both organs (ATSDR, 1996). Protein deficiency may significantly increase acute toxaphene toxicity (Boyd and Taylor, 1971).

Toxaphene has not been shown to cause reproductive harm in animals at levels that do not also cause parental toxicity. For example, decreased fetal weights, fetal death, or increased incidence of encephaloceles were reported in rats and mice exposed to toxaphene during the period of organogenesis, but only at doses that also caused maternal toxicity and death (Chernoff and Carver, 1976). In a three-generation study, rats fed 0, 25 or 100 ppm toxaphene showed no adverse effects on reproductive outcomes such as litter size, pup survival or weanling body weights; however, liver cytoplasmic vacuolization was seen in the majority of adults at the 100 ppm dose (Kennedy et al., 1973). Similarly, while dietary toxaphene concentrations of 20 ppm and above caused increased liver weights as well as histopathological changes in liver, thyroid and kidney in adults rats during a reproductive study, there were no effects on fertility, litter size, pup weight, or other indices of gestation or survival in rats fed dietary concentrations up to 500 ppm toxaphene (0.38 mg/kg-day) (Chu et al., 1988).

Developmental effects have been reported following toxaphene exposure in rats. Olson et al. (1980) found that juvenile rats exposed to 0.05 mg/kg-day toxaphene in the pre- and postnatal periods had decreased swimming and righting ability compared to controls, although differences in swimming ability between groups had disappeared by postnatal day 16. Time to master righting reflex was also prolonged in offspring of rats exposed to 6 mg/kg-day from gestation day 7 until parturition (Crowder et al., 1980).

A few studies have found immunotoxic effects resulting from toxaphene exposure. Adult mice fed 100 or 200 ppm dietary toxaphene for eight weeks showed a dose-dependent decrease in antibody response to bovine serum albumin (Allen et al., 1983). Liver-to-body weight ratios were also increased at both dose levels and histopathological changes were noted in livers. Immunological effects were more pronounced in offspring exposed *in utero* or during lactation (Allen et al., 1983). An immunotoxicity study in cynomolgus monkeys is described below (Tryphonas et al., 2001). *In vitro* human studies have confirmed that neutrophils are a significant immunologic target of toxaphene toxicity (Gauthier et al., 2001).

There are no data available to evaluate the carcinogenicity of toxaphene in humans; however, toxaphene has been found to be a liver carcinogen in mice and to cause thyroid cancer in rats (Litton Bionetics, 1978; Reuber, 1979; NCI, 1979). IARC has listed toxaphene as a possible human carcinogen, based on inadequate data in humans and sufficient evidence in experimental animals (IARC, 2001). U.S. EPA lists toxaphene as a probable human carcinogen, based on no data in humans and sufficient evidence of carcinogenicity in experimental animals (IRIS, 1991). OEHHA has administratively listed toxaphene on the Proposition 65 list of chemicals known to the State of California to cause cancer.

DERIVATION OF A REFERENCE DOSE AND CANCER SLOPE FACTOR FOR TOXAPHENE

U.S. EPA has not developed an RfD for toxaphene. However, in 2003, OEHHA published a PHG for toxaphene in drinking water, selecting a study by Chu et al. (1986) to determine the NOAEL for non-cancer effects (OEHHA, 2003). Rats fed diets containing 20 to 500 ppm toxaphene (corresponding to approximately 0.35 to 63 mg/kg-day) had biologically significant histopathological changes in liver, thyroid, and kidney at doses of approximately 1.8 mg/kg-day and above. Liver-to-body weight ratios and hepatic mixed function oxidase activities were also increased at the highest dose level. The NOAEL and LOAEL values in this study were determined to be 0.35 and 1.8 mg/kg-day, respectively. To the NOAEL, an uncertainty factor of 1000 (10 for interspecies extrapolation, 10 for sensitive individuals, and 10 for extrapolation from subchronic to chronic) can be applied to develop a reference dose of 3.5×10^{-4} mg/kg-day.

A more recent study in cynomolgus monkeys by Tryphonas et al. (2001) can also be used to support the RfD for toxaphene. Monkeys were fed 0, 0.1, 0.4, or 0.8 mg/kg-day toxaphene for 75 weeks. Doses of 0.4 and 0.8 mg/kg-day significantly reduced humoral immunity in female monkeys, as evidenced by decreased primary and secondary immune response to sheep erythrocytes. The NOAEL of 0.1 mg/kg-day in this study was similar to that derived by Chu (Chu et al., 1986). As the Chu et al. study produced the highest NOAEL below the lowest LOAEL, it will be used to set the reference dose to evaluate toxaphene non-cancer risk for fish consumption guidelines.

Human dose-response data for cancer are also inadequate; thus, the toxaphene CSF has been generated from animal studies. Two long-term rodent carcinogenicity assays have been published for toxaphene (Litton Bionetics, 1978; NCI, 1979). In their 1991 carcinogenicity assessment, U.S. EPA chose the Litton Bionetics study for determination of the toxaphene cancer slope factor. A significantly increased incidence of hepatocellular carcinomas was found in male B6C3F1 mice at a dietary dose of 50 ppm. Using a linearized multistage model, U.S. EPA determined the oral CSF for toxaphene in this study to be 1.1 $(mg/kg\text{-}day)^{-1}$ (IRIS, 1991). OEHHA (2003) employed a CSF of 1.2 $(mg/kg\text{-}day)^{-1}$ in their toxaphene PHG, using the same data set as U.S. EPA but making slightly different assumptions regarding the conversion of dietary toxaphene concentrations to mg/kg body weight doses. For the purpose of evaluating cancer risk for fish consumption guidelines, the CSF of 1.2 $(mg/kg\text{-}day)^{-1}$ will be used.

In summary, the non-cancer and cancer critical values used to evaluate toxaphene in fish for the development of consumption guidelines will be **$3.5x10^{-4}$ mg/kg-day** and **1.2 $(mg/kg\text{-}day)^{-1}$**, respectively.

FISH CONTAMINANT GOALS FOR CHLORDANE, DDTs, DIELDRIN, METHYLMERCURY, PCBs, SELENIUM, AND TOXAPHENE

As is also the case for air, drinking water, or any other food, the ultimate goal of agencies responsible for the protection of public health is for fish to be devoid of biological or chemical contamination. FCGs can be derived for chemicals found in fish, comparable to PHGs for drinking water (Health and Safety Code, Section 116365). FCGs are estimates of contaminant levels in fish that pose no significant health risk to individuals consuming sport fish at a standard consumption rate of eight ounces per week (32 g/day), prior to cooking, over a lifetime and can provide a starting point for OEHHA to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. FCGs were developed for chlordane, DDTs, dieldrin, methylmercury, PCBs, selenium, and toxaphene. FCGs are based solely on public health considerations relating to exposure to each individual contaminant, without regard to economic considerations, feasibility, the counterbalancing benefits of fish consumption, or alternative risks of other protein sources that may be consumed in place of fish.

FCGs can be found in Table 1. OEHHA used the following assumptions in the development of FCGs for fish contaminants. Agencies developing fish tissue-based criteria may choose to alter one or more of these assumptions in order to meet their own specific goals or requirements:

Body Weight:

The default value for adult body weight for these calculations was assumed to be 70 kg, which is recommended in most risk assessment guidelines. While, at one time, 70 kg was the approximate combined average weight for adult males and females in the United States, it is now significantly less than the average weight for both adult females and males in this country (about 75 and 87 kg, respectively) (Ogden et al., 2004). The use of a lower default body weight for risk assessment calculations results in lower allowable contaminant concentrations in fish.

Serving Size and Consumption Rate:

Serving size assumptions vary considerably. The American Heart Association (AHA) recommends eating fish at least two times a week (AHA, 2006), and considers a single serving size to be four ounces (113.5 g) of fish prior to cooking (corresponding to three ounces [85 g] of cooked fish). The Institute of Medicine (IOM) also considers serving size to be three ounces of cooked fish, based on the National Health and Nutrition Examination Survey (NHANES) 1999-2002 data showing three ounces to be the average daily consumption rate for people who eat fish (IOM, 2007). In their 2006 food pyramid, the U.S. Department of Agriculture recommends five to six ounces, *total*, of meat, poultry, fish, dried beans or peas, eggs, nuts, and seeds *per day* for adult women and men,

suggesting that the typical serving size of a single animal protein source in a given day is three to four ounces (USDA, 2006). In contrast, U.S. EPA assumed a serving size of eight ounces of fish, prior to cooking, in their fish advisory guidance document (U.S. EPA, 2000b), as did both U.S. EPA and FDA in their joint national advisory for mercury in fish (U.S. EPA, 2004c). While OEHHA contemplated reducing serving sizes to four ounces, prior to cooking, to align with federal nutrition, IOM and AHA guidelines, focus groups interviewed by the California Department of Public Health indicated that sport fishers typically consume significantly larger portion sizes. Thus, an 8-ounce serving size was retained for use in fish advisories. OEHHA considers it to be a reasonable goal to provide recreational fish that, at a minimum, are safe to eat at the AHA recommended consumption rate for adults of at least eight ounces of fish per week, prior to cooking (an average of 32 g/day) and that this is an appropriate consumption rate for development of an FCG. Because of their smaller body weights, children will be advised to eat approximately one-half as much fish (in either quantity or frequency) as are women aged 18 to 45 years.

Hazard Quotient:

Standard risk assessment guidelines generally recommend limiting non-cancer exposures to no more than the RfD, which results in a hazard quotient (HQ; the ratio of exposure to the RfD) that does not exceed 1. FCGs were set using a maximum HQ of 1 at the consumption rate of 32 g/day.

Risk Level:

FCGs were developed using a maximum cancer risk level (RL) of $1x10^{-6}$, estimating that, at a given consumption rate, not more than one additional cancer case would be expected in a population of one million people consuming fish over a lifetime. This risk level is at the lower end of the acceptable range of risks ($1x10^{-4}$ to $1x10^{-6}$) used by U.S. EPA in regulatory criteria for drinking water (Fed. Reg., 1998) and is provided as an example of an acceptable risk level in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories (U.S. EPA, 2000a,b). FCGs were set using a maximum RL of $1x10^{-6}$ at the consumption rate of 32 g/day.

Exposure Duration and Averaging Time:

For carcinogenic chemicals, the exposure duration and averaging time was assumed to be 30 years over a 70 year lifespan, based on the 95th percentile of U.S. residence time (U.S. EPA, 1997). This may be modified in cases where a carcinogenic contaminant is widespread throughout state water bodies and the source is relatively ubiquitous.

Cooking Reduction Factor:

OEHHA strongly recommends to all consumers that they skin and thoroughly cook their fish prior to eating. Skinning and cooking remove or reduce a variety of chemical and

biological hazards. FCGs take into account organochlorine contaminant loss during the cooking process. The concentration of PCBs and other organic contaminants in fish are generally reduced by at least 30 percent, depending on cooking method (Anderson et al., 1993; Sherer and Price, 1993; Santerre, 2000; Wilson et al., 1998; Zabik et al., 1996). As such, a cooking reduction factor of 0.7 was included in the FCG equation for organic compounds (allowing for 70 percent of the contaminant to remain after cooking). Although fish analytical data are generally provided to OEHHA as skin-off fillets, when contaminant levels are determined using skin-on fillets, a cooking and skinning reduction factor of 0.5 is used to account for organic chemical losses of approximately 50 percent that occur during both processes combined (Anderson et al., 1993). Mercury and selenium concentrations in fish are not reduced by cooking or cleaning techniques and, thus, no reduction factor has been applied for these chemicals.

Nutrients:

Unlike the case for other fish contaminants listed above, selenium is a required nutrient and fish are a major dietary source of selenium. Thus, it should be ensured that the FCGs for selenium do not unduly limit sport fish as a potential source of selenium and that they also take into account additional dietary exposures to this element. As reported above, the current RDA for selenium is 55 µg/day for the general adult population, 60 µg/day for pregnant women, and 70 µg/day during lactation (IOM, 2000). Data from NHANES III show that the mean selenium intake for all individuals from diet alone is 113.7 µg/day, while the mean intake from diet plus supplements is 116 µg/day (IOM, 2000). This indicates that most individuals in the United States easily meet their nutritional needs for selenium and do not consume selenium supplements. Thus, the mean selenium intake from diet alone (114 µg/day; IOM, 2000) will be used as the background dietary selenium consumption rate for developing FCGs for selenium. As in all cases of supplement intake, consumers who take selenium supplements should take them with caution and under the advisement of their physician.

Use/Application of FCGs:

OEHHA has developed FCGs, using standard exposure factors and a consumption rate of eight ounces prior to cooking (six ounces after cooking), to provide a starting point to assist other agencies that wish to develop fish tissue-based criteria with a goal toward pollution mitigation or elimination. Any agency using FCGs provided in this report to establish fish tissue-based criteria for their own purposes must accept the assumptions described herein.

Table 1. Fish Contaminant Goals (FCGs) for Selected Fish Contaminants Based on Cancer and Non-Cancer Risk* Using an 8-Ounce/Week (prior to cooking) Consumption Rate (32 g/day)**	
	FCGs (ppb, wet weight)
Contaminant Cancer Slope Factor $(mg/kg/day)^{-1}$	
Chlordane (1.3)	**5.6**
DDTs (0.34)	**21**
Dieldrin (16)	**0.46**
PCBs (2)	**3.6**
Toxaphene (1.2)	**6.1**
Contaminant Reference Dose (mg/kg-day)	
Chlordane ($3.3x10^{-5}$)	100
DDTs ($5x10^{-4}$)	1600
Dieldrin ($5x10^{-5}$)	160
Methylmercury ($1x10^{-4}$)[S]	**220**
PCBs ($2x10^{-5}$)	63
Selenium ($5x10^{-3}$)	**7400**
Toxaphene ($3.5x10^{-4}$)	1100

*The most health protective Fish Contaminant Goal for each chemical (cancer slope factor- versus reference dose-derived) for each meal category is bolded.
**g/day represents the average amount of fish consumed daily, distributed over a 7-day period, using an 8-ounce serving size, prior to cooking.
[S]Fish Contaminant Goal for sensitive populations (i.e., women aged 18 to 45 years and children aged 1 to 17 years.)

Tabled values are rounded based on laboratory reporting of three significant digits in results, where the third reported digit is uncertain (estimated). Tabled values are rounded to the second digit, which is certain. When data are compared to this table they should also first be rounded to the second significant digit as in this table.

EQUATIONS USED TO CALCULATE FISH CONTAMINANT GOALS

The following general equations were used to calculate Fish Contaminant Goals for chemicals at the consumption rates listed in Table 1, using an 8-ounce (prior to cooking) serving size. Separate equations are used for carcinogenic effects, non-carcinogenic effects, and nutrients with non-carcinogenic effects.

The following general equation can be used to calculate Fish Contaminant Goals (in µg/kg) at which the consumption exposure from a chemical with a ***carcinogenic*** effect is equal to the risk level for that chemical at any consumption level:

$$\text{Tissue concentration (ppb)} = \frac{\text{(Risk Level)(kg BW)(1000 µg/mg)}}{\text{[CSF (mg/kg/day)}^{-1}\text{] (CR kg/day)(ED/AT)(CRF)}}$$

As an example, for dieldrin, the Fish Contaminant Goal using a risk level of $1x10^{-6}$ and a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{(1x10^{-6})(70\text{ kg})(1000\text{ µg/mg})}{[16\text{ (mg/kg/day)}^{-1}](0.032\text{ kg/day})(30/70)(0.7)} = 0.46\text{ ppb}$$

The following general equation can be used to calculate Fish Contaminant Goals (in µg/kg) at which the consumption exposure from a chemical with a ***non-carcinogenic effect*** is equal to the reference level for that chemical at any consumption level:

$$\text{Tissue concentration (ppb)} = \frac{\text{(RfD mg/kg-day)(kg BW)(1000 µg/mg)}}{\text{(CR kg/day)(CRF)}}$$

As an example, for mercury, the Fish Contaminant Goal using a consumption rate of one, 8-ounce serving per week (32.0 g/day) for women aged 18 to 45 years and children aged 1 to 17 years would be calculated as follows:

$$\frac{(1x10^{-4}\text{ mg/kg-day})(70\text{ kg BW})(1000\text{ µg/mg})}{(0.032\text{ kg/day})(1)} = 219\text{ ppb}$$

The following general equation can be used to calculate the Fish Contaminant Goals (in mg/kg) at which consumption exposure from a ***nutrient with a non-carcinogenic effect*** is equal to the reference level for that chemical at any consumption level:

Tissue Concentration (ppb) =

$$\frac{\text{[(RfD mg/kg-day)(kg BW) – mg/day Background Dietary Level](1000 µg/mg)}}{\text{(CR kg/day)}}$$

As an example, for selenium, the Fish Contaminant Goal using a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{[(5\times10^{-3}\ \text{mg/kg-day})(70\ \text{kg}) - 0.114\ \text{mg/day}](1000\ \mu\text{g/mg})}{0.032\ \text{kg/day}} = 7{,}375\ \text{ppb}$$

Where,
Risk Level = 1×10^{-6}
BW = Body weight of consumer (70 kg default)
CSF = Cancer Slope Factor
CR = Consumption Rate as the daily amount of fish consumed
CRF = Cooking Reduction Factor (0.7 for organic contaminants in skin-off fillet)
ED/AT = Exposure Duration/Averaging Time (30 yr exposure/70 yr lifetime)
RfD = Chemical specific reference dose or other reference level

POTENTIAL BENEFITS OF FISH CONSUMPTION

Fish consumption advice is generally provided to the public from disparate arms of the biomedical community: physicians and nutritionists, who focus on the health benefits of eating fish, and toxicologists, who concentrate on the risks from exposure to contaminants that may be found in fish. The conflicting messages that often result likely confuse the consumer, who may then ignore recommendations to limit consumption of contaminated fish or, alternatively, avoid eating fish altogether (see, e.g., Oken et al., 2003). Only recently has there been a more focused attempt to craft unified guidance that addresses benefits and risks of fish consumption, although beneficial aspects are generally only discussed qualitatively.

With the discovery in the 1970s that, despite their high fat diet, Greenlandic Eskimos were virtually devoid of ischemic heart disease and diabetes mellitus, came the earliest recognition that fatty acids found in fish and marine mammals may have particular benefits to human health (Bang and Dyerberg, 1972; Dyerberg et al., 1975; Bang et al., 1976; Dyerberg et al., 1978; Dyerberg and Bang, 1979; Bang et al., 1980). The diet and blood lipid profile of the Eskimos were found to be very high in omega-3 fatty acids and very low in omega-6 fatty acids, in direct contrast to a typical "Western" diet in which the reverse is true (Dyerberg et al., 1975; Bang et al., 1980).

Omega-3 fatty acids, such as α-linolenic acid, eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), are long-chain polyunsaturated fatty acids (PUFAs) with the first double bond inserted at the *third* carbon atom from the methyl end, while omega-6 fatty acids, such as linoleic acid, γ-linolenic acid and arachidonic acid, have the first double bond inserted at the *sixth* carbon atom from the methyl end (IOM, 2005). Fatty acids are designated by their number of carbon atoms, followed by the number of double bonds and the placement of the first double bond. For example, linoleic acid is denoted as 18:2n-6 because it has 18 carbons and two double bonds, with the first double bond located six carbons from the methyl end (the "n" or "omega" position). α-Linolenic (18:3n-3) and linoleic acids cannot be synthesized by humans and are thus required in the diet (IOM, 2005). α-Linolenic acid's only known function is as the precursor to the very long chain PUFAs EPA (20:5n-3) and DHA (22:6n-3), omega-3 fatty acids that are also consumed directly from fish (IOM, 2005). Because the conversion of α-linolenic acid to EPA and DHA is so inefficient (estimated at less than 5 percent) (Wang et al., 2006), and DHA and EPA levels are so low in other foods, fish or fish oil consumption is by far the most important dietary source of these fatty acids (Marszalek and Lodish, 2005). DHA serves as an important structural lipid in nervous tissue, spermatozoa, and the retina, and may be retroconverted to EPA; linoleic acid (18:2n-6), the most common dietary PUFA, is the precursor to arachidonic acid (20:4n-6) (IOM, 2005; Kris-Etherton et al., 2000). Arachidonic acid is also consumed directly from dietary sources such as meat, egg yolk and dairy (Calder, 2006; Richardson, 2006).

Once dietary omega-3 and omega-6 fatty acid precursors are converted *in vivo* to EPA or arachidonic acid, respectively, they can then be metabolized to produce different

eicosanoids, including various prostaglandins, thromboxanes, and leukotrienes, which, in turn, have contravening physiological actions (Robinson and Stone, 2006; Calder, 2006). The omega-3 derived eicosanoids, such as thromboxane A_3 and B_3, prostaglandins PGI_3 and PGE_3, and leukotriene B_5, induce vasodilation, inhibit arrhythmia, decrease platelet aggregation, and are anti-inflammatory. In contrast, eicosanoids derived from omega-6 fatty acids, such as thromboxane A_2 and B_2, prostaglandins PGI_2 and PGE_2, and leukotriene B_4, cause vasoconstriction, are pro-arrhythmic, and increase platelet aggregation and inflammation (Robinson and Stone, 2006; Simopoulos, 1999; DeFilippis and Sperling, 2006). A proper ratio of dietary omega-6 to omega-3 fatty acids is thus imperative to protect health (Simopoulos, 1999; 2002), particularly since high dietary omega-6 levels inhibit the *in vivo* conversion of α-linolenic acid to DHA and EPA (Kris-Etherton et al., 2000). Similarly, high dietary omega-3 fatty acid levels reduce the formation of 2-series eicosanoids from arachidonic acid (IOM, 2005). It has been speculated that conflicting results in clinical trials on the benefits of dietary omega-3 fatty acids may have resulted from failure to take into account background dietary omega-6 fatty acid consumption, high levels of which may inhibit the production of anti-aggregatory eicosanoids and thus undermine the effectiveness of omega-3 fatty acids in disease prevention (Hibbeln et al., 2006).

Humans evolved consuming a diet that was largely equivalent in omega-6 and omega-3 fatty acids. In the 1960s, however, a dramatic shift in the level and composition of dietary fat occurred following the recommendation that saturated fats in the diet be replaced with vegetable oils, such as corn oil and safflower oil, which contain omega-6 to omega-3 ratios greater than 60:1 (Simopoulos, 2001). At the same time, the proportion of farm-raised to wild fish consumption increased (DeFilippis and Sperling, 2006). Farm-raised fish, like farm-raised cows, pigs, and chickens, are often fed diets rich in omega-6 fatty acids and many have tissue omega-6 to omega-3 ratios considerably higher than wild fish of the same species (Hamilton et al., 2005; DeFilippis and Sperling, 2006; Kris-Etherton et al., 2002; Foran et al., 2005; Marszalek and Lodish, 2005). The typical "Western" diet has been estimated to have an omega-6 to omega-3 ratio of 10:1 to 20:1 (Simopoulos, 2003), with a total omega-3 fatty acid consumption of approximately 1.6 g/day (Johnson and Schaefer, 2006). Of that, mean consumption of EPA + DHA is about 0.1 g/day (IOM, 2007). In NHANES 1999-2002, all age/sex population groups were reported to consume an average of less than 0.2 g/day EPA + DHA (IOM, 2007).

Since the Greenlandic Eskimo studies in the 1970s, an explosion of research has examined potential health benefits of fish consumption, with a particular emphasis on omega-3 fatty acids. In 1996, the AHA published their first statement on fish consumption, fish oils, lipids, and coronary heart disease (Stone, 1996). While considering it "premature" at that time to recommend the use of fish oil supplements for the prevention of cardiovascular disease by the general public, the AHA did nonetheless recognize that consumption of marine sources of omega-3 fatty acids seemed "reasonable" because of the low content of saturated fat in fish compared to other meat products and the potential for cardiovascular benefits that might be borne out by future research (Stone, 1996). Subsequently, the most recent AHA statement on the subject

(Kris-Etherton et al., 2002) was strengthened significantly from its original version, as additional research since 1996 has provided even more compelling evidence of the benefits of fish and fish oil consumption.

Currently, the AHA recommends that *individuals without documented coronary heart disease* "eat a variety of (preferably fatty) fish at least twice a week," *individuals with documented coronary heart disease* "consume about 1 g of EPA + DHA per day, preferably from fatty fish (EPA + DHA from capsule form could be considered in consultation with the physician)," and *individuals who need to reduce triglycerides* should consume "two to four grams of EPA + DHA per day provided as capsules under a physician's care" (AHA, 2006). The AHA considers a serving size to be four ounces of fish prior to cooking, or three ounces after cooking, one-half of the serving size typically assumed in fish consumption advisories. The WHO also recommends consumption of 1-2 servings of fish per week (to provide 200-500 mg of EPA + DHA per serving) to protect against coronary heart disease and ischemic stroke (WHO, 2003), while the 2005 Dietary Guidelines Advisory Committee (DGAC) Report concludes that "consumption of two servings (approximately eight ounces) per week of fish high in EPA and DHA is associated with reduced risk of both sudden death and CHD (coronary heart disease) death in adults." The Committee further states that "to benefit from the potential cardioprotective effects of EPA and DHA, the weekly consumption of two serving of fish, particularly fish rich in EPA and DHA, is suggested" (DGAC, 2005). In their report assessing the risks and benefits of fish consumption, the Scientific Advisory Committee on Nutrition (SACN) of the Food Standards Agency and Department of Health in the United Kingdom recommends that all individuals, including pregnant women, "eat at least two portions of fish per week, of which one should be oily," providing approximately 450 mg/day long chain omega-3 fatty acids (SACN, 2004; see also IOM, 2007, for additional discussion).

Presented below is a brief summary of many of the potential benefits of fish or fish oil consumption, given the current state of scientific knowledge. This review is not intended as an exhaustive evaluation of the merits and weaknesses of the vast number of articles on this subject, but merely to be illustrative of significant, and generally recent, research or review articles in the field. Many studies are observational, as is also commonly the case with human toxicity studies on fish contaminants, and cannot prove cause and effect relationships with certainty. Even randomized controlled trials (RCTs), the gold standard of human medical experimentation, may suffer in the case of fish or fish oil studies from the inability to blind the subject to the treatment. Although current scientific consensus recommends fish consumption as a likely way to prevent specific chronic disease conditions, it is unclear to what extent potential benefits from fish or fish oil consumption listed below may be realized through the following mechanisms: increased consumption of omega-3 fatty acids, decreased dietary omega-6 to omega-3 fatty acid ratio (as generally occurs to a lesser extent with fish oil supplementation and to a greater extent with fish consumption), simple replacement of other high fat dietary protein sources with fish, or other nutritive or non-nutritive factors that may covary with fish consumption

(e.g., an overall healthy lifestyle). Many of these issues are discussed in the recent IOM report on balancing the risks and benefits of seafood consumption (IOM, 2007).

Cardiovascular Disease and Total Mortality:

The most thoroughly evaluated potential beneficial effect of fish or fish oil consumption has been on the prevention and treatment of cardiovascular disease. In a recent meta-analysis, Hooper et al. (2006) concluded that evidence to date does not support the position that short or long chain omega-3 fatty acids have a clear effect on this condition. Numerous researchers criticized this review, however, particularly with respect to inappropriate pooling of study participants, outcomes, and marine- and plant-based omega-3 fatty acids, as well as the inclusion of a "methodologically poor" study, which, in and of itself, "changed the conclusion of the meta-analysis from clear benefit to no benefit" (Deckelbaum and Akabas, 2006; Geleijnse et al., 2006; He and Song, 2006; Twisselmann, 2006; von Schacky et al., 2006). A subsequent systematic review of the literature addressed some of these shortcomings (Deckelbaum and Akabas, 2006). After evaluating 46 studies meeting strict selection criteria, Wang et al. (2006) found that omega-3 fatty acids from fish or fish oil supplements, but not α-linolenic acid, appeared to reduce the risk of all-cause mortality, cardiac and sudden death, and stroke. Because RCTs on the effects of omega-3 fatty acids in individuals already suffering from cardiovascular disease (secondary prevention) have been conducted, the strength of the evidence for that outcome is greater than that for prevention of cardiovascular disease in healthy individuals (primary prevention), for which only cohort studies are available (Wang et al., 2006). Mozaffarian and Rimm (2006) also reported that evidence generated from pooling published prospective or randomized primary and secondary prevention trials indicated that consumption of 250 to 500 mg/d of EPA + DHA reduced the relative risk of coronary heart disease death by 36 percent compared to little or no EPA + DHA intake. Additional intake did not appear to confer additional benefits; risk reduction was most closely linked to consumption of fatty fish, not lean fish. Other recent meta-analyses or systematic literature reviews have supported the conclusion that omega-3 fatty acid consumption has a significant beneficial effect on cardiovascular disease (He et al., 2004a; Bucher et al., 2002; Jacobson, 2006; Whelton et al., 2004; Konig et al., 2005; Harper et al., 2005).

Several studies have suggested that mercury may attenuate cardioprotective effects of omega-3 fatty acids in fish (e.g., Salonen et al., 1995; Rissanen et al., 2000; Guallar et al., 2002; Virtanen et al., 2005), particularly in Finnish men, although at least one study did not find such an association (Yoshizawa et al., 2002). Current evidence suggests that fish or fish oils provide more health benefits to those individuals who also have low methylmercury body burdens (IOM, 2007).

Stroke:

Early research on the potentially protective effects of omega-3 fatty acid and/or fish consumption and stroke showed conflicting results (see, for example, Gillum et al., 1996;

Keli et al., 1994; Orencia et al., 1996). This may have occurred, in part, because of a failure to differentiate ischemic and hemorrhagic strokes in study populations (He et al., 2004b), which are caused by opposing mechanisms. A recent meta-analysis of nine cohorts suggested that fish consumption and ischemic stroke were inversely related, with the possibility that as few as one to three fish meals a month might significantly reduce the incidence of this disorder (He et al., 2004b). In a study of 79,839 women, Iso et al. (2001) found that risk of thrombotic infarction was decreased 48 percent for women who ate fish two to four times per week compared to those who ate fish less than once per month. In another analysis of published studies, Bouzan et al. (2005) found that any fish consumption provided significant reduction in stroke risk compared to no fish consumption. The authors noted that an incremental increase in fish consumption may reduce stroke risk even further. In a review of the literature, Wang et al. (2006) found that studies on the effect of marine-based omega-3 fatty acids on stroke were not consistent, but suggested a possible role of fish or fish oils in the prevention of stroke.

Cognitive Function:

Brain tissue is highly enriched in DHA, which is considered essential for the functional development of neural tissues. Much of DHA and other long chain PUFA content of fetal brain is obtained from the maternal blood supply, as *in vivo* synthesis from shorter chain PUFAs is minimal during this period (Cheruku et al., 2002; Marszalek and Lodish, 2005; Uauy and Dangour, 2006). Studies have suggested that fish consumption by the mother during pregnancy or by the young child may improve several neurological outcomes during early development (Mozaffarian and Rim, 2006). Language and social skills, for example, were higher in 6- and 12-month-old infants who ate fish once or more per week compared to those who rarely or never ate fish (Daniels et al., 2004). Maternal fish intake was also positively associated with infant cognitive scores in this study. Sleep-state patterns indicative of greater cognitive maturity were seen in infants whose mothers had higher plasma phospholipid DHA levels compared to those whose mothers had lower plasma phospholipid DHA levels (Cheruku et al., 2002). Oken et al. (2005) showed that infant cognitive scores were positively correlated with fish consumption, but inversely related to maternal hair mercury concentrations. Scores were highest among infants whose mothers had hair mercury concentrations of 1.2 ppm or less and consumed two or more fish meals per week. Conversely, scores were lowest among infants whose mothers had hair mercury concentrations greater than 1.2 ppm and ate two or fewer fish meals per week. Hibbeln et al. (2007) found that, after adjusting for 28 potentially confounding variables, the risk of suboptimal scores for verbal intelligence, prosocial behavior, fine motor, communication, and social development in children six months to eight years old was greater when maternal fish consumption was less than 340 g per week compared to when maternal fish consumption was greater than 340 g per week.

Several studies have shown that DHA levels are reduced in brain and plasma of patients with Alzheimer disease (AD) or other forms of dementia (Johnson and Schaefer, 2006). Potential mechanisms by which these fatty acids may modify the risk for dementia include the prevention or reduction of atherosclerosis, thrombosis, and inflammation

(Barberger-Gateau et al., 2002). In one of the first studies to investigate the potential relationship between fish consumption and dementia, Kalmijn et al. (1997) found that the incident risk of developing all forms of dementia was reduced 60 percent in people 55 years or older who consumed 18.5 or more g/day of fish compared to those consuming 3.0 or fewer g/day fish. The risk for developing AD without cerebrovascular disease in these respective populations was reduced 70 percent. Similarly, Morris et al. (2003) found that people who ate fish at least once per week reduced their risk of incident AD by 60 percent compared to those who rarely or never ate fish. In a subsequent study using the same population group, fish consumption was also found to be significantly inversely related to expected cognitive decline in individuals 65 years and older over a six year period (Morris et al., 2005). Fatty fish consumption and EPA + DHA consumption were also inversely related to mild cognitive decline in a cross-sectional study of middle-aged males and females (Kalmijn et al., 2004). Huang et al. (2005) specifically showed that fatty fish consumption, but not consumption of lean or fried fish, decreased the risk of dementia in a dose-dependent fashion in individuals who did not carry the *APOE* ε4 allele (a risk factor for AD). Fatty fish consumption more than twice per week decreased the risk of incident dementia and AD by 28 and 41 percent, respectively, compared to those eating fish less than once per month. Using a more accurate estimate of omega-3 fatty acid exposure, Heude et al. (2003) found that omega-3 fatty acid concentration and omega-3 to omega-6 ratio of erythrocyte membranes was inversely related to cognitive decline in 63-74 year-old men and women over a four year period.

Although omega-3 fatty acids are often considered the physiologically active agents responsible for positive health effects of fish, some research indicates that other components may have benefits as well. For example, fish, but not omega-3 fatty acid, consumption was inversely associated with a reduced rate of cognitive deterioration over a six-year period in a study of 6,158 males and females, aged 65 or older (Morris et al., 2005). Consumers who ate fish once a week or more maintained the mental status of a person three to four years younger compared to those who ate fish less than once a week.

Preliminary studies have found that omega-3 fatty acids mitigate symptoms in some children with attention-deficit/hyperactivity disorder; however, other studies have not supported these results (Richardson, 2006; Young and Conquer, 2005). Additionally, several epidemiological studies and intervention trials have shown that fish or omega-3 fatty acid consumption may be useful for the prevention or treatment of depression or other mood disorders, which may reflect the well-recognized link between depression and cardiovascular disease (see Parker et al., 2006; Nemets et al., 2006). Numerous authors have reported decreased blood omega-3 fatty acid levels in patients with psychiatric disorders (Tiemeier et al., 2003; Peet and Stokes, 2005; Sublette et al., 2006; Young and Conquer, 2005; Richardson, 2006). Additional research is needed to elucidate the potential role of fish or fish oils in the treatment of neuropsychiatric disorders (Parker et al., 2006; Richardson, 2006; Young and Conquer, 2005).

Visual Function:

DHA is found in very high concentrations in the retina and has a functional role in visual development (Connor et al., 1992; Neuringer, 2000; Cho et al., 2001; Uauy and Dangour, 2006; Johnson and Schaefer, 2006). As noted above, fetal DHA is largely obtained through the maternal blood supply and, postnatally, through breast milk (Marszalek and Lodish, 2005). The degree to which DHA supplementation of infant formulas is necessary or beneficial is not known (Mozaffarian and Rimm, 2006), although the evidence supporting its benefit for preterm infants is more persuasive than it is for term infants (Heird and Lapillonne, 2005; Cheatham et al., 2006). A recent meta-analysis of 14 controlled trials of DHA supplementation of infant formulas showed a strong positive relationship between DHA dose and visual acuity measurements in four-month-old infants (Uauy et al., 2003). Some studies show that the relationship between low dietary omega-3 fatty acids and slowed development of visual acuity may be transitory; however, long-term sequelae of early visual impairments that may occur with low-DHA diets have not been studied and could be significant (Neuringer, 2000).

Numerous studies have also shown that fish and/or omega-3 fatty acid consumption provides benefits to the aging eye and may protect against retinal pathologies associated with ischemia, light, oxygen, inflammation, and age (SanGiovanni and Chew, 2005). Age-related macular degeneration (AMD) is the primary cause of visual disability and blindness in older Americans (Chua et al. 2006; Seddon et al., 2006). In a cross-sectional population-based study, Smith et al. (2000) reported that individuals consuming fish more than once per week were at significantly lower risk of developing late AMD than individuals consuming fish less than once per month. Similarly, in two large prospective cohort studies, fish consumption was inversely related to AMD development; consumption of four or more servings per week reduced the risk of AMD 35 percent compared to eating fish three or fewer times per week. DHA consumption had a smaller, but still significant, inverse relation with AMD development, indicating that substances in fish other than fatty acids may also decrease AMD risk (Cho et al., 2001). In prospective cohort and case control studies, Seddon et al. (2001; 2003; 2006) showed that the risk for development and progression of AMD was significantly reduced or slowed, respectively, with increasing fish or omega-3 fatty acid consumption. In two of the three studies, however, this relationship existed only if consumption of linoleic acid was also low, indicating that the omega-6 to omega-3 ratio may be an important component to the protective effect of omega-3 fatty acids in the development and progression of this disease (Seddon et al., 2006). Chua et al. (2006) found that weekly fish consumption reduced the 5-year incidence of early AMD about 40 percent, while eating fish three times per week or more reduced the 5-year incidence of late AMD about 75 percent. In a review of published studies, Hodge et al. (2006) found that, while there is evidence to suggest that omega-3 fatty acids may play a role in prevention of AMD, variability among studies and the lack of a RCT prevent clinical conclusions from being drawn.

Inflammatory Diseases:

The effect of omega-3 fatty acids on inflammation and inflammatory diseases has been recently reviewed (Ariza-Ariza et al., 1998; Calder, 2006; Cleland et al., 2005; Simopoulos, 2002). Omega-3 fatty acids have been theorized to be useful as anti-inflammatory agents because they generate anti-inflammatory mediators, decrease production of arachidonic acid-derived pro-inflammatory eicosanoids, and modify the expression of inflammatory genes (Calder, 2006). Research has strongly supported the role of long-chain omega-3 fatty acids in the treatment of rheumatoid arthritis (Calder, 2006), including the reduced need for traditional non-steroidal anti-inflammatory drugs (NSAIDS) in patients taking sufficient doses of fish oils (Ariza-Ariza et al., 1998; Cleland, 2005; 2006). However, the data are less robust for the use of long chain omega-3 fatty acids in the treatment of other inflammatory diseases, such as inflammatory bowel disease or asthma, and additional clinical trials are recommended to further define their potential role in the treatment of these conditions (Calder, 2006). Currently, the effective dose for anti-inflammatory effect in rheumatoid arthritis is estimated to be 2.7 g/day EPA + DHA (Cleland, 2005), a dose not easily obtainable through fish consumption alone. It is recommended that this dose not be achieved through the use of cod liver oil supplementation because of the high vitamin A concentration of this product (Cleland, 2005). The shorter chain α-linolenic acid has not been shown to possess anti-inflammatory properties at practical intakes (Calder, 2006).

CONSIDERATION OF THE RISKS AND BENEFITS OF FISH CONSUMPTION

Since the recognition in the 1960s and 1970s that dietary fish might play a significant role in both health and disease, a vast number of studies have been conducted on the benefits and risks of fish consumption. As noted above, though, these areas of research are typically evaluated independently. Risk assessments on contaminants found in fish are occasionally published in the peer-reviewed literature (e.g., Hites et al., 2004; Mahaffey et al., 2004; Knobeloch et al., 2006); a recent risk assessment of organic contaminants in wild and farmed salmon (Hites et al., 2004) sparked intense controversy over whether the known benefits of fish consumption had been adequately considered in comparison to the relatively small lifetime cancer risks associated with organochlorine compounds (Stokstad, 2004; Rembold, 2004; Tuomisto et al., 2004; Lund et al., 2004; Foran et al., 2006; Willett, 2005; 2006). Recently, a few authors have published risk-benefit analyses for fish consumption that considered one or more contaminants and incorporated a quantitative estimate of benefit (Anderson and Wiener, 1995; Foran et al. 2005; Cohen et al., 2005; Gochfeld and Burger, 2005; Ponce et al., 2000; Sidhu, 2003). Using one method of calculating the combined risks and benefits of fish consumption, for example, Foran et al. (2005) found that consumption of farmed salmon was estimated to prevent nearly 300 times more cardiac-related deaths than it potentially caused from PCB-associated cancer. In most assessments, the comparative risks of alternate foods are not taken into account. Other sources of animal protein that may be consumed in place of fish, such as beef, pork, or chicken, also contain undesirable components (e.g., PCBs, dioxins, saturated fat, and hormone or antibiotic residues) whose risk has not been characterized or estimated in a fashion similar to that of fish.

As early as 1986, OEHHA held a workshop on balancing the risks and benefits of fish consumption (CDHS, 1988). In more recent years, OEHHA, and similar agencies from other states, have incorporated benefit statements into their fish consumption advisories that assure the public that fish should be part of a healthy diet. In a technical memorandum describing the derivation of a noncommercial fish consumption recommendation for women who may become pregnant, pregnant women, nursing mothers, and young children, U.S. EPA and FDA noted that their advice "balances the risk from mercury with the benefits of fish" (U.S. EPA, 2004).

Conclusions:

OEHHA determines that there is a significant body of evidence and general scientific consensus that eating fish at dietary levels that are easily achievable, but well above national average consumption rates, appears to promote significant health benefits, including decreased mortality**.** As is the case with all foods, fish contain constituents that may be harmful when consumed in unrestricted quantities. However, because of the unique health benefits associated with fish consumption, the advisory process should be

expanded beyond a simple risk paradigm in order to best promote the overall health of the fish consumer.

ADVISORY TISSUE LEVELS FOR CHLORDANE, DDTs, DIELDRIN, METHYLMERCURY, PCBs, SELENIUM, AND TOXAPHENE

To include the benefits of fish consumption in the advisory process, ATLs were calculated for each of the contaminants for which FCGs were derived. In comparison to FCGs, which were based on a single meal frequency, ATLs were calculated for several meal frequency categories that are used to provide advice to the consumer that balances the benefits and risks of fish consumption. This yields a range of corresponding contaminant concentrations in fish within categories as shown in Table 2. ATLs were calculated using the same general formulas as those used to calculate FCGs, with some adjustments in order to incorporate the benefits of fish consumption. Because benefits are integrated differently into ATL equations for cancer and non-cancer risk, these methods are discussed separately. All factors and assumptions not specifically addressed are the same as those used to develop FCGs.

Cancer Risk:

$$\text{Tissue concentration (ppb)} = \frac{\text{(Risk Level)(kg BW)(1000 µg/mg)}}{\text{[CSF (mg/kg/day)}^{-1}\text{] (CR kg/day)(ED/AT)(CRF)}}$$

Risk Level:

For FCGs, the maximum risk level was set at $1x10^{-6}$, estimating that, at the given consumption rate, not more than one additional cancer case would be expected in a population of one million people consuming fish over a lifetime. OEHHA acknowledges that, while it should be a goal to maintain a risk level of $1x10^{-6}$ for fish and other foods, the counterbalancing nutritional benefits of foods, particularly the unique benefits of fish, must be considered. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued through fish consumption.

Thus, OEHHA concludes that, for the purposes of developing fish consumption advisories, ATLs should be calculated using a maximum risk level of $1x10^{-4}$, estimating that, at the given consumption rate, not more than one additional cancer case would be expected in a population of 10,000 people consuming fish over a lifetime. This risk level is within the acceptable range of risks ($1x10^{-4}$ to $1x10^{-6}$) used by U.S. EPA in regulatory criteria for drinking water (Fed. Reg., 1998) and is provided as an example of a maximum acceptable risk level in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories (U.S. EPA, 2000a). OEHHA considers that a maximum risk level of $1x10^{-4}$ appropriately balances the cancer risk associated with fish consumption with the numerous known health benefits that can be accrued from eating fish. Because each meal frequency category encompasses a range of fish

contaminant levels (see consumption rate discussion and ATL table below), fishers, over time, will be exposed to a range of risk levels as they catch and eat different fish. Thus, when the *maximum* risk level is set at $1x10^{-4}$ for each meal frequency category, the actual *average* cancer risk for fish consumers over their lifetime is less than $1x10^{-4}$ (ranging from approximately $5x10^{-5}$ to $1x10^{-4}$), when consumption advisories are based on carcinogens detected in fish.

Consumption Rate (CR):

FCGs were calculated using a single consumption rate (32 g/day, or a single serving of eight ounces of fish, prior to cooking, per week) aligning with the AHA's minimum recommended fish consumption rate for adults and exceeding the typical consumption rate for the vast majority of sport fishers (see, for example, SFEI, 2000). This consumption rate is also used to begin issuing fish consumption advisories that are based on cancer risk using the ATLs and other considerations. Because OEHHA also considers it important to offer advice for the small segment of fishers who choose to consume fish more frequently than one 8-ounce serving per week, ATLs for two and three 8-ounce servings per week, prior to cooking (64 and 96 g/day, respectively), were also calculated based on cancer risk.

Example Calculation:

Using a risk level of $1x10^{-4}$, the slope factor for each chemical, and consumption rates of 32, 64, and 96 g of fish/day in the above equation will yield three numbers that are the cutoff values for one, two, and three servings per week, respectively, for cancer risk.

As an example, for dieldrin, the ATL using a risk level of $1x10^{-4}$ and a consumption rate of one, 8-ounce serving per week (32.0 g/day) would be calculated as follows:

$$\frac{(1x10^{-4})(70\text{ kg})(1000\ \mu g/mg)}{[16\ (mg/kg/day)^{-1}](0.032\text{ kg/day})(30/70)(0.7)} = 46\text{ ppb}$$

Thus, fish containing 46 ppb dieldrin, or less, can be consumed in the amount of at least one, 8-ounce serving per week.

Non-Cancer Risk:

$$\text{Tissue concentration (ppb)} = \frac{(\text{RfD mg/kg-day})(\text{kg BW})(1000\ \mu g/mg)}{(\text{CR kg/day})(\text{CRF})}$$

Hazard Quotient and Consumption Rate:

For FCGs, the maximum HQ was set at 1, indicating that the *maximum* exposure (based on CR in the equation) is equivalent to the RfD. In order to balance the risks and benefits

of fish consumption when considering non-cancer risk, however, OEHHA determined that the *average* exposure should be equivalent to the RfD. With the ATLs, each meal frequency category (one, two and three servings per week) encompasses a range of fish contaminant levels, as noted above. Thus, fishers over time will be exposed to a range of HQs as they catch and eat different fish. When the *maximum* HQ for each meal consumption frequency is set at 1, using the maximum consumption rate in the equation (32, 64, and 96 g/day for one, two, and three servings per week, respectively) to set the cutoff for each meal frequency leads to an actual *average* HQ for fish consumers, over a multiple week basis, of less than 1. This is because the majority of fish caught in each meal frequency category will have a lower contaminant level than the maximum contaminant level used to set the cutoff. However, if the cutoffs are adjusted slightly so that the *average* rather than the maximum HQ is 1, over a multiple week basis, and an acceptable maximum HQ is still maintained, fishers who follow the advice will be able to consume a greater amount of fish and consequently enjoy a higher level of health benefits without incurring significant non-cancer risks from contaminants in fish.

U.S. EPA adjusted a meal frequency cutoff to establish its national advisory for mercury of one serving per week of sport fish from untested water bodies. They combined several meal categories (two, three and four servings per month), as do many states, in order to balance the risks and benefits of fish consumption and simplify communication (U.S. EPA, 2004). U.S. EPA used the contaminant concentration that would otherwise be associated with a recommendation of two servings per month as the cutoff for the one serving per week advice. Although this results in an HQ higher than 1 for some fish that fall into the 1 serving per week category, this advice is still health protective because, on average, fishers will be consuming fish with lower mercury levels than those used to establish the one serving per week cutoff.

OEHHA incorporated an "average HQ" concept into the ATLs by modifying the fish consumption rate used in the ATL equation. As explained above, one, 8-ounce serving of fish per week is equivalent to a consumption rate of 32 g/day. Consumption of two servings of fish per month would be equivalent to 0.5 servings per week, or 16 g/day. Following the example of U.S. EPA in their national advisory (see above), OEHHA also used a 16 g/d consumption rate to calculate the cutoff for the one serving per week category when considering non-cancer risk for the ATLs. As can be seen in the sample calculation below, this allows for greater consumption of fish (and a better balancing of risks and benefits) than if a consumption rate of 32 g/day were used. In a similar fashion, OEHHA used a consumption rate of 48 g/day (approximately 1.5 servings per week) to compute the ATLs for the two servings per week category for non-cancer risk. A consumption rate of 96 g/day was used, as it was for cancer risk, to determine the ATLs for three servings per week. As a consequence of making these adjustments, the *average* HQ, over the entire range of potential exposures, is approximately 1. OEHHA considers this average HQ appropriate to balance the risk and benefits of fish consumption when considering non-cancer risk.

Example Calculation:

Using the RfD for each chemical, and consumption rates of 16, 48, and 96 g/day, in the above equation will yield three numbers that are the cutoff values for one, two, and three servings per week, respectively, for non-cancer risk.

As an example, for mercury, the ATL for one, 8-ounce serving per week for women aged 18-45 years would be calculated as follows:

$$\frac{(1\times10^{-4}\ \text{mg/kg-day})(70\ \text{kg BW})(1000\ \mu\text{g/mg})}{(0.016\ \text{kg/day})(1)} = 440\ \text{ppb}$$

Thus, fish containing 440 ppb mercury, or less, can be consumed in the amount of at least one, 8-ounce serving per week.

Final ATL Calculations:

For each chemical, ATLs were calculated separately for cancer and non-cancer risk, if appropriate, for consumption frequency categories of one, two, and three 8-ounce servings per week. Values for cancer and non-cancer risk were then compared to determine whether the cancer or non-cancer value was the most health-protective. For all chemicals except DDTs, either cancer or non-cancer risk determined the ATL for each consumption frequency category. For DDTs, consumption advice for one serving per week was based on cancer risk, while consumption advice for two and three servings per week was based on non-cancer risk.

OTHER CONSIDERATIONS USED IN THE DEVELOPMENT OF FISH CONSUMPTION ADVISORIES AND SAFE EATING GUIDELINES

ATLs are used as part of the process to develop traditional health advisories (which focus on fish whose consumption should be restricted or avoided altogether) as well as the newer "safe eating guidelines," which inform consumers of fish with low contaminant levels considered safe to eat frequently. Other factors, including the following, will also be used by OEHHA to develop advisories and safe eating guidelines, as appropriate.

Omega-3 Fatty Acid Levels:

The fatty acid content of fish is highly variable within and among species; fish diet, sex, age, and reproductive status, as well as location and season all affect the total concentration and composition of tissue fat (Nettleton, 1995). At the present time, omega-3 fatty acids levels are not available specifically for California sport fish, although applicable national averages have been published for some species. If acceptable surrogate or actual omega-3 fatty acid data exist for California sport fish, this information may be used to alter fish consumption advice. For example, OEHHA may recommend higher consumption of fish with high omega-3 levels than fish with identical levels of contaminants but lower omega-3 levels.

Contaminant Data:

Once the consumption frequency categories and ATLs are established, the data must then be carefully examined to determine what contaminant values will be compared to the ATLs. Fish contaminant data collected from a water body are often highly variable, reflecting environmental factors such as seasonal effects and localized sources or sediment methylation processes. Evaluating these data prior to developing site-specific (water body) or regional consumption advice is a complex process that may involve one or more approaches. The most common and simplest method of interpreting fish contaminant data collected from a site is to calculate a value of central tendency such as the geometric mean, arithmetic mean, median or mode. OEHHA often uses the arithmetic mean for developing safe eating guidelines; however, each of these measurements is helpful in interpreting the distribution of the data. Another method of interpreting a data set is to examine the regression line between species length and chemical contaminant level. Consumption guidance can then be tailored to different fish size classes or to the predicted contaminant concentration of the most typical length of fish consumed, provided adequate creel data are available to make this determination. This method is most useful for contaminants, such as mercury, where the concentration is largely dependent on fish size in specific fish species.

After careful selection of an appropriate contaminant concentration for each species at a site (e.g., an arithmetic mean, mode or a regression analysis), that value or values can then be compared to the range of concentrations presented in the ATL table (Table 2).

Risk Communication:

After thorough evaluation of fish contaminant data for a site and comparison of appropriate contaminant values to the ATLs, OEHHA may determine that strict adherence to established consumption frequency categories results in consumption advice that is too complex for the fisher to follow, particular for large water bodies. In these cases, OEHHA may make minor adjustments to recommended consumption limits for a species in order to best facilitate communication. For example, if contaminant levels in a species vary along a discreet coastal region, OEHHA may choose the most restrictive or most common advice for that species for the entire region, depending on circumstances and communication considerations. Additionally, in safe eating guidelines, fishers who do not skin or cook their fish may be advised to consume less fish than guidelines recommend for their population group, if organochlorine contaminants are present in quantities that affect consumption guidelines. Skinning and cooking do not reduce methylmercury concentrations in fish tissue. Serving sizes are based on fish consumption by an average 160 pound person. Individuals weighing less than 160 pounds will be encouraged to eat proportionately smaller amounts. As noted previously, because of their smaller body weights, children will be advised to eat approximately one-half as much fish (in either quantity or frequency) as are women of childbearing age.

Conclusions:

The ATLs described in this report should not be misinterpreted as static “bright lines” that others can use to duplicate state fish consumption advisories. As noted, ATLs are but one component of a complex process of data evaluation and interpretation used by OEHHA in the assessment and communication of fish consumption risks. The nature of the contaminant data or omega-3 fatty acid concentrations in a given species in a water body, as well as risk communication needs, may alter strict application of ATLs when developing site-specific advisories. For example, OEHHA may recommend that consumers eat fish containing low levels of omega-3 fatty acids less often than the ATL table would suggest based solely on contaminant concentrations. OEHHA will use the guidelines set forth in this report as a framework, along with best professional judgment, to provide fish consumption guidance on an *ad hoc* basis that best combines the needs for health protection and ease of communication for each site.

Table 2. Advisory Tissue Levels (ATLs) for Selected Fish Contaminants Based on Cancer or Non-Cancer Risk Using an 8-Ounce Serving Size (Prior to Cooking) (ppb, wet weight)				
Contaminant	**Three 8-ounce Servings* a Week**	**Two 8-ounce Servings* a Week**	**One 8-ounce Servings* a Week**	**No Consumption**
Chlordane[c]	≤190	>190-280	>280-560	>560
DDTs[nc**]	≤520	>520-1,000	>1,000-2,100	>2,100
Dieldrin[c]	≤15	>15-23	>23-46	>46
Methylmercury (Women aged 18-45 years and children aged 1-17 years)[nc]	≤70	>70-150	>150-440	>440
Methylmercury (Women over 45 years and men)[nc]	≤220	>220-440	>440-1,310	>1,310
PCBs[nc]	≤21	>21-42	>42-120	>120
Selenium[nc]	≤2500	>2500-4,900	>4,900-15,000	>15,000
Toxaphene[c]	≤200	>200-300	>300-610	>610

[c]ATLs are based on cancer risk
[nc]ATLs are based on non-cancer risk
*Serving sizes are based on an average 160 pound person. Individuals weighing less than 160 pounds should eat proportionately smaller amounts (for example, individuals weighing 80 pounds should eat one 4-ounce serving a week when the table recommends eating one 8-ounce serving a week).
**ATLS for DDTs are based on non-cancer risk for two and three servings per week and cancer risk for one serving per week.

Tabled values are rounded based on laboratory reporting of three significant digits in results, where the third reported digit is uncertain (estimated). Tabled values are rounded to the second digit, which is certain. When data are compared to this table they should also first be rounded to the second significant digit as in this table.

APPENDIX 1: RESPONSE TO COMMENTS

Comments and Responses to the Original Draft Document:
Development of Guidance Tissue Levels and Screening Values for Common Contaminants in California Sport Fish:
Chlordane, DDTs, Dieldrin, Methylmercury, PCBs, Selenium, and Toxaphene.

Commenter 1:
Sheila Hamilton
General Manager
Big Bear Municipal Water District
P.O. Box 2863
Big Bear Lake, CA 92315

Comment 1.1
Because the final guidance tissue levels and screening values will, no doubt, play a significant role in future regulatory decisions throughout the state, we urge OEHHA to be more specific on the proper and improper use of these proposed thresholds. For example, the State Water Resources Control Board recently misinterpreted OEHHA's screening values (SVs) as thresholds defining impaired water quality. The report does not caution against using the screening values as informal Water Quality Objectives or Maximum Contaminant Levels.

Response 1.1
OEHHA has reconsidered the usefulness of establishing SVs as part of our protocol to develop fish consumption recommendations and determined that the SVs should be removed from the final document. We are providing Fish Contaminant Goals that can be used as a starting point for agencies to develop fish tissue-based criteria. Agencies that require screening criteria for mandated activities may still seek OEHHA's advice for their development. Any screening criteria employ numerous assumptions, particularly the consumption rate and risk level, and may be targeted to different population groups. These issues must be considered and agreed upon as relevant to the purpose of the criteria prior to their development and use by any agency.

Comment 1.2
The draft document was developed using a wide variety of assumptions. We recommend that these assumptions be summarized in a single table.

Response 1.2
The assumptions are explained carefully and individually in the text where they are used, which is considered most appropriate.

Comment 1.3
Table 1 shows a range of recommended GTLs that vary in relation to the average amount of fish consumed in a month. The presentation should be expanded to show how changes in other key assumptions will cause the GTL or SV to increase or decrease.

Response 1.3
While Fish Contaminant Goals (FCGs) and GTLs (now the Advisory Tissue Levels, or ATLs) will change if the assumptions change, the assumptions made by OEHHA in development of this document are fairly standard in risk assessment and have been clearly described in the document. As OEHHA is responsible for issuing sport fish consumption guidelines in the state of California, there is no reason to present alternative assumptions that will not be used to issue fish consumption advice.

Comment 1.4:
We recommend that OEHHA develop a simple spreadsheet tool, based on the equations shown on page 39-40 (now page 43-44) of the draft report, that allow end users to modify the underlying assumption and graph the range of recommended values. With minor modifications, that tool could be adapted for general use by other state agencies.

Response 1.4:
As noted previously, it is OEHHA's mandate to issue health advisories for sport fish consumption in the State of California. As such, OEHHA is the only "end user" of the GTLs (now ATLs), although the ATLs may be used by counties to issue interim advice in consultation with OEHHA. The sole purpose of releasing the document was to improve transparency of the fish advisory process, not to provide other agencies with a tool to provide their own fish consumption advice to the public. To prevent such confusion in the future, OEHHA will rename the final document: Development of Fish Contaminant Goals and Advisory Tissue Levels for Common Contaminants in California Sport Fish: Chlordane, DDTs, Dieldrin, Methylmercury, PCBs, selenium, and toxaphene. OEHHA recognizes that use of the word "guidance" in Guidance Tissue Level has led some to think that this is a "guidance document" to be used by other agencies in developing their own advisories. We are making the change to correct this misinterpretation.

Comment 1.5:
The draft document does not describe what constitutes "sufficient fish tissue data" (p. 2) nor does it provide an explanation as to how to perform the highly-specialized risk analyses recommended.

Response 1.5:
The GTL (now ATL) document is not intended as a guidance document to be used by other agencies (see response to comments above) to develop their own advisories. OEHHA performs the risk analyses; recommendations provided to other agencies responsible for data collection and analyses are provided in another document (Gassel and Brodberg, 2006; General Protocol for Sport Fish Sampling and Analysis). Because each water body is unique, agencies should consult OEHHA prior to collecting fish from

California water bodies so that OEHHA can direct sampling and analysis to collect data sufficient to adequately estimate human health risks. The discussion of sampling and analysis has been removed from the document.

Comment 1.6:
We are concerned that OEHHA elected to make very large adjustments to the estimated reference dose to account for various "uncertainty factors." The published GTLs and SVs should be presented with and without such adjustments so that it is clear to other state agencies that a safety factor has already been applied. Otherwise, it is likely that other agencies will incorrectly assume that the GTL or SV represents the No-Observed-Effect-Threshold and seek to add on their own safety factors. It would be useful to explain that the magnitude of adjustment applied was somewhat arbitrary. Higher or lower multipliers may be equally well justified.

Response 1.6:

Uncertainty factors (UFs) are always included in the development of an RfD. After evaluating the original toxicity data, toxicologists apply uncertainty factors to the point of departure value (e.g., the NOAEL or LOAEL), taking into account any deficiencies in the data (such as short-term exposure, the use of an animal model, or lack of a reproductive study) in order to arrive at the RfD. UFs are not arbitrary but are routinely and rather consistently applied using accepted risk assessment principles. With the exception of toxaphene and chlordane, the UFs and RfDs used for each chemical in this document were originally developed by U.S. EPA and are in general use by the risk assessment community. After reviewing the most current literature, OEHHA has chosen to maintain these RfDs. Again, other agencies should not attempt to modify OEHHA advisories by manipulating any of the parameters used by OEHHA in developing the advisories.

Comment 1.7:
It is unclear if OEHHA considered the published recommendation of other federal agencies (e.g., FDA's less restrictive "Action Levels") and, if so, why those recommendations were rejected. Nor is it clear why OEHHA declined to use EPA's more stringent recommendations.

Response 1.7:

OEHHA conducted a thorough evaluation of federal and other state's methods of providing fish consumption recommendations and selected methods that appropriately balanced benefits and risks. FDA action levels are not appropriate for setting sport fish consumption guidelines. In their guidance document, U.S. EPA does not propose a single, specific method of providing fish consumption recommendations but, instead, illustrates one possible scenario using only the RfD and a risk level of 1×10^{-5}. The U.S. EPA acknowledges that states and tribes may modify this method in multiple ways to make it more or less conservative as they see fit. Examples of RLs from 10^{-4} to 10^{-7} are also included in their guidance document. OEHHA uses the most up-to-date data and

methodology and considers sensitive populations. OEHHA's advisories are within the range of guidance provided by U.S. EPA but, in several cases, are more conservative.

Comment 2.1
Clarification of the reduction factor for organic chemicals for skinning of fillets is needed. You have applied a reduction factor to your GTL calculations that assumes people consume fish as skin-off fillets. Since you assume a 30% reduction due to contaminant loss during cooking and you assume a 50% loss due to cooking and skinning combined, skinning alone appears to account for about a 20% reduction in contaminants in your calculations. This reduction factor for skinning should be explicitly stated.

Response 2.1
Data on the contaminant reduction achieved by various trimming and cooking techniques are variable. It is known that removing the skin and associated fat as well as cooking remove a significant amount of organic contaminants. The general cooking reduction factors of 50% and 30% are typical values that have been generated with experiments using either skin-on or skin-off fillets, respectively. Therefore, there is no explicit reduction factor for skinning alone. The 30% and 50% reduction factors are used, for example, by the Protocol for a Uniform Great Lakes Sport Fish Consumption Advisory and by other states in their fish consumption advisories.

Comment 2.2
Incorporating an assumption that people eat skin-off fillets results in GTLs that are not adequately health protective for a significant number of people. In a survey of San Francisco Bay anglers (SFEI 2001), DHS found that significant numbers of anglers report eating the skin of fish. Specifically, we found that 21% of striped bass consumers and 38% of white croaker consumers reported eating the skin more than half of the time. Generally, among anglers who reported eating skin, there were more non-white anglers, particularly African Americans and Asians. Thus, using a skin-off fillet as the default to develop GTLs for organic chemicals will disproportionately affect these groups.

Response 2.2
OEHHA recommends fish preparation methods, such as skinning, that allow anglers to safely eat more fish. In order to protect anglers who choose not to follow these guidelines, however, OEHHA may provide separate advice, as part of risk

communication, to fishers who do not skin or otherwise trim fish or cook it by methods recommended to reduce contaminant levels when guidance is based on chlorinated hydrocarbon contaminants.

Comment 2.3
The draft document states that "if fishers choose not to follow this advice and cook fish as skin-on fillets, they should reduce their consumption by approximately one-fourth…to achieve and equivalent exposure." From a practical perspective, it does not make sense to base the GTLs on a consumption pattern that people "should" follow, rather than what they already do. The GTLs should not assume that a significant proportion of people will take additional measures in order for the advisory to be adequately health protective. Furthermore, advisory messages need to be as simple as possible. Adding another qualifier to the advisory message (e.g., this advice will only be health protective if you remove the skin) complicates the message.

Response 2.3
Based on the study cited, the majority of anglers *do* skin fish, whether doing this of their own accord or following recommendations that OEHHA provides. OEHHA does not issue consumption and cleaning/cooking advice only to protect the most exposed individual but makes recommendations that all fishers can choose to follow – or not – to lower their exposure to contaminants. Fishers who do not follow advice to skin and/or cook their fish also may not follow advice to limit fish consumption. In the case of mercury, separate advice is provided for two populations groups so that less sensitive individuals (women beyond childbearing age and men) do not have their fish consumption unduly restricted by the needs of the other group (women of childbearing age and children). So it should be with cooking and cleaning methods, i.e., the majority of fishers who do consume/prepare fish in the safest manner should be offered advice that allows them to consume the most fish safely while fishers who choose to eat the skin or prepare fish in a way that does not reduce contaminant loads should be offered separate advice tailored to their needs. This is particularly important in the case of subsistence fishers, for example, where unwarranted fish consumption restrictions may impose an economic burden. The draft report recommended that fishers who do not follow advice to skin fish should reduce their consumption by approximately one-fourth. However, newer data indicate that the amount of contaminants found in skin may be more variable (and ultimately higher) that previously thought. In some cases, fish that could be eaten once or twice a week without skin will fall into the "do not consume" category with skin. For additional consideration in the final report and in future advisories for chlorinated hydrocarbons, OEHHA will consider site- or species-specific advice to reduce consumption if fishers do not cook or clean their fish in the safest manner.

Comment 2.4
Additionally, the decision to use skin-off fillets for scaled fish is not consistent with U.S. EPA guidance for fish advisories. U.S. EPA recommends that contaminant concentrations be measured using skin-on fillets for scaled fish species and skinless fillets for scaleless fish species (e.g., catfish).

Response 2.4
Historically, fish monitoring programs in California have analyzed skinless fillets of fish. See response 2.3 for further discussion. Analyzing skin-on fillets actually dilutes the measured mercury concentrations, making the advice less conservative. As mercury is the predominant fish contaminant in California, OEHHA recommends measuring contaminant concentrations in skin-off fillets.

Comment 2.5
On page 39, a correction to the example equation for dieldrin is needed; 1000 µg/kg should be 1000 µg/mg.

Response 2.5
Corrected. The mistake was the result of a typographical error. Calculated values were correct in the original version.

Commenter 3:
Roberta Blank

San Francisco, CA 94105

Comment 3.1
A major component of the EPA Institutional Controls Program for the Palos Verdes Shelf site is educating the public on the current state sport fish consumption guidelines. The current state fish advisory for DDTs uses an excess cancer risk of 10^{-5}. The proposed GTLs use a 10^{-4} level. The GTLs guidance cites that other states (e.g., Georgia and West Virginia) use the risk level of 10^{-4} in fish consumption advisories. However, these states have not used a risk level of 10^{-5} before, while California has been using 10^{-5} cancer risk endpoint for at least 15 years. No rationale for this change is provided.

Response 3.1
The rationale for the current protocol was discussed in the draft document. The 10^{-5} risk level was not consistently used for all chemicals in the Southern California sport fish consumption guidelines and has not been the basis for other advisories. Over the last 15 years, a tremendous amount of data has been published on the benefits of fish consumption – information that was not available when the 10^{-5} risk level was initially used. As scientific knowledge and protocols continue to expand or develop, our understanding of the risk and benefits of fish consumption have increased. The revised document has greatly expanded the discussion of the benefits of fish consumption and the reasoning behind the choice of the 10^{-4} risk level. In their fish advisory guidance document, U.S. EPA allows states to choose risk levels ranging from 10^{-4} to 10^{-7}. OEHHA concludes that, while it should be a goal to maintain a risk level of $1x10^{-6}$, when considering the counterbalancing benefits of fish consumption, a risk level of $1x10^{-4}$ is

appropriate. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption.

Comment 3.2
The draft GTLs are consistent with the FDA cancer risk level used for establishing tolerance levels in fish. However, the underlying assumptions used in the FDA methodology were not intended to be protective of recreational, ethnic, and subsistence fishers who typically consume larger quantities of fish than the general population and often harvest the fish and shellfish they consume from the same local water bodies repeatedly over many years, such as in the case for PV Shelf. The EPA national guidance states that "the FDA action levels and tolerances are indicators of chemical residue levels in fish and shellfish typically purchased in supermarkets or fish markets that sell products that are harvested from a wide geographic area, including imported fish and shellfish products."

Response 3.2
The reference to the FDA tolerance level for PCBs has been removed.

Comment 3.3
Using a cooking reduction of 30% in volume of fish consumed would increase the allowable contaminant intake in the screening value. Using this factor is inconsistent with the EPA national guidance for fish advisories. In addition, the assumption of skin-off fillet is not protective of sensitive populations such as ethnic populations who often eat whole fish, and fish stew and/or soup.

Response 3.3
Appendix C in U.S. EPA's Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories, Vol. 2, discusses dose modifications that may be used to adjust for food preparation and cooking. Various surveys in California have shown that the majority of fishers eat skin-off, cooked fish. OEHHA will provide differential advice for those that prepare and cook fish in the safest manner as well as those that do not (see 2.3 above).

Comment 3.4
For chlordane, DDT and PCBs, the noncancer endpoint is not protective of effects for children. The 10^{-5} indirectly provides protection to these sensitive populations as the 10^{-5} value is the more conservative value. However, the use of 10^{-4} risk level does not provide this indirect buffer.

Response 3.4
OEHHA is not aware of any compelling evidence that children have increased susceptibility to DDTs that is not accounted for by the current RfD. OEHHA is currently assessing whether children may have increased susceptibility to PCBs under our SB 25 toxic air contaminants program. RfDs are generated taking into account the most

sensitive population; in particular, the RfD for PCBs is deemed protective of neurodevelopmental effects in fetuses and children as those occurred at a higher dose than the critical effect. The RfDs for DDTs and PCBs have uncertainty factors of 100 and 300, respectively, which should offer ample protection should additional adverse effects of these contaminants be determined later. If new research allows development of a childhood-specific RfD, like that for mercury or chlordane, OEHHA will reevaluate fish consumption guidelines at that time.

Comment 3.5
The draft GTLs guidance states that "Even if fishers fish the same location for 70 years, their exposure to such chemicals will undoubtedly decline significantly over this period" due to decline in levels in the environment. When the duration of exposure increases, even if there is a decline in contaminant levels, it is possible that the increase in the exposure time outweighs the decline in contaminant levels. At this time, we have not fully evaluated the existing and current data to corroborate the assumption that the levels of these contaminants are declining in the environment.

Response 3.5
The assumption of a 30 year exposure from fish consumption for a particular water body is a reasonable high-end health protective assumption for assessing risk from carcinogens, given current knowledge about population mobility from various studies. This assumption may need further consideration for bioaccumulating, carcinogenic contaminants ubiquitously present in water bodies.

Comment 4.1
OEHHA should decrease the allowed cancer risk level in calculating GTLs and SVs to maintain the 10^{-5} end point for carcinogens to adequately protect sensitive subpopulations such as ethnic subsistence fishers, pregnant women and children. The lines of reasoning provided by OEHHA for the 10^{-4} risk level are not sufficient to justify the increase in allowed cancer risk. The FDA methodology used to calculate their level of acceptable risk cited in the draft report assumes that the population consumes a smaller number of fish from multiple sources; in this case, the draft report calculations are intended to protect people who consume fish from *local* water bodies. Finally, the draft report implies that consuming a certain amount of fish may be more important than avoiding contaminant exposure. Not only does this conclusion appear to be outside the purview of OEHHA, it is not well justified in the draft report. In sum, there is no appropriate

rationale provided in the Draft Report to justify the change to a less protective endpoint. OEHHA should use an allowed cancer risk level of 10^{-5} in calculating GTLs and SVs to be sufficiently protective of human health particularly under circumstances that occur in California. This lower value would serve as a "buffer" for other non-conservative assumptions relied upon by OEHHA as discussed below.

Reponse 4.1
OEHHA has removed the SVs from the draft report; see additional discussion below. Instead, OEHHA has provided Fish Contaminant Goals (FCGs) that maintain very conservative assumptions and may be used by other agencies as a starting point for developing fish tissue-based criteria.

The reference to the FDA tolerance limit for PCBs has been removed.

OEHHA (formerly of the Department of Health Services) has discussed balancing the risk and benefits of fish consumption since as early as 1986 (California Department of Health Services. Balancing the scales: Weighing the benefits and risks of fish consumption. Proceedings of a workshop held in Concord, California, October 20, 1988.). With the vast amount of data that has become available on the benefits of fish consumption in the last few years, OEHHA determined that this section should be significantly expanded in the final report. OEHHA believes that using a 10^{-4} risk level best balances known health benefits with cancer risks of fish consumption. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption.

Comment 4.2
OEHHA should ensure that GTLs and SVs are protective of the entire population including several sensitive subpopulations. The GTLs and SVs are not protective of certain highly relevant population groups, including children, pregnant women, and ethnic subsistence fishers. For example, the authors make various assumptions about the consumer in developing the GTLs and SVs, such as assuming a body weight of 160 pounds and a normal meal size of 6 ounces after cooking. While these assumptions are accounted for somewhat in the Draft Report by including recommendations to adjust the amount of fish consumed based on the weight of the consumer, OEHHA is also proposing to base the screening values upon the same characteristics of an average adult, thus failing to account for other routinely exposed groups of the population. In addition, under this assumption, OEHHA appears to recommend that children under 40 pounds should not eat any fish at all and kids under 80 pounds should not eat a tuna fish sandwich (based on a 2 oz serving size). This is not realistic. There is ample evidence that children in California consume local fish regularly and often, and thus are exposed to these contaminants. To adequately protect all consumers, OEHHA should use a much more conservative (lower) body weight in calculating the GTLs and SVs.

Response 4.2
The assumption of a 70 kg adult body weight is standard risk assessment protocol and six ounces after cooking is considered a standard fish meal size. Because there is a strong positive correlation between food consumption and body weight, particularly when averaged over a lifetime as the risks and hazards are, most risk assessments simply assume the concomitantly reduced consumption rate for lower body weights rather than stating it explicitly. In the final document, simplified instructions will be added to reduce meal sizes proportionately to body weight. Additionally, 70 kg is currently well below the average adult body weight for males and females, making the use of this default value a conservative assumption.

Comment 4.3
The cooking reduction factor of 30 percent and skin-on reduction factor of 20 percent should be removed from the calculations of GTLs and SVs. The GTL calculations also incorporate a cooking reduction factor of 30 percent and a skin-on reduction factor of 20 percent based on a theory that the process of heating the fish will break down organic contaminants and most consumers do not eat skin-on fish. This may be appropriate under some circumstances, but not in *all* cases. First, the specific method of cooking may determine the extent of breakdown of these organic constituents. For instance, searing the fish or cooking the fish in a stew may lead to a reduction in organic contaminants that is much lower than 30 percent. Second, methylmercury will not likely breakdown during the cooking process. Third, ethnic subsistence fishermen are put at additional risk under this assumption because they often use the whole fish (not a fillet) with skin-on. For instance, a fish consumption study found that of Asian anglers surveyed, 50 percent consume the whole fish. In fact, white croaker, a popular fish in Asian communities, is *rarely* eaten as a fillet. Thus, as just one example, Asian populations are not properly protected using these reduction factor assumptions. And again, while the draft report recommends reducing consumption if skin-on fillets are used, the screening values do not take this variable into account. Plainly, the reduction factors increase the allowable contaminated fish consumption in the screening values and will lead to fewer fish advisories and thus less protection for all groups of consumers. OEHHA should remove the 30 percent cooking reduction factor and 20 percent skin-on reduction factor in calculating the GTLs and SVs.

Response 4.3
See response to comments 2.2, 2.3, and 3.3. As noted in the draft document, the cooking and skinning reduction factors are not applied to mercury data. Mercury analysis of skin-off fillets provides more conservative fish consumption advice than analysis of skin-on fillets would (see response 2.4).

Comment 4.4
OEHHA should consider the policy implications of the draft report. There are additional water quality policy issues tied to the finalization of this draft report. Currently, California's Clean Water Act 303(d) list relies heavily on OEHHA Screening Values to determine fish tissue impairment. In fact, the *Water Quality Control Policy for*

Developing California's Clean Water Act 303(d) List ("Listing Policy") specifies that evaluation guidelines for protection from the consumption of fish and shellfish published by OEHHA can be used in evaluating fish tissue data for 303(d) listing and de-listing purposes. (Listing Policy at 20.) As a result, various listings and delistings in the Draft 2006 303(d) List are based upon the current OEHHA SVs or "benchmarks." In addition, the Listing Policy specifies that a waterbody "…shall be placed on the section 303(d) list if a health advisory against the consumption of edible resident organisms, or a shellfish harvesting ban has been issued by the Office of Environmental Health Hazard Assessment (OEHHA)." (Listing Policy at 5.) Further, numeric targets in certain TMDLs are derived from these screening values.

As discussed above, the Draft Report uses a risk level of 10^{-4}. In contrast, water quality standards, such as CTR standards, were set using the 10^{-6} risk level. Thus, there may be conflict between the protection offered through the Clean Water Act and policy decisions based upon the GTLs and SVs that are calculated using the 10^{-4} risk levels. In addition, the SVs included in the Draft Report are as much as 6 times higher than the 1999 OEHHA SVs. This may result in many inappropriate de-listings from the 303(d) list, resulting, in turn, in a failure to address the underlying problem at the source. Given the seriousness of the risks here, this is entirely inappropriate.

Response 4.4
As noted above, the SVs have been removed from the final document. Fish Contaminant Goals (FCGs), developed in this final report, use a 10^{-6} risk level. Agencies can use these values as a starting point to develop fish tissue-based criteria. GTLs (now ATLs) are not regulatory standards. OEHHA does not determine policies developed by other state programs. However, if other state programs choose to consider or use values that OEHHA has developed for some other purpose, then it is advisable that they consult with OEHHA to avoid any misuse or misinterpretation. (See response 1.1).

Comment 4.5
In general, OEHHA will be taking a step backward in terms of protecting public health if it adopts the non-conservative assumptions proposed in this Draft Report. As discussed above, there are major implications for sensitive subpopulations – particularly children and ethnic Asian subpopulations. An allowable cancer risk level of one in 10,000 is just not acceptable given these variable consumption patterns and practices. Therefore, we *strongly* urge OEHHA to maintain the 10^{-5} endpoint, as well as to use more conservative assumptions in calculating the GTLs and SVs.

Response 4.5
OEHHA has addressed the "non-conservative" assumptions in prior responses to comments. OEHHA has determined that highly conservative assumptions, as used in traditional risk assessment paradigms, are not protective of overall health when considering fish consumption. However, in response to comments regarding the cooking reduction factor, separate advice may be tailored to those who do not cook or clean according to OEHHA recommendations. OEHHA maintains that using a 10^{-4} risk level

best balances the cancer risks and benefits (health and economic) of sport fish consumption as well as the risks of alternate protein sources that might be consumed in place of sport fish. Setting the risk level at $1x10^{-5}$ or $1x10^{-6}$ would restrict fish consumption to the extent that it could largely deny fishers the numerous health benefits that can be accrued by fish consumption. OEHHA does not agree with the premise that "sensitive subpopulations" are not accounted for in the advisory process. All consumers who follow the advice are equally protected based on known sensitivities. When there is compelling evidence that women or children are more susceptible to a contaminant (e.g., mercury), the advisories provide separate advice for their protection.

Comment 5.1
This is a wonderfully well done report that should be viewed as "state of the art" in its niche.

Comment 5.2
"Avians" is not an accepted noun.

Response 5.2
Changed "avians" to birds.

Comment 5.3
It would be helpful to provide the reference dose as µg/day, in addition to mg/kg-day, to facilitate comparison to the RDA.

Response 5.3
Additional units included.

Comment 5.4
Is the advice for reducing consumption by approximately one-fourth for skin-on fillets really applicable to selenium?

Response 5.4
Language altered to indicate that, of the chemicals evaluated, reduction of contaminant levels by cooking and skinning is only applicable to chlorinated hydrocarbons, rather than "organics" as stated.

Comment 5.5
The equations presented on page 39 result in calculated outcomes expressed on a ppm (mg/kg) basis, yet the summary table of outcomes, Table 1, presents everything on a ppb basis. It would be an improvement to make the equations and outcomes table internally consistent.

Response 5.5
The equations include mg/kg units because the reference doses and cancer slope factors are presented in those units. Conversion factors were included in the equations to change the outcome units to ppb (µg/kg), to coincide with the most convenient way of expressing fish contaminant levels as presented in Table 1 and Table 2.

Comment 5.6
The selenium screening value is expressed on a wet weight basis. Many historic fish tissue databases are expressed on a dry weight basis without corresponding percent moistures and, thus, there is no way to convert the values to a wet weight basis. EPAs new tissue-based chronic criterion value for selenium will be issued on a dry weight basis. It would be useful to provide a conversion to dry weight basis for a range of fish species.

Response 5.6
Screening values have been eliminated from the document. However, fish collected for human health assessments must be based on wet weight analysis; dry weight data for individual or composite fish samples are not consistently available. OEHHA will leave developing national conversion factors for multiple species to other agencies.

Comment 6.1
Overall the document read well and its purpose was clearly stated. Calculations of GTLs and screening level values were checked and consistent with our calculations. Appropriate studies are cited to support your selection of toxicity criteria.

Comment 6.2
Within the introduction, it may be useful to give subheadings to the sections dealing with the development of screening level values and for establishing GTLs. A brief description of the equation for deriving GTLs for cancer endpoints similar to the noncancer equation would be useful. The differences in the two equations could be explained, briefly describing the differences in averaging times used in the two calculations.

Response 6.2
An equation for deriving GTLs (now ATLs) for cancer endpoints was included. The SVs are no longer included in the final document.

Comment 6.3
Within the introduction, it would be helpful to list major data sources and give a brief description of the programs that they are collected under. Fish tissue collection and analysis is often conducted for reasons other than to evaluate human health concerns. Therefore, the adequacy of the database should first be determined.

Response 6.3
This information is outside the scope of this document. It is presented in the Health Advisory and Safe Eating Guidelines for each water body. Recommendations for sampling are included in the report "General Protocol for Sport Fish Sampling and Analysis," by Gassel and Brodberg, 2006.

Comment 6.4
A summary table should be included with the contaminants of concern and their corresponding cancer and noncancer values separate from the GTL calculated concentrations.

Response 6.4
Cancer and noncancer values are presented in at least two places in the document, including Table 1. OEHHA feels that including another separate table of these values is not necessary, given that they are clearly presented in the toxicology profiles and in the derivation of the ATLs.

Comment 6.5
A brief discussion on the consumption rate used to establish screening level values. What are they based on and what populations do they protect or not protect?

Response 6.5
The screening values have been removed from the final document.

Comment 6.6
The discussion of the Guidance Tissue Levels for the various contaminants is easy to follow and provides appropriate background on use of various parameters considered.

Comment 6.7
Consider graphing contaminant meal recommendations with contaminant concentrations.

Response 6.7
Graphs were presented by the commenter as another way of looking at GTLs (now ATLs). We didn't find that these added to the clarity or usefulness of the document.

Comment 6.8
We find that people often get hung up on the numbers such as GTLs but are unaware that these values are generally a starting point in determining what the recommended meal limits should be. Left out of the discussion is the risk management and risk communication aspects in evaluating fish.

Response 6.8
OEHHA agrees that the ATLs are just a starting point for developing fish consumption guidelines. We have attempted to strengthen the language in the document to make that point. A brief discussion of risk communication has been added to the document, but risk communication details are developed as part of individual safe eating guidelines for specific water bodies.

Human Health Criteria Issue Paper

Toxics Rulemaking

A. Introduction

Purpose of this issue paper

DEQ's currently effective human health toxics criteria are based on a fish consumption rate (FCR) that does not adequately protect Oregonians based on the amount of fish and shellfish they are known to consume. On June 1, 2010, EPA disapproved Oregon's human health toxics criteria that were submitted for approval in 2004 and were based on a fish consumption rate of 17.5 grams per day (g/d). EPA disapproved the human health toxics criteria because the fish consumption rate used to calculate the criteria does not protect Oregonians based on the amount of fish and shellfish they are known to consume. DEQ is addressing EPA's disapproval by proposing to use a higher, more protective fish consumption rate of 175 g/d in its calculation of revised human health toxics criteria. If DEQ does not promulgate revised standards in a timely manner addressing EPA's disapproval, EPA must conduct rulemaking to promulgate human health toxics criteria for Oregon.

This issue paper includes information relevant to DEQ's development of proposed human health toxics criteria based on a higher fish consumption rate. It also describes the human health toxics criteria methodology used to calculate criteria. Proposed changes will affect the criteria values contained in Tables 20, 33A, and 33B, as well as the narrative toxics provision in OAR 340-041-0033 (Toxic Substances).

B. Background

B.1. Brief History of EPA's Recommended Human Health Toxics Criteria

The Clean Water Act requires EPA to publish recommended water quality criteria based upon the most recent science. States typically use these values in developing their own water quality standards regulations. In 1986, EPA published a compilation of these values in the Quality Criteria for Water 1986[1], also known as the "Gold Book." In 1992, EPA promulgated water quality criteria for toxic pollutants for 14 States. These updated criteria became known as the National Toxics Rule[2] and differed substantially from the EPA Gold Book. In 1995, EPA applied the methodology and data used in the Great Lakes Water Quality Initiative[3] to derive new national aquatic life criteria for 15 toxic pollutants in freshwater. In 1999, EPA published the next major update of water quality criteria[4]. In 2000, EPA promulgated water

[4] EPA. National Recommended Water Quality Criteria—Correction. EPA 822-Z-99-001.

quality criteria for toxic pollutants for California known as the California Toxics Rule[5] and also in that same year published a revised methodology[6] for deriving human health criteria. EPA did not publish a summary criteria table to accompany the revised methodology. Since 2000, EPA has updated the human health criteria for some individual compounds as well (e.g. cadmium). In late 2002, EPA published another major update[7] of criteria values using the EPA revised human health methodology, which included more extensive criteria revisions for 15 other toxic pollutants.

B.2. Oregon 2004 Submission of Water Quality Standards

In 1999, DEQ initiated a Water Quality Standards Review (triennial review) to update DEQ toxics criteria based on the 1986 EPA Gold Book (contained in Table 20 of Oregon's water quality standards). This review was completed in 2003. During this review, DEQ made significant revisions to both the aquatic life and human health criteria based on the updated EPA methodologies and science for deriving aquatic life and human health criteria (as described above) that had occurred since the Gold Book had been published. DEQ's criteria that it adopted in 2004 reflected an increase in the fish consumption rate from 6.5 g/d to 17.5 g/d, based on the rate used EPA's national criteria recommendations. However, despite being based on this higher fish consumption rate, some of the 2004 criteria were actually less stringent than Oregon's previous criteria due to updated scientific information affecting other factors that go into calculating human health criteria. To be consistent with the federal requirements, DEQ specified that the criteria that were less stringent than the older Table 20 criteria were not effective for Clean Water Act purposes until after EPA approval.

The Environmental Quality Commission (commission) adopted these new and revised water quality standards on May 20, 2004. Upon adoption, DEQ submitted these criteria changes along with revisions to the narrative toxics provision to EPA on July 8, 2004.

EPA did not act on these revised water quality standards, and a lawsuit was filed on April 7, 2006 noting EPA's failure to act on Oregon's revised human health water quality criteria among other revisions. On May 29, 2008, a U.S. District Court in the District of Oregon issued a consent decree setting forth deadlines by which EPA must take action on Oregon's 2004 water quality standards submission, under Section 303(c) of the CWA (*Northwest Environmental Advocates v. U.S. EPA,* No. 06-479-HA (D. Or. 2006)). The court subsequently issued several extensions of the applicable deadlines for action. The consent decree's applicable deadline for EPA action on the human health criteria was ultimately extended to June 1, 2010.

B.3. EPA Action on Oregon's 2004 Submission of Human Health Toxics Criteria

B.3.1. Disapproved Human Health Criteria

On June 1, 2010, EPA concluded that human health criteria based on a fish consumption rate of 17.5 g/d were not protective of Oregon's designated use of fishing, and thus, did not protect Oregonians who consume higher levels of fish. Consequently, EPA disapproved the majority of the human health criteria that were based on 17.5 g/d (i.e. 48 non-carcinogens and 55 carcinogens). Accompanying footnotes to the disapproved criteria were subsequently disapproved as well. For specific details on EPA's actions, refer to EPA's Technical Support Document[8] accompanying its action.

Oregon's water quality standards included a provision specifying that if a value in Table 33A was disapproved by EPA, the corresponding value in Table 20 would become effective immediately. Values that were the same in Tables 20 and 33A would remain in effect. Consequently, as a result of EPA's disapproval, DEQ's human health toxics criteria reverted back to Table 20 values which are largely based on a fish consumption rate of 6.5 g/d. The few exceptions where EPA did approve criteria from DEQ's 2004 adoption are noted below in the "Approved Human Health Criteria" section.

Under CWA Section 303(c)(3) and EPA's regulations at 40 CFR Parts 131.21 and 131.22, if EPA disapproves a state's new or revised water quality standards, it must "specify the changes" necessary to meet the applicable requirements of the Act and EPA's regulations. If the state does not adopt necessary changes, EPA must propose and promulgate appropriate changes. In the EPA letter[9] disapproving DEQ's 2004 submission, EPA indicated that revising the human health toxics criteria based on a higher fish consumption rate of 175 g/d will address the EPA's disapproval. This rate represents the value that DEQ recommended to the commissioners at the October 23, 2008 Environmental Quality Commission meeting and that they subsequently directed DEQ to use in its revisions. For more information on DEQ's recommended fish consumption rate, see section C.

B.3.2. Approved Human Health Criteria

The human health criteria identified in this section that EPA approved on June 1, 2010, will be included in the new Table 40 along with the proposed human health criteria.

1. **Human health criteria for copper and asbestos**

   Copper

   The "water + organism" criterion of 1300 ug/L is consistent with EPA's 304(a) recommendation and was therefore approved by EPA. Since human health risks from copper are primarily from

[8] EPA. Technical Support Document for Action on the State of Oregon's New and Revised Human Health Water Quality Criteria for Toxics and Revisions to Narrative Toxics Provisions Submitted on July 8, 2004. June 1, 2010.
[9] EPA. Mike Bussell, EPA Region 10 Division Director to Neil Mullane, DEQ Water Quality Division Administrator. EPA's Action on New and Revised Human Health Water Quality Criteria for Toxics and Revisions to Narrative Toxics Provisions in Oregon's Water Quality Standards. June 1, 2010

drinking water and not fish consumption, the lower fish consumption rate of 17.5 g/d was not relevant to EPA's decision.

Asbestos
The "water + organism" criterion of 7,000,000 fibers/L is consistent with EPA's 304(a) recommendation and was therefore approved by EPA. Since human health risks from copper are primarily from drinking water and not fish consumption, the lower fish consumption rate of 17.5 g/d was not relevant to EPA's decision.

2. Footnote K insofar as it applies to the "water + organism" human health criteria for iron and manganese

Footnote K states: "Human Health criterion is for "dissolved" concentration based on the 1976 EPA Red Book conclusion that adverse effects from exposure at this level are aesthetic rather than toxic." EPA approved this footnote for the "water + organism" criteria for both iron and manganese, but disapproved the footnote for the manganese "organism only" criterion because EPA could not ensure the protectiveness of using the dissolved form of manganese. In a separate rulemaking for manganese, DEQ therefore, expressed the criterion as an "organism only" total manganese criterion for marine waters. The criterion is based on human health toxicity endpoints related to the consumption of marine mollusks.

In same rulemaking, DEQ withdrew the "water + organism" iron and manganese human health criteria and the "organism only" manganese criterion for fresh waters. The criteria were not based on levels needed to protect human health. Rather, the primary effects considered were aesthetic (e.g., taste and laundry staining). Iron and manganese are a naturally occurring earth metals that sometimes exceeded the previous criteria due to natural background levels.

The Environmental Quality Commission adopted the revisions to the iron and manganese criteria on December 9, 2010. The revisions are reflected in the new Table 40 and will become applicable upon EPA approval.

3. Withdrawal of the human health criteria for eight toxic pollutants

Consistent with EPA's action under the National Toxics Rule, Oregon withdrew its human health criteria for the following toxic pollutants and was approved by EPA:

- Beryllium
- Cadmium
- Chromium III
- Chromium VI
- Lead
- Mercury
- Silver

- Trichloroethane 1, 1, 1

4. Revisions to the narrative toxic provisions at OAR 340-041-0033(1) and (2).

Revisions to OAR 340-041-0033(1) were approved by EPA as minor editorial changes. Revisions to (2) describe effective dates for human health and aquatic life toxics criteria in Tables 20, 33A and 33B.

B.4. Applicability of EPA's June 2010 Action to 2011 Proposed Human Health Criteria Revisions

In the current effort to develop the human health criteria proposed revisions, DEQ generally relied on the scientific information, policy decisions, and subsequent recommendations from the 1999 triennial review and 2004 submission as the basis for these human health criteria revisions. The major difference between criteria that were submitted in 2004 and the proposed 2011 criteria is the fish consumption rate (i.e. 175 g/d versus 17.5 g/d). In addition, DEQ is not proposing any revisions to the aquatic life criteria. These criteria were adopted and submitted to EPA in 2004 and are still undergoing Endangered Species Act consultation by EPA, the U.S. Fish and Wildlife Service, and NOAA's National Marine Fisheries Service and are not the subject of this review.

C. Development of a Fish Consumption Rate

C.1. Background

DEQ's water quality standards play an important role in maintaining and restoring the environmental quality and quality of life that Oregonians value. Human health criteria are used to limit the amount of toxic pollutants that enter Oregon's waterways and accumulate in the fish and shellfish consumed by many Oregonians as a traditional and/or healthful lifestyle. Human health criteria help to ensure that people may eat fish and shellfish (from here forward referred to as "fish") from local waters without incurring unacceptable health risks.

In 2004, the commission, at DEQ's recommendation, adopted water quality criteria based on EPA's 2002 recommended toxic pollutants criteria for aquatic life and for human health. The human health criteria were based on a fish consumption rate of 17.5 g/d, which represents the 90th percentile of consumption among consumers and non-consumers of fish nationwide. Prior to adopting the 2004 revisions, DEQ's human health criteria were based on EPA's 1986 recommended criteria and a fish consumption rate of 6.5 g/d. A fish consumption rate of 17.5 g/d equals about 0.6 ounces per day or three 6-ounce meals per month. Based on concerns that the fish consumption rate used in the EPA criteria may not accurately represent Oregonian's consumption patterns, the commission requested that DEQ seek resources to conduct a fish consumption rates study in Oregon.

Following DEQ's 2004 adoption of EPA's recommended criteria, concerns about Oregon's human health criteria heightened. Native American tribal governments objected to the criteria, stating that the criteria

did not protect tribal members who eat much greater amounts of fish and for whom fish consumption is a critical part of their cultural tradition and religion. Tribes have rights to catch fish in Oregon waters and EPA has a trust responsibility to protect the interests of the tribes. The Oregon tribes who were most involved in the fish consumption rate workshops and discussions and the subsequent rulemaking process include the Umatilla, Warm Springs, Klamath, Siletz and Grand Ronde tribes.

Although DEQ's 2004 human health criteria reflected EPA's guidance contained in the Human Health Methodology including use of 17.5 g/d as a default value, the guidance also recommends using local fish consumption data when it is available. In this circumstance, local data was available from a study conducted by the Columbia River Inter-Tribal Fish Commission [10] or "CRITFC Study", which included surveys of four Columbia River Tribes, two of whom reside in Oregon, the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) and the Confederated Tribes of the Warms Springs Reservation.

C.2. Fish Consumption Rate Review Project

For the above reasons and with the recognition that many Oregonians eat more than 17.5 g/d of fish and shellfish, DEQ embarked on a project to review the fish consumption rate and subsequently revise the human health water quality criteria for Oregon. DEQ was not able to obtain funding for a study of Oregon fish consumption rates, so the review was based on available literature and data.

DEQ launched the fish consumption rate review project in the fall of 2006 and conducted seven workshops in cooperation with the EPA and the Confederated Tribes of the Umatilla Indian Reservation. The objective for these workshops was to allow any member of the public to receive and provide input on the information being gathered and evaluated, and express views on the policy issues inherent in choosing a fish consumption rate.

DEQ also formed two workgroups, the Human Health Focus Group (HHFG), to assist with gathering and evaluating relevant information. The Human Health Focus Group, made up of public health professionals and toxicologists, reviewed the available data on fish consumption patterns in the Pacific Northwest and elsewhere. The group wrote a report[11] summarizing the science and made recommendations about the quality and appropriate use of the available information. DEQ considered the HHFG's analysis in its selection of a fish consumption rate. The report, materials and agendas from the HHFG process, are contained on DEQ's website.

C.3. Choosing an Appropriate Fish Consumption Rate

Oregon's existing human health criteria are based either on a defined acceptable level of cancer risk (1 in 1,000,000 additional incidents of cancer) or a reference dose beyond which effects in test populations begin to be observed. People who eat more fish have a greater probability of incurring a health effect

[10] Columbia River Inter-Tribal Fish Commission. October 1994. A Fish Consumption Survey of the Umatilla, Nez Perce, Yakama, and Warm Springs Tribes of the Columbia River Basin. Technical Report 94.3.
[11] Human Health Focus Group Report. Oregon Fish and Shellfish Consumption Rate Project. June 2008.

from this exposure to contaminants and those who eat less fish will have less risk. As the fish consumption rate increases, the water quality criteria values will decrease and the costs to meet requirements associated with the revised criteria may rise. How much the criterion for any given pollutant will change with a change in the fish consumption rate also depends on the degree to which that pollutant accumulates in fish tissue. Therefore, a ten-fold increase in the fish consumption rate will not necessarily result in a ten-fold decrease for all criteria; the change in the criteria will vary by pollutant.

A major policy decision inherent in developing human health criteria is whether to base the criteria on a fish consumption rate that includes Oregonians who eat large amounts of fish and shellfish for cultural, economic, health or other reasons, or whether to use a fish consumption rate reflective of Oregon's total population, including people who do not eat fish or eat it rarely. A related decision is what proportion or percentile of the population(s) to base the fish consumption rate on. Within any group, whether Native-Americans, Asian-Americans or commercial fishermen, there will be some individuals who eat more than any chosen rate and some who eat less than that rate.

An additional issue discussed during this process was whether to include salmon (an anadromous fish) and/or marine fish in the consumption rate. The Human Health Focus Group recommended that DEQ include salmon and marine fish in the fish consumption rate because these fish are an important part of the fish diet in the Northwest and represent a potential source of exposure to contaminants. In addition, they found that for non-carcinogens, given the status of the relative source contribution (RSC) approach and values, it would be more accurate to account for the consumption of marine fish in the consumption rate than to use the RSCs in deriving criteria for non-carcinogens. Counter arguments to including (or fully counting) salmon and marine fish in the fish consumption rate assert that these fish accumulate most of their contaminant body burden in ocean waters, outside the influence of Oregon's water quality standards and pollution controls. In addition, salmon tend to contain lower levels of contaminants than resident fish. DEQ ultimately recommended that salmon be included in the rate given the large number of Oregonians who traditionally consume large amounts of salmon and noted that they represent a potential path of exposure to toxic pollutants. Consequently, the recommended rate reflects consumption of salmon and lamprey relative to rates documented in the CRITFC study (to protect at least 95% of fish consumers in Oregon), as well as marine fish and shellfish relative to the rates documented in the Puget Sound studies (to protect at least 90% of fish consumers in Oregon).

C.4. DEQ Recommendation on Selecting a Fish Consumption Rate

DEQ determined that a fish consumption rate of 175 g/d is a reasonable and protective fish consumption rate to use as the basis for Oregon's human health criteria. A fish consumption rate of 175 g/d equals approximately 6.2 ounces per day (or approximately 23 8-oz fish or shellfish meals per month). This rate represents the 95th percentile value from the Columbia River Inter-Tribal Fish Commission study and is within the range of the 90th percentile values from various studies from the Northwest assembled by the HHFG. The 175 g/d rate is consistent with the HHFG recommendation to use 90th or 95th percentile values to represent the proportion of the population the criteria should be

designed to protect. It is also consistent with HHFG recommendations to use a fish consumption rate that represents fish consumers only, rather than a rate derived from the overall population including both consumers and non-consumers of fish, and to include salmon and other marine species in the rate.

Another question raised during the 2004 water quality standards review was whether Oregon should use different fish consumption rates for basins or water bodies that reflect consumption patterns in those areas. Although the Technical Advisory Committee proposed applying different consumption rates for different geographic areas within the state, DEQ did not recommend this option based on the following considerations:

- While there is data only for the Umatilla and Warm Springs Tribes in Oregon, studies from the Pacific Northwest and elsewhere show that many Tribes and other groups (e.g. Asian Americans) eat moderate to large amounts of fish. Input at public workshops indicates that there may be other groups that eat large amounts of fish as well, such as commercial or sport fishermen.
- Nearly all the major river basins in Oregon are usual and accustomed fishing areas for an Oregon Tribe.
- People may catch fish in many locations around the state, not just in the river basin in which they live.
- Having different criteria in different basins would create complexities in the regulations and their implementation.

The EPA, CTUIR, and DEQ collaborated on this project throughout the process and issued a joint recommendation[12] to the Environmental Quality Commission on October 23, 2008, to revise Oregon's toxics criteria for human health based on a FCR of 175 g/d. The commission agreed with this recommendation and directed DEQ to proceed with this fish consumption rate as a basis for revising human health criteria.

D. New and Revised Human Health Water Quality Criteria

D.1. Technical Review Process for 2004 Submission

During the development of the 2004 water quality standards revisions, the Technical Advisory Committee (TAC) reviewed EPA's 2000 Methodology in comparison to the 1980 methodology used to derive Table 20 toxics criteria.

The formulae in the 2000 EPA Methodology used to calculate the criteria values differed from those in the 1980 EPA methodology by:

[12] DEQ. October 6, 2008 Memo from Dick Peterson, Director DEQ, to the Environmental Quality Commission. Agenda Item G, Action Item: Oregon's Fish Consumption Rate – For Use in Setting Water Quality Standards for Toxic Pollutants October 23, 2008 commission Meeting.

1) the addition of a new formula to calculate criteria for compounds where the mode of carcinogenicity shows a non-linear relationship between dose and effect;
2) the use of a bioaccumulation factor rather than bioconcentration factor (bioconcentration refers to the uptake and retention of a chemical from the water only; bioaccumulation refers to the uptake and retention of a chemical from all the surrounding environment, e.g. water, food, and sediment); and
3) the use of a new fish consumption rate.

Unless otherwise specified, DEQ relied on the review and decisions made during the development of the 2004 water quality standards to form the technical basis of revising criteria for this rulemaking. The major difference is the use of a higher fish consumption rate of 175 g/d.

D.2. Applicability of "water + organism" and "organism only" Criteria

The criteria calculations for both carcinogens and non-carcinogens differ depending upon the exposure scenario for which the criteria are derived. Oregon's criteria were developed to protect human health from long term exposure to toxic pollutants in drinking water and through eating fish and shellfish contaminated with toxics. The "water + organism" criteria refer to values that if met, ensure exposure through the consumption of drinking water and fish, including shellfish does not result in adverse health effects. The "organism only" criteria refer to values that if met, ensure exposure through the consumption of fish and shellfish only does not result in adverse health effects. These criteria apply where Oregon has designated waters as either a public or private domestic water supply, or as a fishing beneficial use. Generally, the majority of Oregon's waterbodies have been designated as both a domestic or private domestic water supply and as a fishing beneficial use. Therefore, human health toxics criteria will be widely applicable across the state. Table 1 indicates where the "organism only" criteria are the only human health criteria applicable, since a drinking water use has not been designated in these waters (e.g. non-potable estuarine waters).

TABLE 1: Waters Where "Organism Only" Criteria are Solely Applicable: Waters designated as having a fishing use, but not a domestic or private water supply

Table Reference Number	Basin	Segment Name
140A	Goose and Summer Lakes Basin	Goose Lake; and Highly Alkaline and Saline Lakes
190A	Malheur Lake Basin	Natural Lakes
220A	Mid Coast Basin	Estuaries and Adjacent Marine Waters
230A	North Coast Basin	Estuaries and Adjacent Marine Waters
271A	Rogue Basin	Rogue River Estuary and Adjacent Marine Waters; and Bear Creek Main Stem
286A	Sandy Basin	Streams Forming Waterfalls Near Columbia River Highway
300A	South Coast Basin	Estuaries and Adjacent Marine Waters
320A	Umpqua Basin	Umpqua River Estuary to Head of Tidewater and Adjacent Marine Waters

D.3. Criteria Derivation

The methodology for calculating human health toxics criteria takes into consideration three major factors: risk assessment, exposure, and to what degree the pollutant accumulates in fish tissue. Risk assessment includes the potency of the compound to cause a toxic effect that is either cancerous or noncancerous, and for cancer causing compounds, the level of risk that is acceptable for society (e.g. one additional cancer per million people). Exposure includes consideration of body weight, water intake, and fish intake. Bioconcentration is the degree to which an organism accumulates the contaminant from water only, while bioaccumulation describes the net accumulation of a contaminant from all sources.

D.3.1. Non-Carcinogens

DEQ utilized the 2000 Methodology to derive ambient water quality criteria for pollutants. This section describes how DEQ used the methodology as it applies to non-carcinogens.

Equation for Non-Carcinogens:

$$AWQC = RfD \times RSC \times \frac{(BW)}{[DI + (FCR \times BAF)]}$$

where:

AWQC = Ambient Water Quality Criterion (mg/L)

RfD = Reference dose for noncancer effects (mg/kg-day)

RSC = Relative source contribution factor to account for non-water sources of exposure

BW = Human body weight (kg) =70 kg

DI = Drinking water intake (L/day) = 2 L/day

FCR = Fish consumption rate (kg/d) = 175 g/d

BAF = Bioaccumulation factor (L/kg)

Body Weight and Drinking Water Intake

DEQ used EPA's national default values for body weight (70 kilograms or 154 lbs) and drinking water intake (2 L/day). DEQ also relied on EPA's reference doses used as part of its nationally recommended criteria[13]. A reference dose is defined[14] as an estimate (with uncertainty spanning approximately an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects over a lifetime.

[13] EPA. 2002. Nationally Recommended Water Quality Criteria 2002 – Human Health Criteria Calculation Matrix. USEPA, Office of Water, Washington, DC. EPA 822-R-02012.

[14] EPA. 1993. Reference Dose (RfD): Description and Use in Health Risk Assessments. Integrated Risk Information System (IRIS). Intra-Agency Reference Dose (RfD) Work Group, Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, USEPA, Cincinnati, OH.

Bioconcentration Factors (BCF) Versus Bioaccumulation Factors (BAF)

Water quality criteria for the protection of human health are derived, in part, by considering human exposure to pollutants that have been stored within fish after that fish has been exposed to a toxic pollutant. A BCF accounts for the uptake of a pollutant by a fish from the surrounding water, while a BAF accounts for the uptake of a pollutant from all sources (including the surrounding water, food, and sediment). While the consideration of a BAF in EPA's 2000 Methodology was considered an improvement over BCFs, developing BAFs is a complex process and can vary from site to site. EPA has not yet developed a national list of BAFs for its nationally recommended criteria. Consequently, EPA recommends criteria be developed using BCFs until such time local or regional BAFs that would be applicable to Oregon are developed. As a result, proposed criteria for this rulemaking reflect EPA recommended BCF values.

Reference Dose (RfD)

A reference dose is an estimate (with uncertainty spanning approximately an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects over a lifetime[15]. Proposed criteria for this rulemaking reflect EPA recommended RfD values. Reference Dose values are based on real studies that reflect health effects from these pollutants at specific levels.

Relative Source Contribution

Criteria for pollutants that are non-carcinogens are based on a total cumulative dose over time that causes an observable effect. Because the human health water quality criteria address exposure only through drinking water and eating fish, a relative source contribution (RSC) factor is used to calculate the criteria. The RSC identifies or estimates the portion of total exposure attributed to water and fish consumption, and therefore, accounts for potential exposure from other sources, such as skin absorption, inhalation, other foods and occupational exposures. The RSC value is either multiplied by the reference dose or subtracted from the reference dose, depending on the chemical and known exposure sources of contaminants. Table 2 identifies the pollutants for which DEQ applied RSC values to the revised human health water quality criteria. For all of the pollutants but Endrin, DEQ used EPA's recommended RSC value. The other non-carcinogen pollutants used a RSC of 1, which indicates that all of the exposure to that pollutant is assumed to come from water and fish ingestion. In some cases, EPA does not have enough data to establish RSC values for other chemicals.

TABLE 2: Criteria Where Relative Source Contribution Values Were Applied

1) Antimony (40%)	9) Thallium (20%)
2) Chlorobenzene (20%)	10) Toluene (20%)
3) Chlorodibromomethane (80%)	11) 1,1,2-Trichloroethane (20%)

[15] EPA. Reference dose (RfD): Description and use in health risk assessments. Integrated Risk Information System (IRIS). Online. Intra-Agency Reference Dose (RfD) Work Group, Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office. Cincinnati, OH. March 15, 1993.

4) Cyanide (20%)	12) 1,1-Dichloroethylene (20%)
5) Endrin (80%)	13) 1,2,4-Trichlorobenzene (20%)
6) Ethylbenzene (20%)	14) 1,2-Dichlorobenzene(o) (20%)
7) gamma-BHC (Lindane) (20%)	15) 1,2-trans-Dichloroethylene (20%)
8) Hexachlorocyclopentadiene (20%)	16) 1,4-Dichlorobenzene(p) (20%)

RSC for Methylmercury

EPA established a RSC value that is subtracted from the reference dose to derive the tissue based methyl mercury criterion. EPA's recommended criterion uses a RSC because EPA's national default fish consumption rate does not include the consumption of marine species of fish (including Pacific salmon), which are a significant potential exposure route for methylmercury. Because the primary human route of exposure to methylmercury comes from ingestion of fish and shellfish, and because DEQ included marine species in the development of its fish consumption rate, it would be "double counting" the exposure if DEQ incorporated the same RSC value used in EPA's recommended methylmercury criterion. Methylmercury is unique in that it is a fish tissue criterion and the primary route of exposure to humans is through the consumption of fish and shellfish. The other criteria where RSC values have been established have other contributing sources of pollutant (e.g., consumption of food or other exposure routes), so removing the RSC would not be appropriate in those circumstances.

RSC for Endrin

EPA used a default RSC value of 20% for Endrin based on a recommendation from EPA's drinking water program. DEQ's final proposed criteria for Endrin use a RSC value of 80%. The primary reason DEQ proposes using an alternate default value is because DEQ does not anticipate exposure to this chemical outside of water and fish ingestion. This is consistent with EPA guidance for use of default RSC values:

> Default RSC Percentage Values: Floor of 20%, Ceiling of 80% (65 FR 66472)
> - EPA has recommended using the 20% RSC default when routes of water exposures other than oral or sources of exposure other than fish and water are anticipated, but adequate data are lacking to quantify those exposures.
> - Utilize local data to quantify exposures from other routes where available: When data are adequate to quantify exposures to other sources (oral or exposure to fish and water), EPA recommends that they be used instead of the default 20% RSC value.
> - If it can be demonstrated that other sources and routes of exposure are not anticipated for the chemical in question (based on information about its known/anticipated uses and chemical/physical properties), then the 80% ceiling is recommended. This 80% ceiling is a way to provide adequate protection for those who experience exposures (from any or several sources) higher than available data may indicate.

Due to the properties of this chemical and the fact that it has not been in use for about 25 years, it is highly unlikely that people in Oregon would gain only 20% of their exposure to Endrin from water and fish and 80% of their exposure from other sources. Endrin bioconcentrates in aquatic organisms, but is not very soluble in water. The bioconcentration factor used to derive the human health criteria is 3970,

resulting in the same criteria value (when rounded to significant digits) for water + organism and for organism only ingestion.

The following information from the US Department of Health and Human Services Toxicological Profile for Endrin (1996, Chapter 5) supports DEQ's decision to use an RSC of 80% rather than 20% to derive Oregon's water quality criteria:

- The use of Endrin ended in the mid-1980s and "consequently, there are no longer any significant releases of Endrin to the environment in the United States."
- "Information on current levels of Endrin in the environment is limited; however, the available data indicate that concentrations in all environmental media are generally negligible or below levels of concern. "
- "The FDA has concluded that Endrin is no longer present in the environment to the extent that it may be contaminating food or feed at levels of regulatory concern (USDA 1995)."
- Endrin tends to persist in the environment mainly in forms sorbed to sediments and soil particles. A conservative estimate of its half-disappearance time in sandy loam soils is approximately 14 years. "Therefore, the exposure risks from Endrin to the general population of the United States are likely to steadily decrease over time."
- Limited information on the physical and/or chemical properties of Endrin aldehyde indicates that it is highly insoluble in water (EPA 1981a), highly immobile in soil, and will not volatilize significantly from water or soil.
- Endrin has been found to volatilize significantly (20-30%) from soils within days after application (Nash 1983). Because Endrin has not been in use for many years, this exposure route no longer occurs in Oregon.
- The main sources for potential human exposure to Endrin are residues on imported food items, unused stocks, unregistered use, inappropriate disposal, and hazardous waste sites; however, there is no current evidence of significant exposures from any of these sources. Furthermore, it should be noted that in environmental media, especially in contaminated soils and sediments, the amount of Endrin chemically identified by analysis is not necessarily the amount that is toxicologically available.
- Endrin was identified at 102 and Endrin ketone was identified at 37 of 1430 current or former hazardous waste sites in the United States. None of these sites were in Oregon (Figures 5-1 and 5-2).

D.3.2. Carcinogens

DEQ utilized the 2000 Methodology to derive ambient water quality criteria for pollutants that are carcinogens.

Equation for linear dose-response carcinogens:

$$AWQC = \frac{(Risk\ Level \times BW)}{[CSF \times (DI + (FCR \times BAF))]}$$

where:

AWQC = Ambient Water Quality Criterion (mg/L)

Risk Level = Risk Level (unitless)

CSF = Cancer slope factor (mg/kg-day)

BW = Human body weight (kg) =70 kg

DI = Drinking water intake (L/day) = 2 L/day

FCR = Fish consumption rate (kg/d) = 175 g/d

BAF = Bioaccumulation factor (L/kg)

The equation to derive ambient water quality criteria for pollutants that are carcinogens (i.e. cancer-causing pollutants) uses many of the same variables as the equation for non-carcinogens (i.e. body weight, drinking water intake, fish consumption rate, and bioaccumulation factor). The main difference is that a risk level and a cancer slope factor are used, and a relative source concentration is not used.

Cancer Slope Factor and Risk Level

The cancer slope factor is a measure of chemical potency. For most cancer-causing chemicals there is no toxicity threshold or reference dose. Because carcinogenic chemicals are thought to initiate the cancer process at almost any concentration, a dose-response parameter referred to as the cancer slope factor is used for chemicals that display toxic behavior such that the carcinogenic risk increases linearly as the chemical dose increases. Cancer slope factors are specific to individual pollutants. DEQ utilized EPA's nationally recommended slope factors to calculate criteria for carcinogens. Cancer slope factors are based on real studies that reflect health effects from carcinogenic pollutants at specific levels.

Risk estimates for carcinogens are expressed as the incremental probability of developing cancer (e.g., an additional one in one million chance of developing cancer) over a lifetime of exposure to potential carcinogens. EPA has identified a risk level range of 1×10^{-6} (1 in 1,000,000) to 1×10^{-5} (1 in 100,000) to be an appropriate risk management goal for the general population, as long as the most sensitive population is protected at 1×10^{-4} (1 in 10,000). As a matter of policy, DEQ has historically chosen to protect Oregonians at a risk level of 1×10^{-6} and will continue with this recommendation for the proposed human health toxics criteria. As a result, the proposed criteria will protect highly exposed populations in Oregon consuming up to 175 g/d of fish at a risk level of 1×10^{-6}.

D.3.3. Criteria Not Dependent on a Fish Consumption Rate

Although the majority of DEQ's proposed human health criteria are affected by the fish consumption rate, several of Oregon's existing criteria are not based on a fish consumption rate. For these criteria,

human health risks are primarily from drinking water and the existing criteria are based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act. Therefore, DEQ has not developed any "organism only" criteria. As a result, DEQ is not proposing to change the existing human health criteria identified in Table 3.

TABLE 3: Human health toxics criteria not dependent on a fish consumption rate

Asbestos	Methoxychlor
Barium	Nitrates
Chlorophenoxy Herbicide (2,4,5,-TP)	Copper
Chlorophenoxy Herbicide (2,4,-D)	Manganese

D.3.4. Toxics Criteria DEQ is Proposing to Withdraw

The following toxics pollutants have currently effective human health criteria, however, there are no longer EPA criteria for these pollutants. In some cases, like PAHs, the revised criteria include individual species of the more toxic forms of PAH, rather than a single criterion for a chemical family. Therefore, DEQ's proposed final rule withdraws the human health criteria for these pollutants.

TABLE 4: Pollutants for which DEQ Proposes to Withdraw Criteria

Dinitrotoluene
Dinitro-o-Cresol 2,4
Diphenylhydrazine
Halomethanes
Monochlorobenzene
Polynuclear Aromatic Hydrocarbons (PAHs)
Endosulfan

Based on information gathered during the public comment period, DEQ learned it had inadvertently included a "benzene range" as part of Table 40. In addition, DEQ included revisions to the "benzene" criteria that are single values. In investigating the basis for the "benzene range" DEQ identified that EPA does not have any recommended criteria for a "benzene range" and noted that DEQ has no precedent for expressing criteria as a range of values. Further investigations show there is a range of values presented in EPA's IRIS database for the cancer slope factor associated with benzene associated with the use of different modeling methods for the data. The cancer slope factor used for the development of the benzene criteria is consistent with the factor EPA used in deriving the national benzene criterion. Given this information, including both the "benzene range" criteria in addition to the benzene criteria is duplicative. As a result, DEQ removed the benzene range criteria from Table 40.

D.3.5. Proposed Toxics Criteria Additions

DEQ's final proposed rules add criteria for 39 toxic pollutants to the human health criteria table. DEQ included criteria for these pollutants in its 2004 water quality standards based on updated EPA criteria,

but EPA subsequently disapproved those criteria on June 1, 2010, because of an inadequate fish consumption rate. Revised criteria for these pollutants now reflect a fish consumption rate of 175 g/d.

TABLE 5: Pollutants for Which DEQ Proposes to Add Criteria

Acenapthene	Dimethyl phenol 2,4
Anthracene	Dinitrophenol 2,4
Benzene [represents range]	Dinitrophenols
Benz(a)anthracene	Diphenylhydrazine 1,2
Benzo(a)pyrene	Endosulfan alpha
Benzo(b)fluoranthene 3,4	Endosulfan beta
Benzo(k)fluoranthene	Endosulfan sulfate
Bromoform	Endrin aldehyde
Butylbenzyl phthalate	Fluorene
Chlorodibromomethane	Heptachlor epoxide
Chloronaphthalene 2	Indeno(1,2,3-cd)pyrene
Chlorophenol 2	Methyl bromide
Chrysene	Methyl-4,6-dinitrophenol 2
DDD 4, 4'	Methylene chloride
DDE 4, 4'	Methylmercury (mg/kg)
Dibenz(a,h)anthracene	Nitrosodi-n-propylamine, n
Dichlorobenzene(p) 1,4	Pyrene
Dichlorobromomethane	Trichlorobenzene 1,2,4
Dichloroethylene trans 1,2	Zinc
Dichloropropane	

D.3.6. Less Stringent Toxics Criteria

Although the majority of proposed toxics criteria are more stringent than the currently effective values based on a higher fish consumption rate, several of the criteria values became less stringent. As new risk-based data and studies become available, EPA updates risk values (e.g. cancer slopes, reference doses, bioconcentration factors) associated with exposure to environmental contaminants in EPA's IRIS (Integrated Risk Information System) database. DEQ, unless otherwise specified, used EPA's default values in IRIS as the basis for revising criteria. For the pollutants identified in Table 6, changes to values other than the fish consumption rate resulted in proposed criteria that were less stringent than current criteria despite utilizing a higher fish consumption rate.

TABLE 6: Less Stringent Toxics Criteria

Chloroform
Nickel
Phenol
Selenium

E. New, Revised, and Removed Footnotes

DEQ included new or removed footnotes for some human health criteria in Table 40. The majority of these footnotes clarify the source of information upon which the proposed criteria are based. Several of these footnotes with similar language were proposed as part of the 2004 water quality standards submittal, but were subsequently disapproved in conjunction with EPA's disapproval of the associated criteria.

TABLE 7: New Footnotes

Toxic Pollutant	New Footnote
1. Arsenic	This footnote was not included as part of the separate rulemaking for arsenic which was adopted by the EQC on April 21, 2011. A new footnote is now proposed to clarify how arsenic is expressed, as well as the associated risk level the criteria are based upon. *The arsenic criteria are expressed as total inorganic arsenic. The "organism only" criteria are based on a risk level of approximately of 1.1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1 x 10^{-4}*
2. Asbestos	*The human health risks from asbestos are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
3. Barium	*The human health criterion for barium is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
4. Chlorophenoxy Herbicide (2,4,5,-TP)	*The Chlorophenoxy Herbicide (2,4,5,-TP) criterion is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*
5. Chlorophenoxy Herbicide (2,4-D)	*The Chlorophenoxy Herbicide (2,4-D) criterion is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also*

2. Nitrates	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*	*The human health criterion for nitrates is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.*

TABLE 6: Footnotes Removed

Bioconcentration factors for the three toxic pollutants in Table 6 are now available and were used to calculate criteria. For this reason, DEQ removed the footnotes because they are no longer applicable.

Toxic Pollutant	Current Footnote To Be Removed
1. Hexachlorocyclo-hexane-Technical	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*
2. Nitrosamines	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*
3. N-Nitrosodiethylamine	*No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.*

F. Proposed Redline/Strikethrough Revisions to the Toxic Substances Rule

DEQ proposed several changes to 340-041-0033 in the rules DEQ published for public comment. The proposed revisions addressed the separation of the aquatic life criteria and the human health criteria in different tables. In addition, DEQ proposed a "Background Pollutant Allowance" for public comment.

In the revisions shown below, DEQ reorganized provisions relating to the aquatic life criteria and the human health criteria as separate sections. In addition, DEQ added a new section (1) specifying that the 112 toxics human health criteria revised by this rule are not applicable for purposes of the Clean Water Act until they are approved by EPA. This section also applies to the revised iron, manganese, and arsenic criteria the commission adopted in December 2010 and April 2011, respectively.

The provisions addressing background pollutants (now termed "Site-Specific Background Pollutant Criteria") remain in OAR 340-041-0033(6). These revisions are discussed in the *Implementing Water*

Quality Standards in NPDES Permits issue paper, and therefore, are not included in the revisions shown below.

In April 2011, EQC also adopted the arsenic reduction policy as OAR 340-041-0033(3). To accommodate revisions associated with this rulemaking, DEQ reorganized the rule to move the arsenic reduction policy section further back in this rule to OAR 340-041-0033(7), but did not revise any of the rule as adopted by the commission.

340-041-0033

Toxic Substances

(1) Amendments to sections (4) and (6) of this rule (OAR 340-041-0033) and associated revisions to Tables 20, 33A, 33B and 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until they are approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

(~~1~~2) Toxic substances may not be introduced above natural background levels in waters of the state in amounts, concentrations, or combinations that may be harmful, may chemically change to harmful forms in the environment, or may accumulate in sediments or bioaccumulate in aquatic life or wildlife to levels that adversely affect public health, safety, or welfare or aquatic life, wildlife, or other designated beneficial uses.

(~~2~~3) Aquatic Life Criteria. Levels of toxic substances in waters of the state may not exceed the applicable aquatic life criteria listed in Tables 20, 33A, and 33B. Tables 33A and 33B, adopted on May 20, 2004, update Table 20 as described in this section.

(a) Each value for criteria in Table 20 is effective until the corresponding value in Tables 33A or 33B becomes effective.

(A) Each value in Table 33A is effective on February 15, 2005, unless EPA has disapproved the value before that date. If a value is subsequently disapproved, any corresponding value in Table 20 becomes effective immediately. Values that are the same in Tables 20 and 33A remain in effect.

(B) Each value in Table 33B is effective upon EPA approval.

~~(b) The arsenic criteria in Table 20 established by this rule do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until they are approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).~~

(~~c~~b) The department will note the effective date for each value in Tables 20, 33A, and 33B as described in this section.

~~(3) To establish permit or other regulatory limits for toxic substances for which criteria are not included in Tables 20, 33A, or 33B, the department may use the guidance values in Table 33C, public health advisories, and other published scientific literature. The department may also require or conduct bio-~~

assessment studies to monitor the toxicity to aquatic life of complex effluents, other suspected discharges, or chemical substances without numeric criteria.

(4) Arsenic Reduction Policy: The inorganic arsenic criterion for the protection of human health from the combined consumption of organisms and drinking water is 2.1 micrograms per liter. While this criterion is protective of human health and more stringent than the federal maximum contaminant level (MCL) for arsenic in drinking water, which is 10 micrograms per liter, it nonetheless is based on a higher risk level than the Commission has used to establish other human health criteria. This higher risk level recognizes that much of the risk is due to naturally high levels of inorganic arsenic in Oregon's waterbodies. In order to maintain the lowest human health risk from inorganic arsenic in drinking water, the Commission has determined that it is appropriate to adopt the following policy to limit the human contribution to that risk.

(a) The arsenic reduction policy established by this rule section does not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act unless and until the numeric arsenic criteria established by this rule are approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

(b) It is the policy of the Commission that the addition of inorganic arsenic from new or existing anthropogenic sources to waters of the state within a surface water drinking water protection area be reduced the maximum amount feasible. The requirements of this rule section [OAR 340-041-0033(4)] apply to sources that discharge to surface waters of the state with an ambient inorganic arsenic concentration equal to or lower than the applicable numeric inorganic arsenic criteria for the protection of human health.

(c) The following definitions apply to this section [OAR 340-041-0033(4)]:

(A) "Add inorganic arsenic" means to discharge a net mass of inorganic arsenic from a point source (the mass of inorganic arsenic discharged minus the mass of inorganic arsenic taken into the facility from a surface water source).

(B) A "surface water drinking water protection area," for the purpose of this section, means an area delineated as such by DEQ under the source water assessment program of the federal Safe Drinking Water Act, 42 U.S.C. § 300j-13. The areas are delineated for the purpose of protecting public or community drinking water supplies that use surface water sources. These delineations can be found at DEQ's drinking water program website.

(C) "Potential to significantly increase inorganic arsenic concentrations in the public drinking water supply source water" means:

(i) to increase the concentration of inorganic arsenic in the receiving water for a discharge by 10 percent or more after mixing with the harmonic mean flow of the receiving water; or

(ii) as an alternative, if sufficient data are available, the discharge will increase the concentration of inorganic arsenic in the surface water intake water of a public water system by 0.021 micrograms per liter or more based on a mass balance calculation.

~~*(d) Following the effective date of this rule, applications for an individual NPDES permit or permit renewal received from industrial dischargers located in a surface water drinking water protection area and identified by DEQ as likely to add inorganic arsenic to the receiving water must include sufficient data to enable DEQ to determine whether:*~~

~~*(A) The discharge in fact adds inorganic arsenic; and*~~

~~*(B) The discharge has the potential to significantly increase inorganic arsenic concentrations in the public drinking water supply source water.*~~

~~*(e) Where DEQ determines that both conditions in subsection (d) of this section (4) are true, the industrial discharger must develop an inorganic arsenic reduction plan and propose all feasible measures to reduce its inorganic arsenic loading to the receiving water. The proposed plan, including proposed measures, monitoring and reporting requirements, and a schedule for those actions, will be described in the fact sheet and incorporated into the source's NPDES permit after public comment and DEQ review and approval. In developing the plan, the source must:*~~

~~*(A) Identify how much it can minimize its inorganic arsenic discharge through pollution prevention measures, process changes, wastewater treatment, alternative water supply (for groundwater users) or other possible pollution prevention and/or control measures;*~~

~~*(B) Evaluate the costs, feasibility and environmental impacts of the potential inorganic arsenic reduction and control measures;*~~

~~*(C) Estimate the predicted reduction in inorganic arsenic and the reduced human health risk expected to result from the control measures;*~~

~~*(D) Propose specific inorganic arsenic reduction or control measures, if feasible, and an implementation schedule; and*~~

~~*(E) Propose monitoring and reporting requirements to document progress in plan implementation and the inorganic arsenic load reductions.*~~

~~*(f) In order to implement this section, DEQ will develop the following information and guidance within 120 days of the effective date of this rule and periodically update it as warranted by new information:*~~

~~*(A) A list of industrial sources or source categories, including industrial stormwater and sources covered by general permits, that are likely to add inorganic arsenic to surface waters of the State.*~~

~~*(i) For industrial sources or source categories permitted under a general permit that have been identified by DEQ as likely sources of inorganic arsenic, DEQ will evaluate options for reducing inorganic arsenic during permit renewal or evaluation of Stormwater Pollution Control Plans.*~~

~~*(B) Quantitation limits for monitoring inorganic arsenic concentrations.*~~

~~*(C) Information and guidance to assist sources in estimating, pursuant to paragraph (d) (C) of this section, the reduced human health risk expected to result from inorganic arsenic control measures based on the most current EPA risk assessment.*~~

~~*(g) It is the policy of the Commission that landowners engaged in agricultural or development practices on land where pesticides, fertilizers, or soil amendments containing arsenic are currently being or have previously been applied, implement conservation practices to minimize the erosion and runoff of inorganic arsenic to waters of the State or to a location where such material could readily migrate into waters of the State.*~~

(4) Human Health Criteria. The criteria for waters of the state listed in Table 40 are established to protect Oregonians from potential adverse health effects associated with long-term exposure to toxic substances associated with consumption of fish, shellfish, and water.

(~~3~~5) To establish permit or other regulatory limits for toxic substances for which criteria are not included in Tables 20, 33A, or 33B, the department may use the guidance values in Table 33C, public health advisories, and other published scientific literature. The department may also require or conduct bio-assessment studies to monitor the toxicity to aquatic life of complex effluents, other suspected discharges, or chemical substances without numeric criteria.

Hist.: DEQ 17-2003, f. & cert. ef. 12-9-03; DEQ 3-2004, f. & cert. ef. 5-28-04; DEQ 17-2010, f. & cert. ef. 12-21-10

G. Implementation

G.1. Effective Dates

DEQ is proposing that the human health criteria revisions established by OAR 340-041-0033 and shown in Table 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act until approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

In contrast, for DEQ's 2004 water quality standards submission, the revised toxics criteria became effective for NPDES purposes nine months following the date of commission adoption. DEQ also specified that if the values were subsequently disapproved after that date, any corresponding value in Table 20 would become effective. EPA disapproved the majority of DEQ's 2004 human health criteria on June 1, 2010, nearly six years after the effective date. As a result, many of the criteria adopted in 2004 that had become effective subsequently reverted back to human health criteria based on a FCR of 6.5 g/day. Given the potential ramifications of criteria becoming effective in advance of EPA's action, DEQ is proposing that the human health criteria only become applicable for CWA programs upon EPA approval, rather than at the time of commission adoption.

G.2. NPDES Compliance

Dischargers will not need to modify existing permits to immediately incorporate new limits or requirements associated with the revised criteria at the time of EPA approval if that approval occurs during their permit cycle. However, at the time of permit renewal, permits will be evaluated and water quality-based effluent limitations (WQBELs) will be developed or revised in the renewed permit, if needed, to meet revised water quality criteria.

G.3. Methylmercury

In January 2001, EPA published a new water quality criterion for methylmercury that, for the first time, expresses a human health criterion as a concentration in fish and shellfish tissue rather than in the water. In 2004, the EQC adopted a tissue-based methylmercury criterion to replace its previous mercury water column criteria, but it was subsequently disapproved by EPA based on a fish consumption rate that was too low (i.e. 17.5 g/day). DEQ's final proposed rules includes a revised methylmercury fish tissue criterion based on a fish consumption rate of 175 g/day. Because the adoption of tissue-based criteria can pose challenges in implementing the criteria, DEQ has begun exploring options for incorporating the new criteria into various DEQ programs. Generally, DEQ intends to develop implementation procedures similar to EPA's *Guidance for Implementing the January 2001 Methylmercury Criterion*.

G.3.1. NPDES Permitting

DEQ intends to develop implementation procedures based on EPA's *Guidance for Implementing the January 2001 Methylmercury Criterion*. A variety of situations exist throughout Oregon that are addressed in EPA's implementation guidance, including waterbodies with mercury TMDLs, waters listed as impaired without TMDLs, and other waters with insufficient methylmercury data. DEQ will use the options as described in EPA's guidance to develop additional detail regarding how DEQ will implement the new criterion in various circumstances, once adopted by the Environmental Quality Commission and approved by EPA.

G.3.1.2. TMDLs

DEQ intends to make use of EPA's guidance in developing TMDLs and notes that it is fairly flexible and provides DEQ with several options. However, the guidance is written to address waterbodies that are dominated by direct air deposition of mercury, as found in the mid-west and east coast states. In contrast, Oregon is not dominated by direct air deposition of mercury.

In addition to EPA's Guidance, DEQ may also utilize EPA Region 10's Mercury Reduction Strategy in implementing a methylmercury criterion of which DEQ was a key stakeholder in the development of this strategy. Additionally, implementation may include the results of Region 10's *"Development of a Monitoring Guide to Support Water-Resource Assessments for Mercury within EPA Region X"*. This work may help answer questions related to mercury methylation and bioaccumulation in fish tissue.

Oregon's methylmercury criterion implementation strategy from a TMDL perspective would:

- Utilize an environmentally relevant analytical approach that could be conducted on a seasonal basis and include general water and sediment quality parameters that are known to methylate mercury, which could allow for a spatially appropriate bioaccumulation factor to be calculated.
- Focus either on a regional or grouped (likely basin scale) spatial approach that would evaluate both mercury loading and methylmercury methylation.
- Spatially detailed models could be used that are dynamic for modeling fate and transport of both mercury and methylmercury, or a simplified regression model depending on the amount of data available for the analytical area.
- A linked model approach may be likely, especially in data rich areas such as the Willamette Basin. This method would include the use of EPA models: GBMM, WASP, and / or BASS
- Fish tissue could be monitored at a frequency of every 5 years at a minimum(DEQ is already developing a statewide baseline with the Toxics Monitoring Program).
- Relative source contribution analysis would include REMSAD air modeling from EPA for both far field (Asia) and near-field (in-basin sources) analysis.

Further discussion with EPA and DEQ staff in implementing the methylmercury criterion will occur following the commission's adoption of the rules.

G.4. Quantitation Limits

Approximately 48 percent of the proposed human health criteria have Quantification Limits (QLs) that are higher than the criterion. For that reason, pollutants may occur in Oregon's waterbodies at concentrations greater than the proposed criteria that cannot be measured given limitations in analytical methods. As a point of reference, approximately 40 percent of the currently effective criteria have QLs that are higher than the criterion. For permitting purposes, the QL becomes the compliance point for dischargers. Consequently, if the criterion for a particular pollutant becomes more stringent, but the QL remains higher than the criterion, there would be no effective change in the point of compliance until and unless analytical methods improve. Historically, the pace of change in laboratory methods has not been rapid. However, when methods do improve, there will likely be additional toxics impairment listings and more stringent water quality based effluent limits (WQBELs) for permit holders.

G.5. Effective Toxics Criteria Tables

DEQ is proposing a new Table 40 which will only contain criteria applicable to human health. Human health criteria will be deleted from Table 20, Table 33A, and Table 33B. These tables will remain a part of Oregon's water quality standards and only contain the aquatic life criteria. Once EPA takes action on the aquatic life criteria, DEQ will take action to combine the aquatic life criteria in Tables 20, 33A, and Table 33B into one table containing all of the aquatic life criteria.

Appendix A. Table 20 Redline/Strikethrough

TABLE 20

AQUATIC LIFE WATER QUALITY CRITERIA SUMMARY[1]

The concentration for each compound listed in Table 20 is a criterion not to be exceeded in waters of the state in order to protect aquatic life ~~and human health~~. All values are expressed as micrograms per liter (µg/L) except where noted. Compounds are listed in alphabetical order with the corresponding designations as to whether EPA has identified it as a priority pollutant and a carcinogen, aquatic life freshwater acute and chronic criteria, and aquatic life marine acute and chronic criteria, ~~human health water & organism and fish consumption only criteria, and Drinking Water Maximum Contaminant Level (MCL)~~. The acute criteria refer to the average concentration for one (1) hour and the chronic criteria refer to the average concentration for 96 hours (4 days), and that these criteria should not be exceeded more than once every three (3) years.

MEANING OF SYMBOLS:

g = grams ~~M.C.L = Maximum Contaminant Level~~

mg = milligrams + = Hardness Dependent Criteria (100 mg/L used).

The freshwater criterion for this metal is expressed as a function of hardness (mg/L) in the water column. Criteria values for hardness may be calculated from the following formulae (CMC refers to Acute Criteria; CCC refers to Chronic Criteria):

$CMC = (\exp(m_A*[\ln(hardness)] + b_A))*CF$

$CCC = (\exp(m_C*[\ln(hardness)] + b_C))*CF$

Chemical	m_A	b_A	m_C	b_C
Cadmium	1.128	-3.828	0.7852	-3.49
Chromium III	0.819	3.688	0.819	1.561
Copper	0.9422	-1.464	0.8545	-1.465
Lead	1.273	-1.46	1.273	-4.705
Nickel	0.846	3.3612	0.846	1.1645
Silver	1.72	-6.52		
Zinc	0.8473	0.8604	0.8473	0.7614

ug = micrograms

* = Insufficient data to develop criteria; value presented is the L.O.E.L – Lower Observed Effect Level.

ng = nanograms

pg = picograms

f = fibers

Y = Yes

N = No

** = Human health criteria for carcinogens reported for three risk levels. Value presented is the 10-6 risk level, which means the probability of one concern case per million people at the stated concentration.

*** = pH Dependent Criteria (7.8 pH used).

1 = Values in Table 20 are applicable to all basins.

Water and Fish Ingestion

Values represent the maximum ambient water concentration for consumption of both contaminated water and fish or other aquatic organisms.

Fish Ingestion

Values represent the maximum ambient water concentrations for consumption of fish or other aquatic organisms

Appendix B. Table 33A Redline/Strikethrough

TABLE 33A

Note: The Environmental Quality Commission adopted the following criteria on May 20, 2004 to become effective February 15, 2005. However, EPA has not yet (as of June 2006) approved the criteria. Thus, Table 33A criteria may be used in NPDES permits, but not for the section 303(d) list of impaired waters.

AQUATIC LIFE WATER QUALITY CRITERIA SUMMARY[A]

The concentration for each compound listed in Table 33A is a criterion not to be exceeded in waters of the state in order to protect aquatic life ~~and human health~~. All values are expressed as micrograms per liter (µg/L) except where noted. Compounds are listed in alphabetical order with the corresponding EPA number (from National Recommended Water Quality Criteria: 2002, EPA-822-R-02-047), the Chemical Abstract Service (CAS) number, aquatic life freshwater acute and chronic criteria, aquatic life saltwater acute and chronic criteria~~, human health water & organism and organism only criteria~~, and Drinking Water Maximum Contaminant Level (MCL). The acute criteria refer to the average concentration for one (1) hour and the chronic criteria refer to the average concentration for 96 hours (4 days), and that these criteria should not be exceeded more than once every three (3) years.

Footnotes for Tables 33A and 33B:

A Values in Table 20 are applicable to all basins.

~~B Human Health criteria values were calculated using a fish consumption rate of 17.5 grams per day (0.6 ounces/day) unless otherwise noted.~~

C Ammonia criteria for freshwater may depend on pH, temperature, and the presence of salmonids or other fish with ammonia-sensitive early life stages. Values for freshwater criteria (of total ammonia nitrogen in mg N/L) can be calculated using the formulae specified in *1999 Update of Ambient Water Quality Criteria for Ammonia* (EPA-822-R-99-014; http://www.epa.gov/ost/standards/ammonia/99update.pdf):

Freshwater Acute:

salmonids present….CMC = $\frac{0.275}{1+10^{7.204-pH}}+\frac{39.0}{1+10^{pH-7.204}}$

salmonids not present…CMC= $\frac{0.411}{1+10^{7.204-pH}}+\frac{58.4}{1+10^{pH-7.204}}$

Freshwater Chronic:

fish early life stages present

CCC = $\frac{0.0577}{1+10^{7.688-pH}}+\frac{2.487}{1+10^{pH-7.688}}$ * $MIN(2.85, 1.45*10^{0.028*(25-T)})$

fish early life stages not present

CCC= $\frac{0.0577}{1+10^{7.688-pH}}+\frac{2.487}{1+10^{pH-7.688}}$ * $1.45*10^{0.028*(25-MAX(T,7))}$

Note: these chronic criteria formulae would be applied to calculate the 30-day average concentration limit; in addition, the highest 4-day average within the 30-day period should not exceed 2.5 times the CCC.

D Ammonia criteria for saltwater may depend on pH and temperature. Values for saltwater criteria (total ammonia) can be calculated from the tables specified in *Ambient Water Quality Criteria for Ammonia (Saltwater)--1989* (EPA 440/5-88-004; http://www.epa.gov/ost/pc/ambientwqc/ammoniasalt1989.pdf).

E Freshwater and saltwater criteria for metals are expressed in terms of "dissolved" concentrations in the water column, except where otherwise noted (e.g. aluminum).

F The freshwater criterion for this metal is expressed as a function of hardness (mg/L) in the water column. Criteria values for hardness may be calculated from the following formulae (CMC refers to Acute Criteria; CCC refers to Chronic Criteria):

$$CMC = (\exp(m_A*[\ln(hardness)] + b_A))*CF$$

$$CCC = (\exp(m_C*[\ln(hardness)] + b_C))*CF$$

where CF is the conversion factor used for converting a metal criterion expressed as the total recoverable fraction in the water column to a criterion expressed as the dissolved fraction in the water column.

Chemical	m_A	b_A	m_C	b_C
Cadmium	1.0166	-3.924	0.7409	-4.719
Chromium III	0.8190	3.7256	0.8190	0.6848
Copper	0.9422	-1.700	0.8545	-1.702
Lead	1.273	-1.460	1.273	-4.705
Nickel	0.8460	2.255	0.8460	0.0584
Silver	1.72	-6.59		
Zinc	0.8473	0.884	0.8473	0.884

Conversion factors (CF) for dissolved metals (the values for total recoverable metals criteria were multiplied by the appropriate conversion factors shown below to calculate the dissolved metals criteria):

Chemical	Freshwater		Saltwater	
	Acute	Chronic	Acute	Chronic
Arsenic	1.000	1.000	1.000	1.000
Cadmium	1.136672-[(ln hardness)(0.041838)]	1.101672-[(ln hardness)(0.041838)]	0.994	0.994
Chromium III	0.316	0.860	--	--
Chromium VI	0.982	0.962	0.993	0.993
Copper	0.960	0.960	0.83	0.83
Lead	1.46203-[(ln hardness)(0.145712)]	1.46203-[(ln hardness)(0.145712)]	0.951	0.951
Nickel	0.998	0.997	0.990	0.990
Selenium	0.996	0.922	0.998	0.998
Silver	0.85	0.85	0.85	--
Zinc	0.978	0.986	0.946	0.946

~~G Human Health criterion is the same as originally published in the 1976 EPA Red Book (Quality Criteria for Water, EPA-440/9-76-023) which predates the 1980 methodology and did not use the fish ingestion BCF approach.~~

~~H This value is based on a Drinking Water regulation.~~

I This value is based on criterion published in Ambient Water Quality Criteria for Endosulfan (EPA 440/5-80-046) and should be applied as the sum of alpha- and beta-endosulfan.

~~J No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.~~

~~K Human Health criterion is for "dissolved" concentration based on the 1976 EPA Red Book conclusion that adverse effects from exposure at this level are aesthetic rather than toxic.~~

~~L This value is expressed as the fish tissue concentration of methylmercury.~~

M Freshwater aquatic life values for pentachlorophenol are expressed as a function of pH, and are calculated as follows: CMC=(exp(1.005(pH)-4.869); CCC=exp(1.005(pH)-5.134).

N This number was assigned to the list of non-priority pollutants in National Recommended Water Quality Criteria: 2002 (EPA-822-R-02-047).

O This criterion is based on EPA recommendations issued in 1980 that were derived using guidelines that differed from EPA's 1985 Guidelines for minimum data requirements and derivation procedures. For example, a "CMC" derived using the 1980 Guidelines was derived to be used as an instantaneous maximum. If assessment is to be done using an averaging period, the values given should be divided by 2 to obtain a value that is more comparable to a CMC derived using the 1985 Guidelines.

P Criterion shown is the minimum (i.e. CCC in water should not be below this value in order to protect aquatic life).

Q Criterion is applied as total arsenic (i.e. arsenic (III) + arsenic (V)).

R Arsenic criterion refers to the inorganic form only.

S This criterion is expressed as µg free cyanide (CN)/L.

T This criterion applies to DDT and its metabolites (i.e. the total concentration of DDT and its metabolites should not exceed this value).

U This criterion applies to total PCBs (e.g. the sum of all congener or all isomer or homolog or Arochlor analyses).

V The CMC=1/[(f1/CMC1)+(f2/CMC2)] where f1 and f2 are the fractions of total selenium that are treated as selenite and selenate, respectively, and CMC1 and CMC2 are 185.9 µg/L and 12.82 µg/L, respectively.

W The acute and chronic criteria for aluminum are 750 µg/L and 87 µg/L, respectively. These values for aluminum are expressed in terms of "total recoverable" concentration of metal in the water column. The criterion applies at pH<6.6 and hardness<12 mg/L (as $CaCO_3$).

X The effective date for the criterion in the column immediately to the left is 1991.

Y No criterion.

Appendix C. Table 33B Redline/Strikethrough

TABLE 33B

Note: The Environmental Quality Commission adopted the following criteria on May 20, 2004 to become effective on EPA approval. EPA has not yet (as of June 2006) approved these criteria. The Table 33B criteria may not be used until they are approved by EPA.

AQUATIC LIFE WATER QUALITY CRITERIA SUMMARY[A]

The concentration for each compound listed in Table 33A is a criterion not to be exceeded in waters of the state in order to protect aquatic life ~~and human health~~. All values are expressed as micrograms per liter (µg/L) except where noted. Compounds are listed in alphabetical order with the corresponding EPA number (from National Recommended Water Quality Criteria: 2002, EPA-822-R-02-047), the Chemical Abstract Service (CAS) number, aquatic life freshwater acute and chronic criteria, aquatic life saltwater acute and chronic criteria, ~~human health water & organism and organism only criteria~~, and Drinking Water Maximum Contaminant Level (MCL). The acute criteria refer to the average concentration for one (1) hour and the chronic criteria refer to the average concentration for 96 hours (4 days), and that these criteria should not be exceeded more than once every three (3) years.

Footnotes for Tables 33A and 33B:

A Values in Table 20 are applicable to all basins.

~~B Human Health criteria values were calculated using a fish consumption rate of 17.5 grams per day (0.6 ounces/day) unless otherwise noted.~~

C Ammonia criteria for freshwater may depend on pH, temperature, and the presence of salmonids or other fish with ammonia-sensitive early life stages. Values for freshwater criteria (of total ammonia nitrogen in mg N/L) can be calculated using the formulae specified in *1999 Update of Ambient Water Quality Criteria for Ammonia* (EPA-822-R-99-014; http://www.epa.gov/ost/standards/ammonia/99update.pdf):

Freshwater Acute:

salmonids present….CMC = $\frac{0.275}{1+10^{7.204-pH}}+\frac{39.0}{1+10^{pH-7.204}}$

salmonids not present…CMC= $\frac{0.411}{1+10^{7.204-pH}}+\frac{58.4}{1+10^{pH-7.204}}$

Freshwater Chronic:

fish early life stages present

CCC = $\left(\frac{0.0577}{1+10^{7.688-pH}}+\frac{2.487}{1+10^{pH-7.688}}\right)*MIN(2.85,1.45*10^{0.028*(25-T)})$

fish early life stages not present

CCC= $\left(\frac{0.0577}{1+10^{7.688-pH}}+\frac{2.487}{1+10^{pH-7.688}}\right)*1.45*10^{0.028*(25-MAX(T,7))}$

Note: these chronic criteria formulae would be applied to calculate the 30-day average concentration limit; in addition, the highest 4-day average within the 30-day period should not exceed 2.5 times the CCC.

D Ammonia criteria for saltwater may depend on pH and temperature. Values for saltwater criteria (total ammonia) can be calculated from the tables specified in *Ambient Water Quality Criteria for Ammonia (Saltwater)--1989* (EPA 440/5-88-004; http://www.epa.gov/ost/pc/ambientwqc/ammoniasalt1989.pdf).

E Freshwater and saltwater criteria for metals are expressed in terms of "dissolved" concentrations in the water column, except where otherwise noted (e.g. aluminum).

F The freshwater criterion for this metal is expressed as a function of hardness (mg/L) in the water column. Criteria values for hardness may be calculated from the following formulae (CMC refers to Acute Criteria; CCC refers to Chronic Criteria):

$$CMC = (\exp(m_A*[\ln(hardness)] + b_A))*CF$$

$$CCC = (\exp(m_C*[\ln(hardness)] + b_C))*CF$$

where CF is the conversion factor used for converting a metal criterion expressed as the total recoverable fraction in the water column to a criterion expressed as the dissolved fraction in the water column.

Chemical	**m_A**	**b_A**	**m_C**	**b_C**
Cadmium	1.0166	-3.924	0.7409	-4.719
Chromium III	0.8190	3.7256	0.8190	0.6848
Copper	0.9422	-1.700	0.8545	-1.702
Lead	1.273	-1.460	1.273	-4.705
Nickel	0.8460	2.255	0.8460	0.0584
Silver	1.72	-6.59		
Zinc	0.8473	0.884	0.8473	0.884

Conversion factors (CF) for dissolved metals (the values for total recoverable metals criteria were multiplied by the appropriate conversion factors shown below to calculate the dissolved metals criteria):

Chemical	Freshwater		Saltwater	
	Acute	Chronic	Acute	Chronic
Arsenic	1.000	1.000	1.000	1.000
Cadmium	1.136672-[(ln hardness)(0.041838)]	1.101672-[(ln hardness)(0.041838)]	0.994	0.994
Chromium III	0.316	0.860	--	--
Chromium VI	0.982	0.962	0.993	0.993
Copper	0.960	0.960	0.83	0.83
Lead	1.46203-[(ln hardness)(0.145712)]	1.46203-[(ln hardness)(0.145712)]	0.951	0.951
Nickel	0.998	0.997	0.990	0.990
Selenium	0.996	0.922	0.998	0.998
Silver	0.85	0.85	0.85	--
Zinc	0.978	0.986	0.946	0.946

~~G Human Health criterion is the same as originally published in the 1976 EPA Red Book (Quality Criteria for Water, EPA-440/9-76-023) which predates the 1980 methodology and did not use the fish ingestion BCF approach.~~

~~H This value is based on a Drinking Water regulation.~~

I This value is based on criterion published in Ambient Water Quality Criteria for Endosulfan (EPA 440/5-80-046) and should be applied as the sum of alpha- and beta-endosulfan.

~~J No BCF was available; therefore, this value is based on that published in the 1986 EPA Gold Book.~~

~~K Human Health criterion is for "dissolved" concentration based on the 1976 EPA Red Book conclusion that adverse effects from exposure at this level are aesthetic rather than toxic.~~

~~L This value is expressed as the fish tissue concentration of methylmercury.~~

M Freshwater aquatic life values for pentachlorophenol are expressed as a function of pH, and are calculated as follows: CMC=(exp(1.005(pH)-4.869); CCC=exp(1.005(pH)-5.134).

N This number was assigned to the list of non-priority pollutants in National Recommended Water Quality Criteria: 2002 (EPA-822-R-02-047).

O This criterion is based on EPA recommendations issued in 1980 that were derived using guidelines that differed from EPA's 1985 Guidelines for minimum data requirements and derivation procedures. For example, a "CMC" derived using the 1980 Guidelines was derived to be used as an instantaneous maximum. If assessment is to be done using an averaging period, the values given should be divided by 2 to obtain a value that is more comparable to a CMC derived using the 1985 Guidelines.

P Criterion shown is the minimum (i.e. CCC in water should not be below this value in order to protect aquatic life).

Q Criterion is applied as total arsenic (i.e. arsenic (III) + arsenic (V)).

R Arsenic criterion refers to the inorganic form only.

S This criterion is expressed as µg free cyanide (CN)/L.

T This criterion applies to DDT and its metabolites (i.e. the total concentration of DDT and its metabolites should not exceed this value).

U This criterion applies to total PCBs (e.g. the sum of all congener or all isomer or homolog or Arochlor analyses).

V The CMC=1/[(f1/CMC1)+(f2/CMC2)] where f1 and f2 are the fractions of total selenium that are treated as selenite and selenate, respectively, and CMC1 and CMC2 are 185.9 µg/L and 12.82 µg/L, respectively.

W The acute and chronic criteria for aluminum are 750 µg/L and 87 µg/L, respectively. These values for aluminum are expressed in terms of "total recoverable" concentration of metal in the water column. The criterion applies at pH<6.6 and hardness<12 mg/L (as $CaCO_3$).

X The effective date for the criterion in the column immediately to the left is 1991.

Y No criterion.

Appendix E. TABLE 40: Human Health Water Quality Criteria for Toxic Pollutants

DRAFT

Human Health Criteria Summary

The concentration for each pollutant listed in Table 40 was derived to protect Oregonians from potential adverse health impacts associated with long-term exposure to toxic substances associated with consumption of fish, shellfish, and water. The "organism only" criteria are established to protect fish and shellfish consumption and apply to waters of the state designated for fishing. The "water + organism" criteria are established to protect the consumption of drinking water, fish, and shellfish, and apply where both fishing and domestic water supply (public and private) are designated uses. All criteria are expressed as micrograms per liter (µg/L), unless otherwise noted. Pollutants are listed in alphabetical order. Additional information includes the Chemical Abstract Service (CAS) number, whether the criterion is based on carcinogenic effects (can cause cancer in humans), and whether there is an aquatic life criterion for the pollutant (i.e. "y"= yes, "n" = no). All the human health criteria were calculated using a fish consumption rate of 175 grams per day unless otherwise noted. A fish consumption rate of 175 grams per day is approximately equal to 23 8-ounce fish meals per month. For pollutants categorized as carcinogens, values represent a cancer risk of one additional case of cancer in one million people (i.e. 10^{-6}), unless otherwise noted. All metals criteria are for total metal concentration, unless otherwise noted. Italicized pollutants represent non-priority pollutants. The human health criteria revisions established by OAR 340-041-0033 and shown in Table 40 do not become applicable for purposes of ORS chapter 468B or the federal Clean Water Act until approved by EPA pursuant to 40 CFR 131.21 (4/27/2000).

No.	Pollutant	CAS No.	Carcinogen	Aquatic Life Criterion	Human Health Criteria for the Consumption of:	
					Water + Organism (µg/L)	Organism Only (µg/L)
1	Acenaphthene	83329	n	n	95	99
2	Acrolein	107028	n	n	0.88	0.93
3	Acrylonitrile	107131	y	n	0.018	0.025
4	Aldrin	309002	y	y	0.0000050	0.0000050
5	Anthracene	120127	n	n	2900	4000
6	Antimony	7440360	n	n	5.1	64
7	Arsenic (inorganic)[A]	7440382	y	n	2.1	2.1(freshwater) 1.0 (saltwater)
	[A] The arsenic criteria are expressed as total inorganic arsenic. The "organism only" criteria are based on a risk level of approximately of 1.1 x 10^{-5}, and the "water + organism" criterion is based on a risk level of 1 x 10^{-4}					
8	Asbestos[B]	1332214	y	n	7,000,000 fibers/L	--
	[B] The human health risks from asbestos are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.					
9	*Barium*[C]	7440393	n	n	1000	--
	[C] The human health criterion for barium is the same as originally published in the 1976 EPA Red Book which predates the 1980 methodology and did not utilize the fish ingestion BCF approach. This same criterion value was also published in the 1986 EPA Gold Book. Human health risks are primarily from drinking water, therefore no "organism only" criterion was developed. The "water + organism" criterion is based on the Maximum Contaminant Level (MCL) established under the Safe Drinking Water Act.					
10	Benzene	71432	y	n	0.44	1.4

FEDERAL REGISTER

Vol. 80 Monday,
No. 177 September 14, 2015

Pages 55015–55216

OFFICE OF THE FEDERAL REGISTER

The **FEDERAL REGISTER** (ISSN 0097–6326) is published daily, Monday through Friday, except official holidays, by the Office of the Federal Register, National Archives and Records Administration, Washington, DC 20408, under the Federal Register Act (44 U.S.C. Ch. 15) and the regulations of the Administrative Committee of the Federal Register (1 CFR Ch. I). The Superintendent of Documents, U.S. Government Publishing Office, Washington, DC 20402 is the exclusive distributor of the official edition. Periodicals postage is paid at Washington, DC.

The **FEDERAL REGISTER** provides a uniform system for making available to the public regulations and legal notices issued by Federal agencies. These include Presidential proclamations and Executive Orders, Federal agency documents having general applicability and legal effect, documents required to be published by act of Congress, and other Federal agency documents of public interest.

Documents are on file for public inspection in the Office of the Federal Register the day before they are published, unless the issuing agency requests earlier filing. For a list of documents currently on file for public inspection, see *www.ofr.gov.*

The seal of the National Archives and Records Administration authenticates the Federal Register as the official serial publication established under the Federal Register Act. Under 44 U.S.C. 1507, the contents of the **Federal Register** shall be judicially noticed.

The **Federal Register** is published in paper and on 24x microfiche. It is also available online at no charge at *www.fdsys.gov*, a service of the U.S. Government Publishing Office.

The online edition of the **Federal Register** is issued under the authority of the Administrative Committee of the Federal Register as the official legal equivalent of the paper and microfiche editions (44 U.S.C. 4101 and 1 CFR 5.10). It is updated by 6:00 a.m. each day the **Federal Register is** published and includes both text and graphics from Volume 59, 1 (January 2, 1994) forward. For more information, contact the GPO Customer Contact Center, U.S. Government Publishing Office. Phone 202-512-1800 or 866-512-1800 (toll free). E-mail, *gpocusthelp.com.*

The annual subscription price for the **Federal Register** paper edition is $749 plus postage, or $808, plus postage, for a combined **Federal Register, Federal Register** Index and List of CFR Sections Affected (LSA) subscription; the microfiche edition of the **Federal Register** including the **Federal Register** Index and LSA is $165, plus postage. Six month subscriptions are available for one-half the annual rate. The prevailing postal rates will be applied to orders according to the delivery method requested. The price of a single copy of the daily **Federal Register,** including postage, is based on the number of pages: $11 for an issue containing less than 200 pages; $22 for an issue containing 200 to 400 pages; and $33 for an issue containing more than 400 pages. Single issues of the microfiche edition may be purchased for $3 per copy, including postage. Remit check or money order, made payable to the Superintendent of Documents, or charge to your GPO Deposit Account, VISA, MasterCard, American Express, or Discover. Mail to: U.S. Government Publishing Office—New Orders, P.O. Box 979050, St. Louis, MO 63197-9000; or call toll free 1-866-512-1800, DC area 202-512-1800; or go to the U.S. Government Online Bookstore site, see *bookstore.gpo.gov.*

There are no restrictions on the republication of material appearing in the **Federal Register.**

How To Cite This Publication: Use the volume number and the page number. Example: 80 FR 12345.

Postmaster: Send address changes to the Superintendent of Documents, Federal Register, U.S. Government Publishing Office, Washington, DC 20402, along with the entire mailing label from the last issue received.

7 CFR Part 319

[Docket No. APHIS–2015–0005]

RIN 0579–AE09

Importation of Citrus From Peru; Expansion of Citrus-Growing Area

AGENCY: Animal and Plant Health Inspection Service, USDA.

ACTION: Final rule.

SUMMARY: We are amending the fruits and vegetable regulations to allow citrus fruit from the entire country of Peru to be imported into the continental United States. Currently, the regulations allow the importation of citrus fruit to the United States from five approved citrus-producing zones in Peru, subject to a systems approach. However, based on the findings of a pest list and commodity import evaluation document, we have determined that this systems approach also mitigates the plant pest risk associated with citrus fruit produced in all other areas of Peru. This action will allow the importation of citrus fruit from the entire country of Peru while continuing to provide protection against the introduction of plant pests into the continental United States.

DATES: Effective September 14, 2015.

FOR FURTHER INFORMATION CONTACT: Mr. Tony Román, Senior Regulatory Policy Specialist, PPQ, APHIS, 4700 River Road Unit 39, Riverdale, MD 20737–1231; (301) 851–2242.

SUPPLEMENTARY INFORMATION:

Background

The regulations in "Subpart—Fruits and Vegetables" (7 CFR 319.56–1 through 319.56–72, referred to below as the regulations) prohibit or restrict the importation of fruits and vegetables into the United States from certain parts of the world to prevent the introduction and dissemination of plant pests within the United States. The regulations in § 319.56–41 have provided conditions for the importation of citrus from five approved citrus-producing zones in Peru.

On May 1, 2015, we published in the **Federal Register** (80 FR 24838–24840, Docket No. APHIS–2015–0005) a proposal [1] to amend § 319.56–41 to allow citrus from the entire country of Peru to be imported into the continental United States based on the findings of a pest list and commodity import evaluation document (CIED).

We solicited comments on the proposal, pest list, and CIED for 60 days ending June 30, 2015. We received 13 comments by that date. They were from producers, exporters, representatives of State and foreign governments, U.S. citrus industry representatives, a chamber of commerce, a pork producers organization, a port representative, and private citizens. All of the commenters supported the action; however, one commenter asked if the citrus would be required to undergo cold treatment.

As explained in the proposal, citrus from Peru may be imported into the continental United States under a systems approach designated to mitigate the risk presented by four species of fruit fly (*Anastrepha fraterculus, A. obliqua, A. serpentina,* and *Ceratitis capitata*) and a Tortricid (*Ecdytolopha aurantiana*). One of the conditions of the systems approach requires that citrus from Peru, except limes, be cold treated for fruit flies in accordance with 7 CFR part 305.

Therefore, for the reasons given in the proposed rule, we are adopting the proposed rule as a final rule, without change.

Effective Date

This is a substantive rule that relieves restrictions and, pursuant to the provisions of 5 U.S.C. 553, may be made effective less than 30 days after publication in the **Federal Register**.

Immediate implementation of this rule is necessary to provide relief to those persons who are adversely affected by restrictions we no longer find warranted. The shipping season for citrus from Peru is in progress. Making this rule effective immediately will allow interested producers and others in the marketing chain to benefit during this year's shipping season. Therefore, the Administrator of the Animal and Plant Health Inspection Service has determined that this rule should be effective upon publication in the **Federal Register**.

Executive Order 12866 and Regulatory Flexibility Act

This final rule has been determined to be not significant for the purposes of Executive Order 12866 and, therefore, has not been reviewed by the Office of Management and Budget.

In accordance with the Regulatory Flexibility Act, we have analyzed the potential economic effects of this action on small entities. The analysis is summarized below. Copies of the full analysis are available on the Regulations.gov Web site (see footnote 1 in this document for a link to Regulations.gov) or by contacting the person listed under **FOR FURTHER INFORMATION CONTACT**.

The regulations have allowed the importation of fresh grapefruit, lime, mandarin, orange, tangerine or hybrids, sweet orange, and tangelo from five approved citrus-producing zones in Peru to the United States. This rule will allow the importation of these fruits from the entire country of Peru into the continental United States under the same conditions that have been in place for the five zones. This change is expected to increase the area in Peru approved to produce citrus for export to the United States to about 1,500 hectares over 3 years. Additional volumes of citrus expected to be shipped to the United States are 5,000 metric tons (MT) in the first year that the rule is in effect, 6,500 MT in the second year, and 8,000 MT in the third year. These quantities are equivalent to less than 1 percent of annual U.S. citrus production or U.S. citrus imports.

The primary entities that may be affected by this rule are citrus producers, citrus importers, and support industries such as packinghouses. Based on data from the 2012 Census of Agriculture and Small Business Administration small-entity standards, the majority of these operations are small.

[1] To view the proposed rule, pest list, CIED, and the comments we received, go to *http://www.regulations.gov/#!docketDetail;D=APHIS-2015-0005.*

Under these circumstances, the Administrator of the Animal and Plant Health Inspection Service has determined that this action will not have a significant economic impact on a substantial number of small entities.

Executive Order 12988

This final rule allows citrus to be imported into the continental United States from the entire country of Peru. State and local laws and regulations regarding citrus imported under this rule will be preempted while the fruit is in foreign commerce. Fresh fruits are generally imported for immediate distribution and sale to the consuming public, and remain in foreign commerce until sold to the ultimate consumer. The question of when foreign commerce ceases in other cases must be addressed on a case-by-case basis. No retroactive effect will be given to this rule, and this rule will not require administrative proceedings before parties may file suit in court challenging this rule.

Paperwork Reduction Act

In accordance with section 3507(d) of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*), the information collection or recordkeeping requirements included in this final rule, which were filed under 0579–0433, have been submitted for approval to the Office of Management and Budget (OMB). When OMB notifies us of its decision, if approval is denied, we will publish a document in the **Federal Register** providing notice of what action we plan to take.

E-Government Act Compliance

The Animal and Plant Health Inspection Service is committed to compliance with the E-Government Act to promote the use of the Internet and other information technologies, to provide increased opportunities for citizen access to Government information and services, and for other purposes. For information pertinent to E-Government Act compliance related to this rule, please contact Ms. Kimberly Hardy, APHIS' Information Collection Coordinator, at (301) 851–2727.

List of Subjects in 7 CFR Part 319

Coffee, Cotton, Fruits, Imports, Logs, Nursery stock, Plant diseases and pests, Quarantine, Reporting and recordkeeping requirements, Rice, Vegetables.

Accordingly, we are amending 7 CFR part 319 as follows:

PART 319—FOREIGN QUARANTINE NOTICES

■ 1. The authority citation for part 319 continues to read as follows:

Authority: 7 U.S.C. 450, 7701–7772, and 7781–7786; 21 U.S.C. 136 and 136a; 7 CFR 2.22, 2.80, and 371.3.

§ 319.56–41 [Amended]

■ 2. Section 319.56–41 is amended as follows:

■ a. In the introductory text, by adding the word "continental" between the words "the" and "United States".

■ b. By removing paragraph (c).

■ c. By redesignating paragraphs (d) through (h) as paragraphs (c) through (g), respectively.

■ d. By adding the words "(Approved by the Office of Management and Budget under control number 0579–0433)" at the end of the section.

Done in Washington, DC, this 9th day of September 2015.

Michael C. Gregoire,

Associate Administrator, Animal and Plant Health Inspection Service.

[Docket No. APHIS–2014–0028]

RIN 0579–AD97

Importation of Fresh Peppers From Peru into the Continental United States and the Territories

AGENCY: Animal and Plant Health Inspection Service, USDA.

ACTION: Final rule.

SUMMARY: We are amending the fruits and vegetables regulations to allow the importation of fresh peppers into the continental United States and the Territories from Peru. As a condition of entry, the fruit will have to be produced in accordance with a systems approach that includes requirements for fruit fly trapping, pre-harvest inspections, production sites, and packinghouse procedures designed to exclude quarantine pests. The fruit will also be required to be imported in commercial consignments and accompanied by a phytosanitary certificate issued by the national plant protection organization of Peru with an additional declaration stating that the consignment was produced in accordance with the requirements of the systems approach. This action allows for the importation of untreated fresh peppers from Peru while continuing to provide protection against the introduction of plant pests into the continental United States and the Territories.

DATES: Effective October 14, 2015.

FOR FURTHER INFORMATION CONTACT: Mr. George Balady, Senior Regulatory Policy Specialist, Plant Health Programs, PPQ, APHIS, 4700 River Road Unit 133, Riverdale, MD 20737; (301) 851–2240.

SUPPLEMENTARY INFORMATION:

Background

The regulations in "Subpart–Fruits and Vegetables" (7 CFR 319.56–1 through 319.56–72, referred to below as the regulations) prohibit or restrict the importation of fruits and vegetables into the United States from certain parts of the world to prevent the introduction and dissemination of plant pests that are new to or not widely distributed within the United States.

On April 24, 2015, we published in the **Federal Register** (80 FR 22934–22938, Docket No. APHIS–2014–0028) a proposal [1] to amend the regulations in order to allow the common chili pepper (*Capsicum annuum* L.), aji pepper (*Capsicum baccatum* L.), habanero chili (*Capsicum chinense* Jacq.), Thai pepper (*Capsicum frutescens* L.), and rocoto (*Capsicum pubescens* Ruiz & Pav.) (hereafter we refer to these species as "fresh peppers") to be imported into the continental United States and the Territories (the Commonwealth of Northern Mariana Islands, the Commonwealth of Puerto Rico, Guam, the Virgin Islands of the United States, and any other territory or possession of the United States).

We prepared a pest risk assessment (PRA) and a risk management document (RMD) to accompany the proposed rule. Based on the conclusions of the PRA and the RMD, we proposed to allow the importation of fresh peppers from Peru into the continental United States and the Territories, provided that the fresh peppers were produced in accordance with a systems approach consisting of the following requirements: Provision of an operational workplan to the Animal and Plant Health Inspection Service (APHIS) by the national plant protection organization (NPPO) of Peru; importation in commercial consignments only; fresh peppers grown in a pest-free, pest-exclusionary structure approved by and registered

[1] To view the proposed rule, supporting documents, and the comments we received, go to *http://www.regulations.gov/#!docketDetail;D=APHIS-V2014-0028.*

with the Peruvian NPPO; inspection of registered production sites prior to harvest for the fruit boring moth, *Neoleucinodes elegantalis* (Guenée), and *Puccinia pampeana* Speg., the pathogenic fungus that causes pepper and green pepper rust, by the Peruvian NPPO or its approved designee; trapping both within and around the production site for the South American fruit fly (*Anastrepha fraterculus* (Wiedemann)) and the Mediterranean fruit fly (Medfly, *Ceratitis capitata* (Wiedemann)); packinghouse procedures including registration and insect-proof cartons, containers, or coverings; and issuance of a phytosanitary certificate.

We also proposed to add a definition for *continental United States* to the regulations in § 319.56–2, as it is used throughout the regulations but not defined.

We solicited comments concerning our proposal for 60 days ending June 23, 2015. We received 23 comments by that date. They were from trade organizations, the Peruvian NPPO, consumer groups, ports, the Peruvian embassy, and private citizens. All comments except one were supportive of the proposed action. The remaining comment is discussed below.

The commenter said that APHIS is dependent on local authorities in Peru to enforce the requirements set forth in the regulations and the operational workplan. The commenter cited the 2015 Index of Economic Freedom issued by The Heritage Foundation [2] as proof that corruption within Peru will most certainly occur in connection with the export of fresh peppers.

Like the United States, Peru is a signatory to the World Trade Organization's Agreement on Sanitary and Phytosanitary Measures (SPS Agreement). As such, it has agreed to respect the phytosanitary measures the United States imposes on the importation of plants and plant products from Peru when the United States demonstrates the need to impose these measures in order to protect plant health within the United States. The PRA that accompanied the proposed rule provided evidence of such a need. That being said, as we mentioned in the proposed rule, APHIS will monitor and audit Peru's implementation of the systems approach for the importation of fresh peppers into the continental United States and the Territories. If we determine that the systems approach has not been fully implemented or maintained, we will take appropriate remedial action to ensure that the importation of fresh peppers from Peru does not result in the dissemination of plant pests within the United States.

The commenter argued that the interests of pepper producers in the United States need to be given the same consideration as U.S. consumers or Peruvian producers. The commenter said that, therefore, APHIS needs to ensure that U.S. pepper producers would truly be marginally affected. To achieve this end, the commenter suggested that APHIS limit the importation of fresh peppers from Peru to domestic out-of-season growing months.

APHIS bases market access on potential pest risk and our capacity to mitigate that risk. APHIS may implement different entry requirements for a commodity based upon port of entry and time of year in order to mitigate the risk posed by a pest, but APHIS does not restrict market access for the purposes of eliminating market competition.

We prepared an initial regulatory flexibility analysis to assess the potential economic impacts associated with the proposed rule. The commenter stated that the initial regulatory flexibility analysis did not fully account for the impacts to domestic producers. The commenter said that, in addition to reduced sales, domestic pepper producers are at a financial disadvantage due to the fact that reductions in crop premium insurance for fresh peppers as detailed in the Agricultural Act of 2014 [3] could potentially lead to further financial losses in the event that a portion of a producer's pepper crop was destroyed and the remaining crop sold at a lower price due to the increased availability of imported peppers in the marketplace.

The purpose of the economic analysis was to examine whether or not the rule will have a significant economic impact on a substantial number of small entities. Despite the other pressures on the financial viability of domestic pepper producers cited by the commenter, any additional impact associated with this rule is expected to be very small. An increase in the U.S. fresh pepper supply of less than 0.03 percent is unlikely to have a significant impact on domestic fresh pepper prices and therefore on domestic producers.

Finally, the commenter maintained that the United States should examine any importation requests from Peru in light of what the commenter categorized as unfair taxation of U.S. biodiesel in that country.

We disagree. Under the authority of the Plant Protection Act (7 U.S.C. 7701 *et seq.*), APHIS may prohibit or restrict the entry of plants and plant products into the United States in order to prevent the introduction of plant pests or noxious weeds. Trade considerations such as those suggested by the commenter do not factor into such determinations.

Therefore, for the reasons given in the proposed rule and in this document, we are adopting the proposed rule as a final rule, without change.

Executive Order 12866 and Regulatory Flexibility Act

This final rule has been determined to be not significant for the purposes of Executive Order 12866 and, therefore, has not been reviewed by the Office of Management and Budget.

In accordance with the Regulatory Flexibility Act, we have analyzed the potential economic effects of this action on small entities. The analysis is summarized below. Copies of the full analysis are available on the Regulations.gov Web site (see footnote 1 in this document for a link to Regulations.gov) or by contacting the person listed under **FOR FURTHER INFORMATION CONTACT.**

The rule will amend the regulations to allow the importation of fresh peppers from Peru into the continental United States and the Territories when a systems approach to pest risk mitigation is used to prevent the introduction of quarantine pests. The systems approach will integrate prescribed mitigation measures that cumulatively achieve the appropriate level of phytosanitary protection.

Peru produced an average of about 9,600 metric tons (MT) of fresh peppers annually from 2005 through 2011. From 2010 to 2014, fresh pepper exports from Peru averaged 356 MT annually, the equivalent of about 4 percent of its annual fresh pepper production.

Based on Peru's pepper production area and yields, APHIS estimates in the pest risk assessment for this rule that no more than 22 containers (440 MT) of fresh peppers will be imported from Peru into the United States annually. This quantity is the equivalent of less than 0.03 percent of annual U.S. fresh pepper consumption.

U.S. pepper producers and current foreign suppliers will face increased competition because of the Peruvian exports. However, economic effects of the rule will be minimal, given the very

[2] The 2015 Index of Economic Freedom may be viewed here: *http://www.heritage.org/index/country/peru.*

[3] You may view the Agricultural Act of 2014 on the Internet at *https://agriculture.house.gov/bill/agricultural-act-2014.*

small quantity of pepper expected to be imported from Peru.

Under these circumstances, the Administrator of the Animal and Plant Health Inspection Service has determined that this action will not have a significant economic impact on a substantial number of small entities.

Executive Order 12988

This final rule allows fresh peppers to be imported into the continental United States and the Territories from Peru. State and local laws and regulations regarding fresh peppers imported under this rule would be preempted while the fruit is in foreign commerce. Fresh vegetables are generally imported for immediate distribution and sale to the consuming public and would remain in foreign commerce until sold to the ultimate consumer. The question of when foreign commerce ceases in other cases must be addressed on a case-by-case basis. No retroactive effect will be given to this rule, and this rule will not require administrative proceedings before parties may file suit in court challenging this rule.

Paperwork Reduction Act

In accordance with section 3507(d) of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*), the information collection or recordkeeping requirements included in this final rule, which were filed under 0579–0434, have been submitted for approval to the Office of Management and Budget (OMB). When OMB notifies us of its decision, if approval is denied, we will publish a document in the **Federal Register** providing notice of what action we plan to take.

E-Government Act Compliance

The Animal and Plant Health Inspection Service is committed to compliance with the EGovernment Act to promote the use of the Internet and other information technologies, to provide increased opportunities for citizen access to Government information and services, and for other purposes. For information pertinent to E-Government Act compliance related to this final rule, please contact Ms. Kimberly Hardy, APHIS' Information Collection Coordinator, at (301) 851–2727.

List of Subjects in 7 CFR Part 319

Coffee, Cotton, Fruits, Imports, Logs, Nursery stock, Plant diseases and pests, Quarantine, Reporting and recordkeeping requirements, Rice, Vegetables.

Accordingly, we are amending 7 CFR part 319 as follows:

PART 319—FOREIGN QUARANTINE NOTICES

■ 1. The authority citation for part 319 continues to read as follows:

Authority: 7 U.S.C. 450, 7701–7772, and 7781–7786; 21 U.S.C. 136 and 136a; 7 CFR 2.22, 2.80, and 371.3.

■ 2. Section 319.56–2 is amended by adding in alphabetical order a definition of *continental United States* to read as follows:

§ 319.56–2 Definitions.

* * * * *

Continental United States. The 48 contiguous States, Alaska, and the District of Columbia.

* * * * *

■ 3. Section 319.56–73 is added to read as follows:

§ 319.56–73 Peppers From Peru.

Fresh peppers (*Capsicum annum* L., *Capsicum baccatum* L., *Capsicum chinense* Jacq., *Capsicum frutescens* L., and *Capsicum pubescens* Ruiz & Pav.) may be imported into the continental United States and its Territories only under the conditions described in this section. These conditions are designed to prevent the introduction of the following quarantine pests: *Anastrepha fraterculus* (Wiedemann), South American fruit fly; *Ceratitis capitata* (Wiedemann), Mediterranean fruit fly; *Neoleucinodes elegantalis* (Guenée), a fruit boring moth; and *Puccinia pampeana* Speg., a pathogenic fungus that causes pepper and green pepper rust.

(a) *Operational workplan.* The national plant protection organization (NPPO) of Peru must provide an operational workplan to APHIS that details the activities that the NPPO of Peru will, subject to APHIS' approval of the workplan, carry out to meet the requirements of this section. The operational workplan must include and describe the quarantine pest survey intervals and other specific requirements as set forth in this section.

(b) *Commercial consignments.* Peppers from Peru may be imported in commercial consignments only.

(c) *Production site requirements.* (1) Pepper production sites must consist of pest-exclusionary structures, which must have double self-closing doors and have all other windows, openings, and vents covered with 1.6 mm (or less) screening.

(2) All production sites that participate in the export program must be registered with the Peruvian NPPO.

(3) The production sites must be inspected prior to harvest for *Neoleucinodes elegantalis* (Guenée) and *Puccinia pampeana* Speg. If either of these pests, or other quarantine pests, are found to be generally infesting or infecting the production site, the NPPO of Peru will immediately prohibit that production site from exporting peppers to the continental United States and its Territories and notify APHIS of this action. The prohibition will remain in effect until the Peruvian NPPO and APHIS determine that the pest risk has been mitigated.

(4) The production sites must contain traps for the detection of *Anastrepha fraterculus* (Wiedemann) and *Ceratitis capitata* (Wiedemann) both within and around the structures. Internal traps must be set for the duration of the time the production site is used to produce peppers for export to the continental United States or the Territories. External traps must be set for at least 2 months before export and trapping must continue to the end of the harvest as follows:

(i) Traps with an approved protein bait must be placed inside the production site at a density of four traps per hectare, with a minimum of two traps per structure. Traps must be serviced once every 7 days.

(ii) If a single *Anastrepha fraterculus* (Wiedemann) or *Ceratitis capitata* (Wiedemann) is detected inside a registered production site or in a consignment, the registered production site will lose its ability to export peppers to the continental United States or its Territories until APHIS and the Peruvian NPPO mutually determine that risk mitigation is achieved.

(iii) Traps with an approved protein bait must be placed inside a buffer area 500 meters wide around the registered production site, at a density of 1 trap per 10 hectares and a minimum of 10 traps. These traps must be checked at least once every 7 days. At least one of these traps must be near the production site.

(iv) Capture of 0.7 or more *Anastrepha fraterculus* (Wiedemann) or *Ceratitis capitata* (Wiedemann) per trap per week will delay or suspend the harvest, depending on whether harvest has begun, for consignments of peppers from that registered production site until APHIS and the Peruvian NPPO can agree that the pest risk has been mitigated.

(v) The Peruvian NPPO must maintain records of trap placement, checking of traps, and any quarantine pest captures. The Peruvian NPPO must maintain an APHIS-approved quality control program to monitor or audit the trapping program. The trapping records must be maintained for APHIS review.

(d) *Packinghouse procedures.* (1) All packinghouses that participate in the export program must be registered with the Peruvian NPPO.

(2) The peppers must be packed within 24 hours of harvest in a pest-exclusionary packinghouse. The peppers must be safeguarded by an insect-proof mesh screen or plastic tarpaulin while in transit to the packinghouse and while awaiting packing. The peppers must be packed in insect-proof cartons or containers, or covered with insect-proof mesh or plastic tarpaulin, for transit into the continental United States or its Territories. These safeguards must remain intact until arrival in the continental United States or its Territories or the consignment will be denied entry into the continental United States or its Territories.

(3) During the time the packinghouse is in use for exporting peppers to the continental United States or its Territories, the packinghouse may only accept peppers from registered approved production sites.

(e) *Phytosanitary certificate.* Each consignment of peppers must be accompanied by a phytosanitary certificate of inspection issued by the Peruvian NPPO stating that the fruit in the consignment has been produced in accordance with the requirements of the systems approach in 7 CFR 319.56–73.

(Approved by the Office of Management and Budget under control number 0579–0434)

Done in Washington, DC, this 9th day of September 2015.

Michael C. Gregoire,

Associate Administrator, Animal and Plant Health Inspection Service.

BILLING CODE 3410–34–P

SMALL BUSINESS ADMINISTRATION

13 CFR Part 127

RIN 3245–AG72

Women-Owned Small Business Federal Contract Program

AGENCY: U.S. Small Business Administration.

ACTION: Final rule.

SUMMARY: This rule makes changes to the regulations governing the Women-Owned Small Business (WOSB) program. The U.S. Small Business Administration (SBA) is making changes to those regulations to implement section 825 of the National Defense Authorization Act for Fiscal Year 2015. Specifically, this rule implements the authority set forth in section 825 of the 2015 NDAA allowing sole source awards to Women-Owned Small Businesses (WOSBs) or Economically Disadvantaged Women-Owned Small Businesses (EDWOSBs) in appropriate circumstances.

DATES: This rule is effective October 14, 2015.

FOR FURTHER INFORMATION CONTACT: Brenda Fernandez, U.S. Small Business Administration, Office of Policy, Planning & Liaison, 409 Third Street SW., Washington, DC 20416; (202) 205–7337; *brenda.fernandez@sba.gov.*

SUPPLEMENTARY INFORMATION:

I. Background

The WOSB Program, set forth in section 8(m) of the Small Business Act, 15 U.S.C. 637(m), authorizes Federal contracting officers to restrict competition to eligible Women-Owned Small Businesses (WOSBs) or Economically Disadvantaged Women-Owned Small Businesses (EDWOSBs) for Federal contracts in certain industries. Section 8(m) establishes criteria for the WOSB Program, including the eligibility and contract requirements for the program. Congress recently amended the WOSB Program in section 825 of the National Defense Authorization Act for Fiscal Year 2015, Public Law 113–291, 128 Stat. 3292 (December 19, 2014) (2015 NDAA), which included language granting contracting officers the authority to award sole source awards to WOSBs and EDWOSBs and shortening the time period for SBA to conduct a required study to determine the industries in which WOSBs are underrepresented in Federal contracting. In addition, section 825 of the 2015 NDAA created a requirement that a firm be certified as a WOSB or EDWOSB by a Federal Agency, a State government, SBA, or a national certifying entity approved by SBA.

On May 1, 2015, SBA published in the **Federal Register** a proposed rule to implement the sole source authority for WOSBs and EDWOSBs and the revised timeline for SBA to conduct a study to determine the industries in which WOSBs are underrepresented. 80 FR 24846. The rule proposed amendments to Sec. 127.101 to include sole source contracts as a type of contracting assistance available under part 127. The rule also proposed to revise Sec. 127.102 by adding the term "sole source contracts" to the definitions of "EDWOSB requirement" and "WOSB requirement" and establishing that the terms "Substantial underrepresentation" and "Underrepresentation" would be determined by the study to be conducted. The term "sole source contracts" was also a proposed addition to Sec. 127.500, which concerns the industries in which a contracting officer is authorized to restrict competition under the WOSB program. This change to Sec. 127.500 proposed to authorize contracting officers to award sole source contracts in those industries as well. SBA also proposed amendments to Sec. 127.503 to establish the conditions for awarding a sole source contract. Essentially if, after conducting market research in an industry where a WOSB or EDWOSB set-aside is authorized, a contracting officer cannot identify two or more WOSBs or EDWOSBs that can perform at a fair and reasonable price but identifies one WOSB or EDWOSB that can perform at a fair and reasonable price, a contract may be awarded on a sole source basis, provided the value of the contract, including options, does not exceed $6.5 million for manufacturing contracts and $4 million for all other contracts. SBA also proposed to amend Sec. 127.507 to authorize contracting officers to award sole source contracts in the WOSB program if the contract requirement is valued at or below the simplified acquisition threshold. Finally, the rule proposed to amend the protest regulations in Sec. 127.600 to make them consistent with the protest procedures for sole source contracts involving service-disabled veteran owned small business concerns (SDVO SBC) (Sec. 125.24(a) and HUBZone small business concerns (Sec. 126.800(a).

Paragraph (a) of Sec. 127.501 sets out that the agency will designate "the industries in which WOSBs are underrepresented and substantially underrepresented" by NAICS code. However, because paragraph (b) uses the term "disparity" instead, SBA intended to propose a technical amendment to this paragraph to replace that term with "underrepresentation"; such an amendment would make the paragraph consistent with amendments to the definitions and other sections of the WOSB regulations. This purely technical conforming change to Sec. 127.501 is included in this final rule.

As explained in the proposed rule, SBA recognized that the new certification requirement for WOSBs would require a more prolonged rulemaking. Because SBA did not want to delay the implementation of the WOSB sole source authority by combining it with the new certification requirement, SBA did not propose any changes to implement the certification requirement but rather indicated that it

would do so through a separate future rulemaking. SBA received 495 comments on the proposed rule. With the exception of comments which did not set forth any rationale or make suggestions, SBA discusses and responds fully to all the comments below.

II. Summary of Comments

Most of the comments supported the rule. Specifically, most of the comments favored SBA's decision to quickly implement the sole source authority granted by the 2015 NDAA. Many of the commenters noted that they believe this authority and the quick implementation by SBA will help WOSB and EDWOSB businesses, and will put the program on more equal footing with SBA's other socio-economic contracting programs. In addition, the comments supported incorporating the statutory authority for sole source awards into the regulations and suggested no meaningful changes to the proposed regulatory text. As such, this final rule adopts the changes set forth in the proposed rule regarding sole source awards to WOSBs and EDWOSBs.

The second most covered topic in the comments received pertained to the language of the 2015 NDAA requiring the certification of WOSB and EDWOSB firms. As noted above, SBA did not propose to address the certification portion of the 2015 NDAA in the proposed rule because its implementation is more complicated, could not be accomplished by merely incorporating the statutory language into the regulations, and would have delayed the implementation of the sole source authority unnecessarily. In addition, SBA noted in the supplementary information to the proposed rule that there is no evidence that Congress intended to halt the existing WOSB Program until such time as SBA establishes the infrastructure and issues regulations implementing the statutory certification requirement. SBA continues to believe that the new WOSB sole source authority can and should be implemented as quickly as possible, using existing program rules and procedures, while SBA proceeds with development of the certification requirement through a separate rulemaking.

SBA believes that any certification process must be fair, efficient and comprehensive, but should not be burdensome or prevent new WOSBs and EDWOSBs from entering into the Federal marketplace. SBA wants to balance the need to protect the Government and other participants from fraud, with the goal of increasing WOSB and EDWOSB participation in the program. SBA believes that this process should be implemented in a systematic and thoughtful manner, and that increased public participation in the process will help SBA develop the best possible certification program.

The comments pertaining to certification of WOSBs and EDWOSBs were varied and covered a wide range of topics. SBA is in the process of developing its strategy for implementation of the certification language in the 2015 NDAA. SBA will consider the comments relating to certification received in response to this proposed rule when drafting the rule implementing the certification requirement. The certification rulemaking will give the public an opportunity to provide SBA with comments relating to SBA's proposed approach to the certification process and assist SBA in crafting the best possible certification program.

SBA also received several comments on the definitional changes related to the mandatory study to determine the industries in which WOSBs are underrepresented. The comments were generally supportive of SBA's proposed changes. As such, this final rule adopts the proposed changes to the definitions of the terms "Underrepresentation," "Substantial underrepresentation," "EDWOSB requirement," and "WOSB requirement" in § 127.102.

Several comments recommended that all NAICS codes should be available for WOSB and EDWOSB set-asides. Determining the industries in which WOSB and/or EDWOSB contracts are available is outside the scope of this rule. In addition, section 825 of the 2015 NDAA specifically requires the Administrator to conduct a study to identify the industries in which small business concerns owned and controlled by women are underrepresented with respect to Federal procurement contracting in order to determine the industries in which WOSB and/or EDWOSB contracts can be awarded.

III. Compliance With Executive Orders 12866, 12988, 13132, 13563, the Paperwork Reduction Act (44 U.S.C. Ch. 35), and the Regulatory Flexibility Act (5 U.S.C. 601–612)

Executive Order 12866

The Office of Management and Budget (OMB) has determined that this rule does not constitute a significant regulatory action under Executive Order 12866. This is not a major rule under the Congressional Review Act (CRA), 5 U.S.C. 800.

Executive Order 12988

This action meets applicable standards set forth in Sections 3(a) and 3(b)(2) of Executive Order 12988, Civil Justice Reform, to minimize litigation, eliminate ambiguity, and reduce burden. The action does not have retroactive or preemptive effect.

Executive Order 13132

For the purpose of Executive Order 13132, SBA has determined that the rule will not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government. Therefore SBA has determined that this rule has no federalism implications warranting the preparation of a federalism assessment.

Executive Order 13563

A description of the need for this regulatory action, the benefits and costs associated with this action, and any alternatives are included in the Initial Regulatory Flexibility Analysis. In drafting this rule, SBA considered input submitted by three coalitions of women's groups representing women-owned small businesses that support this rule and encourage its quick implementation.

Paperwork Reduction Act, 44 U.S.C., Ch. 35

For the purpose of the Paperwork Reduction Act, SBA has determined that this proposed rule does not impose additional reporting or recordkeeping requirements.

Regulatory Flexibility Act, 5 U.S.C., 601–612

According to the Regulatory Flexibility Act (RFA), when an agency issues a rulemaking, it must prepare a regulatory flexibility analysis to address the impact of the rule on small entities. In accordance with this requirement, SBA has prepared a Final Regulatory Flexibility Analysis addressing the impact of this rule.

1. What are the need for and objective of this final rule?

This final rule is necessary to implement section 825 of the National Defense Authorization Act for Fiscal Year 2015, Public Law 113–291, December 19, 2014, 128 Stat. 3292 (2015 NDAA). Section 825 of the 2015 NDAA included language granting contracting officers the authority to award sole source contracts to Women-Owned Small Businesses (WOSBs) and Economically Disadvantaged Women-

Owned Small Businesses (EDWOSBs). The purpose of this rule is to establish the procedures whereby Federal agencies may award sole source contracts to WOSBs and EDWOSBs and to provide a mechanism to protest such awards. The rule provides an additional tool for Federal agencies to ensure that WOSBs have an equal opportunity to participate in Federal contracting and ensures consistency among SBA's socio-economic small business contracting programs. The objectives of this final rule are to put the WOSB Program on a level playing field with other SBA government contracting programs with sole source authority, and to provide an additional, needed tool for agencies to meet the statutorily mandated 5% prime contracting goal for WOSBs.

Section 825 of the 2015 NDAA also revised the timeline for SBA to conduct a study to determine the industries in which WOSBs are underrepresented. This final rule is necessary to allow SBA to conduct the most reliable and relevant study of WOSB participation in Federal contracting and comply with the new statutorily mandated timeline.

2. What is the legal basis for this final rule?

The legal basis for this final rule is section 825 of the National Defense Authorization Act for Fiscal Year 2015, Public Law 113–291, December 19, 2014, 128 Stat. 3292, which amended section 8(m) of the Small Business Act, 15 U.S.C. 637(m).

3. What is SBA's description and estimate of the number of small entities to which the rule will apply?

The RFA directs agencies to provide a description, and where feasible, an estimate of the number of small business concerns that may be affected by the rule. This final rule establishes a new procurement mechanism to benefit WOSBs. Therefore, WOSBs and EDWOSBs available to compete for Federal contracts under the WOSB Program are the specific group of small business concerns most directly affected by this rule.

SBA searched the Dynamic Small Business Search (DSBS) database and determined that there were approximately 34,000 firms listed as either WOSBs or EDWOSBs under the WOSB Program. In addition, according to the fiscal year 2013 small business goaling report, there were a little over 250,000 actions concerning women-owned small businesses and the total dollar value of those actions was approximately $15 billion. An analysis of the Federal Procurement Data System from April 1, 2011, (the implementation date of the WOSB Program) through January 1, 2013, revealed that there were approximately 26,712 women-owned small business concerns, including 131 EDWOSBs and 388 WOSBs eligible under the WOSB Program, that received Federal contract awards, task or delivery orders, and modifications to existing contracts.

Therefore, this rule could affect a smaller number of EDWOSBs and WOSBs than those eligible under the WOSB Program. We note that the sole source authority can only be used where a contracting officer conducts market research in an industry where a WOSB or EDWOSB set-aside is authorized, and the contracting officer cannot identify two or more WOSBs or EDWOSBs that can perform at a fair and reasonable price, but identifies one WOSB or EDWOSB that can perform. In addition, the sole source authority for WOSBs and EDWOSBs is limited to contracts valued at $6.5 million or less for manufacturing contracts and $4 million or less for all other contracts.

Nonetheless, we believe that this rule may have a significant positive economic impact on EDWOSB concerns competing for Federal contracting opportunities in industries determined by SBA to be underrepresented by WOSB concerns and likewise may positively affect WOSB concerns eligible under the WOSB Program competing in industries determined by SBA to be substantially underrepresented by WOSB concerns, since the sole source authority will still provide greater access to Federal contracting opportunities.

4. What are the projected reporting, recordkeeping, Paperwork Reduction Act, and other compliance requirements?

SBA has determined that this rule does not impose additional reporting or recordkeeping requirements.

5. What relevant federal rules may duplicate, overlap, or conflict with this rule?

SBA has not identified any relevant Federal rules currently in effect that duplicate this rule. The sole source mechanism of the WOSB program will be an addition to the procurement mechanisms available under the existing small business contracting programs that agencies currently administer, such as the HUBZone Program, the Service-Disabled Veteran-Owned (SDVO) Small Business Program, and the 8(a) Business Development Program. The sole source mechanism for WOSBs and EDWOSBs is only authorized where a contracting officer conducts market research in an industry where a WOSB or EDWOSB set aside is authorized, and the contracting officer cannot identify two or more WOSBs or EDWOSBs that can perform at a fair and reasonable price, but identifies one WOSB or EDWOSB that can perform (and so long as the value of the contract, including options, does not exceed $6.5 million for manufacturing contracts and $4 million for all other contracts). Therefore, the addition of the sole source mechanism for WOSBs and EDWOSBs should complement rather than conflict with the goals of existing small business procurement programs.

SBA believes that the Federal Acquisition Regulations (FAR) will need to be amended to include this authority so that there is no conflict between the SBA's rules and the FAR.

6. What significant alternatives did SBA consider that accomplish the stated objectives and minimize and significant economic impact on small entities?

The RFA requires agencies to identify alternatives to the rule in an effort to minimize any significant economic impact of the rule on small entities. The statutory authority for the sole source awards sets forth specific criteria, including dollar value thresholds for the awards. Therefore, the regulations must implement the statutory provisions, and there are no alternatives for these regulations.

List of Subjects in 13 CFR Part 127

Government contracts, Reporting and recordkeeping requirements, Small businesses.

Accordingly, for the reasons stated in the preamble, SBA amends 13 CFR part 127 as follows:

PART 127—WOMEN-OWNED SMALL BUSINESS FEDERAL CONTRACT PROGRAM

■ 1. The authority for part 127 continues to read as follows:

Authority: 15 U.S.C. 632, 634(b)(6), 637(m), and 644.

■ 2. Revise § 127.101 to read as follows:

§ 127.101 What type of assistance is available under this part?

This part authorizes contracting officers to restrict competition or award sole source contracts or orders to eligible Economically Disadvantaged Women-Owned Small Businesses (EDWOSBs) for certain Federal contracts or orders in industries in which the Small Business Administration (SBA) determines that WOSBs are underrepresented in Federal

procurement. It also authorizes contracting officers to restrict competition or award sole source contracts or orders to eligible WOSBs for certain Federal contracts or orders in industries in which SBA determines that WOSBs are substantially underrepresented in Federal procurement and has waived the economically disadvantaged requirement.

■ 3. Amend § 127.102 by revising the definitions of the terms "EDWOSB requirement", "Substantial underrepresentation", "Underrepresentation", and "WOSB requirement" to read as follows:

§ 127.102 What are the definitions of the terms used in this part?

* * * * *

EDWOSB requirement means a Federal requirement for services or supplies for which a contracting officer has restricted competition or awarded a sole source contract or order to eligible EDWOSBs, including Multiple Award Contracts, partial set-asides, reserves, sole source awards, and orders set aside for EDWOSBs issued against a Multiple Award Contract.

* * * * *

Substantial underrepresentation is determined by a study using a reliable and relevant methodology.

* * * * *

Underrepresentation is determined by a study using a reliable and relevant methodology.

* * * * *

WOSB requirement means a Federal requirement for services or supplies for which a contracting officer has restricted competition or awarded a sole source contract or order to eligible WOSBs, including Multiple Award Contracts, partial set-asides, reserves, sole source awards, and orders set aside for WOSBs issued against a Multiple Award Contract.

■ 4. Revise § 127.500 to read as follows:

§ 127.500 In what industries is a contracting officer authorized to restrict competition or make a sole source award under this part?

A contracting officer may restrict competition or make a sole source award under this part only in those industries in which SBA has determined that WOSBs are underrepresented or substantially underrepresented in Federal procurement, as specified in § 127.501.

§ 127.501 [Amended]

■ 5. Amend § 127.501 by removing the word "disparity" in the two places where it appears in paragraph (b) and adding the word "underrepresentation" in its place.

■ 6. Amend § 127.503 as follows:

■ a. Revise the section heading;

■ b. Revise paragraph (a) subject heading and paragraph (b) subject heading;

■ c. Redesignate paragraphs (c), (d), (e) and (f) as paragraphs (e), (f), (g) and (h); and

■ d. Add new paragraphs (c) and (d).

The revisions and additions read as follows:

§ 127.503 When is a contracting officer authorized to restrict competition or award a sole source contract or order under this part?

(a) *Competition restricted to EDWOSBs.* * * *

(b) *Competition restricted to WOSBs.* * * *

(c) *Sole source awards to EDWOSBs.* For requirements in industries designated by SBA as underrepresented pursuant to § 127.501, a contracting officer may issue a sole source award to an EDWOSB when the contacting officer determines that:

(1) The EDWOSB is a responsible contractor with respect to performance of the requirement and the contracting officer does not have a reasonable expectation that 2 or more EDWOSBs will submit offers;

(2) The anticipated award price of the contract (including options) will not exceed $6,500,000 in the case of a contract assigned a North American Industry Classification System (NAICS) code for manufacturing, or $4,000,000 in the case of any other contract opportunity; and

(3) In the estimation of the contracting officer, the award can be made at a fair and reasonable price.

(d) *Sole source awards to WOSBs.* For requirements in industries designated by SBA as substantially underrepresented pursuant to § 127.501, a contracting officer may issue a sole source award to a WOSB when the contacting officer determines that:

(1) The WOSB is a responsible contractor with respect to performance of the requirement and the contracting officer does not have a reasonable expectation that 2 or more WOSBs will submit offers;

(2) The anticipated award price of the contract (including options) will not exceed $6,500,000 in the case of a contract assigned a NAICS code for manufacturing, or $4,000,000 in the case of any other contract opportunity; and

(3) In the estimation of the contracting officer, the award can be made at a fair and reasonable price.

* * * * *

■ 7. Revise § 127.507 to read as follows:

§ 127.507 Are there EDWOSB and WOSB contracting opportunities at or below the simplified acquisition threshold?

If the requirement is valued at or below the simplified acquisition threshold, the contracting officer may set aside the requirement or award the requirement on a sole source basis as set forth in § 127.503.

■ 8. Revise § 127.600 to read as follows:

§ 127.600 Who may protest the status of a concern as an EDWOSB or WOSB?

(a) *For sole source procurements.* SBA or the contracting officer may protest the proposed awardee's EDWOSB or WOSB status.

(b) *For all other EDWOSB or WOSB requirements.* An interested party may protest the apparent successful offeror's EDWOSB or WOSB status.

Maria Contreras-Sweet,

Administrator.

BILLING CODE 8025–01–P

COMMODITY FUTURES TRADING COMMISSION

17 CFR Part 170

RIN 3038–AE09

Membership in a Registered Futures Association

AGENCY: Commodity Futures Trading Commission.

ACTION: Final rule.

SUMMARY: The Commodity Futures Trading Commission ("Commission" or "CFTC") is adopting a new rule ("Final Rule") to require that all persons registered with the Commission as introducing brokers ("IB"), commodity pool operators ("CPO"), or commodity trading advisors ("CTA"), subject to an exception for those persons who are exempt from registration as a CTA pursuant to a particular provision of the Commission's regulations, must, in each case, become and remain a member of at least one registered futures association ("RFA").

DATES: The Final Rule will become effective November 13, 2015. All persons subject to the Final Rule must comply with the Final Rule by not later than December 31, 2015.

FOR FURTHER INFORMATION CONTACT: Katherine Driscoll, Associate Chief

Counsel, 202–418–5544, *kdriscoll@cftc.gov;* or Jacob Chachkin, Special Counsel, 202–418–5496, *jchachkin@cftc.gov,* Division of Swap Dealer and Intermediary Oversight, Commodity Futures Trading Commission, Three Lafayette Centre, 1155 21st Street NW., Washington, DC 20581.

SUPPLEMENTARY INFORMATION:

I. Background

Part 170 of the Commission's regulations relates to RFAs. An RFA is an association of persons registered with the Commission as such pursuant to Section 17 of the Commodity Exchange Act ("CEA" or "Act").[1] Subject to Commission oversight, RFAs serve a vital self-regulatory role by functioning as frontline regulators of their members (which members also remain subject to Commission oversight).

An RFA cannot enforce its rules over Commission registrants who are not members of the RFA.[2] As such, the Commission promulgated regulations 170.15 and 170.16 to require each registered futures commission merchant ("FCM"), and each registered swap dealer ("SD") and major swap participant ("MSP"), respectively, to be an RFA member, subject to an exception for certain notice registered securities brokers or dealers.[3] Because the National Futures Association ("NFA") was the only RFA under Section 17(a) of the CEA[4] at the time § 170.15 and § 170.16, respectively, were promulgated, these registered FCMs, SDs, and MSPs were required to be NFA members and, thus, were subject to NFA's rules. The Commission did not promulgate regulations requiring other Commission registrants, including IBs,[5] CPOs,[6] and CTAs,[7] to be members of an RFA. One of the NFA rules to which NFA members are subject, however, is NFA's Bylaw 1101. NFA Bylaw 1101 requires that, generally, no NFA member may "carry an account, accept an order or handle a transaction in commodity futures contracts" for, or on behalf of, any non-member of NFA that is required to be registered with the Commission as, among other things, an IB, CPO, or CTA.[8] Accordingly, any IB, CPO, or CTA required to be registered with the Commission that desires to conduct business with respect to commodity futures contracts directly with an FCM that is an NFA member must also become an NFA member, and derivatively, must ensure that it only conducts such business with those IBs, CPOs, or CTAs that also are NFA members. Therefore, § 170.15, at the time it was promulgated, operated in conjunction with NFA Bylaw 1101 "to assure essentially complete NFA membership from the universe of commodity professionals: [FCMs, CPOs, CTAs, and IBs]."[9]

Title VII of the Dodd-Frank Wall Street Reform and Consumer Protection Act ("Dodd-Frank Act") amended the

[1] 7 U.S.C. 21.

[2] Those Commission registrants that are not RFA members are nevertheless subject to the rules and regulations of the Commission. *See* 7 U.S.C. 21(e), which specifies that any person registered under the CEA, who is not an RFA member, "in addition to the other requirements and obligations of [the CEA] and the regulations thereunder shall be subject to such other rules and regulations as the Commission may find necessary to protect the public interest and promote just and equitable principles of trade."

[3] 17 CFR 170.15 and 170.16. *See also* Registration of Swap Dealers and Major Swap Participants, 77 FR 2613 (Jan. 19, 2012).

[4] 7 U.S.C. 21(a). NFA remains the only RFA under Section 17(a) of the CEA and is also a self-regulatory organization ("SRO"). Per Commission regulation 1.3(ee), SROs are designated contract markets, swap execution facilities, and registered futures associations. 17 CFR 1.3(ee). Certain SROs maintain and update, among other things, a standardized audit program and coordinate audit and financial statement surveillance activities over certain types of firms that are members of more than one SRO. *See* 17 CFR 1.52.

[5] IB is defined, subject to certain exclusions and additions, in CEA Section 1a(31) as any person (except an individual who elects to be and is registered as an associated person of a futures commission merchant) (i) who (I) is engaged in soliciting or in accepting orders for (aa) the purchase or sale of any commodity for future delivery, security futures product, or swap; (bb) any agreement, contract, or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i); (cc) any commodity option authorized under Section 4c; or (dd) any leverage transaction authorized under Section 19; and (II) does not accept any money, securities, or property (or extend credit in lieu thereof) to margin, guarantee, or secure any trades or contracts that result or may result therefrom; or (ii) who is registered with the Commission as an IB. 7 U.S.C. 1a(31).

IB is further defined, subject to certain exclusions and additions, in Commission regulation 1.3(mm) as (1) Any person who, for compensation or profit, whether direct or indirect: (i) Is engaged in soliciting or in accepting orders (other than in a clerical capacity) for the purchase or sale of any commodity for future delivery, security futures product, or swap; any agreement, contract or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i) of the Act; any commodity option transaction authorized under Section 4c; or any leverage transaction authorized under Section 19; or who is registered with the Commission as an IB; and (ii) Does not accept any money, securities, or property (or extend credit in lieu thereof) to margin, guarantee, or secure any trades or contracts that result or may result therefrom. 17 CFR 1.3(mm).

IBs are subject to registration with the Commission under CEA Section 4d(g) and Commission regulation 3.4(a). 7 U.S.C. 6d(g) and 17 CFR 3.4(a).

[6] CPO is defined, subject to certain exclusions and additions, in CEA Section 1a(11) as any person (i) engaged in a business that is of the nature of a commodity pool, investment trust, syndicate, or similar form of enterprise, and who, in connection therewith, solicits, accepts, or receives from others, funds, securities, or property, either directly or through capital contributions, the sale of stock or other forms of securities, or otherwise, for the purpose of trading in commodity interests, including any (I) commodity for future delivery, security futures product, or swap; (II) agreement, contract, or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i); (III) commodity option authorized under Section 4c; or (IV) leverage transaction authorized under Section 19; or (ii) who is registered with the Commission as a CPO. 7 U.S.C. 1a(11).

CPO is further defined, subject to certain exclusions and additions, in Commission regulation 1.3(cc) as any person engaged in a business which is of the nature of a commodity pool, investment trust, syndicate, or similar form of enterprise, and who, in connection therewith, solicits, accepts, or receives from others, funds, securities, or property, either directly or through capital contributions, the sale of stock or other forms of securities, or otherwise, for the purpose of trading in commodity interests, including any commodity for future delivery, security futures product, or swap; any agreement, contract or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i) of the Act; any commodity option authorized under Section 4c of the Act; any leverage transaction authorized under Section 19 of the Act; or any person who is registered with the Commission as a CPO, but does not include such persons not within the intent of the definition as the Commission may specify by rule or regulation or by order. 17 CFR 1.3(cc).

CPOs are subject to registration with the Commission under CEA Section 4m and Commission regulation 3.4(a). 7 U.S.C. 6m and 17 CFR 3.4(a).

[7] CTA is defined, subject to certain exclusions and additions, in CEA Section 1(a)(12) as any person who (i) for compensation or profit, engages in the business of advising others, either directly or through publications, writings, or electronic media, as to the value of or the advisability of trading in (I) any contract of sale of a commodity for future delivery, security futures product, or swap; (II) any agreement, contract, or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i); (III) any commodity option authorized under Section 4c; or (IV) any leverage transaction authorized under Section 19; (ii) for compensation or profit, and as part of a regular business, issues or promulgates analyses or reports concerning any of the activities referred to in clause (i); (iii) is registered with the Commission as a CTA; or (iv) the Commission, by rule or regulation, may include if the Commission determines that the rule or regulation will effectuate the purposes of the Act. 7 U.S.C. 1a(12).

CTA is further defined, subject to certain exclusions and additions, in Commission regulation 1.3(bb) as any person who, for compensation or profit, engages in the business of advising others, either directly or through publications, writings or electronic media, as to the value of or the advisability of trading in any contract of sale of a commodity for future delivery, security futures product, or swap; any agreement, contract or transaction described in Section 2(c)(2)(C)(i) or Section 2(c)(2)(D)(i) of the Act; any commodity option authorized under Section 4c of the Act; any leverage transaction authorized under Section 19 of the Act; any person registered with the Commission as a CTA; or any person, who, for compensation or profit, and as part of a regular business, issues or promulgates analyses or reports concerning any of the foregoing. 17 CFR 1.3(bb).

CTAs are subject to registration with the Commission under CEA Section 4m and Commission regulation 3.4(a). 7 U.S.C. 6m and 17 CFR 3.4(a).

[8] NFA Bylaw 1101 is available at: *http://www.nfa.futures.org/nfamanual/NFAManual.aspx?RuleID=BYLAW%201101&Section=3.*

[9] Futures Associations: Futures Commission Merchants: Mandatory Membership, 48 FR 26304, 26306 and n.22 (June 7, 1983).

CEA to establish a comprehensive new regulatory framework for swaps and security-based swaps.[10] The new regulatory framework provides that, among other things, persons that engage in regulated activity with respect to swaps will be required to register with the Commission as IBs, CPOs, or CTAs, as appropriate. Because of these definitional amendments, the intersection of § 170.15 and NFA Bylaw 1101 no longer assures NFA membership for IBs, CPOs, or CTAs that are required to register with the Commission because, as noted above, NFA Bylaw 1101 relates only to commodity futures contracts.[11]

II. Proposed Rule

On November 8, 2013, the Commission proposed to amend part 170 by adding § 170.17, which would, if adopted, have required each IB, CPO, and CTA registered with the Commission to become and remain a member of at least one RFA ("Proposal").[12]

In the Proposal, the Commission specifically solicited comments regarding, among other things, the impact of the Proposal on CTAs that are registered with the Commission despite being eligible to rely on the exemption from registration set forth in Commission regulation 4.14(a)(9) ("§ 4.14(a)(9) Exempted CTAs").[13] Regulation 4.14(a)(9) provides that a person is not required to register with the Commission as a CTA if it does not: (i) Direct any client accounts; or (ii) provide commodity trading advice based on, or tailored to, the commodity interest or cash market positions or other circumstances or characteristics of particular clients.[14] When the Commission promulgated regulation 4.14(a)(9), it stated that "[a] CTA exempt under rule 4.14(a)(9) that wishes to apply for registration or retain its current registration may do so."[15] Therefore, CTAs that may avail themselves of the exemption from registration in regulation 4.14(a)(9) may be currently registered with the Commission and may so register in the future.

The comment period for the Proposal ended on January 7, 2014.[16] The Commission received two substantive comments in response to the Proposal[17] and, in consideration of those comments, is adopting the Proposal subject to certain changes, as noted below.

III. Summary of Comments

In response to the Proposal, the Commission received two substantive comments, one from NFA and one from James W. Lovely, Esq. ("Lovely"),[18] Both comments related to the impact of the Proposal on CTAs. No comments were received in response to the CPO and IB aspects of the Proposal.

A. NFA Comment

NFA supported the Proposal as an appropriate and effective way to require IBs, CPOs, and CTAs engaging in swaps activities that otherwise are not captured by the intersection of NFA Bylaw 1101 or NFA Compliance Rule 2–36[19] to become and remain NFA members, and comply with the applicable NFA requirements. However, NFA recommended that the Commission exclude § 4.14(a)(9) Exempted CTAs from the Proposal. In support of its position, NFA stated that its existing rules focus primarily on an intermediary's conduct with respect to clients and thus have little applicability to CTAs that do not direct client accounts or otherwise exercise discretion (*i.e.*, § 4.14(a)(9) Exempted CTAs).

B. Lovely Comment

Conversely, Lovely generally stated that the Proposal "while well-intentioned, is ill-founded in many respects" and argued that the costs associated with further requiring registered CTAs to become and remain RFA members would be disproportionate to any regulatory benefit.

Lovely discussed those CTAs that register with the Commission even though they may not be required to so register (*e.g.*, because they may avail themselves of a registration exception or exclusion provided under Commission regulation 4.14(a) or Sections 1a(12)(B) or 4m(1) of the CEA, respectively). According to Lovely, these CTAs register for legal comfort in light of the "practical ambiguities around concepts [related to CTA registration requirements] such as 'solely incidental', 'principal business or profession', 'holding out' and 'tailored advice'" but do not have to become NFA members, so long as such CTAs do not manage or exercise discretion over customer accounts or funds.[20] He argues that these CTAs' voluntary registration benefits the CFTC and that such persons will likely deregister if the Commission adopts the Proposal.[21]

Lovely further stated that the CFTC "significantly underestimates the cost of NFA [membership]" for these CTAs who are not currently required to become NFA members. He noted that most of such CTAs "have only incidental involvement with commodity interests" and, if required to become NFA members, "would need to retain external legal counsel or compliance consultants to try to ascertain [which NFA rules] apply to their activities and, if so, how to comply with the same." Notwithstanding that Lovely argues that many NFA rules are not applicable to such CTAs,[22] he estimates that "external

[10] Dodd-Frank Wall Street Reform and Consumer Protection Act, Pub. L. 111–203, 124 Stat. 1376 (2010).

[11] For example, as noted in the Proposal, currently Commission-registered CTAs, CPOs, and IBs engaging solely in swap-related activities are not captured by the intersection of § 170.15 and NFA Bylaw 1101 and, thus, are not required to be NFA members. As such, these registrants, to the extent that they have not voluntarily become NFA members, are not being supervised in the same manner as Commission registrants engaging in similar activities relating to commodity futures contracts, which registrants are effectively required to be NFA members.

[12] *See* Membership in a Registered Futures Association, 78 FR 67078 (Nov. 8, 2013).

[13] 78 FR 67080 (Nov. 8, 2013).

[14] 17 CFR 4.14(a)(9). This exemption from CTA registration generally pertains to persons only providing advice to the general public, such as in a newsletter, and not to specific clients.

[15] *See* Exemption from Registration as a Commodity Trading Advisor, 65 FR 12938, 12941 (March 10, 2000).

[16] The Proposal inaccurately stated the comment period ended on January 17, 2014. To reflect the accurate date, the **Federal Register** published a correction that the comment period ended on January 7, 2014. *See* 78 FR 67985 (Nov. 13, 2013). Nonetheless, the Commission considered all comments received by January 17, 2014.

[17] *See http://comments.cftc.gov/PublicComments/CommentList.aspx?id=1424.*

[18] NFA Comment Letter and James Lovely, Esq. Comment Letter.

[19] Clause (d) of NFA Compliance Rule 2–36 applies to forex transactions and requires that no NFA member carry a forex account for, accept a forex order or account from, handle a forex transaction for or on behalf of, receive compensation (directly or indirectly) for forex transactions from, or pay compensation (directly or indirectly) for forex transactions to any non-member of NFA, or suspended member, that is required to be registered with the Commission as, among other things, an FCM, IB, CPO, or CTA in connection with its forex activities. NFA Compliance Rule 2–36 is available at: *http://www.nfa.futures.org/nfamanual/NFAManual.aspx?RuleID=RULE%202-36&Section=4.*

[20] Presumably Lovely means that such CTAs would not be captured by the intersection of § 170.15 and NFA Bylaw 1101.

[21] In this regard, Lovely also asserted that if the Commission adopts the Proposal, the First Amendment rights of these CTAs could be jeopardized, and, in some cases, such CTAs may drop their CFTC registration entirely "in reliance on . . . [their] commercial free speech rights under the U.S. Constitution."

[22] Lovely provided a non-exhaustive list of what he believes to be inapposite NFA member rules including rules regarding: (1) Account opening, risk disclosure and trading authority; (2) bunched orders and order allocation; (3) suitability or churning security futures products; (4) CTA program and performance disclosure for managed accounts or

legal and compliance assistance . . . could easily cost [such a CTA] $15,000.00 to $20,000.00 per year."

IV. Final Rule

The Commission, in consideration of the comments received by it on the Proposal, is adopting the Proposal but excluding § 4.14(a)(9) Exempted CTAs from the Final Rule.[23] The Final Rule will help ensure the integrity of the swaps and futures market and its participants by subjecting all registered IBs, CPOs, and CTAs, except for § 4.14(a)(9) Exempted CTAs, to NFA's developed set of rules and oversight capabilities.[24] As such, the Commission believes that the markets are better served, and the public better protected, by having persons subject to the requirements of the Final Rule become RFA members.[25]

After considering the comments, the Commission is persuaded by Lovely and NFA that NFA's rules have little applicability to § 4.14(a)(9) Exempted CTAs and, thus, there would be little benefit from requiring § 4.14(a)(9) Exempted CTAs to become and remain RFA members.

The Commission, however, is not persuaded that other registered CTAs, regardless of whether such CTAs are required to register with the Commission, should be excluded from the requirements of the Final Rule. Any registered CTA that does not meet the requirements of § 4.14(a)(9) would, by definition, be engaged in either (i) directing client accounts, or (ii) providing commodity trading advice based on, or tailored to, the commodity interest or cash market positions or other circumstances or characteristics of particular clients. As noted above, and consistent with § 170.15, the Commission believes that RFA supervision of registered CTAs engaging in these activities is beneficial to the markets and the clients of such CTAs.

In addition, the Commission believes that Lovely's cost estimates are very high for retaining advisors in relation to NFA's rules. Assuming a CTA was to contact an attorney familiar with Commission regulations and NFA rules applicable to CTAs, the Commission believes that determining which NFA rules are applicable to such a CTA would be a routine task that would not take a substantial amount of time.[26]

Furthermore, with respect to those CTAs that opt into CFTC registration to avoid making determinations as to their activities in relation to their eligibility for the exceptions or exclusions from the CTA registration requirements noted in Lovely's comments, such persons should review available guidance from the Commission and consult with their advisors and Commission staff, as necessary, to determine if registration is required.[27]

In support of the Final Rule, Section 4p of the CEA authorizes the Commission to "specify by rules and regulations appropriate standards with respect to training, experience, and such other qualifications as the Commission finds necessary or desirable to insure the fitness of persons required to be registered with the Commission." [28]

The Final Rule also provides a means for assuring that the purpose of Section 17(m) of the CEA,[29] allowing for compulsory RFA membership, is achieved.[30] The Commission believes that the Final Rule is reasonably necessary and desirable to effectuate comprehensive and effective market oversight by NFA in its capacity as an SRO. As the only RFA, NFA serves as the frontline regulator of its members, subject to Commission oversight. Without such mandatory membership in NFA or another RFA, effective implementation of the programs required by Section 17 of the CEA and NFA's self-regulatory programs could be impeded.[31]

In summary, by mandating RFA membership by each registered IB, CPO, and CTA, except § 4.14(a)(9) Exempted CTAs, the Final Rule enables the Commission to further ensure the fitness, and provide for direct NFA oversight, of these Commission registrants.

V. Administrative Compliance

A. Paperwork Reduction Act

The Paperwork Reduction Act of 1995 ("PRA") [32] imposes certain requirements on Federal agencies, including the Commission, in connection with their conducting or sponsoring any collection of information, as defined by the PRA. An agency may not conduct or sponsor, and a registered entity is not required to respond to, a collection of information unless it displays a currently valid control number by the Office of Management and Budget ("OMB").

In connection with the Proposal, the Commission anticipated that, if adopted, the Final Rule would simply require an amendment to the number of respondents included in OMB Collection 3038–0023.[33] The basis for this preliminary finding was that, at the time of the Proposal, NFA had indicated that certain CPOs, CTAs, and IBs were registered with the Commission, but not NFA members. Therefore, because registration and membership require the filing of Form 7–R, the Commission initially believed these respondents' paperwork burden would have been affected by the Proposal.

As discussed above, the Final Rule does not require IBs, CPOs, or CTAs to

---

pools; (5) solicitation and execution of customer orders; (6) disaster recovery protocols (other than in connection with CFTC mandated record retention); (7) trading programs, performance and related promotional materials; (8) anti-money laundering; and (9) quarterly reporting of assets under management, trading programs, performance, carrying brokers and the like.

[23] Notwithstanding this exclusion, if a person is a § 4.14(a)(9) Exempted CTA and registered as an IB or CPO, then such person shall still be subject to the requirements of the Final Rule in its capacity as a registered IB or CPO, as the case may be.

[24] The Commission notes that, as a result of the Final Rule, any person not required to register, and not registered, with the CFTC would not subsequently become subject to any NFA-imposed requirement unless such person voluntarily elects to become so registered. Any adverse financial, commercial, or other impact, including the potential chilling effect on free speech, which could result from the Final Rule for such CTAs, could be avoided simply by relying on the proper regulatory exclusion or exemption without having to even incur the cost of filing a notice with the CFTC or NFA.

[25] This is consistent with the Commission's rationale for § 170.15; that there should be essentially complete NFA membership from the universe of commodity professionals. *See supra* at n.10.

[26] As noted above, Lovely himself refers to many of these rules as "inapposite." Such a description belies Lovely's argument that any substantial legal review would be required to determine whether NFA rules would apply to one of the CTAs about which Lovely comments.

Moreover, the Commission believes the costs of compliance review in subsequent years would be significantly less than the initial review costs, because it is likely that only the changes to NFA rules that took place during the prior year would need to be considered.

[27] The Commission notes that it is not of the view that making such a definitive determination is impossible or exceedingly difficult, as Lovely's comment suggests. However, the Commission does recognize that, once this determination has been made, and depending on the determination, a Commission registrant may need time to review and possibly reorganize its business in order to ensure its compliance with NFA's rules or undertake the deregistration process, as the case may be. Therefore, the Commission is providing the extended compliance period described in the DATES section above.

[28] 7 U.S.C. 6p. Also, Section 8a(5) of the CEA authorizes the Commission "to make and promulgate such rules and regulations as, in the judgment of the Commission, are reasonably necessary to effectuate any of the provisions or to accomplish any of the purposes" of the CEA.

[29] 7 U.S.C. 21(m).

[30] *See* Futures Associations: Futures Commission Merchants: Mandatory Membership, 48 FR 26304 (June 7, 1983).

[31] The Commission notes that in addition to the authority discussed herein, as noted previously, CPOs and CTAs are subject to registration with the Commission under Section 4m of the CEA, and IBs are subject to such registration under Section 4d(g) of the CEA. 7 U.S.C. 6m and 6d(g).

[32] 44 U.S.C. 3501 *et seq.*

[33] *See* OMB Control No. 3038–0023, *http://www.reginfo.gov/public/do/PRAOMBHistory?ombControlNumber=3038-0023.*

register with the Commission. Rather, the Final Rule only requires that certain of such persons that register with the Commission *become and remain an NFA member.* To indicate NFA membership an applicant needs to "check a box" on Form 7–R.[34] Current OMB Collection 3038–0023 captures the burdens associated with the registration process for these persons, including the filing of and updating of Form 7–R for registration purposes. Therefore, to comply with the Final Rule, such registrants that are not NFA members, would be required to "check-the-box" on Form 7–R indicating their status as an NFA member.

Accordingly, because the burden associated with updating Form 7–R is currently captured in OMB Collection 3038–0023, and those persons who are directly impacted by the Final Rule are either currently registered with the Commission (*i.e.,* have already filed a Form 7–R) or will be required to file a Form 7–R in connection with their registration with the Commission, no adjustment is necessary to take into account the number of Commission registrants who will have to become NFA members as a result of the Final Rule. Further, the Commission believes the additional burden of "checking the box" on Form 7–R to be non-substantive. Therefore, upon further review and for the reasons stated above, the Final Rule does not require amending existing OMB Collection 3038–0023.[35]

B. Regulatory Flexibility Act

The Regulatory Flexibility Act[36] requires federal agencies, in promulgating regulations, to consider the impact of those regulations on small entities. In the Proposal, the Commission certified that the Proposal would not have a significant economic impact on a substantial number of small entities.

1. CPOs

The Commission has previously determined that CPOs are not small entities for purposes of the Regulatory Flexibility Act.[37] Accordingly, the Chairman, on behalf of the Commission, hereby certifies pursuant to 5 U.S.C. 605(b) that the Final Rule will not have a significant economic impact on a substantial number of small entities with respect to CPOs.

2. IBs and CTAs

The Commission has previously determined to evaluate within the context of a particular rule proposal whether all or some IBs or CTAs should be considered to be small entities and, if so, to analyze the economic impact on them of any such rule.[38]

Since there may be some small entities that are IBs or CTAs and would be required to become NFA members, the Commission has considered whether this rulemaking would have a significant economic impact on these entities.

The Final Rule requires all IBs and CTAs, except § 4.14(a)(9) Exempt CTAs, who register with the Commission to become RFA members. This would require such IBs and CTAs to pay membership dues, "check a box" on Form 7–R, and ensure that they are prepared for an NFA audit.[39] As noted in the Proposal, the Commission is of the view that any costs associated with preparing for an audit by the NFA should not be substantially different from, or significantly exceed, the costs associated with preparing for an audit by the Commission, which every registered person would already be responsible to do.[40] Moreover, because the Final Rule only pertains to Commission Registrants, any audit related costs incident to NFA membership would be negligible, and should not have a significant economic impact on IBs or CTAs that may be small entities. The Commission also stated its preliminary belief that NFA membership would impose few additional compliance costs on affected entities, because these entities are already subject to the majority of regulations that NFA enforces, whether or not they are NFA members. The Commission specifically requested comment on any additional compliance costs beyond those an entity would face as a result of it being registered with the Commission.

a. Comments on Costs to CTAs

In response to the Proposal, a comment from Lovely stated that most CTAs that opt into CFTC registration and do not manage or exercise discretion over customer accounts or funds are "small or one-person operations or may have only incidental involvement with commodity interests." Further, Lovely asserts that, although many of NFA's rules are not relevant to such CTAs, the Commission understates the cost of required NFA membership, including that the costs to these CTAs of reviewing and complying with such rules would be approximately $15,000 to $20,000 annually.

As discussed above, the Commission believes that Lovely's compliance cost estimates are very high. Rather, the Commission believes that the costs faced by a CTA would, at most, be approximately $2,950 in the first year and $1,476 in subsequent years.[41] The Commission does not believe that these amounts plus the $750 membership dues required of all NFA members that are CTAs, results in an unreasonable burden on any CTAs (including those that may be small entities under the Regulatory Flexibility Act).[42] Further, as

[34] The Commission has designated NFA to receive Form 7–R submissions on its behalf. The Commission notes that application for NFA membership is incorporated in Form 7–R.

[35] The Commission further believes that many Commission registrants' recordkeeping obligations associated with preparing for an NFA audit are already covered by other OMB control numbers. For example, §§ 4.23 and 4.33 of the Commission's regulations are recordkeeping requirements associated with registered CPOs and CTAs, respectively, which are covered by OMB control number 3038–0005.

[36] 5 U.S.C. 601 *et seq.*

[37] Policy Statement and Establishment of Definitions of "Small Entities" for Purposes of the Regulatory Flexibility Act, 47 FR 18618, 18619 (Apr. 30, 1982).

[38] *See,* with respect to CTAs, 47 FR at 18620 (Apr. 30, 1982); and *see,* with respect to IBs, Introducing Brokers and Associated Persons of Introducing Brokers, Commodity Trading Advisors and Commodity Pool Operators; Registration and Other Regulatory Requirements, 48 FR 35276 (Aug. 3, 1983).

[39] *See* 78 FR 67083 (Nov. 8, 2013). As stated in the booklet titled "NFA Regulatory Requirements: For FCMs, IBs, CPOs, and CTAs," NFA audits have two major objectives: (1) To determine whether the firm is maintaining records in accordance with NFA rules and applicable CFTC regulations; and (2) to ensure that the firm is being operated in a professional manner and that customers are protected against unscrupulous activities and fraudulent or high-pressure sales practices.

[40] As noted above, the Commission believes that many of the recordkeeping obligations associated with preparing for an NFA audit are already required for Commission registrants. Moreover, given the average periodicity for NFA audits, the magnitude of annual audit-related costs is limited.

[41] This estimate is based on the following labor estimates for this determination: for the first year, 6 hours of an attorney; in subsequent years, 3 hours of an attorney, in each case at approximately $492.21/hour. The estimate of the hourly cost is from the Securities Industry and Financial Markets Association's Report on Management and Professional Earnings in the Securities Industry—2013, modified by CFTC staff to account for an 1800-hour work-year and multiplied by 5.35 to account for firm size, employee benefits, and overhead. The Commission believes that the use of this multiplier is appropriate here because the Commission is assuming that persons retain outside advisors to assist in complying with NFA rules. The Commission rounds to two significant digits.

[42] Assuming that IBs would face similar compliance costs as CTAs, the Commission does not believe that these costs result in an unreasonable burden on any IBs (including those that may be small entities under the Regulatory Flexibility Act). Further, as of June 30, 2015, all registered IBs that are not members of NFA are pending withdrawal of their Commission registration. Accordingly, the Commission believes that no currently registered IBs will be impacted by this rule.

discussed above, § 4.14(a)(9) Exempted CTAs (*i.e.*, those CTAs that neither manage nor exercise discretion over customer accounts or funds and that do provide clients advice described in § 4.14(a)(9)(ii)) will not be required to become or remain RFA members pursuant to the Final Rule and, thus, will not face any compliance costs from the Final Rule.

b. Commission Determination

Accordingly, for the reasons stated above, the Commission believes that the Final Rule will not have a significant economic impact on a substantial number of small entities. Therefore, the Chairman, on behalf of the Commission, hereby certifies, pursuant to 5 U.S.C. 605(b), that the Final Rule being published today by this **Federal Register** release will not have a significant economic impact on a substantial number of small entities.

C. Considerations of Costs and Benefits

Section 15(a) of the CEA requires the Commission to consider the costs and benefits of its actions before promulgating a regulation under the CEA or issuing an order. Section 15(a) further specifies that the costs and benefits shall be evaluated in light of the following five broad areas of market and public concern: (1) Protection of market participants and the public; (2) efficiency, competitiveness, and financial integrity of futures markets; (3) price discovery; (4) sound risk management practices; and (5) other public interest considerations. The Commission considers the costs and benefits resulting from its discretionary determinations with respect to the section 15(a) factors.

1. Background

As discussed above, the Dodd-Frank Act amended the CEA to establish a comprehensive new regulatory framework for swaps markets and, in doing so, required IBs, CPOs, and CTAs acting in relation to swaps to register with the Commission. These newly registered persons, however, are not currently required to become NFA members because, as discussed above, they are not captured by the intersection of § 170.15 and NFA Bylaw 1101.

NFA cannot enforce its rules over Commission registrants who do not become NFA members, including IBs, CPOs, and CTAs active solely in relation to swap transactions, which are not currently required to become NFA members. Thus, the Final Rule requires registered IBs, CPOs, and CTAs, except § 4.14(a)(9) Exempted CTAs, to become NFA members similarly to how § 170.15 presently requires FCMs to become NFA members and how § 170.16 requires the same of SDs and MSPs. In conjunction with §§ 170.15 and 170.16, the Commission is intending to create an oversight regime that ensures more consistent treatment of its registered intermediaries. The Commission believes that the Final Rule is reasonably necessary to ensure the fitness and comprehensive regulation and appropriate oversight of such persons.

In assessing the costs and benefits of the Final Rule, the Commission employs a status quo baseline. The Commission analyzes the cost and benefit to those registered persons that, but for the Final Rule, would not have to become RFA members. As of June 30, 2015, the following numbers of Commission registered IBs, CPOs, and CTAs (registered in the below categories) were not NFA members ("Non-member Registrants"):[43]

Registration category	Non-member registrants
IB only	21
CPO only	61
CTA only	573
IB & CPO	1
IB & CTA	2
CTA & CPO	41
FCM & CPO	1
Total	700

Of these Non-member Registrants, however, approximately 138 are pending withdrawal of their Commission registration. The Commission is assuming that these Non-member Registrants will withdraw their registration and, thus, will not be impacted by the Final Rule. In addition, only approximately one percent of the Non-member Registrants registered solely as CTAs reported to the Commission in the most recent reporting cycle that they had directed client accounts.[44] As such, the Commission believes that many of the Non-member Registrants registered solely as CTAs will be § 4.14(a)(9) Exempted CTAs and, thus, will not be required to comply with the Final Rule.[45] Accordingly, the Commission estimates that 296[46] persons registered with the CFTC as a CPO, CTA, or IB will be required to become and remain NFA members as a result of the Final Rule.[47]

Because at this time the Commission cannot reasonably estimate the number of Non-member Registrants that may deregister with the Commission as a result of the Final Rule, the Commission is assuming that no Non-member Registrants will deregister as a result of the Final Rule. The Commission believes that this will lead to an overstatement of the compliance costs relating to the Final Rule.

2. Costs

a. Costs to IBs, CPOs, and CTAs

As discussed above, the process for a Non-member Registrant to become an NFA member amounts to checking a box on the CFTC registration form and updating some contact information. Thus, the Commission believes the cost of filing for membership to be non-substantive.[48]

Affected persons are also subject to certain membership fees. NFA imposes initial membership dues and annual membership dues for IBs, CPOs, and CTAs. Currently, such initial membership dues are $750 for the first year, and the annual dues to maintain membership are $750 per year

The Commission also notes that, pursuant to Section 17(d) of the Act, each CTA or IB that is registered with the Commission, but not an RFA member is required to ". . . pay to the Commission such reasonable fees and charges [established by the Commission] as may be necessary to defray the costs of additional regulatory duties required to be performed by the Commission because such person is not a member of an [RFA]." 7 U.S.C. 21(d). The Commission has not yet established any such fees or charges, but noted in the release for § 170.15 that these charges are likely to be greater than the costs attendant to RFA membership. *See* 48 FR at 26311.

[43] *See* NFA's daily directory of CFTC Registrants and Members available at: *http://www.nfa.futures.org/NFA-registration/NFA-directories.HTML.*

[44] The Commission is assuming that all Non-member Registrants registered solely as CTAs have reported to the Commission the amount of assets they have directed, if any.

[45] For purposes of its analysis, the Commission is assuming that approximately half of the 573 Non-member Registrants registered solely as CTAs (286 Non-member Registrants) will be § 4.14(a)(9) Exempted CTAs and will not be required to comply with the Final Rule, and 20 of these 286 Non-member Registrants will be pending withdrawal of their Commission registration.

[46] To arrive at the estimate, the 700 figure was reduced by the sum of (i) 138 (the Non-member Registrants whose withdrawal from Commission registration is pending) and (ii) 266 (the Non-member Registrants that the Commission assumes will be § 4.14(a)(9) Exempted CTAs net of those pending withdrawal, as described above).

[47] For purposes of assessing the costs of this rule, the Commission is assuming that no Non-member Registrant is, absent the Final Rule, required to be an NFA member.

[48] *See* Form 7–R, *http://www.nfa.futures.org/NFA-registration/templates-and-forms/form7-r.HTML.* Applications forms for NFA membership and Associate membership are incorporated in Forms 7–R and 8–R. *See* NFA Membership and Dues, *http://www.nfa.futures.org/NFA-registration/NFA-membership-and-dues.HTML.*

thereafter.[49] Thus, the 296 affected Non-member Registrants, in the aggregate, will incur an initial and ongoing annual registration/membership cost of approximately $222,000.[50]

The Commission agrees with Lovely that the Final Rule will also impose certain compliance costs on affected Non-member Registrants. However, as noted above, the Commission believes that, given the existing requirements imposed on such registrants, the compliance costs of becoming an NFA member and complying with NFA's rules (including preparing for an audit by NFA) will be partially offset by the costs already incurred by these registrants (*i.e.*, the costs associated with complying with Commission regulations and preparing for examinations by the Commission). In that regard, as discussed above, the Commission disagrees with Lovely's cost estimates and estimates that an affected registrant may, at most, face additional compliance costs of approximately $2,950 initially and $1,476 in subsequent years, equating to an industry total of $873,200 in the first year and $436,896 in subsequent years,[51] plus the indirect costs of the periodic audits. The Commission cannot reasonably provide an exact estimate of these costs due to the idiosyncratic nature of the indirect costs incurred.[52]

b. Other Market Costs

In addition to the direct costs to Commission Registrants, the Commission considered other costs to the markets of the Final Rule. In particular, the Commission considered the impact the Final Rule will have on IBs, CPOs, and CTAs (i) election to not register with the Commission and (ii) optional deregistration, in each case, where such persons are not required to be registered with the Commission. Further, the Commission considered that the requirements of the Final Rule may cause fewer persons to elect to become IBs, CPOs, and CTAs because of the added burden of being an RFA member. The Commission is unable to estimate accurately how many IBs, CPOs, and CTAs will deregister with the Commission or elect not to so register in the future, or how many persons will choose to not become such an intermediary, in each case, as a result of the Final Rule. Further, the Commission believes that if a market participant has chosen not to register with the Commission, the costs incurred by that participant for not registering would be less than the costs that would have been incurred to register. Otherwise, the market participant would likely have chosen to register instead. However, the Commission cannot make a more accurate determination of costs beyond this overestimate without knowing more specifics about a particular market participant.

c. Consideration of the Proposal as an Alternative to the Final Rule

The Commission believes the costs in a. and b. above, respectively, are reduced from those that would have resulted had the Proposal been adopted without modification (the Proposal would have required each registered IB, CPO, and CTA, without exception, to become and remain a member of an RFA), because the Commission has excepted § 4.14(a)(9) Exempted CTAs from the requirements of the Final Rule. This exclusion limits the Commission's ability to oversee these persons through delegation to an RFA; however, the Commission has determined that this reduction in the Commission's oversight abilities is reasonable in light of the burden that the Proposal would otherwise impose on § 4.14(a)(9) Exempted CTAs and the markets. The Commission further notes that, as discussed above, § 4.14(a)(9) Exempted CTAs that are not RFA members are still subject to the Commission's rules and regulations.

3. Benefits

The Final Rule enables the Commission to (i) carry out its obligations pursuant to Section 17 of the CEA to delegate certain oversight responsibility for intermediaries, including IBs, CPOs, and CTAs, to an RFA, and (ii) ensure the fitness of its registrants as described under Section 4p of the CEA. The Commission believes that by requiring RFA membership, the Final Rule results in a more efficient deployment of agency resources which would otherwise have to be used to oversee these registrants who would, without the Final Rule, not be overseen by an RFA. Further, the Commission believes that the Final Rule enables NFA to apply its experience as a SRO to oversee and ensure the fitness of all registered IBs, CPOs, and CTAs, except § 4.14(a)(9) Exempt CTAs. The markets and the public will benefit from NFA's developed set of rules and oversight capabilities to ensure the integrity of the swaps market and its participants.

4. Section 15(a) Factors

The Commission requested comment on all aspects of the Section 15(a) factors. Except as discussed above, the Commission did not receive any comments relating to costs and benefits of the Final Rule.

Section 15(a) of the CEA requires the Commission to consider the effects of its actions in light of the following five factors:

a. Protection of Market Participants and the Public

The Final Rule will protect the public by ensuring that registered IBs, CPOs, and CTAs, except § 4.14(a)(9) Exempt CTAs, are subject to the same level of comprehensive NFA oversight.

b. Efficiency, Competitiveness, and Financial Integrity of Markets

The Final Rule ensures that all registered IBs, CPOs, and CTAs, except § 4.14(a)(9) Exempt CTAs, are subject to a similar level of oversight and regulatory responsibility. In so doing, the Commission believes the integrity of markets is enhanced. Furthermore, the Commission also believes that the Final Rule will promote public confidence in the integrity of derivatives markets by ensuring consistent and adequate regulation and oversight of registered IBs, CPOs, and CTAs, except § 4.14(a)(9) Exempt CTAs.

c. Price Discovery

The Commission has not identified an impact on price discovery as a result of the Final Rule.

d. Sound Risk Management

The Commission has not identified an impact on the risk management decisions of market participants as a result of the Final Rule.

e. Other Public Interest Considerations

The Commission has not identified an impact on other public interest considerations as a result of the Final Rule.

List of Subjects in 17 CFR Part 170

Authority delegations (Government agencies), Commodity futures, Membership in a Registered Futures

[49] *See* NFA Membership and Dues, *http://www.nfa.futures.org/NFA-registration/NFA-membership-and-dues.HTML.*

[50] To arrive at the monetary estimate, the 296 figure was multiplied by the $750.00 per-person annual membership dues.

[51] To arrive at the monetary estimate, the 296 figure was multiplied by the estimated per-person compliance costs.

[52] The Commission also considered that, in addition to the Non-member Registrants discussed above, the Final Rule will cause future persons registering with the Commission as IBs, CPOs, and CTAs because of their activities in relation to swaps to incur additional costs similar to those described above. The Commission expects that many persons will apply for registration under the Commission's swaps market regime in such capacities, but the Commission is not able to accurately estimate the exact number of new Commission registrants that will do so and, thus, be affected by the Final Rule.

Association, Reporting and recordkeeping requirements.

For the reasons stated in the preamble, the Commodity Futures Trading Commission amends 17 CFR part 170 as set forth below:

PART 170—REGISTERED FUTURES ASSOCIATIONS

■ 1. The authority citation for part 170 is revised to read as follows:

Authority: 7 U.S.C. 6d, 6m, 6p, 6s, 12a, and 21.

■ 2. Add § 170.17 to read as follows:

§ 170.17 Introducing brokers, commodity pool operators, and commodity trading advisors.

Each person registered as an introducing broker, commodity pool operator, or commodity trading advisor must become and remain a member of at least one futures association that is registered under Section 17 of the Act and that provides for the membership therein of introducing brokers, commodity pool operators, or commodity trading advisors, as the case may be, unless no such futures association is so registered; provided, however that a person registered as a commodity trading advisor shall not be required to become or remain a member of such a futures association, solely in respect of its registration as a commodity trading advisor, if such person is eligible for the exemption from registration as such pursuant to § 4.14(a)(9) of this chapter.

Issued in Washington, DC, on September 9, 2015, by the Commission.

Christopher J. Kirkpatrick,

Secretary of the Commission.

Note: The following appendix will not appear in the Code of Federal Regulations.

Appendix to Membership in a Registered Futures Association—Commission Voting Summary

On this matter, Chairman Massad and Commissioners Bowen and Giancarlo voted in the affirmative. No Commissioner voted in the negative.

[FR Doc. 2015–23046 Filed 9–11–15; 8:45 am]

BILLING CODE 6351–01–P

DEPARTMENT OF LABOR

Wage and Hour Division

29 CFR Part 552

RIN 1235–AA05

Application of the Fair Labor Standards Act to Domestic Service; Announcement of 30-Day Period of Non-Enforcement

AGENCY: Wage and Hour Division, Department of Labor.

ACTION: Policy statement.

SUMMARY: The Department of Labor's (Department) Final Rule amending regulations regarding domestic service employment, which extends Fair Labor Standards Act (FLSA) protections to most home care workers, had an effective date of January 1, 2015. The Department has not begun enforcement of the Final Rule both because of its previously announced time-limited non-enforcement policy and because it is a party to a federal lawsuit regarding the amended regulations. The U.S. Court of Appeals for the District of Columbia issued an opinion in that case in favor of the Department on August 21, 2015. The Department will not bring enforcement actions against any employer for violations of FLSA obligations resulting from the amended domestic service regulations for 30 days after the date the Court of Appeals issues a mandate making its opinion effective.

DATES: This policy statement was signed on September 9, 2015.

FOR FURTHER INFORMATION CONTACT: Mary Ziegler, Assistant Administrator, Office of Policy, U.S. Department of Labor, Wage and Hour Division, 200 Constitution Avenue NW., Room S–3502, FP Building, Washington, DC 20210; telephone: (202) 343–5940 (this is not a toll-free number), email: *HomeCare@dol.gov.* Copies of this Policy Statement may be obtained in alternative formats (Large Print, Braille, Audio Tape, or Disc), upon request, by calling (202) 693–0675 (not a toll-free number). TTY/TTD callers may dial toll-free (877) 889–5627 to obtain information or request materials in alternative formats.

SUPPLEMENTARY INFORMATION:

I. 30-Day Non-Enforcement Period After Mandate Issues

The Department's Final Rule amending regulations regarding domestic service employment, 78 FR 60454, which extends FLSA protections to most home care workers, had an effective date of January 1, 2015. The Department has not begun enforcement of the Final Rule both because of its time-limited non-enforcement policy, 79 FR 60974 (October 9, 2014), and because it is a party to a federal lawsuit regarding the amended regulations in which the U.S. District Court for the District of Columbia issued opinions and orders vacating the rule's major provisions. *Home Care Ass'n of Am.* v. *Weil,* 76 F. Supp. 3d 138 (D.D.C. 2014); *Home Care Ass'n of Am.* v. *Weil,* 78 F. Supp. 3d 123 (D.D.C. 2015). On August 21, 2015, the U.S. Court of Appeals for the District of Columbia Circuit reversed the district court's judgment. *Home Care Ass'n of America* v. *Weil,* . . . F.3d . . . , No. 15–5018, 2015 WL 4978980 (D.C. Cir. Aug. 21, 2015). The Court of Appeals opinion will become effective when that court issues a mandate directing the district court to enter a new judgment in favor of the Department. Although it is not yet known on what date the mandate will issue, the Department will not bring enforcement actions against any employer for violations of FLSA obligations resulting from the amended domestic service regulations for 30 days after the date the mandate issues.

This 30-day non-enforcement policy does not replace or affect the timeline of the Department's existing time-limited non-enforcement policy announced in October 2014. 79 FR 60974. Under that policy, through December 31, 2015, the Department will exercise prosecutorial discretion in determining whether to bring enforcement actions, with particular consideration given to the extent to which States and other entities have made good faith efforts to bring their home care programs into compliance with the FLSA since the promulgation of the Final Rule. The Department will also continue to provide intensive technical assistance to the regulated community, as it has since promulgation of the Final Rule.

II. Regulatory Requirements

This Policy Statement is guidance articulating considerations relevant to the Department's exercise of its enforcement authority under the FLSA. It is therefore exempt from the notice-and-comment rulemaking requirements under the Administrative Procedure Act pursuant to 5 U.S.C. 553(b).

Because no notice of proposed rulemaking is required, the Regulatory Flexibility Act does not require an initial or final regulatory flexibility analysis. 5 U.S.C. 603(a), 604(a). The Department has determined that this guidance does not impose any new or revise any existing recordkeeping,

reporting, or disclosure requirements on covered entities or members of the public that would be collections of information requiring OMB approval under the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.*

Dated: September 9, 2015.

David Weil,

Administrator, Wage and Hour Division.

BILLING CODE 4510–27–P

DEPARTMENT OF HOMELAND SECURITY

Coast Guard

33 CFR Part 117

[Docket No. USCG–2015–0841]

Drawbridge Operation Regulation; Saugus River, Saugus, Massachusetts

AGENCY: Coast Guard, DHS.

ACTION: Notice of deviation from drawbridge regulation.

SUMMARY: The Coast Guard has issued a temporary deviation from the operating schedule that governs the Saugus RR Bridge, across the Saugus River, mile 2.1, at Saugus, Massachusetts. This deviation is necessary to facilitate essential maintenance repairs. This deviation allows the bridge to remain in the closed position during the maintenance repairs.

DATES: This deviation is effective from 12:01 a.m. on September 19, 2015 to 11:59 p.m. on September 20, 2015.

ADDRESSES: The docket for this deviation, [USCG–2015–0841] is available at *http://www.regulations.gov.* Type the docket number in the "SEARCH" box and click "SEARCH." Click on Open Docket Folder on the line associated with this deviation. You may also visit the Docket Management Facility in Room W12–140, on the ground floor of the Department of Transportation West Building, 1200 New Jersey Avenue SE., Washington, DC 20590, between 9 a.m. and 5 p.m., Monday through Friday, except Federal holidays.

FOR FURTHER INFORMATION CONTACT: If you have questions on this temporary deviation, contact Mr. Joe Arca, Project Officer, First Coast Guard District, telephone (212) 514–4336, email *joe.m.arca@uscg.mil.* If you have questions on viewing the docket, call Ms. Cheryl Collins, Program Manager, Docket Operations, telephone (202) 366–9826.

SUPPLEMENTARY INFORMATION: The Saugus RR Bridge, mile 2.1, across Saugus River has a vertical clearance in the closed position of 7 feet at mean high water and 17 feet at mean low water. The existing bridge operating regulations opens on schedule as required by 33 CFR 117.5.

Saugus River is transited by commercial lobstermen and recreational vessel traffic.

Keolis Commuter Railroad requested this temporary deviation from the normal operating schedule to facilitate essential maintenance repairs.

Under this temporary deviation, the Saugus RR Bridge may remain in the closed position from 12:01 a.m. on September 19, 2015 to 11:59 p.m. on September 20, 2015.

There is no alternate route for vessel traffic; however, vessels that can pass under the closed draws during this closure may do so at any time. The bridge will be able to open in the event of an emergency.

The Coast Guard will inform the users of the waterway through our Local Notice to Mariners of the change in operating schedule for the bridge so that vessels can arrange their transits to minimize any impact caused by the temporary deviation.

In accordance with 33 CFR 117.35(e), the drawbridge must return to its regular operating schedule immediately at the end of the effective period of this temporary deviation. This deviation from the operating regulations is authorized under 33 CFR 117.35.

Dated: September 1, 2015.

C.J. Bisignano,

Supervisory Bridge Management Specialist, First Coast Guard District.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 52

[EPA–R07–OAR–2015–0299; FRL–9933–84–Region 7]

Approval and Promulgation of Air Quality Implementation Plans; State of Kansas Regional Haze State Implementation Plan Revision and 2014 Five-Year Progress Report

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: The Environmental Protection Agency (EPA) is taking final action to approve the Kansas State Implementation Plan (SIP) revision submitted to EPA by the State of Kansas on March 10, 2015, documenting that the State's existing plan is making adequate progress to achieve visibility goals by 2018. The Kansas SIP revision addressed the Regional Haze Rule (RHR) requirements under the Clean Air Act (CAA or Act) to submit a report describing progress in achieving reasonable progress goals (RPGs) to improve visibility in Federally designated areas in nearby states that may be affected by emissions from sources in Kansas. EPA is taking final action to approve Kansas' determination that the existing Regional Haze (RH) SIP is adequate to meet the visibility goals and requires no substantive revision at this time.

DATES: This final rule is effective October 14, 2015.

ADDRESSES: EPA has established a docket for this action under Docket ID No. EPA–R07–OAR–2015–0299. All documents in the docket are listed on the *www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, *i.e.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available either electronically through *www.regulations.gov* or at the Environmental Protection Agency, Air Planning and Development Branch, 11201 Renner Boulevard, Lenexa, Kansas 66219. The Regional Office's official hours of business are Monday through Friday, 8:00 a.m. to 4:30 p.m., excluding Federal holidays. The interested persons wanting to examine these documents should make an appointment with the office at least 24 hours in advance.

FOR FURTHER INFORMATION CONTACT: Stephen Krabbe, Environmental Protection Agency, Air Planning and Development Branch, 11201 Renner Boulevard, Lenexa, Kansas 66219 at 913–551–7991, or by email at *krabbe.stephen@epa.gov.*

SUPPLEMENTARY INFORMATION: Throughout this document "we", "us", or "our" refer to EPA. This section provides additional information by addressing the following:

I. Background
II. Summary of SIP Revision
III. Final Action
IV. Statutory and Executive Order Reviews

I. Background

On June 10, 2015, (80 FR 32874), EPA published a notice of proposed rulemaking (NPR) for the State of

Kansas. In the NPR, EPA proposed approval of Kansas's progress report SIP, a report on progress made in the first implementation period towards RPGs for Class I areas that are affected by emissions from Kansas sources. This progress report SIP and accompanying cover letter also included a determination that Kansas's existing regional haze SIP requires no substantive revision to achieve the established regional haze visibility improvement and emissions reduction goals for 2018.

States are required to submit a progress report in the form of a SIP revision every five years that evaluates progress towards the RPGs for each mandatory Class I Federal area within the state and in each mandatory Class I Federal area outside the state which may be affected by emissions from within the state. See 40 CFR 51.308(g). In addition, the provisions under 40 CFR 51.308(h) require states to submit, at the same time as the 40 CFR 51.308(g) progress report, a determination of the adequacy of the state's existing regional haze SIP. The first progress report SIP is due five years after submittal of the initial regional haze SIP. On October 26, 2009, KDHE submitted its regional haze SIP in accordance with the requirements of 40 CFR 51.308. The progress report SIP revision was submitted by Kansas on March 10, 2015, and EPA finds that it satisfies the requirements of 40 CFR 51.308(g) and (h). No comments were received regarding the NPR.

II. Summary of SIP Revision

On March 10, 2015, Kansas submitted a SIP revision to describe the progress made towards the RPGs of Class I areas in and outside Kansas that are affected by emissions from Kansas' sources. This progress report SIP also includes a determination of the adequacy of Kansas' existing regional haze SIP to achieve these RPGs.

Kansas has no Class I areas within its borders. Kansas notes in its progress report SIP that Kansas sources were also identified as potentially impacting four Class I areas in three neighboring states: Caney Creek Wilderness Area in Arkansas, Hercules-Glades Wilderness Area in Missouri, Mingo Wilderness Area in Missouri, and Wichita Mountains Wilderness Area in Oklahoma.

The provisions in 40 CFR 51.308(g) require a progress report SIP to address seven elements. EPA finds that Kansas' progress report SIP addressed each element under 40 CFR 51.308(g). The seven elements and EPA's conclusion are briefly summarized in this rulemaking action.

The provisions in 40 CFR 51.308(g) require progress report SIPs to include a description of the status of measures in the approved regional haze SIP; a summary of emissions reductions achieved; an assessment of visibility conditions for each Class I area in the state; an analysis of changes in emissions from sources and activities within the state; an assessment of any significant changes in anthropogenic emissions within or outside the state that have limited or impeded progress in Class I areas impacted by the state's sources; an assessment of the sufficiency of the approved regional haze SIP; and a review of the state's visibility monitoring strategy. As explained in detail in the NPR, EPA finds that Kansas' progress report SIP addressed each element and has therefore satisfied the requirements under 40 CFR 51.308(g).

In addition, pursuant to 40 CFR 51.308(h), states are required to submit, at the same time as the progress report SIP, a determination of the adequacy of their existing regional haze SIP and to take one of four possible actions based on information in the progress report. One possible action is submission of a negative declaration to EPA that no further substantive revision to the state's existing regional haze SIP is needed. In its progress report SIP, Kansas submitted a negative declaration that it had determined that its existing regional haze SIP requires no further substantive revision to achieve the RPGs for the Class I areas that are affected by emissions from Kansas's sources. As explained in detail in the NPR, EPA concludes Kansas has adequately addressed 40 CFR 51.308(h) because the visibility data trends at the Class I areas impacted by Kansas's sources and the emissions trends of the largest emitters of visibility-impairing pollutants both indicate that the RPGs for 2018 will be met or exceeded. Therefore, EPA concludes Kansas' progress report SIP meets the requirements of 40 CFR 51.308(h).

III. Final Action

EPA is taking final action to approve Kansas' regional haze five-year progress report and SIP revision, submitted March 10, 2015, as meeting the applicable regional haze requirements as set forth in 40 CFR 51.308(g) and 51.308(h).

Statutory and Executive Order Reviews

Under the Clean Air Act (CAA), the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this action merely approves state law as meeting Federal requirements and does not impose additional requirements beyond those imposed by state law. For that reason, this action:

- Is not a significant regulatory action subject to review by the Office of Management and Budget under Executive Orders 12866 (58 FR 51735, October 4, 1993) and 13563 (76 FR 3821, January 21, 2011);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have Federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of Section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and
- Does not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

The SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the rule does not have tribal implications and will not impose substantial direct costs on tribal governments or preempt tribal law as specified by Executive Order 13175 (65 FR 67249, November 9, 2000).

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the

agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this action and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a "major rule" as defined by 5 U.S.C. 804(2).

Under section 307(b)(1) of the CAA, petitions for judicial review of this action must be filed in the United States Court of Appeals for the appropriate circuit by November 13, 2015. Filing a petition for reconsideration by the Administrator of this final rule does not affect the finality of this action for the purposes of judicial review nor does it extend the time within which a petition for judicial review may be filed, and shall not postpone the effectiveness of such rule or action. This action may not be challenged later in proceedings to enforce its requirements. (See section 307(b)(2).)

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Carbon monoxide, Incorporation by reference, Intergovernmental relations, Lead, Nitrogen dioxide, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur oxides, Volatile organic compounds.

Dated: August 20, 2015.

Mark Hague,

Acting Regional Administrator, Region 7.

For the reasons stated in the preamble, EPA amends 40 CFR part 52 as set forth below:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart R—Kansas

■ 2. In § 52.870, the table in paragraph (e) is amended by adding entry (42) at the end of the table to read as follows:

§ 52.870 Identification of plan.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 271

[EPA–R06–2015–0070 RCRA; FRL–9933–79–Region 6]

Louisiana: Final Authorization of State Hazardous Waste Management Program Revision

AGENCY: Environmental Protection Agency (EPA).

ACTION: Direct final rule.

SUMMARY: Louisiana has applied to the Environmental Protection Agency (EPA) for final authorization of the changes to its hazardous waste program under the Resource Conservation and Recovery Act (RCRA). The EPA has determined that these changes satisfy all requirements needed to qualify for final authorization, and is authorizing the State's changes through this direct final action. The EPA is publishing this rule to authorize the changes without a prior proposal because we believe this action is not controversial and do not expect comments that oppose it. Unless we receive written comments which oppose this authorization during the comment period, the decision to authorize Louisiana's changes to its hazardous waste program will take effect. If we receive comments that oppose this action, we will publish a document in the **Federal Register** withdrawing this rule before it takes effect, and a separate document in the proposed rules section of this **Federal Register** will serve as a proposal to authorize the changes.

DATES: This final authorization will become effective on November 13, 2015 unless the EPA receives adverse written comment by October 14, 2015. If the EPA receives such comment, it will publish a timely withdrawal of this direct final rule in the **Federal Register** and inform the public that this authorization will not take effect.

ADDRESSES: Submit any comments identified by Docket ID No. EPA–R06–RCRA–2015–0070, by one of the following methods:

1. *Federal eRulemaking Portal: http://www.regulations.gov.* Follow the on-line instructions for submitting comments.

2. *Email: patterson.alima@epa.gov.*

3. *Mail:* Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas Texas 75202–2733.

4. *Hand Delivery or Courier.* Deliver your comments to Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733.

Instructions: Do not submit information that you consider to be CBI or otherwise protected through regulations.gov, or email. Direct your comment to Docket No. EPA–R06–RCRA–2015–0070. The Federal regulations.gov Web site is an "anonymous access" system, which means the EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to the EPA without going through regulations.gov, your email address will be automatically captured and included as part of the

comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, the EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If the EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, the EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. You can view and copy Louisiana's application and associated publicly available materials from 8:30 a.m. to 4 p.m. Monday through Friday at the following locations: Louisiana Department of Environmental Quality, 602 N. Fifth Street, Baton Rouge, Louisiana 70884–2178, phone number (225) 219–3559 and EPA, Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733, phone number (214) 665–8533. Interested persons wanting to examine these documents should make an appointment with the office at least two weeks in advance.

FOR FURTHER INFORMATION CONTACT: Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733, (214) 665–8533) and Email address *patterson.alima@epa.gov.*

SUPPLEMENTARY INFORMATION:

A. Why are revisions to State programs necessary?

States which have received final authorization from the EPA under RCRA section 3006(b), 42 U.S.C. 6926(b), must maintain a hazardous waste program that is equivalent to, consistent with, and no less stringent than the Federal program. As the Federal program changes, States must change their programs and ask the EPA to authorize the changes. Changes to State programs may be necessary when Federal or State statutory or regulatory authority is modified or when certain other changes occur.

Most commonly, States must change their programs because of changes to the EPA's regulations in 40 Code of Federal Regulations (CFR) parts 124, 260 through 268, 270, 273, and 279.

B. What decisions have we made in this rule?

We conclude that Louisiana's application to revise its authorized program meets all of the statutory and regulatory requirements established by RCRA. Therefore, we grant Louisiana final authorization to operate its hazardous waste program with the changes described in the authorization application. Louisiana has responsibility for permitting treatment, storage, and disposal facilities within its borders (except in Indian Country) and for carrying out the aspects of the RCRA program described in its revised program application, subject to the limitations of the Hazardous and Solid Waste Amendments of 1984 (HSWA). New Federal requirements and prohibitions imposed by Federal regulations that the EPA promulgates under the authority of HSWA take effect in authorized States before they are authorized for the requirements. Thus, the EPA will implement those requirements and prohibitions in Louisiana including issuing permits, until the State is granted authorization to do so.

C. What is the effect of today's authorization decision?

The effect of this decision is that a facility in Louisiana subject to RCRA will now have to comply with the authorized State requirements instead of the equivalent Federal requirements in order to comply with RCRA. Louisiana has enforcement responsibilities under its State hazardous waste program for violations of such program, but the EPA retains its authority under RCRA sections 3007, 3008, 3013, and 7003, which include, among others, authority to:

- Do inspections, and require monitoring, tests, analyses, or reports;
- enforce RCRA requirements and suspend or revoke permits and
- take enforcement actions after notice to and consultation with the State.

This action does not impose additional requirements on the regulated community because the regulations for which Louisiana is being authorized by today's action are already effective under State law, and are not changed by today's action.

D. Why wasn't there a proposed rule before today's rule?

The EPA did not publish a proposal before today's rule because we view this as a routine program change and do not expect comments that oppose this approval. We are providing an opportunity for public comment now. In addition to this rule, in the proposed rules section of today's **Federal Register** we are publishing a separate document that proposes to authorize the State program changes.

E. What happens if the EPA receives comments that oppose this action?

If the EPA receives comments that oppose this authorization, we will withdraw this rule by publishing a document in the **Federal Register** before the rule becomes effective. The EPA will base any further decision on the authorization of the State program changes on the proposal mentioned in the previous paragraph. We will then address all public comments in a later final rule. You may not have another opportunity to comment. If you want to comment on this authorization, you must do so at this time. If we receive comments that oppose only the authorization of a particular change to the State hazardous waste program, we will withdraw only that part of this rule, but the authorization of the program changes that the comments do not oppose will become effective on the date specified above. The **Federal Register** withdrawal document will specify which part of the authorization will become effective, and which part is being withdrawn.

F. For what has Louisiana previously been authorized?

The State of Louisiana initially received final authorization on February 7, 1985, (50 FR 3348), to implement its base Hazardous Waste Management Program. We granted authorization for changes to their program on November 28, 1989 (54 FR 48889) effective January 29, 1990; August 26, 1991 (56 FR 41958), as corrected October 15, 1991 (56 FR 51762) effective October 25, 1991; November 7, 1994 (59 FR 55368) effective January 23, 1995 (Note: on January 23, 1995 (60 FR 4380), the EPA responded to public adverse comments and affirmed the effective date for the November 7, 1994 final rule. Then on April 11, 1995 (60 FR 18360), the EPA also made administrative corrections for the January 23, 1995 **Federal Register** document); December 23, 1994 (59 FR 66200) effective March 8, 1995; October 17, 1995 (60 FR 53704) effective January 2, 1996; March 28, 1996 (61 FR 13777) effective June 11, 1996; December 29, 1997 (62 FR 67572) effective March 16, 1998; October 23, 1998 (63 FR 56830) effective December 22, 1998; August 25, 1999 (64 FR 46302) effective October 25, 1999; September 2, 1999 (64 FR 48099) effective November 1, 1999; February 28, 2000 (65 FR 10411) effective April 28, 2000; January 2, 2001 (66 FR 23) effective March 5, 2001; December 9, 2003 (68 FR 68526) effective February 9, 2004; June 10, 2005 (70 FR 33852) effective August 9, 2005; November 13, 2006 (71 FR 66116) effective January 12,

2007; August 16, 2007 (72 FR 45905) effective October 15, 2007; May 20, 2009 (74 FR 23645) effective July 20, 2009; June 24, 2011(76 FR 122) effective August 23, 2011; and June 28, 2012 (77 FR 38530) effective August 27, 2012. On October 31, 2014, Louisiana applied for approval of its program revisions for specific rules in RCRA Clusters XXI, XXII and XXIII, in accordance with 40 CFR 271.21(b)(3).

Since 1979 through the Environmental Affairs Act, Act 449 enabled the Office of Environmental Affairs within the Louisiana Department of Natural Resources, as well as, the Environmental Control Commission to conduct an effective program designed to regulate those who generate, transport, treat, store, dispose or recycle hazardous waste. During the 1983 Regular Session of the Louisiana Legislature, Act 97 was adopted, which amended and reenacted La. R. S. 30:1051 *et seq.* as the Environmental Quality Act, renaming the Environmental Affairs Act (Act 1938 of 1979). This Act created Louisiana Department of Environmental Quality (LDEQ), including provisions for new offices within this new Department of Environmental Quality. Act 97 also transferred the duties and responsibilities previously delegated to the Department of Natural Resources, Office of Environmental Affairs, to the new Department. The LDEQ has lead agency jurisdictional authority for administering the Resource Conservation and Recovery Act (RCRA) Subtitle C program in Louisiana. Also, the LDEQ is designated to facilitate communication between the EPA and the State. During the 1999 Regular Session of Louisiana Legislature, Act 303 revised the La. R. S. 30:2011 *et seq.*, allowing LDEQ to reengineer the Department to perform more efficiently and to meet its strategic goals.

G. What changes are we authorizing with today's action?

On October 31, 2014, Louisiana submitted a final complete program revision application, seeking authorization of their changes in accordance with 40 CFR 271.21. We now make an immediate final decision, subject to receipt of written comments that oppose this action, that Louisiana's hazardous waste program revision satisfies all of the requirements necessary to qualify for Final authorization. Therefore, we grant the State of Louisiana Final authorization for the following changes: The State of Louisiana's program revisions consist of regulations which specifically govern Revision Checklists 227, 228, and 229 from RCRA Clusters XXI, XXII, XXIII, respectively, as documented in this **Federal Register**:

Description of Federal requirement (include checklist #, if relevant)	**Federal Register** date and page (and/or RCRA statutory authority)	Analogous State authority
1. Revision of the Land Disposal Treatment Standards for Carbamate Wastes. (Checklist 227).	76 FR 34147–34157, June 13, 2011.	Environmental Regulatory Code, Louisiana Department of Environmental Quality, ERC Title 33, Part V. Hazardous Waste and Hazardous Materials, 2013 edition. Section 2299 Appendix Table 2, Treatment Standards for Hazardous Waste, and Table 7, Universal Treatment Standards, effective September 20, 2013.
2. Hazardous Waste Technical Corrections and Clarifications Rule. (Checklist 228).	77 FR 22229–22232 April 13, 2012.	Environmental Regulatory Code, Louisiana Department of Environmental Quality, ERC Title 33, Part V. Hazardous Waste and Hazardous Materials, 2010 edition and the March 2012 Supplement. Sections 4901.C.Table 2, Hazardous Wastes from Specific Sources, and 4139.B.2, effective March 20, 2012.
3. Conditional Exclusions for Solvent Contaminated Wipes. (Checklist 229).	78 FR 46448–46485 July 31, 2013	Environmental Regulatory Code, Louisiana Department of Environmental Quality, ERC Title 33, Part V. Hazardous Waste and Hazardous Materials, 2013 edition and the July 2014 Supplement. Sections 109 No Free Liquids, 109.Solvent Contaminated wipe, 109.Wipe, 105.D.1.w, and 105.D.2.q, effective July 20, 2014.

H. Where are the revised State rules different from the Federal Rules?

In this authorization of the State of Louisiana program revisions for the RCRA Cluster XXI, XXII, and XXIII rules, there are no provisions that are more stringent or broader in scope.

I. Who handles permits after the authorization takes effect?

Louisiana will issue permits for all the provisions for which it is authorized and will administer the permits it issues. The EPA will continue to administer any RCRA hazardous waste permits or portions of permits which we issued prior to the effective date of this authorization. We will not issue any more new permits or new portions of permits for the provisions listed in the Table in this document after the effective date of this authorization. The EPA will continue to implement and issue permits for HSWA requirements for which Louisiana is not yet authorized.

J. How does today's action affect Indian Country in Louisiana?

Louisiana is not authorized to carry out its Hazardous Waste Program in Indian Country within the State. This authority remains with EPA. Therefore, this action has no effect in Indian Country.

K. What is codification and is the EPA codifying Louisiana's Hazardous Waste Program as authorized in this rule?

Codification is the process of placing the State's statutes and regulations that comprise the State's authorized hazardous waste program into the CFR. We do this by referencing the authorized State rules in 40 CFR part 272. We reserve the amendment of 40 CFR part 272, subpart T for this authorization of Louisiana's program changes until a later date. In this authorization application the EPA is not codifying the rules documented in this **Federal Register** notice.

L. Administrative Requirements

The Office of Management and Budget (OMB) has exempted this action (RCRA State Authorization) from the requirements of Executive Order 12866 (58 FR 51735, October 4, 1993) and 13563 (76 FR 3821, January 21, 2011). Therefore, this action is not subject to review by OMB. This action authorizes State requirements for the purpose of RCRA 3006 and imposes no additional requirements beyond those imposed by State law. Accordingly, this action will not have a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5

U.S.C. 601 *et seq.*). Because this action authorizes pre-existing requirements under State law and does not impose any additional enforceable duty beyond that required by State law, it does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4). For the same reason, this action also does not significantly or uniquely affect the communities of Tribal governments, as specified by Executive Order 13175 (65 FR 67249, November 9, 2000). This action will not have substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government, as specified in Executive Order 13132 (64 FR 43255, August 10, 1999), because it merely authorizes State requirements as part of the State RCRA hazardous waste program without altering the relationship or the distribution of power and responsibilities established by RCRA. This action also is not subject to Executive Order 13045 (62 FR 19885, April 23, 1997), because it is not economically significant and it does not make decisions based on environmental health or safety risks. This rule is not subject to Executive Order 13211, "Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use" (66 FR 28355 (May 22, 2001)) because it is not a significant regulatory action under Executive Order 12866.

Under RCRA 3006(b), the EPA grants a State's application for authorization as long as the State meets the criteria required by RCRA. It would thus be inconsistent with applicable law for the EPA, when it reviews a State authorization application, to require the use of any particular voluntary consensus standard in place of another standard that otherwise satisfies the requirements of RCRA. Thus, the requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) do not apply. As required by section 3 of Executive Order 12988 (61 FR 4729, February 7, 1996), in issuing this rule, the EPA has taken the necessary steps to eliminate drafting errors and ambiguity, minimize potential litigation, and provide a clear legal standard for affected conduct. The EPA has complied with Executive Order 12630 (53 FR 8859, March 15, 1988) by examining the takings implications of the rule in accordance with the "Attorney General's Supplemental Guidelines for the Evaluation of Risk and Avoidance of Unanticipated Takings" issued under the Executive Order. This rule does not impose an information collection burden under the provisions of the Paperwork Reduction Act of 1995 (44 U.S.C. 3501 *et seq.*). Executive Order 12898 (59 FR 7629, Feb. 16, 1994) establishes federal executive policy on environmental justice. It's main provision directs federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations in the United States. Because this rule authorizes pre-existing State rules which are at least equivalent to, and no less stringent than existing federal requirements, and impose no additional requirements beyond those imposed by State law, and there are no anticipated significant adverse human health or environmental effects, the rule is not subject to Executive Order 12898.

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. The EPA will submit a report containing this document and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a "major rule" as defined by 5 U.S.C. 804(2). This action nevertheless will be effective November 13, 2015.

List of Subjects in 40 CFR Part 271

Environmental protection, Administrative practice and procedure, Confidential business information, Hazardous waste, Hazardous waste transportation, Indian lands, Intergovernmental relations, Penalties, Reporting and recordkeeping requirements.

Authority: This action is issued under the authority of sections 2002(a), 3006, and 7004(b) of the Solid Waste Disposal Act as amended 42 U.S.C. 6912(a), 6926, 6974(b).

Dated: August 21, 2015.

BILLING CODE 6560–50–P

DEPARTMENT OF TRANSPORTATION

National Highway Traffic Safety Administration

49 CFR Part 577

[Docket No. NHTSA–2015–0048]

RIN 2127–AL60

Defect and Noncompliance Notification

AGENCY: National Highway Traffic Safety Administration (NHTSA), Department of Transportation (DOT).

ACTION: Final rule.

SUMMARY: This final rule amends NHTSA's regulation requiring motor vehicle manufacturers and replacement equipment manufacturers to notify owners and purchasers of a defect or noncompliance in vehicles or equipment that they produced. The amendments in this final rule will clarify that a manufacturer of replacement equipment providing a defect or noncompliance notification pursuant to this regulation can inform the purchaser of the replacement equipment of the manufacturer's intent to remedy the defect or noncompliance by refunding the purchase price of the replacement equipment. NHTSA is amending this regulation so that the regulation conforms to changes in the defect and noncompliance remedy provisions in the National Traffic and Motor Vehicle Safety Act (Safety Act) contained in the Moving Ahead for Progress in the 21st Century Act (MAP–21).

DATES: *Effective date:* This final rule is effective November 13, 2015.

Petitions for reconsideration: Petitions for reconsideration of this final rule must be received not later than October 29, 2015.

ADDRESSES: Any petitions for reconsideration should refer to the docket number of this document and be submitted to: Administrator, National Highway Traffic Safety Administration, 1200 New Jersey Avenue SE., West Building, Ground Floor, Docket Room W12–140, Washington, DC 20590.

FOR FURTHER INFORMATION CONTACT: Thomas Healy, Office of Chief Counsel, NHTSA, 1200 New Jersey Avenue SE., Washington, DC 20590. Mr. Healy's telephone number is (202) 366–2992. His fax number is (202) 493–3820.

SUPPLEMENTARY INFORMATION:

I. Background

The Safety Act requires manufacturers of motor vehicles or items of replacement equipment to notify NHTSA and owners and purchasers of the vehicles or equipment if the manufacturer determines that a motor vehicle or item of motor vehicle equipment contains a defect related to motor vehicle safety or does not comply with an applicable motor vehicle safety standard and to remedy the defect or noncompliance without charge. 49 U.S.C. 30118(c), 30120. Manufacturers must provide notification pursuant to the procedures set forth in section 30119 of the Safety Act. Section 30119 sets forth the contents of the notification, which includes a clear description of the defect or noncompliance, the timing of the notification, means of providing notification and when a second notification is required. 49 U.S.C. 30119.

Section 30120 of the Safety Act provides a list of permissible remedies from which manufacturers must choose when determining how to remedy at defect. Section 30120 contains different remedy provisions for manufacturers of motor vehicles and manufacturers of replacement equipment. Section 30120 allows manufacturers of motor vehicles to remedy a defect or noncompliance "by repairing the vehicle; . . . by replacing the vehicle with an identical or reasonably equivalent vehicle; or . . . by refunding the purchase price, less a reasonable allowance for depreciation." 49 U.S.C. 30120(a)(1)(A). Prior to MAP–21, Section 30120 allowed manufacturers of replacement equipment to remedy a defect or noncompliance by "repairing the equipment or replacing the equipment with identical or reasonable equivalent equipment." 49 U.S.C. 30120(a)(1)(B) (2011). MAP–21 amended section 30120 by expanding the list of permissible remedies available to replacement equipment manufacturers to include refunding the purchase price of the equipment.[1]

The conduct of a recall notification campaign, including how and when owners, dealers, and distributors are notified, is addressed by regulation in 49 CFR part 577, *Defect and Noncompliance Notification.* Section 577.5 specifies the required content and structure of the owner notifications. Section 577.6 specifies the required content and structure of the notification if the owner notification is sent pursuant to an order by the NHTSA Administrator. Section 577.5 and 577.6 both specify that that the owner notification must include a statement notifying the owner of the vehicle or replacement equipment how the manufacturer intends to remedy the defect or noncompliance.

This final rule amends §§ 577.5 and 577.6 of 49 CFR part 577 so that the requirements for the statement notifying owners or purchasers of replacement equipment how the manufacturer intends to remedy a defect or noncompliance reflect the MAP–21 amendment allowing manufacturers of replacement equipment to remedy a defect or noncompliance by refunding the purchase price.

II. Public Comment

NHTSA did not issue an NPRM prior to this final rule. While the Administrative Procedure Act (APA) requires that agencies publish a general NPRM in the **Federal Register** prior to issuing a final rule, an agency is not required to publish an NPRM if the agency is able to make and makes a good cause finding that notice and public comment is "impracticable, unnecessary, or contrary to the public interest." [2]

NHTSA finds that notice and public comment prior to issuing this final rule is unnecessary. The DC Circuit has held that the notice and public comment requirements of APA are unnecessary when the "rule is a routine determination, insignificant in nature and impact, and inconsequential to the industry and to the public." [3] The amendments in this final rule do not create any new rights or obligations not already present in 49 U.S.C. 30120. The amendments in this final rule update the notification requirements in 49 CFR 577.5 and 577.6 to reflect that the option to refund the purchase price of the replacement equipment is available to manufacturers as a remedy for a defect or noncompliance. Furthermore, these changes were made by statutory amendment. Therefore, the amendments contained in this final rule do not involve the exercise of discretion on the part of the agency. Because this final rule does not create any rights or obligations not already present in 49 U.S.C. 30120 or involve the exercise of discretion by the agency, the impacts of this rule are insignificant and inconsequential to industry and the public making notice and public comment unnecessary.

III. Regulatory Notices and Analyses

A. Executive Order 12866, Executive Order 13563, and DOT Regulatory Policies and Procedures

NHTSA has considered the impact of this rulemaking action under Executive Order 12866, Executive Order 13563, and the DOT's regulatory policies and procedures. This final rule was not reviewed by the Office of Management and Budget (OMB) under E.O. 12866, "Regulatory Planning and Review." It is not considered to be significant under E.O. 12866 or the Department's regulatory policies and procedures.

This regulation amends 49 CFR part 577 to include refund of the purchase price of replacement equipment as a remedy available to replacement equipment manufacturers remedying a defect or noncompliance. This final rule does not require replacement equipment manufacturers to take any actions that they are not otherwise already required to take. Because there are not any costs or savings associated with this rulemaking, we have not prepared a separate economic analysis for this rulemaking.

B. Regulatory Flexibility Act

In compliance with the Regulatory Flexibility Act, 5 U.S.C. 601 *et seq.,* NHTSA has evaluated the effects of this action on small entities. I hereby certify that this rule would not have a significant impact on a substantial number of small entities. The final rule affects manufacturers of motor vehicle replacement equipment some of which qualify as small businesses. However, this final rule does not significantly affect these entities because it does not require any additional actions on the part of equipment manufacturers not already required by 49 CFR part 577.

C. Executive Order 13132

NHTSA has examined this rule pursuant to Executive Order 13132 (64 FR 43255, August 10, 1999) and concluded that no additional consultation with States, local governments or their representatives is mandated beyond the rulemaking process. The agency has concluded that the rulemaking would not have sufficient federalism implications to warrant consultation with State and local officials or the preparation of a federalism summary impact statement. The final rule would not have "substantial direct effects on the States, on the relationship between the national government and the States, or on the

[1] Public Law 112–141, 126 Stat. 771 (2012), Section 31311.

[2] 5 U.S.C. 553.

[3] *Mack Trucks, Inc.* v. *E.P.A.* 682 F.3d 87, 92 (D.C. Cir. 2012) (quoting *Util. Solid Waste Activities Grp.* v. *E.P.A.*, 236 F.3d 749, 754 (D.C. Cir. 2001).

distribution of power and responsibilities among the various levels of government." This final rule also will not preempt any state law.

D. National Environmental Policy Act

NHTSA has analyzed this final rule for the purposes of the National Environmental Policy Act. The agency has determined that implementation of this action will not have any significant impact on the quality of the human environment.

E. Paperwork Reduction Act

Under the procedures established by the Paperwork Reduction Act of 1995, a person is not required to respond to a collection of information by a Federal agency unless the collection displays a valid OMB control number. The information collection requirements for 49 CFR part 577, *Defect and Noncompliance Notification,* are covered by OMB control number 2127–0004. The amendments in this final rule have no impact on the burden associated with this information collection.

F. National Technology Transfer and Advancement Act

Under the National Technology Transfer and Advancement Act of 1995 (NTTAA) (Pub. L. 104–113), "all Federal agencies and departments shall use technical standards that are developed or adopted by voluntary consensus standards bodies, using such technical standards as a means to carry out policy objectives or activities determined by the agencies and departments." The amendments in this final rule consist of minor revisions to the required content of letters that manufacturers of replacement equipment for motor vehicles must sent to purchasers and owners to notify them of a defect or noncompliance and do not involve any voluntary consensus standards.

G. Civil Justice Reform

With respect to the review of the promulgation of a new regulation, section 3(b) of Executive Order 12988, "Civil Justice Reform" (61 FR 4729, February 7, 1996) requires that Executive agencies make every reasonable effort to ensure that the regulation: (1) Clearly specifies the preemptive effect; (2) clearly specifies the effect on existing Federal law or regulation; (3) provides a clear legal standard for affected conduct, while promoting simplification and burden reduction; (4) clearly specifies the retroactive effect, if any; (5) adequately defines key terms; and (6) addresses other important issues affecting clarity and general draftsmanship under any guidelines issued by the Attorney General. This document is consistent with that requirement.

Pursuant to this Order, NHTSA notes as follows. The preemptive effect of this final rule is discussed above. NHTSA notes further that there is no requirement that individuals submit a petition for reconsideration or pursue other administrative proceeding before they may file suit in court.

H. Unfunded Mandates Reform Act

The Unfunded Mandates Reform Act of 1995 requires agencies to prepare a written assessment of the costs, benefits and other effects of proposed or final rules that include a Federal mandate likely to result in the expenditure by State, local or tribal governments, in the aggregate, or by the private sector, of more than $100 million annually (adjusted for inflation with base year of 1995). This final rule would not result in expenditures by State, local or tribal governments, in the aggregate, or by the private sector in excess of $100 million annually.

I. Executive Order 13211

Executive Order 13211 (66 FR 28355, May 18, 2001) applies to any rulemaking that: (1) Is determined to be economically significant as defined under E.O. 12866, and is likely to have a significantly adverse effect on the supply of, distribution of, or use of energy; or (2) that is designated by the Administrator of the Office of Information and Regulatory Affairs as a significant energy action. This rulemaking is not subject to E.O. 13211.

J. Regulation Identifier Number (RIN)

The Department of Transportation assigns a regulation identifier number (RIN) to each regulatory action listed in the Unified Agenda of Federal Regulations. The Regulatory Information Service Center publishes the Unified Agenda in April and October of each year. You may use the RIN contained in the heading at the beginning of this document to find this action in the Unified Agenda.

List of Subjects in 49 CFR Part 577

Imports, Motor vehicle safety, Motor vehicles, Tires, Reporting and recordkeeping requirements.

In consideration of the foregoing, NHTSA amends 49 CFR part 577 as follows:

PART 577—DEFECT AND NONCOMPLIANCE NOTIFICATION

■ 1. The authority citation for part 577 continues to read as follows:

Authority: 49 U.S.C. 30102, 30103, 30116–30121, 30166; delegation of authority at 49 CFR 1.95 and 49 CFR 501.8.

■ 2. Section 577.5 is amended by revising paragraphs (g)(1)(i) and (vi) to read as follows:

§ 577.5 Notification pursuant to a manufacturer's decision.

* * * * *

(g) * * *

(1) * * *

(i) A statement that he will cause such defect to be remedied without charge, and whether such remedy will be by repair, replacement, or refund of the purchase price (in the case of remedy of a vehicle, less depreciation).

* * * * *

(vi) In the case of a remedy of a vehicle by refund of purchase price, the method or basis for the manufacturer's assessment of depreciation.

* * * * *

■ 3. Section 577.6 is amended by revising paragraph (b)(9)(i)(B) to read as follows:

§ 577.6 Notification pursuant to Administrator's decision.

* * * * *

(b) * * *

(9) * * *

(i) * * *

(B) A statement of the method of remedy. If the manufacturer has not yet determined the method of remedy, he will select either repair, replacement with an equivalent vehicle or item of replacement equipment, or refund of the purchase price (in the case of remedy of a vehicle, less depreciation); and

Proposed Rules

Federal Register
Vol. 80, No. 177
Monday, September 14, 2015

This section of the FEDERAL REGISTER contains notices to the public of the proposed issuance of rules and regulations. The purpose of these notices is to give interested persons an opportunity to participate in the rule making prior to the adoption of the final rules.

DEPARTMENT OF ENERGY

10 CFR Part 430

[Docket Number EERE–2014–BT–STD–0031]

RIN 1904–AD20

Energy Conservation Program for Consumer Products: Energy Conservation Standards for Residential Furnaces

AGENCY: Office of Energy Efficiency and Renewable Energy, Department of Energy.

ACTION: Notice of data availability.

SUMMARY: The U.S. Department of Energy (DOE) has completed a provisional analysis of the potential economic impacts and energy savings that could result from promulgating amended energy conservation standards for residential non-weatherized gas furnaces (NWGFs) that include two product classes defined by input capacity and has published the data on its Web page. DOE encourages stakeholders to provide any additional data or information that may improve the analysis.

DATES: DOE will accept comments, data, and information regarding this NODA no later than October 14, 2015. See section IV for details.

ADDRESSES: Any comments submitted must identify the NODA for Energy Conservation Standards for Residential Furnaces, and provide docket number EERE–2014–BT–STD–0031 and/or regulatory information number (RIN) number 1904–AD20. Comments may be submitted using any of the following methods:

1. *Federal eRulemaking Portal: www.regulations.gov.* Follow the instructions for submitting comments.

2. *Email: ResFurnaces2014STD0031@ee.doe.gov.* Include the docket number and/or RIN in the subject line of the message. Submit electronic comments in Word Perfect, Microsoft Word, PDF, or ASCII file format, and avoid the use of special characters or any form on encryption.

3. *Postal Mail:* Ms. Brenda Edwards, U.S. Department of Energy, Building Technologies Office, Mailstop EE–5B, 1000 Independence Avenue SW., Washington, DC 20585–0121. If possible, please submit all items on a compact disc (CD), in which case it is not necessary to include printed copies.

4. *Hand Delivery/Courier:* Ms. Brenda Edwards, U.S. Department of Energy, Building Technologies Office, 950 L'Enfant Plaza SW., Suite 600, Washington, DC 20024. Telephone: (202) 586–2945. If possible, please submit all items on a CD, in which case it is not necessary to include printed copies.

No telefacsimilies (faxes) will be accepted. For detailed instructions on submitting comments and additional information on the rulemaking process, see section IV of this document (Submission of Comments).

Docket: The docket, which includes **Federal Register** documents, comments, and other supporting documents/materials, is available for review at *www.regulations.gov.* All documents in the docket are listed in the *www.regulations.gov* index. However, not all documents listed in the index may be publicly available, such as information that is exempt from public disclosure.

A link for access to the docket Web page can be found at: *https://www1.eere.energy.gov/buildings/appliance_standards/rulemaking.aspx?ruleid=62.* The *www.regulations.gov* Web page contains instructions on how to access all documents in the docket.

FOR FURTHER INFORMATION CONTACT: Mr. John Cymbalsky, U.S. Department of Energy, Office of Energy Efficiency and Renewable Energy, Building Technologies Office, EE–5B, 1000 Independence Avenue SW., Washington, DC 20585–0121. Telephone: (202) 287–1692. Email: *residential_furnaces_and_boilers@ee.doe.gov.*

Ms. Johanna Hariharan, U.S. Department of Energy, Office of the General Counsel, GC–33, 1000 Independence Avenue SW., Washington, DC 20585–0121. Telephone: (202) 586–9507 or (202) 287–6307. Email: *Johanna.Hariharan@hq.doe.gov.*

For further information on how to review other public comments and the docket, contact Ms. Brenda Edwards at (202) 586–2945 or by email: *Brenda.Edwards@ee.doe.gov.*

IV. Submission of Comments

I. Background

On March 10, 2015, DOE published in the **Federal Register** a notice of proposed rulemaking (NOPR) and public meeting to amend energy conservation standards for residential non-weatherized gas furnaces (NWGF) and mobile home gas furnaces (MHGF). 80 FR 13119. The proposed standards, which are expressed as minimum annual fuel utilization efficiencies (AFUE), are shown in Table I.1. These proposed standards, if adopted, would apply to all products listed in Table I.1 and manufactured in, or imported into, the United States on or after the date 5 years after the publication of the final rule for this rulemaking.

TABLE I.1—PROPOSED AFUE ENERGY CONSERVATION STANDARDS FOR NON-WEATHERIZED GAS FURNACES AND MOBILE HOME GAS FURNACES (TSL 3)

Product class	AFUE %
Non-Weatherized Gas-Fired Furnaces	92
Mobile Home Gas-Fired Furnaces	92

A number of stakeholders objected to a national standard at 92 percent AFUE, which would effectively only be able to be met by using condensing technology. The objections raised by stakeholders covered a wide range of issues, but the negative impacts of the proposed

standards on some furnace consumers were highlighted by many stakeholders.

A letter dated June 8, 2015, signed by 121 members of the U.S. House of Representatives, expressed concern that a nationwide energy efficiency standard that effectively precludes a consumer from choosing to install a non-condensing furnace would result in many homeowners either abandoning the use of natural gas to heat their homes or paying substantially more for the installation of a furnace that meets the new standard. It stated that many families will be faced with the difficult choice of having to replace their non-condensing furnace with either a condensing furnace with higher installation costs or electric heat and accompanying higher monthly energy bills. (United States House of Representatives, No. 67 at p. 1) Comments from the Pennsylvania Chambers of Commerce, Business, and Industry, Meeks, Payne, Jr., Bishop, Jr., and Carrier make similar statements. (Pennsylvania Chambers of Commerce, Business, and Industry, No. 82 at p. 1; Meeks, No. 140 at p. 1; Payne, Jr., No. 75 at p. 1; Bishop, Jr., No. 76 at p. 1)

The American Gas Association (AGA), Goodman, and American Energy Alliance (AEA *et al.*) stated that even assuming DOE's analysis is correct, many consumers could incur costs under the proposed standard. They stated that, according to DOE's analysis, 20 percent of households nationwide would face higher life-cycle costs under the proposed standard, and in the replacement market, one-quarter of all households replacing their natural gas furnaces would see a life-cycle cost increase. (AGA, No. 118 at p. 27; AEA *et al.*, No. 69 at p. 1; Goodman, No. 135 at p. 2) AGA, Goodman, and Southern Gas Association (SGA) added that consumers in the South and low-income families would be disproportionately impacted. (AGA, No. 118 at p. 27; Goodman, No. 135 at p. 2; SGA, No. 145 at p. 1)

The Air-Conditioning, Heating, and Refrigeration Institute (AHRI), Carrier, Rheem, and Ingersoll Rand expressed concern that the proposed standards will result in 10–20 percent of homes switching from gas furnaces to electric heat pumps because venting of a condensing gas furnace is difficult to impossible. (AHRI, No. 159 at p. 3; Carrier, No. 116 at p. 2; Rheem, No. 142 at p. 3; Ingersoll Rand, No. 156 at p. 2) AGA expressed a similar concern, and asserted that the resulting adverse energy and environmental impacts of this fuel switching are very substantial. (AGA, No. 118 at p. 28)

Several stakeholders, who expressed general support for the proposed standards and suggested more stringent standards could be justified, provided a recommendation for reducing negative impacts on some furnace consumers while maintaining the overall economic and environmental benefits of the standards. The American Council for an Energy-Efficient Economy (ACEEE) recommended that DOE establish a separate product class for small furnaces (tentatively those with an input capacity of 50,000 Btu/hour or less) and leave the standard level for these units at 80-percent AFUE, while adopting a higher standard level of 95-percent AFUE for larger furnaces. (ACEEE, No. 113 at p. 1) The Alliance to Save Energy made a similar recommendation, but referred to an input capacity of no more than 50,000 to 65,000 Btu/hour for smaller furnaces. (Alliance to Save Energy, No. 115 at p. 1) The Natural Resources Defense Council (NRDC) urged DOE to adopt an 80-percent AFUE standard level for furnaces below a specified maximum capacity threshold, and set the capacity threshold low enough that the national energy, economic, and environmental benefits are largely preserved while allowing consumers in small and moderately-sized, well insulated and weatherized homes in moderate and warm climates to have a non-condensing option. (NRDC, No. 134 at p. 2) AGLR stated that DOE should establish a separate product class for small furnaces with an input capacity of less than 45,000 Btu/hour, citing section 305(f) of EPCA as authority for DOE to establish separate product classes based on product capacity. (AGLR, No. 112 at pp. 15–16)

ACEEE also stated that creating two product classes based on furnace size would reduce the number of households that would experience net costs under the proposed standard (many of whom are in the south). ACEEE stated that many of the consumers who would experience net costs will have small furnaces and recommended that DOE specifically examine this issue and estimate the economics of separate standard levels as a function of furnace input capacity. ACEEE noted that a size threshold provides another option for some households with very high installation costs—if they weatherize their home and get the needed capacity below 50,000 Btu/h, they can avoid the extra installation cost of a condensing furnace. ACEEE added that a size threshold would not present the potential enforcement challenges associated with regional standards. (ACEEE, No. 113 at p. 3)

Although DOE believes that the standards proposed in the March 2015 NOPR meet the statutory criteria for amended standards, given the concerns and suggestions described above, DOE undertook an analysis of the consumer economics and national impacts of establishing separate standard levels for large and small residential furnaces. In so doing, it examined the effect of alternative size thresholds for a small furnace. Because the issues raised by stakeholders primarily concern NWGFs, DOE only considered that product in its analysis and did not examine mobile home gas furnaces. The analysis is described in section II of this NODA; section III provides the results of the analysis.

DOE notes that this NODA does not propose any energy conservation standards for residential furnaces. DOE may revise the analyses presented in today's NODA based on any new or updated information or data it obtains during the course of the rulemaking. DOE encourages stakeholders to provide any additional data or information that may improve the analysis.

II. Summary of the Analyses Performed by DOE

DOE conducted an analysis of the consumer impacts (life-cycle cost and payback period) and national impacts (national energy savings and net present value of national benefits) of potential standard levels for the considered NWGF product classes. The tools used in preparing these analyses and their respective results are available at: *https://www1.eere.energy.gov/buildings/appliance_standards/rulemaking.aspx?ruleid=62.* Each individual spreadsheet includes an introduction that provides an overview of the contents of the spreadsheet. These spreadsheets present the various inputs and outputs to the analysis and, where necessary, instructions. Brief descriptions of the analyses and of the supporting spreadsheet tools are provided below.

If DOE were to consider adopting energy conservation standards for residential furnaces that set separate levels based on input capacity, it would do so in a future supplemental NOPR (SNOPR). DOE would also publish a technical support document (TSD) containing a detailed written account of the analyses performed in support of the SNOPR, which will include updates to the analyses made available in this NODA.

The analysis conducted for this NODA used the same analytical

framework as the March 2015 NOPR.[1] Key aspects of the present analysis and DOE's updates to the NOPR analysis are described in the sections below.

A. Introduction

The analysis conducted for this NODA estimated impacts for the potential standard level combinations shown in Table II.1. The key aspect of this analysis is that only large furnaces would need to use condensing technology to meet the standard. Thus, households installing a small furnace would not need to incur the costs associated with installing a condensing furnace.

TABLE II.1—POTENTIAL STANDARD LEVEL COMBINATIONS ANALYZED FOR LARGE AND SMALL FURNACES

Furnance size	Annual fuel utilization efficiency (%)			
Large	90	92	95	98
Small	80	80	80	80

This NODA analysis used the same sample of residential furnace consumers as the March 2015 NOPR. Each sample household was assigned a furnace size (in terms of input capacity) based on a number of features, as discussed in section II.C. The share of households that would install a small furnace depends on how "small furnace" is defined in terms of input capacity. For this analysis, DOE considered the following small furnace definitions: ≤45 kBtu/hour, ≤50 kBtu/hour, ≤55 kBtu/hour, ≤60 kBtu/hour, and ≤65 kBtu/hour. In each case, large furnaces would be defined as all sizes above the given thresholds. The share of households that would install a furnace meeting a small furnace standard rises as the size cutoff in the small furnace definition increases, as illustrated in Table II.2.[2]

TABLE II.2—SHARE OF SAMPLE HOUSEHOLDS BY FURNACE SIZE

[percent]

Furnace size	Small furnace definition				
	≤45 kBtu/hour	≤50 kBtu/hour	≤55 kBtu/hour	≤60 kBtu/hour	≤65 kBtu/hour
Large	92	86	85	68	62
Small	8	14	15	32	38
Total	100	100	100	100	100

B. Engineering Analysis

The engineering analysis establishes the relationship between the manufacturer production cost (MPC) and energy efficiency for residential furnaces. This relationship between MPC and energy efficiency serves as the basis for calculations performed in the other analysis tools to estimate the costs and benefits to individual consumers, manufacturers, and the nation. For each NWGF efficiency level that was analyzed, the MPC was estimated for four furnace capacities (60 kBtu/hour, 80 kBtu/hour, 100 kBtu/hour, and 120 kBtu/hour). For the NODA analysis, DOE updated the MPCs from the NOPR to incorporate the most recent available data for material,[3] component, labor, and overhead costs, and also updated the MPCs to 2014$.

C. Life-Cycle Cost and Payback Period Analyses

The life-cycle cost (LCC) and payback period (PBP) analyses determine the economic impact of potential standards on individual consumers who purchase a furnace in the expected compliance year (assumed to be 2021 for this analysis). The LCC is the total cost of purchasing, installing and operating a residential furnace over the course of its lifetime. DOE determines the LCC by considering: (1) The total installed cost to the consumer (which consists of manufacturer selling price, distribution channel markups, sales taxes, and installation costs); (2) the annual energy consumption (natural gas or LPG and electricity) of residential furnaces as they are used in the field; (3) the operating cost of residential furnaces (*i.e.*, energy cost and maintenance and repair cost); (4) equipment lifetime; and (5) a discount rate that reflects the consumer cost of capital and puts the LCC in present-value terms. The PBP represents the number of years needed to recover the increase in purchase price of higher-efficiency residential furnaces through savings in the operating cost.

For each considered standards case, DOE measures the change in LCC relative to a no-new-standards case, which reflects the market in the absence of amended energy conservation standards, including market trends for equipment that exceeds the current energy conservation standards.

In the March 2015 NOPR and in today's NODA, DOE developed nationally-representative household samples for residential furnaces from the 2009 Residential Energy Consumption Survey (RECS).[4] DOE analyzed the net effect of potential amended residential furnace standards on consumers by calculating the LCC savings and PBP for each household by efficiency level.

DOE performed the LCC and PBP analyses using a spreadsheet model

[1] Please see the March 2015 NOPR and the accompanying TSD for details, which are available at *http://www1.eere.energy.gov/buildings/appliance_standards/rulemaking.aspx?ruleid=62*.

[2] The shares in Table II.2 reflect the likelihood that some consumers would down-size a new furnace to meet the "small furnace" definition. See section II.C for discussion.

[3] DOE uses 5-year averages for metal materials and current prices for all other materials.

[4] U.S. Department of Energy: Energy Information Administration, Residential Energy Consumption Survey: 2009 RECS Survey Data (2013), available at: *http://www.eia.gov/consumption/residential/data/2009/* (last accessed July 29, 2015).

combined with Crystal Ball [5] to account for uncertainty and variability among the input variables. Each Monte Carlo simulation consists of 10,000 LCC and PBP calculations using input values that are either sampled from probability distributions and household samples or characterized with single point values. The analytical results include a distribution of 10,000 data points showing the range of LCC savings for a given efficiency level relative to the no-new-standards case efficiency distribution. In performing an iteration of the Monte Carlo simulation for a given consumer, product efficiency is chosen based on its probability. If the chosen product efficiency is greater than or equal to the efficiency of the standard level under consideration, the LCC and PBP calculation reveals that a consumer is not impacted by the standard level. By accounting for consumers who already purchase more-efficient products, DOE avoids overstating the potential benefits from increasing product efficiency.

1. Furnace Size Assignment

For the March 2015 NOPR, DOE assigned an input capacity for the existing furnace of each housing unit based on an algorithm that correlates the heating square footage and the outdoor design temperature for heating (*i.e.*, the temperature that is exceeded by the 30-year minimum average temperature 1 percent of the time) with the distribution of input capacity of furnaces.[6] DOE assumed that, for the new furnace installation, the input capacity would remain the same. DOE's analysis accounted for the typical over-sizing of furnace capacity (*i.e.*, the furnace is larger than it needs to be to fulfill the building heating load).

If there is a separate standard for small furnaces, DOE expects that some consumers who would otherwise install a typically-oversized furnace would choose to down-size in order to be able to purchase a non-condensing furnace. For the NODA analysis, DOE identified those sample households that might down-size at the considered small furnace definitions. DOE first determined if a household would install a non-condensing furnace with an input capacity greater than the small furnace size limit without amended standards. In the standards case, DOE assumed that a fraction of such consumers would down-size to the input capacity limit for small furnaces.

2. Energy Prices

For this NODA, DOE updated current energy prices and also the projection of future energy prices. Current average and marginal monthly energy prices are based on the latest data (2013 energy prices) from EIA (Form 861 data [7] to calculate commercial electricity prices, Natural Gas Navigator [8] to calculate commercial natural gas prices, and State Energy Data System [9] to calculate LPG prices). The update to 2013 energy prices had a very small impact on the LCC and PBP results.[10] Future energy prices are based on the projection of average annual percent change in national-average residential natural gas and electricity prices in the *Annual Energy Outlook 2015* (*AEO 2015*).

3. Other Updates

For this NODA, DOE updated the efficiency distribution in the no-new-standards case to reflect AHRI shipments data from 2010 to 2014.[11] The update resulted in decreased fraction of consumers being impacted by an efficiency standard requiring efficiencies of 90-percent AFUE and above.[12] DOE also made minor updates to the markups, product price trend, and the building shell efficiency and climate indexes used to adjust energy use. These are described in the LCC spreadsheet.

D. National Impact Analysis

The national impacts analysis (NIA) estimates the national energy savings (NES) and the net present value (NPV) of total consumer costs and savings expected to result from potential new standards. DOE calculated NES and NPV as the difference between a case without amended standards and each standards case.

DOE calculated the annual energy consumption for each case using the appropriate per-unit annual energy use data multiplied by the projected residential furnaces shipments for each year. To estimate impacts of separate standards for small and large furnaces, DOE needed to disaggregate NWGF shipments by input capacity. To do so, DOE assumed that the shares of each size category in NWGF shipments are the same as the shares estimated for the household sample. The shares were assumed to remain constant over time.

Cumulative energy savings are the sum of the annual NES determined for the lifetime of furnaces shipped during a 30-year period assumed to start in the expected compliance year. Energy savings include the full-fuel cycle energy savings (*i.e.*, the energy needed to extract, process, and deliver primary fuel sources such as coal and natural gas, and the conversion and distribution losses of generating electricity from those fuel sources).

To develop the national NPV of consumer benefits from potential energy conservation standards, DOE calculated projected annual operating costs (energy costs and repair and maintenance costs) and annual installation costs for the no-new-standards case and the standards cases. DOE calculated annual energy expenditures from annual energy consumption using forecasted energy prices in each year. DOE calculated annual product expenditures by multiplying the price per unit times the projected shipments in each year.

The aggregate difference each year between operating cost savings and increased installation costs is the net savings or net costs. DOE multiplies the net savings in future years by a discount factor to determine their present value. DOE estimates the NPV of consumer benefits using both a 3-percent and a 7-percent real discount rate, in accordance with guidance provided by the Office of Management and Budget (OMB) to Federal agencies on the development of regulatory analysis.[13]

[5] Crystal Ball is a commercial software program developed by Oracle and used to conduct stochastic analysis using Monte Carlo simulation. A Monte Carlo simulation uses random sampling over many iterations of the simulation to obtain a probability distribution of results. Certain key inputs to the analysis are defined as probability distributions rather than single-point values.

[6] The distribution of input capacity is based on shipments data by input capacity bins for the year 2000 provided by AHRI (AHRI (formerly GAMA). Furnace and Boiler Shipments data provided to DOE for Furnace and Boiler ANOPR. January 23, 2002). AHRI data was further disaggregated into 5-kBtu/h bins using the reduced models dataset from the NOPR analysis. Appendix 7B of the NOPR TSD provides details about furnace sizing method.

[7] Energy Information Administration (EIA), Survey form EIA–861—Annual Electric Power Industry Report (Available at: *http://www.eia.gov/electricity/data/eia861/index.html*) (Last accessed July 15, 2015).

[8] Energy Information Administration (EIA), Natural Gas Navigator (Available at: *http://tonto.eia.doe.gov/dnav/ng/ng_pri_sum_dcu_nus_m.htm*) (Last accessed July 15, 2015).

[9] Energy Information Administration (EIA), State Energy Data System (SEDS) (Available at: *http://www.eia.gov/state/seds/*) (Last accessed July 15, 2015).

[10] For the NOPR, 2012 energy prices from the same sources were used.

[11] Air-Conditioning, Heating, and Refrigeration Institute, Personal communication. May 12, 2015. *http://www.regulations.gov/#!documentDetail;D=EERE-2014-BT-STD-0031-0052.*

[12] For the NOPR, the AHRI shipments data was not available and DOE instead relied on shipments data from the ENERGY STAR program to derive its estimates. Based on the AHRI shipments data, DOE's estimate of the condensing furnace market share in 2021 increased from 47-percent in the NOPR to 53-percent in the NODA.

[13] Office of Management and Budget, OMB Circular A–4, section E, Identifying and Measuring Benefits and Costs (2003), *available at http://www.whitehouse.gov/omb/memoranda/m03-21.html.*

For the NODA analysis, DOE updated energy price trends and several other inputs with data from *AEO 2015*, as described in the NIA spreadsheet.

III. Results of the Analysis

A. Economic Impacts on Consumers

As mentioned in section II.C, for each considered standards case, DOE measures the change in LCC relative to a no-new-standards case. For example, in the case of a separate standard of 90-percent AFUE for large furnaces and 80-percent AFUE for small furnaces, the analysis reflects the likelihood that some consumers would purchase a furnace at or above those efficiency levels without standards, and thus would not be affected by the standards. The average LCC savings in Table III.1 only include those consumers who would be affected at a given standard level.

Table III.2 shows the percentage of consumers that would experience a net cost under each considered standards case, and Table III.3 shows the percentage of consumers in the South that would experience a net cost.[14] For these consumers, the LCC would increase under the standard compared to the furnace they would purchase in no-new-standards case. As expected, the percentage of consumers that would experience a net cost declines as the definition of small furnace expands to include more furnaces.

TABLE III.1—AVERAGE LCC SAVINGS FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS

[2014$]

Minimum AFUE (%)		Average LCC savings (2014$) *				
Large	Small	Small furnace definition (kBtu/hour)				
		≤45	≤50	≤55	≤60	≤65
90	80	$383	$400	$400	$492	$484
92	80	463	478	479	553	525
95	80	439	447	449	479	437
98	80	365	372	374	388	347

* The average LCC savings only include those consumers who would be affected at a given standard level.

TABLE III.2—SHARE OF ALL CONSUMERS EXPERIENCING A NET COST FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS

Minimum AFUE (%)		% of consumers experiencing a net cost				
Large	Small	Small furnace definition (kBtu/hour)				
		≤45	≤50	≤55	≤60	≤65
90	80	19	15	13	11	7
92	80	17	13	12	10	6
95	80	21	17	15	12	9
98	80	35	34	33	26	23

TABLE III.3—SHARE OF CONSUMERS IN THE SOUTH EXPERIENCING A NET COST FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS

Minimum AFUE (%)		% of consumers in the south experiencing a net cost				
Large	Small	Small furnace definition (kBtu/hour)				
		≤45	≤50	≤55	≤60	≤65
90	80	27	20	19	13	7
92	80	25	18	17	11	7
95	80	28	22	21	14	10
98	80	35	31	30	20	14

Table III.4 compares the key consumer economic impacts of a single standard for all furnaces to a separate standard for large and small furnaces.[15] Under a separate standard for large and small furnaces, the average LCC savings increase somewhat but the share of consumers with a net cost declines considerably. The impacts of a separate standard for large and small furnaces would vary depending on the small furnace definition. For example, if the definition was ≤60 kBtu/hour instead of ≤55 kBtu/hour, the difference between the single standard for all furnaces and separate standards for large and small furnaces would be greater than shown.

[14] The analysis used the same definition of the South region as the March 2015 NOPR.

[15] The results for a single standard for all furnaces differ slightly from the results in the March 2015 NOPR because of the input revisions discussed in section II. DOE believes that showing a direct comparison with the NOPR results would not serve the purpose of the NODA analysis.

TABLE III.4—COMPARISON OF CONSUMER IMPACTS OF SINGLE STANDARD VS. SEPARATE STANDARD FOR LARGE AND SMALL FURNACES *

Single standard for all furnaces			Separate standard for large and small furnaces		
AFUE (%)	Avg. LCC savings (2014$)	Share of consumers with net cost (%)	AFUE (%) large/small	Avg. LCC savings (2014$)	Share of consumers with net cost (%)
90	$347	20	90/80	$400	13
92	425	18	92/80	479	12
95	420	22	95/80	449	15
98	343	41	98/80	374	33

* Using small furnace definition of ≤55 kBtu/hour.

Table III.5 and Table III.6 show a similar comparison for consumers in the south and low-income consumers, with similar results.[16]

TABLE III.5—COMPARISON OF IMPACTS FOR CONSUMERS IN THE SOUTH OF SINGLE STANDARD VS. SEPARATE STANDARD FOR LARGE AND SMALL FURNACES *

Single standard for all furnaces			Separate standard for large and small furnaces		
AFUE (%)	Avg. LCC savings (2014$)	Share of consumers with net cost (%)	AFUE (%) large/small	Avg. LCC savings (2014$)	Share of consumers with net cost (%)
90	$291	31	90/80	$335	19
92	357	28	92/80	405	17
95	357	33	95/80	379	21
98	319	44	98/80	368	30

* Using small furnace definition of ≤55 kBtu/hour.

TABLE III.6—COMPARISON OF IMPACTS FOR LOW-INCOME CONSUMERS OF SINGLE STANDARD VS. SEPARATE STANDARD FOR LARGE AND SMALL FURNACES *

Single standard for all furnaces			Separate standard for large and small furnaces		
AFUE (%)	Avg. LCC savings (2014$)	Share of consumers with net cost (%)	AFUE (%) large/small	Avg. LCC savings (2014$)	Share of consumers with net cost (%)
90	$210	22	90/80	$274	12
92	301	20	92/80	379	11
95	363	24	95/80	423	13
98	356	44	98/80	447	31

* Using small furnace definition of ≤55 kBtu/hour.

In the NOPR analysis, DOE estimated that some consumers faced with significant costs to install a condensing furnace would instead choose to switch to electric heating with a heat pump or electric furnace. If there were a separate, lower standard level for small furnaces, fewer consumers would be faced with installing a condensing furnace, and there would be less switching. Table III.7 shows this outcome.

TABLE III.7—COMPARISON OF FUEL SWITCHING IMPACTS OF SINGLE STANDARD VS. SEPARATE STANDARD FOR LARGE AND SMALL FURNACES *

Single standard for all furnaces			Separate standard for large and small furnaces		
AFUE (%)	Switch to heat pump (% of consumers)	Switch to electric furnace (% of consumers)	AFUE (%) large/small	Switch to heat pump (% of consumers)	Switch to electric furnace (% of consumers)
90	6.7	3.0	90/80	2.9	1.8
92	6.9	3.1	92/80	3.0	1.9
95	8.3	3.5	95/80	3.9	2.3
98	11.7	4.2	98/80	6.5	2.8

* Using small furnace definition of ≤55 kBtu/hour.

[16] The results in Table III.6 overstate the percentage of low-income households that would actually be negatively impacted by proposed higher-efficiency furnace standards. Close to 60 percent of low-income households in RECS 2009 are either renters or residents of public housing. In these cases, the furnace would be purchased by the property owner, and the cost of a higher-efficiency furnace might be passed on over time in the rent (or perhaps not all in the case of public housing). DOE's current analysis assumes that in cases where the property owner does not pay for energy, the cost of a higher-efficiency furnace is passed on immediately, which would tend to overstate any negative impact.

B. National Impacts

The estimated national energy savings (full-fuel-cycle) of the considered combinations of minimum AFUE for large and small furnaces are shown in Table III.8.

Table III.9 and Table III.10 show the national NPV of benefits for alternative furnace standard level combinations at 7-percent and 3-percent discount rates, respectively. The national energy savings decrease as the small furnace definition expands.

TABLE III.8—NATIONAL ENERGY SAVINGS FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS

[Quads]

Minimum AFUE (%)		Small furnace definition (kBtu/hour)				
Large	Small	≤45	≤50	≤55	≤60	≤65
92	80	2.9	2.9	2.9	2.3	1.8
95	80	4.2	4.2	4.1	3.4	2.8
98	80	5.8	5.7	5.7	4.9	4.2

TABLE III.9—NATIONAL NET PRESENT VALUE OF BENEFITS FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS AT 7-PERCENT DISCOUNT RATE

[Billion 2014$]

Minimum AFUE (%)		Small furnace definition (kBtu/hour)				
Large	Small	≤45	≤50	≤55	≤60	≤65
92	80	3.1	3.5	3.5	3.0	2.4
95	80	4.2	4.6	4.6	4.2	3.6
98	80	3.8	4.4	4.4	4.6	4.0

TABLE III.10—NATIONAL NET PRESENT VALUE OF BENEFITS FOR ALTERNATIVE FURNACE STANDARD LEVEL COMBINATIONS AT 3-PERCENT DISCOUNT RATE

[Billion 2014$]

Minimum AFUE (%)		Small furnace definition (kBtu/hour)				
Large	Small	≤45	≤50	≤55	≤60	≤65
92	80	14.7	14.8	14.8	11.8	9.1
95	80	20.2	20.1	20.0	16.9	13.9
98	80	23.9	24.0	23.9	21.3	18.4

Table III.11 compares the national energy savings and NPV of a single standard for all furnaces vs. a separate standard for large and small furnaces. The national energy savings are higher in the case of a separate standard for large and small furnaces mainly because there is less switching from gas to electric heating.[17] The NPV is higher in the case of a separate standard for large and small furnaces mainly because the LCC savings are higher. The impacts of a separate standard for large and small furnaces would vary depending on the small furnace definition.

TABLE III.11—COMPARISON OF NATIONAL IMPACTS OF SINGLE STANDARD VS. SEPARATE STANDARD FOR LARGE AND SMALL FURNACES *

Single standard for all furnaces			Separate standard for large and small furnaces		
AFUE (%)	National energy savings (quads)	National net present value, 7% (billion 2014$)	AFUE (%) large/small	National energy savings (quads)	National net present value, 7% (billion 2014$)
92	2.6	2.2	92/80	2.9	3.5
95	3.9	3.3	95/80	4.1	4.6
98	5.4	2.6	98/80	5.7	4.4

* Using small furnace definition of ≤55 kBtu/hour.

[17] In terms of FFC energy, switching from gas to electricity increases energy use considerably because of the losses in thermal electricity generation.

IV. Submission of Comments

DOE will accept comments, data, and information regarding this analysis before or after the public meeting, but no later than the date provided in the **DATES** section at the beginning of this document. Interested parties may submit comments, data, and other information using any of the methods described in the **ADDRESSES** section at the beginning of this document.

Submitting comments via *www.regulations.gov*. The *www.regulations.gov* Web page will require you to provide your name and contact information. Your contact information will be viewable to DOE Building Technologies staff only. Your contact information will not be publicly viewable except for your first and last names, organization name (if any), and submitter representative name (if any). If your comment is not processed properly because of technical difficulties, DOE will use this information to contact you. If DOE cannot read your comment due to technical difficulties and cannot contact you for clarification, DOE may not be able to consider your comment.

However, your contact information will be publicly viewable if you include it in the comment itself or in any documents attached to your comment. Any information that you do not want to be publicly viewable should not be included in your comment, nor in any document attached to your comment. Otherwise, persons viewing comments will see only first and last names, organization names, correspondence containing comments, and any documents submitted with the comments.

Do not submit to *www.regulations.gov* information for which disclosure is restricted by statute, such as trade secrets and commercial or financial information (hereinafter referred to as Confidential Business Information (CBI)). Comments submitted through *www.regulations.gov* cannot be claimed as CBI. Comments received through the Web site will waive any CBI claims for the information submitted. For information on submitting CBI, see the Confidential Business Information section below.

DOE processes submissions made through *www.regulations.gov* before posting. Normally, comments will be posted within a few days of being submitted. However, if large volumes of comments are being processed simultaneously, your comment may not be viewable for up to several weeks. Please keep the comment tracking number that *www.regulations.gov* provides after you have successfully uploaded your comment.

Submitting comments via email, hand delivery/courier, or mail. Comments and documents submitted via email, hand delivery/courier, or mail also will be posted to *www.regulations.gov*. If you do not want your personal contact information to be publicly viewable, do not include it in your comment or any accompanying documents. Instead, provide your contact information in a cover letter. Include your first and last names, email address, telephone number, and optional mailing address. The cover letter will not be publicly viewable as long as it does not include any comments

Include contact information each time you submit comments, data, documents, and other information to DOE. If you submit via mail or hand delivery/courier, please provide all items on a CD, if feasible, in which case it is not necessary to submit printed copies. No telefacsimiles (faxes) will be accepted.

Comments, data, and other information submitted to DOE electronically should be provided in PDF (preferred), Microsoft Word or Excel, WordPerfect, or text (ASCII) file format. Provide documents that are not secured, that are written in English, and that are free of any defects or viruses. Documents should not contain special characters or any form of encryption and, if possible, they should carry the electronic signature of the author.

Confidential Business Information. Pursuant to 10 CFR 1004.11, any person submitting information that he or she believes to be confidential and exempt by law from public disclosure should submit via email, postal mail, or hand delivery/courier two well-marked copies: One copy of the document marked "confidential" including all the information believed to be confidential, and one copy of the document marked "non-confidential" with the information believed to be confidential deleted. Submit these documents via email or on a CD, if feasible. DOE will make its own determination about the confidential status of the information and treat it according to its determination.

Factors of interest to DOE when evaluating requests to treat submitted information as confidential include: (1) A description of the items; (2) whether and why such items are customarily treated as confidential within the industry; (3) whether the information is generally known by or available from other sources; (4) whether the information has previously been made available to others without obligation concerning its confidentiality; (5) an explanation of the competitive injury to the submitting person that would result from public disclosure; (6) when such information might lose its confidential character due to the passage of time; and (7) why disclosure of the information would be contrary to the public interest.

It is DOE's policy that all comments may be included in the public docket, without change and as received, including any personal information provided in the comments (except information deemed to be exempt from public disclosure).

Issued in Washington, DC, on September 4, 2015.

Kathleen B. Hogan,

Deputy Assistant Secretary for Energy Efficiency, Energy Efficiency and Renewable Energy.

BILLING CODE 6450–01–P

DEPARTMENT OF TRANSPORTATION

Federal Aviation Administration

14 CFR Part 39

[Docket No. FAA–2015–3628; Directorate Identifier 2015–NM–025–AD]

RIN 2120–AA64

Airworthiness Directives; The Boeing Company Airplanes

AGENCY: Federal Aviation Administration (FAA), DOT.

ACTION: Notice of proposed rulemaking (NPRM).

SUMMARY: We propose to supersede Airworthiness Directive (AD) 2012–12–04, which applies to certain The Boeing Company Model 737–300, –400, and –500 series airplanes. AD 2012–12–04 currently requires repetitive external detailed inspections and nondestructive inspections to detect cracks in the fuselage skin along the chem-mill steps at stringers S–1 and S–2R, between station (STA) 400 and STA 460, and repair if necessary. Since we issued AD 2012–12–04, we have determined that, for certain airplanes, the skin pockets adjacent to the Air Traffic Control (ATC) antenna are susceptible to widespread fatigue damage. This proposed AD would require a preventive modification of the fuselage skin at crown stringers S–1 and S–2R. This proposed AD would reduce inspection thresholds and repetitive intervals for certain airplanes. We are proposing this AD to detect and correct fatigue cracking of the fuselage skin panels at the chem-mill steps, which could result in sudden fracture and failure of the fuselage skin panels,

and consequent rapid decompression of the airplane.

DATES: We must receive comments on this proposed AD by October 29, 2015.

ADDRESSES: You may send comments, using the procedures found in 14 CFR 11.43 and 11.45, by any of the following methods:

- Federal eRulemaking Portal: Go to *http://www.regulations.gov*. Follow the instructions for submitting comments.
- Fax: 202–493–2251.
- Mail: U.S. Department of Transportation, Docket Operations, M–30, West Building Ground Floor, Room W12–140, 1200 New Jersey Avenue SE., Washington, DC 20590.
- Hand Delivery: Deliver to Mail address above between 9 a.m. and 5 p.m., Monday through Friday, except Federal holidays.

For service information identified in this proposed AD, contact Boeing Commercial Airplanes, Attention: Data & Services Management, P.O. Box 3707, MC 2H–65, Seattle, WA 98124–2207; telephone 206–544–5000, extension 1; fax 206–766–5680; Internet *https://www.myboeingfleet.com*. You may view this referenced service information at the FAA, Transport Airplane Directorate, 1601 Lind Avenue SW., Renton, WA. For information on the availability of this material at the FAA, call 425–227–1221. It is also available on the Internet at *http://www.regulations.gov* by searching for and locating Docket No. FAA–2015–3628.

Examining the AD Docket

You may examine the AD docket on the Internet at *http://www.regulations.gov* by searching for and locating Docket No. FAA–2015–3628; or in person at the Docket Management Facility between 9 a.m. and 5 p.m., Monday through Friday, except Federal holidays. The AD docket contains this proposed AD, the regulatory evaluation, any comments received, and other information. The street address for the Docket Office (phone: 800–647–5527) is in the **ADDRESSES** section. Comments will be available in the AD docket shortly after receipt.

FOR FURTHER INFORMATION CONTACT: Wayne Lockett, Aerospace Engineer, Airframe Branch, ANM–120S, FAA, Seattle Aircraft Certification Office, 1601 Lind Avenue SW., Renton, WA 98057–3356; phone: 425–917–6447; fax: 425–917–6590; email: *wayne.lockett@faa.gov*.

SUPPLEMENTARY INFORMATION:

Comments Invited

We invite you to send any written relevant data, views, or arguments about this proposed AD. Send your comments to an address listed under the **ADDRESSES** section. Include "Docket No. FAA–2015–3628; Directorate Identifier 2015–NM–025–AD" at the beginning of your comments. We specifically invite comments on the overall regulatory, economic, environmental, and energy aspects of this proposed AD. We will consider all comments received by the closing date and may amend this proposed AD because of those comments.

We will post all comments we receive, without change, to *http://www.regulations.gov*, including any personal information you provide. We will also post a report summarizing each substantive verbal contact we receive about this proposed AD.

Discussion

On May 31, 2012, we issued AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), for certain The Boeing Company Model 737–300, –400, and –500 series airplanes. AD 2012–12–04 requires repetitive external detailed inspections and nondestructive inspections to detect cracks in the fuselage skin along the chem-mill steps at stringers S–1 and S–2R, between station (STA) 400 and STA 460, and repair if necessary. AD 2012–12–04 resulted from reports of crack findings of the fuselage skin at the chem-mill steps. We issued AD 2012–12–04 to detect and correct fatigue cracking of the fuselage skin panels at the chem-mill steps, which could result in sudden fracture and failure of the fuselage skin panels, and consequent rapid decompression of the airplane.

Widespread Fatigue Damage

Structural fatigue damage is progressive. It begins as minute cracks, and those cracks grow under the action of repeated stresses. This can happen because of normal operational conditions and design attributes, or because of isolated situations or incidents such as material defects, poor fabrication quality, or corrosion pits, dings, or scratches. Fatigue damage can occur locally, in small areas or structural design details, or globally. Global fatigue damage is general degradation of large areas of structure with similar structural details and stress levels. Multiple-site damage is global damage that occurs in a large structural element such as a single rivet line of a lap splice joining two large skin panels. Global damage can also occur in multiple elements such as adjacent frames or stringers. Multiple-site-damage and multiple-element-damage cracks are typically too small initially to be reliably detected with normal inspection methods. Without intervention, these cracks will grow, and eventually compromise the structural integrity of the airplane, in a condition known as widespread fatigue damage (WFD). As an airplane ages, WFD will likely occur, and will certainly occur if the airplane is operated long enough without any intervention.

The FAA's WFD final rule (75 FR 69746, November 15, 2010) became effective on January 14, 2011. The WFD rule requires certain actions to prevent structural failure due to WFD throughout the operational life of certain existing transport category airplanes and all of these airplanes that will be certificated in the future. For existing and future airplanes subject to the WFD rule, the rule requires that DAHs establish a limit of validity (LOV) of the engineering data that support the structural maintenance program. Operators affected by the WFD rule may not fly an airplane beyond its LOV, unless an extended LOV is approved.

The WFD rule (75 FR 69746, November 15, 2010) does not require identifying and developing maintenance actions if the DAHs can show that such actions are not necessary to prevent WFD before the airplane reaches the LOV. Many LOVs, however, do depend on accomplishment of future maintenance actions. As stated in the WFD rule, any maintenance actions necessary to reach the LOV will be mandated by airworthiness directives through separate rulemaking actions.

In the context of WFD, this action is necessary to enable DAHs to propose LOVs that allow operators the longest operational lives for their airplanes, and still ensure that WFD will not occur. This approach allows for an implementation strategy that provides flexibility to DAHs in determining the timing of service information development (with FAA approval), while providing operators with certainty regarding the LOV applicable to their airplanes.

Actions Since AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), Was Issued

The preamble to AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), specified that we considered the requirements "interim action." AD 2012–12–04 explained that we might consider further rulemaking if final action is later identified. We now

have determined that it is necessary to initiate further rulemaking to require modification of the fuselage skin at crown stringers S–1 and S–2R, and to reduce inspection thresholds and repetitive intervals for certain airplanes.

Related Service Information Under 1 CFR Part 51

We reviewed Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015. The service information describes procedures for repetitive external detailed inspections and non-destructive inspections to detect cracks in the fuselage skin along the chem-mill steps at stringers S–1 and S–2R, between STA 400 and STA 460, and repair of any cracking. The service information also describes procedures for a modification of the chem-milled steps at the locations identified, including related investigative actions and corrective actions. This service information is reasonably available because the interested parties have access to it through their normal course of business or by the means identified in the **ADDRESSES** section of this NPRM.

FAA's Determination

We are proposing this AD because we evaluated all the relevant information and determined the unsafe condition described previously is likely to exist or develop in other products of the same type design.

Proposed AD Requirements

Although this proposed AD does not explicitly restate the requirements of AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), this proposed AD would retain all of the requirements. Those requirements are referenced in the service information identified previously, which, in turn, is referenced in this proposed AD. This proposed AD would require accomplishing the actions specified in the service information described previously, except as discussed under "Difference Between This Proposed AD and the Service Bulletin." For information on the procedures and compliance times, see this service information at *http://www.regulations.gov* by searching for and locating Docket No. FAA–2015–3628.

The phrase "related investigative actions" is used in this proposed AD. "Related investigative actions" are follow-on actions that (1) are related to the primary action, and (2) further investigate the nature of any condition found. Related investigative actions in an AD could include, for example, inspections.

The phrase "corrective actions" is used in this proposed AD. "Corrective actions" are actions that correct or address any condition found. Corrective actions in an AD could include, for example, repairs.

Explanation of Compliance Time

The compliance time for the modification specified in this proposed AD for addressing WFD was established to ensure that discrepant structure is modified before WFD develops in airplanes. Standard inspection techniques cannot be relied on to detect WFD before it becomes a hazard to flight. We will not grant any extensions of the compliance time to complete any AD-mandated service bulletin related to WFD without extensive new data that would substantiate and clearly warrant such an extension.

Difference Between This Proposed AD and the Service Bulletin

Although Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, specifies that operators may contact the manufacturer for disposition of certain repair conditions, this proposed AD would require repairing those conditions in one of the following ways:

- In accordance with a method that we approve; or
- Using data that meet the certification basis of the airplane, and that have been approved by the Boeing Commercial Airplanes Organization Designation Authorization (ODA) whom we have authorized to make those findings.

Costs of Compliance

We estimate that this proposed AD affects 186 airplanes of U.S. registry.

We estimate the following costs to comply with this proposed AD:

ESTIMATED COSTS

Action	Labor cost	Parts cost	Cost per product	Cost on U.S. operators
Retained inspections from AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012).	Between 7 and 15 work-hours × $85 per hour, depending on airplane configuration = between $595 and $1,275 per inspection cycle.	$0	Between $595 and $1,275 per inspection cycle.	Between $110,670 and $237,150 per inspection cycle.
New modification	236 work-hours × $85 per hour = $20,060.	(1)	$20,060	$3,731,160.

[1] We currently have no specific cost estimates associated with the parts necessary for the proposed modification. We cannot determine the cost of the materials because the modification parts must be sized at the time the modification is installed, taking into account any existing repairs in the area.

We have received no definitive data that would enable us to provide a cost estimate for the on-condition actions specified in this proposed AD.

Authority for This Rulemaking

Title 49 of the United States Code specifies the FAA's authority to issue rules on aviation safety. Subtitle I, Section 106, describes the authority of the FAA Administrator. Subtitle VII, Aviation Programs, describes in more detail the scope of the Agency's authority.

We are issuing this rulemaking under the authority described in Subtitle VII, Part A, Subpart III, Section 44701, "General requirements." Under that section, Congress charges the FAA with promoting safe flight of civil aircraft in air commerce by prescribing regulations for practices, methods, and procedures the Administrator finds necessary for safety in air commerce. This regulation is within the scope of that authority because it addresses an unsafe condition that is likely to exist or develop on products identified in this rulemaking action.

Regulatory Findings

We have determined that this proposed AD would not have federalism implications under Executive Order 13132. This proposed AD would not have a substantial direct effect on the States, on the relationship between the national Government and the States, or

on the distribution of power and responsibilities among the various levels of government.

For the reasons discussed above, I certify that the proposed regulation:

(1) Is not a "significant regulatory action" under Executive Order 12866,

(2) Is not a "significant rule" under the DOT Regulatory Policies and Procedures (44 FR 11034, February 26, 1979),

(3) Will not affect intrastate aviation in Alaska, and

(4) Will not have a significant economic impact, positive or negative, on a substantial number of small entities under the criteria of the Regulatory Flexibility Act.

List of Subjects in 14 CFR Part 39

Air transportation, Aircraft, Aviation safety, Incorporation by reference, Safety.

The Proposed Amendment

Accordingly, under the authority delegated to me by the Administrator, the FAA proposes to amend 14 CFR part 39 as follows:

PART 39—AIRWORTHINESS DIRECTIVES

■ 1. The authority citation for part 39 continues to read as follows:

Authority: 49 U.S.C. 106(g), 40113, 44701.

§ 39.13 [Amended]

■ 2. The FAA amends § 39.13 by removing Airworthiness Directive (AD) 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), and adding the following new AD:

The Boeing Company: Docket No. FAA–2015–3628; Directorate Identifier 2015–NM–025–AD.

(a) Comments Due Date

The FAA must receive comments on this AD action by October 29, 2015.

(b) Affected ADs

This AD replaces AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012).

(c) Applicability

This AD applies to The Boeing Company Model 737–300, –400, and –500 series airplanes, certificated in any category, as identified in Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015.

(d) Subject

Air Transport Association (ATA) of America Code 53, Fuselage.

(e) Unsafe Condition

This AD was prompted by reports of cracks found on the fuselage skin at the chem-mill steps, and the determination that, for certain airplanes, the skin pockets adjacent to the Air Traffic Control (ATC) antenna are susceptible to widespread fatigue damage. We are issuing this AD to detect and correct fatigue cracking of the fuselage skin panels at the chem-mill steps, which could result in sudden fracture and failure of the fuselage skin panels, and consequent rapid decompression of the airplane.

(f) Compliance

Comply with this AD within the compliance times specified, unless already done.

(g) Inspections

At the applicable time specified in tables 1, 2, 3, and 5 of paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, except as required by paragraphs (j)(1) and (j)(2) of this AD: Do the actions specified in paragraphs (g)(1) and (g)(2) of this AD, in accordance with the Accomplishment Instructions of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, except as required by paragraph (j)(3) of this AD. Repeat the applicable inspections thereafter at the applicable times specified in paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015.

(1) Do an external detailed inspection for cracking of the fuselage skin chem-mill steps.

(2) Do an external non-destructive (medium frequency eddy current, magneto optical imaging, C-Scan, or ultrasonic phased array) inspection for cracking of the fuselage skin chem-mill steps.

(h) Preventive Modification or Repair

If any cracking is found during any inspection required by paragraph (g) of this AD, do the applicable actions specified in paragraph (h)(1) or (h)(2) of this AD.

(1) Repair before further flight in accordance with Part 2 of the Accomplishment Instructions of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015.

(2) At the applicable time specified in tables 1, 2, 3, and 5 of paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, except as required by paragraphs (j)(1) and (j)(2) of this AD: Do a preventive modification of the fuselage skin at crown stringers S–1 and S–2R, including all applicable related investigative actions in accordance with Part 9 of the Accomplishment Instructions of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015. Do all applicable related investigative actions concurrently with the modification.

(i) Post-Repair Inspections/Post-Modification Inspections

The post-repair/post-modification inspections specified in tables 4 and 6 of paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, are not required by this AD.

Note 1 to paragraph (h) of this AD: The post-repair/post-modification inspections specified in tables 4 and 6 of paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, may be used in support of compliance with section 121.1109(c)(2) or 129.109(c)(2) of the Federal Aviation Regulations (14 CFR 121.1109(c)(2) or 14 CFR 129.109(c)(2)). The corresponding actions specified in the Accomplishment Instructions of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, are not required by this AD.

(j) Exceptions to Service Bulletin Specifications

(1) Where Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, specifies a compliance time "after the Revision 3 date of this service bulletin," this AD requires compliance within the specified compliance time after the effective date of this AD.

(2) Where the Condition column of paragraph 1.E., "Compliance," of Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, specifies a condition based on when an airplane has or has not been inspected, this AD bases the condition on whether an airplane has or has not been inspected on the effective date of this AD.

(3) Where Boeing Alert Service Bulletin 737–53A1293, Revision 3, dated January 23, 2015, specifies to contact Boeing for repair instructions: Before further flight, repair using a method approved in accordance with the procedures specified in paragraph (k) of this AD.

(k) Credit for Previous Actions

(1) This paragraph provides credit for actions required by paragraphs (g) and (h) of this AD, if those actions were performed before July 23, 2012 (the effective date of AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012)), using Boeing Alert Service Bulletin 737–53A1293, Revision 1, dated July 7, 2010, which is not incorporated by reference in this AD.

(2) This paragraph provides credit for actions required by paragraphs (g) and (h) of this AD, if those actions were performed before the effective date of this AD using Boeing Alert Service Bulletin 737–53A1293, Revision 2, dated August 10, 2011, which was incorporated by reference in AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012).

(l) Alternative Methods of Compliance (AMOCs)

(1) The Manager, Los Angeles Aircraft Certification Office (ACO), FAA, has the authority to approve AMOCs for this AD, if requested using the procedures found in 14 CFR 39.19. In accordance with 14 CFR 39.19, send your request to your principal inspector or local Flight Standards District Office, as appropriate. If sending information directly to the manager of the ACO, send it to the attention of the person identified in paragraph (l)(1) of this AD. Information may be emailed to: *9-ANM-LAACO-AMOC-Requests@faa.gov.*

(2) Before using any approved AMOC, notify your appropriate principal inspector,

or lacking a principal inspector, the manager of the local flight standards district office/certificate holding district office.

(3) An AMOC that provides an acceptable level of safety may be used for any repair required by this AD if it is approved by the Boeing Commercial Airplanes Organization Designation Authorization (ODA) that has been authorized by the Manager, Los Angeles ACO, to make those findings. For a repair method to be approved, the repair must meet the certification basis of the airplane, and the approval must specifically refer to this AD.

(4) AMOCs approved for AD 2012–12–04, Amendment 39–17083 (77 FR 36134, June 18, 2012), are approved as AMOCs for the corresponding provisions of paragraph (g) of this AD.

(m) Related Information

(1) For more information about this AD, contact Wayne Lockett, Aerospace Engineer, Airframe Branch, ANM–120S, FAA, Seattle ACO, 1601 Lind Avenue SW., Renton, WA 98057–3356; phone: 425–917–6447; fax: 425–917–6590; email: *wayne.lockett@faa.gov.*

(2) For service information identified in this AD, contact Boeing Commercial Airplanes, Attention: Data & Services Management, P.O. Box 3707, MC 2H–65, Seattle, WA 98124–2207; telephone 206–544–5000, extension 1; fax 206–766–5680; Internet *https://www.myboeingfleet.com.* You may view this referenced service information at the FAA, Transport Airplane Directorate, 1601 Lind Avenue SW., Renton, WA. For information on the availability of this material at the FAA, call 425–227–1221.

Issued in Renton, Washington, on September 1, 2015.

Michael Kaszycki,

Acting Manager, Transport Airplane Directorate, Aircraft Certification Service.

RIN 2120–AA66

Proposed Amendment of Air Traffic Service (ATS) Routes; Northeast United States

AGENCY: Federal Aviation Administration (FAA), DOT.

ACTION: Notice of proposed rulemaking (NPRM).

SUMMARY: This action proposes to modify jet routes J–6, J–97, and J–222, and VOR Federal airways V–196, and V–489, in the northeastern United States due to the planned decommissioning of the Plattsburgh, NY, VORTAC facility.

DATES: Comments must be received on or before October 29, 2015.

ADDRESSES: Send comments on this proposal to the U.S. Department of Transportation, Docket Operations, M–30, 1200 New Jersey Avenue SE., West Building Ground Floor, Room W12–140, Washington, DC 20590–0001; telephone: (202) 366–9826. You must identify FAA Docket No. FAA–2015–3361 and Airspace Docket No. 15–AEA–4 at the beginning of your comments. You may also submit comments through the Internet at *http://www.regulations.gov.*

FAA Order 7400.9Y, Airspace Designations and Reporting Points, and subsequent amendments can be viewed online at *http://www.faa.gov/air_traffic/publications/.* For further information, you can contact the Airspace Policy and Regulations Group, Federal Aviation Administration, 800 Independence Avenue, SW., Washington, DC, 20591; telephone: 202–267–8783. The Order is also available for inspection at the National Archives and Records Administration (NARA). For information on the availability of this material at NARA, call 202–741–6030, or go to *http://www.archives.gov/federal_register/code_of_federal-regulations/ibr_locations.html.*

FAA Order 7400.9, Airspace Designations and Reporting Points, is published yearly and effective on September 15.

FOR FURTHER INFORMATION CONTACT: Paul Gallant, Airspace Policy and Regulations Group, Office of Airspace Services, Federal Aviation Administration, 800 Independence Avenue SW., Washington, DC 20591; telephone: (202) 267–8783.

SUPPLEMENTARY INFORMATION:

Authority for This Rulemaking

The FAA's authority to issue rules regarding aviation safety is found in Title 49 of the United States Code. Subtitle I, Section 106 describes the authority of the FAA Administrator. Subtitle VII, Aviation Programs, describes in more detail the scope of the agency's authority. This rulemaking is promulgated under the authority described in Subtitle VII, Part A, Subpart I, Section 40103. Under that section, the FAA is charged with prescribing regulations to assign the use of the airspace necessary to ensure the safety of aircraft and the efficient use of airspace. This regulation is within the scope of that authority as it modifies the air traffic service route structure in the northeast United States to maintain the efficient flow of air traffic.

Comments Invited

Interested parties are invited to participate in this proposed rulemaking by submitting such written data, views, or arguments as they may desire. Comments that provide the factual basis supporting the views and suggestions presented are particularly helpful in developing reasoned regulatory decisions on the proposal. Comments are specifically invited on the overall regulatory, aeronautical, economic, environmental, and energy-related aspects of the proposal.

Communications should identify both docket numbers (FAA Docket No. FAA–2015–3361 and Airspace Docket No. 15–AEA–4) and be submitted in triplicate to the Docket Management Facility (see **ADDRESSES** section for address and phone number). You may also submit comments through the Internet at *http://www.regulations.gov.*

Commenters wishing the FAA to acknowledge receipt of their comments on this action must submit with those comments a self-addressed, stamped postcard on which the following statement is made: "Comments to FAA Docket No. FAA–2015–3361 and Airspace Docket No. 15–AEA–4." The postcard will be date/time stamped and returned to the commenter.

All communications received on or before the specified comment closing date will be considered before taking action on the proposed rule. The proposal contained in this action may be changed in light of comments received. All comments submitted will be available for examination in the public docket both before and after the comment closing date. A report summarizing each substantive public contact with FAA personnel concerned with this rulemaking will be filed in the docket.

Availability of NPRMs

An electronic copy of this document may be downloaded through the Internet at *http://www.regulations.gov.*

You may review the public docket containing the proposal, any comments received and any final disposition in person in the Dockets Office (see **ADDRESSES** section for address and phone number) between 9:00 a.m. and 5:00 p.m., Monday through Friday, except Federal holidays. An informal docket may also be examined during normal business hours at the office of the Eastern Service Center, Federal Aviation Administration, Room 210, 1701 Columbia Ave., College Park, GA, 30337.

Persons interested in being placed on a mailing list for future NPRMs should contact the FAA's Office of Rulemaking, (202) 267–9677, for a copy of Advisory Circular No. 11–2A, Notice of Proposed

Rulemaking Distribution System, which describes the application procedure.

Availability and Summary of Documents for Incorporation by Reference

This document proposes to amend FAA Order 7400.9Y, Airspace Designations and Reporting Points, dated August 6, 2014, and effective September 15, 2014. FAA Order 7400.9Y is publicly available as listed in the **ADDRESSES** section of this proposed rule. FAA Order 7400.9Y lists Class A, B, C, D, and E airspace areas, air traffic service routes, and reporting points.

The Proposal

The FAA is proposing an amendment to Title 14, Code of Federal Regulations (14 CFR) part 71 to modify the descriptions of jet routes J–6, J–97 and J–222; and VOR Federal airways V–196 and V–489, due to the planned decommissioning of the Plattsburgh, NY, VORTAC. The proposed route changes are outlined below.

J6 Jet route J–6 extends from Salinas, CA, across the United States to Albany, NY, then terminates at Plattsburgh, NY. The FAA proposes to terminate the route at Albany, eliminating the segment between Albany and Plattsburgh.

J–97 Jet route J–97 extends between the SLATN fix and Plattsburgh, NY. The FAA proposes to terminate the route at Boston, MA, eliminating the segment between Boston and Plattsburgh.

J–222 Jet route J–222 extends between Robbinsville, NJ, and Plattsburgh, NY. The FAA proposes to terminate the route at Cambridge, NY, eliminating the segment between Cambridge and Plattsburgh.

V–196 VOR Federal airway V–196 extends from Utica, NY, to Saranac Lake, NY to Plattsburgh, NY. The FAA proposes to terminate the route at the intersection of the Saranac Lake, NY 058°(T) and the Burlington, VT 296°(T) radials, eliminating the segment between that intersection and Plattsburgh.

V–489 VOR Federal airway V–489 extends between the intersection of the Sparta, NJ 300°(T) and the Huguenot, NY 196°(T) radials and Plattsburgh, NY. The FAA proposes to terminate the route at Glens Falls, NY, eliminating the segment between Glens Falls and Plattsburgh.

Except for VOR Federal airway V–196, all radials in the route descriptions below are stated in True degrees. Both True and Magnetic degrees are used to describe the intersecting radials in V–196 since this intersection would be added to the airway description.

Jet routes are published in paragraph 2004, and VOR Federal airways are published in paragraph 6010(a), respectively, of FAA Order 7400.9Y dated August 6, 2014, and effective September 15, 2014, which is incorporated by reference in 14 CFR 71.1. The jet routes and VOR Federal airways listed in this document would be subsequently published in the Order.

Regulatory Notices and Analyses

The FAA has determined that this proposed regulation only involves an established body of technical regulations for which frequent and routine amendments are necessary to keep them operationally current. Therefore, this proposed regulation: (1) is not a "significant regulatory action" under Executive Order 12866; (2) is not a "significant rule" under Department of Transportation (DOT) Regulatory Policies and Procedures (44 FR 11034; February 26, 1979); and (3) does not warrant preparation of a regulatory evaluation as the anticipated impact is so minimal. Since this is a routine matter that will only affect air traffic procedures and air navigation, it is certified that this proposed rule, when promulgated, will not have a significant economic impact on a substantial number of small entities under the criteria of the Regulatory Flexibility Act.

Environmental Review

This proposal will be subject to an environmental analysis in accordance with FAA Order 1050.1E, "Environmental Impacts: Policies and Procedures" prior to any FAA final regulatory action.

List of Subjects in 14 CFR Part 71

Airspace, Incorporation by reference, Navigation (air).

The Proposed Amendment

In consideration of the foregoing, the Federal Aviation Administration proposes to amend 14 CFR part 71 as follows:

PART 71—DESIGNATION OF CLASS A, B, C, D, AND E AIRSPACE AREAS; AIR TRAFFIC SERVICE ROUTES; AND REPORTING POINTS

■ 1. The authority citation for part 71 continues to read as follows:

Authority: 49 U.S.C. 106(f), 106(g); 40103, 40113, 40120; E.O. 10854, 24 FR 9565, 3 CFR, 1959–1963 Comp., p. 389.

§ 71.1 [Amended]

■ 2. The incorporation by reference in 14 CFR 71.1 of FAA Order 7400.9Y, Airspace Designations and Reporting Points, dated August 6, 2014 and effective September 15, 2014, is amended as follows:

Paragraph 2004 Jet Routes

* * * * *

J–6 [Amended]

From Salinas, CA, via INT Salinas 145° and Avenal, CA, 292° radials; Avenal; INT Avenal 119° and Palmdale, CA, 310° radials; Palmdale; Hector, CA; Needles, CA; Drake, AZ; Zuni, AZ; Albuquerque, NM; Tucumcari, NM; Panhandle, TX; Will Rogers, OK; Little Rock, AR; Bowling Green, KY; Charleston, WV; INT Charleston 076° and Martinsburg, WV, 243° radials; Martinsburg; Lancaster, PA; Broadway, NJ; Sparta, NJ; to Albany, NY.

J–97 [Amended]

From lat. 39°07′00″ N., long. 67°00′00″ W. via Nantucket, MA; to Boston, MA.

J–222 [Amended]

From Robbinsville, NJ; INT Robbinsville 039° and Kennedy, NY, 253° radials; Kennedy; INT Kennedy 022° and Cambridge, NY, 179° radials; to Cambridge.

* * * * *

Paragraph 6010(a) Domestic VOR Federal Airways

V–196 [Amended]

From Utica, NY, Saranac Lake, NY; to INT Saranac Lake 058°(T)/072°(M) and Burlington, VT 296°(T)311°(M) radials.

V–489 [Amended]

From INT Sparta, NJ, 300° and Huguenot, NY, 196° radials; Huguenot; INT Huguenot 008° and Albany, NY, 209° radials; Albany; to Glens Falls, NY.

Issued in Washington, DC, on September 3, 2015.

Gary A. Norek,

Manager, Airspace Policy and Regulations Group.

[Docket No. SSA–2014–0081]

RIN 0960–AH74

Vocational Factors of Age, Education, and Work Experience in the Adult Disability Determination Process

AGENCY: Social Security Administration.

ACTION: Advance notice of proposed rulemaking.

SUMMARY: We are soliciting public input about how we should consider the vocational factors of age, education, and work experience in adult disability claims under titles II and XVI of the Social Security Act (Act). There have been significant changes in technology

use and workforce demographics since we first adopted our vocational factor regulations in 1978. We are requesting public comments, along with any supporting data, to assist in our efforts to streamline, simplify, and ensure the ongoing relevance of our disability determination programs.

DATES: To be sure that we consider your comments, we must receive them no later than November 13, 2015.

ADDRESSES: You may submit comments by any one of three methods—Internet, fax, or mail. Do not submit the same comments multiple times or by more than one method. Regardless of which method you choose, please state that your comments refer to Docket No. SSA–2014–0081, so that we may associate your comments with the correct regulation.

Caution: You should be careful to include in your comments only information that you wish to make publicly available. We strongly urge you not to include in your comments any personal information, such as Social Security numbers or medical information.

1. Internet: We strongly recommend that you submit your comments via the Internet. Please visit the Federal eRulemaking portal at *http://www.regulations.gov*. Use the Search function to find docket number SSA–2014–0081. The system will issue a tracking number to confirm your submission. You will not be able to view your comment immediately because we must post each comment manually. It may take up to a week for your comment to be viewable.

2. Fax: Fax comments to (410) 966–2830.

3. Mail: Address your comments to the Office of Regulations and Reports Clearance, Social Security Administration, 3100 West High Rise Building, 6401 Security Boulevard, Baltimore, Maryland 21235–6401.

Comments are available for public viewing on the Federal eRulemaking portal at *http://www.regulations.gov* or in person, during regular business hours, by arranging with the contact person identified below.

FOR FURTHER INFORMATION CONTACT: Mary Quatroche, Office of Disability Policy, Social Security Administration, 6401 Security Boulevard, Baltimore, MD 21235–6401, (410) 966–4794. For information on eligibility or filing for benefits, call our national toll-free number, 1–800–772–1213 or TTY 1–800–325–0778, or visit our Internet site, Social Security Online, at *http://www.socialsecurity.gov*.

SUPPLEMENTARY INFORMATION:

Background

The Act defines "disability" for titles II and XVI as the "inability to engage in any substantial gainful activity by reason of any medically determinable physical or mental impairment which can be expected to result in death or which has lasted or can be expected to last for a continuous period of not less than 12 months." [1] The Act also states that "[a]n individual shall be determined to be under a disability only if his physical or mental impairment or impairments are of such severity that he is not only unable to do his previous work but cannot, considering his age, education, and work experience, engage in any other kind of substantial gainful work which exists in the national economy, regardless of whether such work exists in the immediate area in which he lives, or whether a specific job vacancy exists for him, or whether he would be hired if he applied for work. For purposes of the preceding sentence (with respect to any individual), "work which exists in the national economy" means work which exists in significant numbers either in the region where such individual lives or in several regions of the country.[2]

We use a five-step sequential evaluation process to determine whether an adult is disabled under the Act.[3] If we can make a determination or decision whether a claimant is disabled or not disabled at a step, we do not go on to the next step.[4] If we cannot make a determination or decision at a step, we continue to the next step in the sequential evaluation process.[5]

The vocational factors of age, education, and work experience are relevant at step 5 when we consider a claimant's capacity to adjust to other work. Specifically, at step 5 we consider whether a claimant's impairment(s) prevents him or her from doing any other work that exists in significant numbers in the national economy, considering his or her residual functional capacity (RFC) [6] and the vocational factors of age,[7] education,[8] and work experience.[9] If we find that the claimant does not have the capacity to adjust to other work that exists in significant numbers in the national economy, we find the claimant disabled. If we find that the claimant has the capacity to adjust to other work, we find the claimant not disabled. We do not consider an individual's ability to obtain work.[10]

To help make our step 5 determination, we use both the medical-vocational profiles (the profiles) [11] and the medical-vocational guidelines (the guidelines) when appropriate.[12] The profiles and the guidelines are based on several assumptions:

- We consider aging to be a limiting factor in a person's ability to adjust to other work.
- We consider higher levels of education and certain types of recent education to enhance a person's ability to adjust to other work.
- We consider that an individual who has done skilled or semi-skilled work may have acquired skills and abilities from that past work. Those acquired skills and abilities may be transferable to other work. Under our rules, unskilled work does not convey transferable skills to an individual.

What is the purpose of this ANPRM?

We are soliciting public comments along with supporting research and data about how vocational factors such as age, education, and work experience affect an individual's ability to adjust to other work that exists in the national economy. In addition to seeking public input on the specific questions below, we are also asking for public assistance to help identify research and data to assist us.

What will we consider when we decide whether to propose revisions?

We will consider the public comments in addition to other input, research, and data that we obtain through other methods. This ANPRM is one component of the our larger effort to collect information about how we consider the vocational factors of age, education, and work experience when we determine whether an individual can adjust to other work. We commissioned several studies and are examining how the vocational factors influence an individual's ability to adjust to doing new work. For your consideration while preparing your comments to this ANPRM, these studies are included in the References section of

this notice, and are included in the docket folder for this rule at *http://www.regulations.gov*. In addition, we are undertaking outreach efforts to engage federal and private stakeholders, including the scientific community. We will consider the results of these information-gathering efforts collectively when we evaluate how to consider the vocational factors in determining whether an individual can adjust to other work.

What should you comment about?

When we determine whether an individual can adjust to other work, we consider an individual's functional capacities and limitations, the occupational base in the national economy, and the vocational factors of age, education, and work experience. We have ongoing activities related to each of these considerations. Although complementary, our activities related to functional limitations and the occupational base are independent and are occurring on separate timeframes from our effort on the vocational factors. Accordingly, we are narrowing the scope of this ANPRM to solicit public comments on only the vocational factors. We are not soliciting public comments on how we assess an individual's functional limitations. We are also not soliciting public comments in this notice on sources of occupational data we use at step 5, such as the Dictionary of Occupational Titles, because we are working with the Bureau of Labor Statistics (BLS) to test the collection of updated occupational information that we intend to use to develop a new occupational information system.[13]

Specifically, given today's work environment and advances in technology and medicine, we are seeking public input, research, and data about the following:

1. Is the factor of age predictive in determining an individual's ability to work or to adjust to other work? If it is predictive, what are the vocationally significant age milestones we should consider? If it is not predictive, what data support that assertion?

2. When determining if age affects an individual's ability to work or to adjust to other work, what other factors or combination of factors should we consider?

3. Does an individual's educational level affect an individual's ability to do work or to adjust to other work? If so, how? What data support the conclusion that an individual's educational level does or does not affect an individual's ability to do work or to adjust to other work? How does literacy affect an individual's ability to do work or adjust to other work?

4. Does the skill level of an individual's past work affect his or her ability to adjust to other work? If so, how? What data support the conclusion that the skill level of an individual's past work does or does not affect an individual's ability to do work or to adjust to other work? How does the skill level of an individual's past work considered along with an individual's educational level affect this adjustment?

5. Are there other vocational factors or combinations of vocational factors that we should consider when determining an individual's ability to do work or to adjust to other work?

Will we respond to your comments?

We will consider all relevant public comments we receive about this notice, but we will not respond directly to them. If we decide to propose specific revisions to the vocational factors we consider when we determine an individual's ability to do work or to adjust to other work, we will publish a notice of proposed rulemaking in the **Federal Register**, and you will have a chance to comment on any revisions we propose.

BILLING CODE 4191–02–P

DEPARTMENT OF DEFENSE

Department of the Army, Corps of Engineers

33 CFR Part 334

Gulf of Mexico, Apalachicola Bay, East Bay, St. Andrew Bay and St. Andrew Sound at Tyndall Air Force Base, Florida; Restricted Areas

AGENCY: U.S. Army Corps of Engineers, Department of Defense.

ACTION: Notice of proposed rulemaking and request for comments.

SUMMARY: The U.S. Army Corps of Engineers (Corps) is proposing to amend its regulations by revising an existing restricted area regulation and establishing a new restricted area along portions of the Tyndall Air Force Base (AFB) facility shoreline that will be activated on a temporary basis. The duration of temporary restricted area activations will be limited to those periods where it is warranted or required by specific and credible security threats and will be inactive at all other times. The restricted area will be partitioned using 23 pairs of coordinates to facilitate quick geographic recognition. Tyndall AFB is surrounded on three sides by water with approximately 129 miles of unprotected coastline. This includes several areas where the lack of security or lack of restriction on access to these areas leaves Tyndall AFB personnel and resources vulnerable to unauthorized activities. This amendment is necessary to implement an enhanced threat security plan for Tyndall AFB which will allow temporary activation of one or more portions of the restricted area as necessary to provide the appropriate level of security required to address the specific and credible threat triggering

the need for activation. This proposal is an amended version of the proposal published in the **Federal Register** on May 9, 2013 (78 FR 27126).

DATES: Written comments must be submitted on or before October 14, 2015.

ADDRESSES: You may submit comments, identified by docket number COE–2013–0003, by any of the following methods:

Federal Rulemaking Portal: http://www.regulations.gov. Follow the instructions for submitting comments.

Email: david.b.olson@usace.army.mil. Include the docket number, COE–2013–0003, in the subject line of the message.

Mail: U.S. Army Corps of Engineers, Attn: CECW–CO (David B. Olson), 441 G Street NW., Washington, DC 20314–1000.

Hand Delivery/Courier: Due to security requirements, we cannot receive comments by hand delivery or courier.

Instructions: Direct your comments to docket number COE–2013–0003. All comments received will be included in the public docket without change and may be made available on-line at *http://www.regulations.gov,* including any personal information provided, unless the commenter indicates that the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI, or otherwise protected, through regulations.gov or email. The regulations.gov Web site is an anonymous access system, which means we will not know your identity or contact information unless you provide it in the body of your comment. If you send an email directly to the Corps without going through regulations.gov, your email address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, we recommend that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If we cannot read your comment because of technical difficulties and cannot contact you for clarification, we may not be able to consider your comment. Electronic comments should avoid the use of any special characters, any form of encryption, and be free of any defects or viruses.

Docket: For access to the docket to read background documents or comments received, go to *www.regulations.gov.* All documents in the docket are listed. Although listed in the index, some information is not publicly available, such as CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form.

FOR FURTHER INFORMATION CONTACT: Mr. David Olson, Headquarters, Operations and Regulatory Community of Practice, Washington, DC at 202–761–4922 or Mr. Edward Sarfert, U.S. Army Corps of Engineers, Jacksonville District, Regulatory Division, Pensacola Regulatory Office at 850–439–9533.

SUPPLEMENTARY INFORMATION:

Executive Summary

External reviews of security at Tyndall AFB identified the lack of jurisdiction to respond to threats from the waterways as a major weakness. Tyndall AFB does not currently have the authority to restrict access to the shoreline of Tyndall AFB if needed to respond to a security threat. The purpose of this regulatory action is to establish a restricted area in the waters surrounding portions of Tyndall AFB that would only be activated on a temporary basis in response to specific and credible security threats. Additionally this amendment provides an administrative correction to the existing regulation at 33 CFR 334.660.

The Corps authority to establish the restricted area is Section 7 of the Rivers and Harbors Act of 1917 (40 Stat 266; 33 U.S.C. 1) and Chapter XIX of the Army Appropriations Act of 1919 (40 Stat. 892; 33 U.S.C. 3).

Background

Pursuant to its authorities in Section 7 of the Rivers and Harbors Act of 1917 (40 Stat 266; 33 U.S.C. 1) and Chapter XIX of the Army Appropriations Act of 1919 (40 Stat 892; 33 U.S.C. 3) the Corps is proposing to revise the regulations at 33 CFR part 334 by establishing a restricted area in the waters surrounding Tyndall AFB. This amendment will allow the Installation Commander, Tyndall AFB to temporarily restrict the passage of persons, watercraft, and vessels in waters contiguous to this facility when a specific and credible security threat is identified, providing greater security for personnel and equipment during those periods. The administrative correction at 33 CFR 334.660(b)(3) will clarify who is responsible for enforcing the provisions of § 334.660.

This proposed rule replaces the proposed rule that was originally published in the May 9, 2013, issue of the **Federal Register** (78 FR 27126). The Corps received many comments on that proposed rule, and after those comments were fully considered, Tyndall AFB made substantial changes to its request for a new restricted area. Those changes are incorporated into this proposed rule.

Procedural Requirements

a. *Review Under Executive Order 12866.* The proposed rule is issued with respect to a military function of the Department of Defense and the provisions of Executive Order 12866 do not apply.

b. *Review Under the Regulatory Flexibility Act.* This rule has been reviewed under the Regulatory Flexibility Act (Pub. L. 96–354). The Regulatory Flexibility Act generally requires an agency to prepare a regulatory flexibility analysis of any rule subject to the notice-and-comment rulemaking requirements under the Administrative Procedure Act or any other statute unless the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities (*i.e.,* small businesses and small governments). Tyndall AFB has approximately 129 miles of unprotected shoreline, including several areas where the lack of security or restriction on access leaves Tyndall AFB personnel and resources vulnerable to unauthorized activities. Therefore, the proposed restricted area regulation is necessary to implement an enhanced threat security plan for Tyndall AFB which will allow for the temporary activation of one or more portions of the restricted area as necessary to provide the appropriate level of security required to address the specific and credible threat triggering the need for the activation. The temporary restrictions in the proposed rule are also necessary to protect the public from potentially hazardous conditions that may develop as a result of military use of the area. When the restricted area is activated, small entities can continue to use the navigable waters surrounding Tyndall AFB that are outside of the restricted area. After considering the economic impacts of this proposed restricted area regulation on small entities, I certify that this action will not have a significant impact on a substantial number of small entities. We are interested in the potential impacts of the proposed regulation on small entities and welcome comments on issues related to such impacts.

c. *Review Under the National Environmental Policy Act.* Due to the administrative nature of this action and because there is no intended change in the use of the area, the Corps expects that this regulation, if adopted, will not have a significant impact on the quality of the human environment and, therefore, preparation of an environmental impact statement will not be required. An environmental assessment will be prepared after the public notice period is closed and all comments have been received and considered.

d. *Unfunded Mandates Act.* This regulation does not impose an enforceable duty among the private sector and, therefore, is not a Federal private sector mandate and is not subject to the requirements of Section 202 or 205 of the Unfunded Mandates Reform Act (Pub. L. 104–4, 109 Stat. 48, 2 U.S.C. 1501 *et seq.*). We have also found under Section 203 of the Act, that small governments will not be significantly or uniquely affected by this regulation.

List of Subjects in 33 CFR Part 334

Danger zones, Navigation (water), Restricted areas, Waterways.

For the reasons set out in the preamble, the Corps proposes to amend 33 CFR part 334 as follows:

PART 334—DANGER ZONE AND RESTRICTED AREA REGULATIONS

■ 1. The authority citation for part 334 continues to read as follows:

Authority: 40 Stat. 266 (33 U.S.C. 1) and 40 Stat. 892 (33 U.S.C. 3).

■ 2. Revise § 334.660(b)(3) to read as follows:

§ 334.660 Gulf of Mexico and Apalachicola Bay south of Apalachicola, Fla., Drone Recovery Area, Tyndall Air Force Base, Fla.

* * * * *

(b) * * *

(3) The federal regulations in this section shall be enforced by the Installation Commander, Tyndall Air Force Base, Florida, and such other agencies as he/she may designate.

■ 3. Add § 334.665 to read as follows:

§ 334.665 East Bay, St. Andrew Bay and St. Andrew Sound, enhanced threat restricted area, Tyndall Air Force Base, Florida.

(a) *The area.* (1) The coordinates provided herein are approximations obtained using a commercial mapping program which utilizes Simple Cylindrical projection with a WGS84 datum for its imagery base and imagery dated February 15 and May 3, 2014.

(2) Each portion of the temporary restricted area described in paragraphs (a)(4)(i) through (xxiii) of this section shall encompass all navigable waters of the United States as defined at 33 CFR part 329 within the area described and includes all contiguous inland navigable waters which lie within the land boundaries of Tyndall AFB.

(3) Because of the dynamic nature of these geographic features near barrier islands, the coordinate points provided may not reflect the current situation regarding the location of a point at the mean high water line or 500 feet waterward of the mean high water line. Even if the landform has shifted through erosion or accretion, the intent of the area description will be enforced from the existing point at the mean high water line that is closest to the shoreline point provided herein out to a point located 500 feet waterward of the mean high water line.

(4) The restricted area will be partitioned using 23 pairs of coordinates to facilitate quick geographic recognition. The first point in each pair of coordinates is located on the shoreline, and the second point is a point 500 feet waterward of the shoreline. From the first point in each pair of coordinates, a line meanders irregularly following the shoreline and connects to the first point in the next pair of coordinates. From the second point in each pair of coordinates, a line beginning 500 feet waterward of the shoreline meanders irregularly following the shoreline at a distance of 500 feet waterward of the shoreline and connects to the second point in the next pair of coordinates. The restricted area shall encompass all navigable waters of the United States as defined at 33 CFR part 329 within the area bounded by lines connecting each of the following pairs of coordinates:

(i) *Farmdale Bayou:* 30°1.156′ N., 85°26.915′ W. to 30°1.238′ N., 85°26.915′ W.

(ii) *Baker Bayou:* 30°1.325′ N., 85°29.008′ W. to 30°1.402′ N., 85°28.977′ W.

(iii) *Blind Alligator Bayou:* 30°2.094′ N., 85°29.933′ W. to 30°2.151′ N., 85°29.864′ W.

(iv) *Little Oyster Bay Point:* 30°3.071′ N., 85°30.629′ W. to 30°3.133′ N., 85°30.568′ W.

(v) *Goose Point South:* 30°3.764′ N., 85°31.874′ W. to 30°3.719′ N., 85°31.795′ W.

(vi) *Goose Point North:* 30°4.599′ N., 85°31.577′ W. to 30° 4.650′ N., 85°31.503′ W.

(vii) *Little Cedar Lake:* 30°4.974′ N., 85°33.476′ W. to 30° 5.024′ N., 85°33.401′ W.

(viii) *Chatters on Bayou:* 30°5.729′ N., 85°34.632′ W. to 30°5.811′ N., 85°34.625′ W.

(ix) *Fred Bayou:* 30° 5.992′ N., 85°35.296′ W. to 30°6.071′ N., 85°35.325′ W.

(x) *Pearl Bayou:* 30°6.039′ N., 85°36.651′ W. to 30°6.043′ N., 85°36.557′ W.

(xi) *Military Point:* 30°7.394′ N., 85°37.153′ W. to 30°7.459′ N., 85°37.096′ W.

(xii) *Freshwater Bayou:* 30°7.425′ N., 85°38.655′ W. to 30°7.473′ N., 85°38.578′ W.

(xiii) *Smack Bayou:* 30°7.826′ N., 85°39.654′ W. to 30°7.838′ N., 85°39.560′ W.

(xiv) *Redfish Point:* 30°8.521′ N., 85°40.147′ W. to 30°8.598′ N., 85°40.113′ W.

(xv) *Davis Point:* 30°7.348′ N., 85°41.224′ W. to 30°7.364′ N., 85°41.317′ W.

(xvi) *Tyndall Marina:* 30°5.827′ N., 85°39.125′ W. to 30°5.762′ N., 85°39.184′ W.

(xvii) *Heritage Bayou:* 30°3.683′ N., 85°35.823′ W. to 30°3.743′ N., 85°35.887′ W.

(xviii) *NCO Beach North:* 30°4.209′ N., 85°37.430′ W. to 30°4.272′ N., 85°37.368′ W. The restricted Area will end on the west side of the land bridge that extends into Shell Island. The Restricted Area resumes on the east side of the land bridge that extends into St. Andrew Sound.

(xix) *St. Andrew Sound west:* 30°1.327′ N., 85°33.756′ W. to 30°1.377′ N., 85°33.681′ W.

(xx) *St. Andrew Sound northwest:* 30° 1.921′ N., 85° 33.244′ W to 30°1.869′ N., 85°33.317′ W.

(xxi) *St. Andrew Sound northeast:* 30°0.514′ N., 85°31.558′ W to 30°0.452′ N., 85°31.619′ W.

(xxii) *Wild Goose Lagoon:* 29°59.395′ N., 85°30.178′ W. to 29°59.319′ N., 85°30.216′ W.

(xxiii) *Crooked Island North:* 29°59.003′ N., 85°30.396′ W. to 29°59.082′ N., 85°30.371′ W.

(b) *The regulations.* (1) Unless one or more portions of the restricted area identified in (a)(4)(i) through (xxiii) of this section is activated, all persons, vessels and other craft are permitted access to all of the navigable waters described in paragraph (a) of this section.

(2) During times when the restricted area defined in paragraphs (a)(4)(i) through (xxiii) of this section is not active, U.S. Air Force boat patrols may operate in the waters adjacent to Tyndall AFB's shoreline to observe the shoreline in order to identify any threats to the installation or personnel. U.S. Air

Force personnel will not have any authority to enforce federal, local or state laws on the water.

(3) Due to the nature of security threats, restricted area activation may occur with little advance notice. Activation will be based on local or national intelligence information related to threats against military installations and/or resources common to Tyndall AFB in concert with evaluations conducted by the Tyndall AFB Threat Working Group and upon direction of the Installation Commander, Tyndall AFB. The Installation Commander activates only those portions of the restricted area identified in paragraphs (a)(4)(i) through (xxiii) of this section necessary to provide the level of security required in response to the specific and credible threat(s) triggering the activation. The duration of activation for any portion(s) of the restricted area defined in paragraph (a) of this section, singularly or in combination, will be limited to those periods where it is warranted or required by security threats. Activated portions of the restricted area will be reevaluated every 48 hours to determine if the threat(s) triggering the activation or related threats warrant continued activation. The activated portion(s) of the restricted area expire if no reevaluation occurs or if the Installation Commander determines that activation is no longer warranted.

(4) Public notification of a temporary restricted area activation will be made via marine VHF broadcasts (channels 13 and 16), local notices to mariners, local news media through Air Force Public Affairs notifications and by on-scene installation personnel. On-scene installation personnel will notify boaters in the restricted area of the restriction and tell them that if they refuse to leave the area they will be trespassing and could be subject to prosecution.

(5) During times when the Installation Commander activates any portion(s) of the temporary restricted area defined in paragraph (a) of this section all entry, transit, drifting, anchoring or attaching any object to the submerged sea-bottom within the activated portion(s) of the restricted area is not allowed without the written permission of the Installation Commander, Tyndall AFB, Florida or his/her authorized representative. Previously affixed mooring balls established to support watercraft during intense weather conditions (*i.e.*, tropical storms, hurricanes, etc.) may remain within the activated portion(s) of the restricted area, however watercraft should not be anchored to the mooring balls without the permission of the Installation Commander, Tyndall AFB, Florida or his/her authorized representative.

(c) *Enforcement.* The regulations in this section shall be enforced by the Installation Commander, Tyndall AFB and/or such persons or agencies as he/she may designate.

Dated: September 4, 2015.

Edward E. Belk, Jr.,

Chief, Operations and Regulatory Division, Directorate of Civil Works.

[FR Doc. 2015–23030 Filed 9–11–15; 8:45 am]

BILLING CODE 3710–58–P

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 52

[EPA–R08–OAR–2015–0493; FRL–9933–90–Region 8]

Approval and Promulgation of Air Quality Implementation Plans; Colorado; Revisions to Common Provisions and Regulation Number 3; Correction

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The Environmental Protection Agency (EPA) is proposing approval of State Implementation Plan (SIP) revisions submitted by the State of Colorado on March 31, 2010, May 16, 2012, and May 13, 2013. The revisions are to Colorado Air Quality Control Commission (Commission) Regulation Number 3, Parts A, B, and D and Common Provisions Regulation. The revisions include administrative changes to permitting requirements for stationary sources, updates to the fine particulate matter less than 2.5 microns in diameter ($PM_{2.5}$) implementation rules related to the federal New Source Review (NSR) Program, changes to address previous revisions to Air Pollutant Emission Notice (APEN) regulations that EPA disapproved or provided comments on, revisions to definitions, and minor editorial changes. Also in this action, EPA is proposing to correct a final rule pertaining to Colorado's SIP published on April 24, 2014. In our April 24, 2014 action, regulatory text and corresponding "incorporation by reference" (IBR) materials were inadvertently excluded for (1) greenhouse gas permitting revisions to the Common Provisions Regulation, and (2) minor editorial changes to the Common Provisions Regulation and Parts A, B, and D of Regulation Number 3 (adopted October 10, 2010). This action is being taken under section 110 of the Clean Air Act (CAA).

DATES: Written comments must be received on or before October 14, 2015.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R08–OAR–2015–0493, by one of the following methods:

- *http://www.regulations.gov.* Follow the on-line instructions for submitting comments.
- *Email: dobrahner.jaslyn@epa.gov.*
- *Fax:* (303) 312–6064 (please alert the individual listed in the **FOR FURTHER INFORMATION CONTACT** if you are faxing comments).
- *Mail:* Director, Air Program, Environmental Protection Agency (EPA), Region 8, Mail Code 8P–AR, 1595 Wynkoop Street, Denver, Colorado 80202–1129.
- *Hand Delivery:* Director, Air Program, Environmental Protection Agency (EPA), Region 8, Mail Code 8P–AR, 1595 Wynkoop Street, Denver, Colorado 80202–1129. Such deliveries are only accepted Monday through Friday, 8:00 a.m. to 4:30 p.m., excluding federal holidays. Special arrangements should be made for deliveries of boxed information.

Instructions: Direct your comments to Docket ID No. EPA–R08–OAR–2015–0493. EPA's policy is that all comments received will be included in the public docket without change and may be made available online at *www.regulations.gov,* including any personal information provided, unless the comment includes information claimed to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Do not submit information that you consider to be CBI or otherwise protected through *www.regulations.gov* or email. The *www.regulations.gov* Web site is an "anonymous access" system, which means EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to EPA, without going through *www.regulations.gov* your email address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment.

Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. For additional information about EPA's public docket visit the EPA Docket Center homepage at *http://www.epa.gov/epahome/dockets.htm.* For additional instructions on submitting comments, go to section I, General Information, of the **SUPPLEMENTARY INFORMATION** section of this document.

Docket: All documents in the docket are listed in the *www.regulations.gov* index. Although listed in the index, some information is not publicly available, *e.g.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, will be publicly available only in hard copy. Publicly available docket materials are available either electronically in *www.regulations.gov* or in hard copy at the Air Program, Environmental Protection Agency (EPA), Region 8, 1595 Wynkoop Street, Denver, Colorado 80202–1129. EPA requests that if at all possible, you contact the individual listed in the **FOR FURTHER INFORMATION CONTACT** section to view the hard copy of the docket. You may view the hard copy of the docket Monday through Friday, 8:00 a.m. to 4:00 p.m., excluding federal holidays.

FOR FURTHER INFORMATION CONTACT: Jaslyn Dobrahner, Air Program, U.S. Environmental Protection Agency (EPA), Region 8, Mail Code 8P–AR, 1595 Wynkoop Street, Denver, Colorado 80202–1129, (303) 312–6252, *dobrahner.jaslyn@epa.gov.*

SUPPLEMENTARY INFORMATION:

I. General Information

What should I consider as I prepare my comments for EPA?

1. *Submitting Confidential Business Information (CBI).* Do not submit CBI to EPA through *http://www.regulations.gov* or email. Clearly mark the part or all of the information that you claim to be CBI. For CBI information on a disk or CD ROM that you mail to EPA, mark the outside of the disk or CD ROM as CBI and then identify electronically within the disk or CD ROM the specific information that is claimed as CBI. In addition to one complete version of the comment that includes information claimed as CBI, a copy of the comment that does not contain the information claimed as CBI must be submitted for inclusion in the public docket. Information so marked will not be disclosed except in accordance with procedures set forth in 40 CFR part 2.

2. *Tips for preparing your comments.* When submitting comments, remember to:

- Identify the rulemaking by docket number and other identifying information (subject heading, **Federal Register**, date, and page number);
- Follow directions and organize your comments;
- Explain why you agree or disagree;
- Suggest alternatives and substitute language for your requested changes;
- Describe any assumptions and provide any technical information and/or data that you used;
- If you estimate potential costs or burdens, explain how you arrived at your estimate in sufficient detail to allow for it to be reproduced;
- Provide specific examples to illustrate your concerns, and suggest alternatives;
- Explain your views as clearly as possible, avoiding the use of profanity or personal threats; and
- Make sure to submit your comments by the comment period deadline identified.

II. Background

A. On March 31, 2010 the State of Colorado submitted a SIP revision containing amendments to the Common Provisions Regulation sections I.A., I.B., I.C., I.D., I.E., I.F., I.G., II.B., II.C., II.E., II.H. and II.J. The amendments update the definition of "negligibly reactive volatile organic compound," add clarification to the definition of "volatile organic compound," and make minor editorial changes. The Commission adopted the amendments on December 17, 2009 (effective January 30, 2010).

B. On May 16, 2012 the State submitted a SIP revision containing amendments to Regulation Number 3, Parts A, B and D. The amendments modify the permitting requirements for stationary sources in Colorado by: (1) Incorporating into state regulations changes to the federal NSR Program related to the $PM_{2.5}$ National Ambient Air Quality Standards (NAAQS); (2) revising state regulations to address past rule revisions that were disapproved or commented on by EPA; (3) deferring permitting requirements for biogenic sources of carbon dioxide emissions to ensure consistency with federal greenhouse gas permitting requirements; and (4) making miscellaneous revisions and minor editorial changes. The Commission adopted the amendments on October 20, 2011 (effective December 15, 2011).

C. On May 13, 2013 Colorado submitted a SIP revision containing amendments to Regulation Number 3, Parts A, B and D. The amendments make administrative revisions to the permitting requirements for stationary sources in Colorado and make minor editorial changes. The Commission adopted the amendments on December 20, 2012 (effective February 15, 2013).

D. On April 24, 2014 EPA published a final rule (79 FR 22772) in the **Federal Register** approving Colorado's May 25, 2011 SIP revisions to the Common Provisions Regulation related to greenhouse gas and minor editorial changes to the Common Provisions Regulation and Regulation Number 3 Parts A, B and D (adopted October 10, 2010). This action includes regulatory text and IBR material intended to be a part of EPA's April 24, 2014 final rule but inadvertently excluded.

III. EPA's Review of the State of Colorado's March 31, 2010; May 16, 2012; and May 13, 2013 Submittals, and Regulatory Text/IBR Correction

We evaluated Colorado's March 31, 2010, May 16, 2012 and May 13, 2013 submittals regarding revisions to the State's Common Provisions Regulation and Regulation Number 3, Parts A, B and D. We propose to approve some of the revisions and not act on others.

A. March 31, 2010 SIP Submittal

The State's March 31, 2010 SIP submittal contained amendments to the Common Provisions Regulation and includes the following types of amendments to the State's air quality rules: Adding compounds to the definition of "negligibly reactive volatile compounds" (NRVOC) and clarifying NRVOC and volatile organic compound (VOC) testing methodologies within the definition of "volatile organic compound." In addition, the State subsequently requested [1] a revision to the definition of "incinerator." The revisions also make minor editorial changes.

EPA's policy is that compounds of carbon with a negligible level of reactivity need not be regulated to reduce ozone (42 FR 35314). EPA determines whether a given carbon compound has "negligible" reactivity by comparing the compound's reactivity to the reactivity of ethane. EPA lists these compounds in its regulations at 40 CFR 51.100(s), and excludes them from the definition of a "VOC." The chemicals on this list are often called "negligibly reactive." EPA may periodically revise the list of negligibly reactive volatile compounds or NRVOCs to add or delete compounds from the list. In its March

[1] Refer to docket #EPA–R08–OAR–2015–0493 for documentation.

31, 2010 submission, the State adds the following compounds: "(1)1, 1, 1, 2, 2, 3, 4, 5, 5, 5, -decafluoro-3-methoxy-4-trifluoromethyl-pentane" [2]; "Propylene carbonate"; and "Dimethyl carbonate," as well as the common names or chemical structure: "n-$C_3F_7OCH_3$, HFE–7000"; "HFE–7500"; "HFC 227ea"; "$HCOOCH_3$"; and "HFE–7300" to the list of NRVOCs. Subsequent to the March 31, 2010 submission, the State also requested [3] to add "1, 1, 1, 2, 2, 3, 3, -heptafluoro-3-methoxy-propane"; "3-ethoxy-1, 1, 1, 2, 3, 4, 4, 5, 5, 6, 6, 6-dodecafluoro-2(trifluoromethyl)hexane"; "1, 1, 1, 2, 3, 3, 3-heptafluoropropane"; and "Methyl formate" to the list of NRVOCs [4] in section I.G. EPA is proposing to approve these additions to the State's Common Provisions Regulation list of NRVOCs per our earlier actions (72 FR 2193; 74 FR 3437; 78 FR 9823) updating EPA's listing of organic compounds determined to have negligible photochemical reactivity at 40 CFR 51.100(s)(1).

The March 31, 2010 revision to the Common Provisions Regulation also revises the definition of "VOC" to include test methods specified in the State's SIP, a Title V Permit, 40 CFR part 51, subpart I or appendix S, and 40 CFR part 52. In accordance with 40 CFR 51.100(s)(2) and (4), EPA proposes to approve revisions to the definition of "VOC" in section I.G. of the Common Provisions Regulation.

In addition to modifying the definitions of NRVOC and VOC, the State also subsequently requested revisions to the definition of "incinerator" in section I.G. The revisions exclude from the definition of "incinerator" devices commonly called Air Curtain Destructors used to burn 100% wood waste, clean lumber, or yard waste generated as a result of projects to reduce the risk of wildfire and not operated at a commercial or industrial facility. The revisions also state that any air curtain destructor (also called air curtain incinerator in the federal rule) subject to 40 CFR part 60 incinerator requirements are also considered incinerators under the State's revised Common Provisions Regulation definition of "incinerator" per EPA's final rule (70 FR 74870) for New Source Performance Standards (NSPS) for new and existing "other" solid waste incineration units. We propose to approve these revisions.

The March 2010 submittal also makes minor editorial revisions to the Common Provisions Regulation. We are proposing to approve the minor editorial revisions in sections I.A., I.B., I.C., I.D., I.E., I.F., I.G., II.B., II.C., II.E.2. and II.H as shown in Table 1. We are not acting on the minor editorial revisions in II.J. as they are either already in the approved SIP or in sections that EPA previously disapproved (Table 2). Also, we note that the March 31, 2010 submittal is missing a quotation mark in Section I.B. and contains the incorrect abbreviation for "microgram" in Section I.F. The State is aware of these errors and will make the necessary corrections in a future submittal.[5]

Finally, the March 31, 2010 submission contains text not currently in the Common Provisions section of the SIP yet also not identified by the State as a revision. This text includes the addition of "Tertiary Butyl Acetate (2-Butanone)" to the list of NRVOCs in section I.G. as well as the last sentence in the definition of "VOC" regarding tertiary butyl acetate as a VOC for the purposes of photochemical dispersion monitoring. On November 29, 2004 (69 FR 69298), EPA revised its definition of VOC to exclude tertiary butyl acetate for purposes of VOC emissions limitations or VOC content requirements; however, tertiary butyl acetate continues to be a VOC for purposes of all recordkeeping, emissions reporting, and inventory purposes as reflected in 40 CFR 51.100(s)(1) and (s)(5). Therefore, EPA is not including these State additions with our proposed approval of IBR material.

B. May 16, 2012 SIP Submittal

The State's May 16, 2012 SIP submittal includes the following types of amendments to Regulation Number 3, Parts A, B and D: Revisions to State permitting requirements for stationary sources to incorporate changes to the federal NSR Program related to $PM_{2.5}$; revisions to address past rule revisions that were disapproved or commented on by EPA; and deferral of the permitting requirements for biogenic sources of carbon dioxide emissions to ensure consistency with federal greenhouse gas permitting requirements. The revisions also make several miscellaneous changes along with minor editorial changes.

The May 16, 2012 submittal incorporates into Regulation Number 3, Parts A, B and D changes to the federal NSR Program related to the $PM_{2.5}$ NAAQS. Specifically, the State revised the definition of "criteria pollutants" to address $PM_{2.5}$ precursors in Part A (I.B.17.) and revised the definition of "significant" to address $PM_{2.5}$ in Part D (II.A.42.). We are proposing to approve both of these revisions to definitions to address $PM_{2.5}$. In addition, the State incorporated portions of 40 CFR 51.165(a)(9)(i)–(iv) into the State's Requirements Applicable to Nonattainment Areas for Major Sources in Part D of Regulation Number 3 . (V.A.3.). This section describes the emissions offsets and emissions offset ratios required prior to the date of commencement of operations. We are proposing to approve this revision. We are also proposing to approve the State's revision to the Table of Significance Levels for nonattainment areas in section VI.D.2. of Part D to address $PM_{2.5}$. Finally, the State added $PM_{2.5}$ increments to their ambient air increments in section X.A.1. of Part D and added $PM_{2.5}$ increments to their Class I variances maximum allowable increases in section XIII.D. of Part D. These revisions align with 40 CFR 52.21(b)(58)(c) and 52.21(p)(5), respectively, and we therefore propose to approve these revisions.

The State also revised the definition of "Subject to Regulation" in Part A of Regulation Number 3 in their May 16, 2012 submittal. In section I.B.44.b.(i) the State added language to instruct how to compute greenhouse gas emissions to exclude carbon dioxide emissions resulting from the combustion or decomposition of non-fossilized and biodegradable organic material originating from plants, animals, or micro-organisms. This addition is consistent with EPA's biogenic deferral regulation found at 40 CFR 52.21(b)(49)(a)(ii); therefore, we are proposing to approve the revision.

The May 16, 2012 submission also makes revisions to Regulation Number 3, Part B based on EPA's comments on previous actions (76 FR 6331; 79 FR 8632). These revisions include reverting back to previously approved SIP exemption language for stationary internal combustion engines that have uncontrolled actual emissions of less than five tons per year for construction permit requirements (II.D.1.c.) [6] and clarifying exemptions associated with oil and gas produced wastewater

[2] In 78 FR 9823, EPA amended its definition of VOC at 40 CFR 51.100(s) to make for clarity technical corrections to the current list of exempt compounds at 40 CFR 51.100(s)(1) by removing the erroneous "(1)" notation in "(1) 1,1,1,2,2,3,4,5,5,5-decafluoro-3-methoxy-4-trifluoromethyl-pentane (HFE–7300)" so that it reads "1,1,1,2,2,3,4,5,5,5-decafluoro-3-methoxy-4-trifluoromethyl-pentane (HFE–7300)."

[3] Refer to docket #EPA–R08–OAR–2015–0493 for documentation.

[4] Refer to docket #EPA–R08–OAR–2015–0493 for documentation.

[5] Refer to docket #EPA–R08–OAR–2015–0493 for documentation.

[6] EPA inadvertently approved a previous version in 79 FR 8632.

impoundments (II.D.1.m). We are proposing to approve these revisions.

Within section VI.B.3. of Part D of the May 16, 2012 submittal, the State revised the PM_{10} surrogate policy for $PM_{2.5}$ based on EPA's previous conclusions that $PM_{2.5}$ implementation issues had been resolved to a degree sufficient for all federal Prevention of Significant Deterioration (PSD) permit reviews to begin direct $PM_{2.5}$ based assessments as of July 15, 2008. In a letter[7] dated January 13, 2011 the State clarified their position on the use of PM_{10} as a surrogate for $PM_{2.5}$ ". . . (CDPHE) now commits to implement $PM_{2.5}$ standards consistent with EPA's latest interpretation of federal case law relevant to the use of the PM_{10} Surrogate Policy . . ." We are proposing to approve this revision, and in doing so, note that as announced in our May 2008 rulemaking to implement preconstruction review provisions for the 1997 $PM_{2.5}$ NAAQS in both attainment and nonattainment areas (73 FR 28321), the 1997 PM_{10} Surrogate Policy ended on May 16, 2011 and can no longer be used for any pending or future State PSD permits.

Also regarding the May 16, 2012 submittal, we are proposing to take no action on several of the State's revisions related to $PM_{2.5}$ implementation in Part D of Regulation Number 3, including section II.A.26.d. describing net emissions increases for $PM_{2.5}$, the introductory paragraph of VI.A.2. and VI.A.2.c. that provide impact levels for $PM_{2.5}$, and VI.B.3.a.(iii) $PM_{2.5}$ monitoring exemption of 4 micrograms/cubic meter over a 24-hour average. We are proposing to not act on these revisions in part due to the January 22, 2013 United States Court of Appeals for the District of Columbia Circuit vacatur of the significant impact levels for $PM_{2.5}$ for attainment areas. Since we are proposing to not take action on the $PM_{2.5}$ monitoring exemption level found at VI.B.3.a.(iii), we also propose to not take action on VI.B.3.d. In absence of a revision to include a $PM_{2.5}$ monitoring exemption level in VI.B.3.a.(iii), $PM_{2.5}$ would be removed from the list of pollutants with monitoring exemption levels contained in VI.B.3.a., therefore exempting $PM_{2.5}$ from monitoring levels completely if we approved VI.B.3.d.

We are also proposing to take no action on several revisions contained in the May 16, 2012 submittal to Definitions in Part D of Regulation Number 3 to address $PM_{2.5}$ in the Baseline Area (II.A.5.a.), Major Source Baseline Date (II.A.23.), Minor Source Baseline Date (II.A.25.) and Regulated NSR Pollutant (II.A.38.) definitions because we already approved these revisions in our September 23, 2013 (78 FR 58186) action. In section II.A.23.c. of Part D, the State also revised the major source baseline date for $PM_{2.5}$ to October 20, 2011. This date is incorrect; the correct major source baseline date for $PM_{2.5}$ is October 20, 2010. In the May 13, 2013 submittal, also part of this action, the State revises the date back to October 20, 2010. The May 13, 2013 submittal supersedes the May 16, 2012 submittal; however, since the current approved SIP already contains the correct date, we are proposing to take no action on either revision.

Additionally, the May 16, 2012 submission addresses EPA's final action on October 3, 2011 (76 FR 61054) partially approving and partially disapproving Colorado's SIP revisions in Regulation Number 3, Part A to Air Pollutant Emission Notice (APEN) and permitting exemptions submitted to EPA in September 1997, June 2003, July 2005, August 2006, and August 2007. In the October 3, 2011 action, EPA partially disapproved APEN exemptions for open burning,[8] mobile sources, stationary internal combustion engines, emergency generators, deaerator/vacuum pump exhaust, and air curtain destructors. In today's action, we are proposing to approve revisions to the open burning APEN requirements (II.D.1.q.) in Regulation Number 3, Part A changing the reference regulation from "9," which is not part of Colorado's SIP, to "1," which is part of Colorado's SIP and clarifying the mobile source APEN (II.D.1.ppp.). Additionally, we are proposing to approve revisions made to the surface water impoundment APEN exemption (II.D.1.uuu.) to include gas production wastewater in addition to oil production wastewater. We are proposing no action on the State's removal of APENs related to stationary internal combustion engines (II.D.1.sss.), emergency power generators (II.D.1.ttt.), deaerator/vacuum pump exhaust (II.D.1.xxx.), and air curtain destructors (II.D.1.ffff.) as these provisions were not approved into the SIP. Finally, we are proposing no action on revisions to identify sections I.B.31.c,[9] and I.B.31.d. as "State-only Requirements" since these are also not part of the SIP.

Finally, the May 16, 2012 submission contains miscellaneous revisions to Parts A, B and D of Regulation Number 3. In Part A, the State clarified the significance level for VOC and NO_X for APEN reporting purposes (II.C.2.b.(ii)). In Part B, section III.G.1., the State changed the timing an applicant must provide notice to the State upon commencement of operation of a source from 30 days prior to startup to 15 days following startup. This revision aligns with 40 CFR 60.7(a)(3) Standards of Performance for New Stationary Sources, Notification and Record Keeping. In Part D, revisions include a correction[10] to move the creditable emissions documentation from II.A.26.d. to II.A.26.c.(iii), remove "total suspended particulate matter" and add NO_X as a precursor to ozone for consistency with federal significant monitoring concentrations requirements in VI.B.3.a.(iii) and VI.B.3.c., respectively. We propose to approve these revisions in addition to minor editorial changes found throughout Parts A, B and D of Regulation Number 3 with exceptions noted in Table 2 because the revisions the State is requesting are already in the SIP.

C. May 13, 2013 SIP Submittal

The State's May 13, 2013 SIP submittal contains amendments to Regulation Number 3 Parts A, B and D and includes administrative revisions to permitting requirements for stationary sources in Colorado and minor editorial changes. The State also updated where materials incorporated by reference are available for public inspection by adding an online web address and deleting reference to the State Publications Depository and Distribution Center in section I.A.

Revisions to section VI.B.5. in Part A of the May 13, 2013 submittal allow the State to issue construction permits prior to receipt of permit processing fees and provide for the option to revoke the permit or assess late fees if such fees are not paid within 90 days of the written request for fees. The purpose of the revisions are to allow applicants to commence construction during the invoicing and payment process; the revisions will not negatively impact permit applicants who pay their permit processing fees on time. A revision to section III.C.1.a. in Part B of the May 13, 2013 submittal clarifies the inclusion of sources in attainment/maintenance areas in the determination of sources

[7] Refer to *January 2011 letter from state_Colorado's Position on the Use of PM_{10} as a Surrogate for $PM_{2.5}$, Relevant to Both the $PM_{2.5}$ Implementation Rules and Interstate Transport* in docket #EPA–R08–OAR–2015–0493 for documentation.

[8] EPA inadvertently approved a previous version in 79 FR 8632.

[9] EPA inadvertently approved a previous version in 79 FR 8632.

[10] Refer to docket #EPA–R08–OAR–2015–0493 for documentation.

subject to public comment. Finally, revisions to Part D of the May 13, 2013 submittal include deleting language EPA previously disapproved (79 FR 8632) in the introductory text for Major Modifications in section II.A.22.[11] and Representative Actual Annual Emissions sections II.A.40.5 and II.A.40.5(a) as well as deleting the associated II.A.40.5(b).[12]

EPA is proposing to approve the revisions in the May 13, 2013 submittal to Parts A, B and D of Regulation Number 3 as well as the minor editorial changes contained throughout, except for sections II.A.22., II.A.40.5 (introductory paragraph), and II.A.40.5(a) in Part D because these are not in the current SIP and the other exceptions noted in Table 2. We are not acting on some of the provisions as listed in Table 2, because they are State-only provisions or because they are not applicable to the current SIP.

Proposed Correction

In our final rule published in the **Federal Register** on April 24, 2014 (79 FR 22772) we inadvertently did not include regulatory text and corresponding IBR materials for our approvals to (1) greenhouse gas permitting revisions to Common Provisions Regulation, and (2) minor editorial changes to the Common Provisions Regulation and Parts A, B and D of Regulation Number 3 (adopted October 10, 2010). EPA is proposing to correct this error with today's action. The IBR material for our April 24, 2014 action is contained within this docket.

IV. What action is EPA taking?

For the reasons expressed above, EPA is proposing to approve revisions to sections I.A., I.B., I.C., I.D., I.E., I.F., I.G., II.B., II.C., II.E.2. and II.H of the State's Common Provisions Regulation from the March 31, 2010 submittal as shown in Table 1 below. We also propose to approve revisions to Parts A, B and D of the State's Regulation Number 3 from the May 16, 2012 and May 13, 2013 submittals (Table 1), except for those revisions we are not taking action on as represented in Table 2 below. Finally, EPA proposes to correct regulatory text and IBR published in the **Federal Register** on April 24, 2014 (79 FR 22772).

A comprehensive summary of the revisions in Colorado's Common Provisions Regulation and Regulation Number 3 Parts A, B and D organized by EPA's proposed rule action, reason for proposed "no action" and submittal date are provided in Table 1 and Table 2 below.

V. Incorporation by Reference

In this rulemaking, the EPA is proposing to include in a final EPA rule regulatory text that includes incorporation by reference. In accordance with requirements of 1 CFR 51.5, the EPA is proposing to incorporate by reference Colorado Air Quality Control Commission regulations discussed in section III, *EPA's Review of the State of Colorado's March 31, 2010; May 16, 2012; and May 13, 2013 Submittals, and Regulatory Text/IBR Correction* of this preamble. The EPA has made, and will continue to make, these documents generally available electronically through *www.regulations.gov* and/or in hard copy at the appropriate EPA office (see the **ADDRESSES** section of this preamble for more information).

VI. Statutory and Executive Orders Review

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable federal regulations (42 U.S.C. 7410(k), 40 CFR 52.02(a)). Thus, in reviewing SIP submissions, EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this proposed action merely approves some state law as meeting federal requirements; this proposed action does not impose additional requirements beyond those imposed by state law. For that reason, this proposed action:

- Is not a "significant regulatory action" subject to review by the Office of Management and Budget under Executive Order 12866 (58 FR 51735, October 4, 1993);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);
- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of section 12(d) of the National

Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and,

• Does not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

The SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the rule does not have tribal implications and will not impose substantial direct costs on tribal governments or preempt tribal law as specified by Executive Order 13175 (65 FR 67249, November 9, 2000).

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Carbon monoxide, Incorporation by reference, Intergovernmental relations, Greenhouse gases, Lead, Nitrogen dioxide, Ozone, Particulate matter, Reporting and recordkeeping requirements, Sulfur oxides, Volatile organic compounds.

Authority: 42 U.S.C. 7401 *et seq*

Dated: September 1, 2015.

Debra H. Thomas,

Acting Regional Administrator, Region 8.

BILLING CODE 6560–50–P

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 70

[Regional Docket No. II–2012–01; FRL–9933–81–Region 2]

Petition for Objection to State Operating Permit; NY; Seneca Energy II, LLC

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice of final action.

SUMMARY: Pursuant to Clean Air Act (CAA) Section 505(b)(2) and 40 CFR 70.8(d), the Environmental Protection Agency (EPA) Administrator signed an Order, dated June 29, 2015, granting in part and denying in part a petition filed by Gary A. Abraham on behalf of Finger Lakes Zero Waste Coalition, Inc. (dated December 22, 2012) asking the EPA to object to the Title V operating permit (Permit No. 8–3244–00040/00002) issued by the New York State Department of Environmental Conservation (DEC) to Seneca Energy II, LLC (Seneca) relating to the Ontario County Landfill Gas-to-Energy Facility (Facility) in western New York. Sections 307(b) and 505(b)(2) of the CAA provide that the petitioner may ask for judicial review by the United States Court of Appeals for the appropriate circuit of those portions of the Order that deny objections raised in the petition.

DATES: Any such petition for review of this Order must be received by November 13, 2015 pursuant to section 307(b) of the CAA.

ADDRESSES: You may review copies of the final Order, the petitions, and other supporting information during normal business hours at EPA Region 2, 290 Broadway, New York, New York. If you wish to examine these documents, you should make an appointment at least 24 hours before the visiting day. Additionally, the final Order is available electronically at: *http://www.epa.gov/region7/air/title5/petitiondb/petitions/seneca_response2012.pdf.*

FOR FURTHER INFORMATION CONTACT: Steven Riva, Chief, Permitting Section, Air Programs Branch, Clean Air and Sustainability Division, EPA, Region 2, 290 Broadway, 25th Floor, New York, New York 10007, telephone (212) 637–4074, email address: *Riva.Steven@epa.gov,* or the above EPA Region 2 address.

SUPPLEMENTARY INFORMATION: The CAA affords the EPA a 45-day period to review, and object to, as appropriate, a title V operating permit proposed by a state permitting authority. Section 505(b)(2) of the CAA authorizes any person to petition the EPA Administrator, within 60 days after the expiration of this review period, to object to a Title V operating permit if the EPA has not done so. Petitions must be based only on objections to the permit that were raised with reasonable specificity during the public comment period provided by the state, unless the petitioner demonstrates that it was impracticable to raise these issues during the comment period or that the grounds for the objection or other issues arose after this period. The claims are described in detail in Section IV of the Order. In summary, the issues raised are that: (1) The Title V permit does not consider the Ontario County Landfill (Landfill) and the Facility a single source even though they together meet the 3-factor source determination test; and (2) the Facility's Title V permit is a "sham permit." The EPA's rationale for partially granting and partially denying the claims raised in the petition are described in the Order.

Dated: August 26, 2015.

Catherine McCabe,

Deputy Regional Administrator.

BILLING CODE 6560–50–P

ENVIRONMENTAL PROTECTION AGENCY

[FRL–9933–86–OAR]

40 CFR Part 97

Allocations of Cross-State Air Pollution Rule Allowances From New Unit Set-Asides for 2015 Control Periods

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice of data availability (NODA).

SUMMARY: The Environmental Protection Agency (EPA) is providing notice of the availability of preliminary lists of units eligible for allocations of emission allowances under the Cross-State Air Pollution Rule (CSAPR). Under the CSAPR federal implementation plans (FIPs), portions of each covered state's annual emissions budgets for each of the four CSAPR emissions trading programs are reserved for allocation to electricity generating units that commenced commercial operation on or after January 1, 2010 (new units) and certain other units not otherwise obtaining allowance allocations under the FIPs. The quantities of allowances allocated to eligible units from each new unit set-aside (NUSA) under the FIPs are calculated in an annual one- or two-round allocation process. EPA previously completed the first round of NUSA allowance allocations for the 2015 control periods for all four CSAPR trading programs and is now making available preliminary lists of units eligible for allocations in the second round of the NUSA allocation process for the CSAPR NO_X Ozone Season Trading Program. EPA has posted a spreadsheet containing the preliminary lists on EPA's Web site. EPA will consider timely objections to the lists of eligible units contained in the spreadsheet and will promulgate a document responding to any such objections no later than November 15, 2015, the deadline for recording the second-round allocations of CSAPR NO_X Ozone Season allowances in sources' Allowance Management System accounts. This notice of availability may concern CSAPR-affected units in the following states: Alabama, Arkansas, Florida, Georgia, Illinois, Indiana, Iowa, Kentucky,

Louisiana, Maryland, Michigan, Mississippi, Missouri, New Jersey, New York, North Carolina, Ohio, Oklahoma, Pennsylvania, South Carolina, Tennessee, Texas, Virginia, West Virginia, and Wisconsin.

DATES: Objections to the information referenced in this notice of availability must be received on or before October 14, 2015.

ADDRESSES: Submit your objections via email to *CSAPR_NUSA@epa.gov.* Include "2015 NUSA allocations" in the email subject line and include your name, title, affiliation, address, phone number, and email address in the body of the email.

FOR FURTHER INFORMATION CONTACT: Questions concerning this action should be addressed to Robert Miller at (202) 343–9077 or *miller.robertl@epa.gov* or Kenon Smith at (202) 343–9164 or *smith.kenon@epa.gov.*

SUPPLEMENTARY INFORMATION: Under the CSAPR FIPs, the mechanisms by which initial allocations of emission allowances are determined differ for "existing" and "new" units. For "existing" units—that is, units commencing commercial operation before January 1, 2010—the specific amounts of CSAPR FIP allowance allocations for all control periods have been established through rulemaking. EPA has announced the availability of spreadsheets showing the CSAPR FIP allowance allocations to existing units in previous notices of availability.[1]

"New" units—that is, units commencing commercial operation on or after January 1, 2010—as well as certain older units that would not otherwise obtain FIP allowance allocations do not have pre-established allowance allocations. Instead, the CSAPR FIPs reserve a portion of each state's total annual emissions budget for each CSAPR emissions trading program as a new unit set-aside (NUSA)[2] and establish an annual process for allocating NUSA allowances to eligible units. States with Indian country within their borders have separate Indian country NUSAs. The annual process for allocating allowances from the NUSAs and Indian country NUSAs to eligible units is set forth in the CSAPR regulations at 40 CFR 97.411(b) and 97.412 (NO_X Annual Trading Program), 97.511(b) and 97.512 (NO_X Ozone Season Trading Program), 97.611(b) and 97.612 (SO_2 Group 1 Trading Program), and 97.711(b) and 97.712 (SO_2 Group 2 Trading Program). Each NUSA allowance allocation process involves up to two rounds of allocations to new units followed by the allocation to existing units of any allowances not allocated to new units. EPA provides public notice at certain points in the process.

EPA has already completed the first round of allocations of 2015 NUSA allowances for all four CSAPR trading programs, as announced in notices of availability previously published in the **Federal Register**.[3] The first-round NUSA allocation process was discussed in those previous notices of availability.

In the case of second-round allocations of NUSA allowances, the annual allocations for the CSAPR NO_X Ozone Season Trading Program occur before the annual allocations for the other three CSAPR trading programs because of differences in the emissions reporting and compliance deadlines for the various programs. This notice of availability concerns the second round of NUSA allowance allocations for the CSAPR NO_X Ozone Season Trading Program for the 2015 control period.[4]

The units eligible to receive second-round NUSA allocations for the CSAPR NO_X Ozone Season Trading Program are defined in §§ 97.511(a)(1)(iii) and 97.512(a)(9)(i). Generally, eligible units include any CSAPR-affected unit that commenced commercial operation between May 1 of the year before the control period in question and August 31 of the year of the control period in question. In the case of the 2015 control period, an eligible unit therefore must have commenced commercial operation between May 1, 2014 and August 31, 2015 (inclusive).

The total quantity of allowances to be allocated through the 2015 NUSA allowance allocation process for each state and emissions trading program—in the two rounds of the allocation process combined—is generally the state's 2015 emissions budget less the sum of (1) the total of the 2015 CSAPR FIP allowance allocations to existing units and (2) the amount of the 2015 Indian country NUSA, if any.[5] The amounts of CSAPR NO_X Ozone Season NUSA allowances may be increased in certain circumstances as set forth in § 97.512(a)(2).

Second-round NUSA allocations for a given state, trading program, and control period are made only if the NUSA contains allowances after completion of the first-round allocations.

The amounts of second-round CSAPR NO_X Ozone Season allowance allocations to eligible new units from each NUSA are calculated according to the procedures set forth in § 97.512(a)(9), (10) and (12). Generally, the procedures call for each eligible unit to receive a second-round 2015 NUSA allocation equal to the positive difference, if any, between its emissions during the 2015 NO_X ozone season (*i.e.,* May 1, 2015 through September 30, 2015) as reported under 40 CFR part 75 and any first-round allocation the unit received, unless the total of such allocations to all eligible units would exceed the amount of allowances in the NUSA, in which case the allocations are reduced on a pro-rata basis.

Any allowances remaining in the CSAPR NO_X Ozone Season NUSA for a given state and control period after the second round of NUSA allocations to new units will be allocated to the existing units in the state according to the procedures set forth in § 97.512(a)(10) and (12).

EPA notes that an allocation or lack of allocation of allowances to a given EGU does not constitute a determination that CSAPR does or does not apply to the EGU. EPA also notes that allocations are subject to potential correction if a unit to which NUSA allowances have been allocated for a given control period is not actually an affected unit as of the start of that control period.[6]

The preliminary lists of units eligible for second-round 2015 NUSA allocations of CSAPR NO_X Ozone Season allowances are set forth in an Excel spreadsheet titled "CSAPR_NUSA_2015_NOx_OS_2nd_Round_Prelim_Data" available on EPA's Web site at *http://www.epa.gov/crossstaterule/actions.html.* The spreadsheet contains a separate worksheet for each state covered by that program showing each unit preliminarily identified as eligible for a second-round NUSA allocation.

[1] The latest spreadsheet of CSAPR FIP allowance allocations to existing units, updated in 2014 to reflect changes to CSAPR's implementation schedule but with allocation amounts unchanged since June 2012, is available at *http://www.epa.gov/crossstaterule/actions.html. See* Availability of Data on Allocations of Cross-State Air Pollution Rule Allowances to Existing Electricity Generating Units, 79 FR 71674 (December 3, 2014).

[2] The NUSA amounts range from two percent to eight percent of the respective state budgets. The variation in percentages reflects differences among states in the quantities of emission allowances projected to be required by known new units at the time the budgets were set or amended.

[3] 80 FR 30988 (June 1, 2015); 80 FR 44882 (July 28, 2015).

[4] At this time, EPA is not aware of any unit eligible for a second-round allocation from any Indian country NUSA.

[5] The quantities of allowances to be allocated through the NUSA allowance allocation process may differ slightly from the NUSA amounts set forth in §§ 97.410(a), 97.510(a), 97.610(a), and 97.710(a) because of rounding in the spreadsheet of CSAPR FIP allowance allocations to existing units.

[6] *See* 40 CFR 97.511(c).

Each state worksheet also contains a summary showing (1) the quantity of allowances initially available in that state's 2015 NUSA, (2) the sum of the 2015 NUSA allowance allocations that were made in the first-round to new units in that state (if any), and (3) the quantity of allowances in the 2015 NUSA available for distribution in second-round allocations to new units (or ultimately for allocation to existing units).

Objections should be strictly limited to whether EPA has correctly identified the new units eligible for second-round 2015 NUSA allocations of CSAPR NO_X Ozone Season allowances according to the criteria described above and should be emailed to the address identified in **ADDRESSES.** Objections must include: (1) Precise identification of the specific data the commenter believes are inaccurate, (2) new proposed data upon which the commenter believes EPA should rely instead, and (3) the reasons why EPA should rely on the commenter's proposed data and not the data referenced in this notice of availability.

Authority: 40 CFR 97.511(b).

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The Environmental Protection Agency (EPA) proposes to revise the current federal Clean Water Act (CWA) human health criteria applicable to waters under the state of Washington's jurisdiction to ensure that the criteria are set at levels that will adequately protect Washington residents, including tribes with treaty-protected rights, from exposure to toxic pollutants. EPA promulgated Washington's existing criteria for the protection of human health in 1992 as part of the National Toxics Rule (NTR), (amended in 1999 for Polychlorinated Biphenyls (PCBs)) using the Agency's recommended criteria values at the time. EPA derived those criteria using a fish consumption rate (FCR) of 6.5 grams per day (g/day) based on national surveys. However, the best available data now demonstrate that fish consumers in Washington, including tribes with treaty-protected rights, consume much more fish than 6.5 g/day. There are also new data and scientific information available to update the toxicity and exposure parameters used to calculate human health criteria. Therefore, EPA proposes to revise the federal human health criteria applicable to waters under Washington's jurisdiction to take into account the best available science, including local and regional information, as well as applicable EPA policies, guidance, and legal requirements, to protect human health.

DATES: Comments must be received on or before November 13, 2015.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–HQ–OW–2015–0174, to the *Federal eRulemaking Portal: http://www.regulations.gov.* Follow the online instructions for submitting comments. Once submitted, comments cannot be edited or withdrawn. EPA may publish any comment received to its public docket. Do not submit electronically any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.* on the web, cloud, or other file sharing system). For additional submission methods, the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *http://www2.epa.gov/dockets/commenting-epa-dockets.*

FOR FURTHER INFORMATION CONTACT: Erica Fleisig, Office of Water, Standards and Health Protection Division (4305T), Environmental Protection Agency, 1200 Pennsylvania Avenue NW., Washington, DC 20460; telephone number: (202) 566–1057; email address: *fleisig.erica@epa.gov.*

SUPPLEMENTARY INFORMATION: This proposed rule is organized as follows:

I. General Information
Does this action apply to me?
II. Background
A. Statutory and Regulatory Background
B. General Recommended Approach for Deriving Human Health Criteria
III. Necessity Determination for Washington
A. Existing Criteria Are Not Protective of Designated Uses of Waters in the State of Washington
B. CWA 303(c)(4)(B) Determination of Necessity
IV. Derivation of Human Health Criteria for Washington
A. Tribal Reserved Fishing Rights and Washington's Designated Uses
B. Scope of EPA's Proposal
C. Washington-Specific Human Health Criteria Inputs
D. Proposed Human Health Criteria for Washington
E. Applicability of Criteria When Final
F. Alternative Regulatory Approaches and Implementation Mechanisms
V. Economic Analysis
A. Identifying Affected Entities
B. Method for Estimating Costs
C. Results
VI. Statutory and Executive Order Reviews
A. Executive Order 12866 (Regulatory Planning and Review) and Executive Order 13563 (Improving Regulation and Regulatory Review)
B. Paperwork Reduction Act
C. Regulatory Flexibility Act
D. Unfunded Mandates Reform Act
E. Executive Order 13132 (Federalism)
F. Executive Order 13175 (Consultation and Coordination with Indian Tribal Governments)
G. Executive Order 13045 (Protection of Children From Environmental Health and Safety Risks)
H. Executive Order 13211 (Actions That Significantly Affect Energy Supply, Distribution, or Use)
I. National Technology Transfer and Advancement Act of 1995
J. Executive Order 12898 (Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations)

I. General Information

Does this action apply to me?

Entities such as industries, stormwater management districts, or publicly owned treatment works (POTWs) that discharge pollutants to waters of the United States under the state of Washington's jurisdiction could be indirectly affected by this rulemaking, because federal water quality standards (WQS) promulgated by EPA would be applicable to CWA regulatory programs, such as National Pollutant Discharge Elimination System (NPDES) permitting. Citizens concerned with water quality in Washington could also be interested in this rulemaking. Categories and entities that could potentially be affected include the following:

Category	Examples of potentially affected entities
Industry	Industries discharging pollutants to waters of the United States in Washington.
Municipalities	Publicly owned treatment works or other facilities discharging pollutants to waters of the United States in Washington.
Stormwater Management Districts.	Entities responsible for managing stormwater runoff in the state of Washington.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities that could be indirectly affected by this action. Any parties or entities who depend upon or contribute to the water quality of Washington's waters could be affected by this proposed rule. To determine whether your facility or activities could be affected by this action, you should carefully examine this proposed rule. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the **FOR FURTHER INFORMATION CONTACT** section.

II. Background

A. Statutory and Regulatory Background

CWA section 101(a)(2) establishes as a national goal "water quality which provides for the protection and propagation of fish, shellfish, and wildlife, and recreation in and on the water, wherever attainable." These are commonly referred to as the "fishable/swimmable" goals of the CWA. EPA interprets "fishable" uses to include, at a minimum, designated uses providing for the protection of aquatic communities and human health related to consumption of fish and shellfish.[1]

CWA section 303(c) (33 U.S.C. 1313(c)) directs states to adopt WQS for their waters subject to the CWA. CWA section 303(c)(2)(A) and EPA's implementing regulations at 40 CFR part 131 require, among other things, that a state's WQS specify appropriate designated uses of the waters, and water quality criteria that protect those uses. EPA's regulations at 40 CFR 131.11(a)(1) provide that such criteria "must be based on sound scientific rationale and must contain sufficient parameters or constituents to protect the designated use." In addition, 40 CFR 131.10(b) provides that "[i]n designating uses of a water body and the appropriate criteria for those uses, the state shall take into consideration the water quality standards of downstream waters and ensure that its water quality standards provide for the attainment and maintenance of the water quality standards of downstream waters."

States are required to review applicable WQS at least once every three years and, if appropriate, revise or adopt new standards (CWA section 303(c)(1)). Any new or revised WQS must be submitted to EPA for review and approval or disapproval (CWA section 303(c)(2)(A) and (c)(3)). CWA section 303(c)(4)(B) authorizes the Administrator to determine, even in the absence of a state submission, that a new or revised standard is needed to meet CWA requirements.

Under CWA section 304(a), EPA periodically publishes criteria recommendations for states to consider when adopting water quality criteria for particular pollutants to meet the CWA section 101(a)(2) goals. In 2015, EPA updated its 304(a) recommended criteria for human health for 94 pollutants.[2] Where EPA has published recommended criteria, states should consider adopting water quality criteria based on EPA's CWA section 304(a) criteria, section 304(a) criteria modified to reflect site-specific conditions, or other scientifically defensible methods (40 CFR 131.11(b)(1)). Ultimately, however, criteria must protect the designated use and be based on sound scientific rationale (40 CFR 131.11(a)(1)). CWA section 303(c)(2)(B) requires states to adopt numeric criteria for all toxic pollutants listed pursuant to CWA section 307(a)(1) for which EPA has published 304(a) criteria, as necessary to support the states' designated uses.

In 1992, EPA promulgated the NTR at 40 CFR 131.36, establishing chemical-specific, numeric criteria for 85 priority toxic pollutants for 14 states and territories (states), including Washington, that were not in compliance with the requirements of CWA section 303(c)(2)(B). When states covered by the NTR subsequently adopted their own criteria for toxic pollutants that EPA approved as consistent with the CWA and EPA's implementing regulations, EPA amended the NTR to remove those states. Half of the original 14 states and territories remain covered for one or more criteria in the NTR. Washington has not yet adopted its own criteria for the protection of human health and, therefore, the Federal human health criteria that EPA promulgated in the NTR remain applicable to waters throughout the state.[3]

B. General Recommended Approach for Deriving Human Health Criteria

Human health criteria are designed to minimize the risk of adverse cancer and non-cancer effects occurring from lifetime exposure to pollutants through the ingestion of drinking water and consumption of fish/shellfish obtained from inland and nearshore waters. EPA's practice is to establish a human health 304(a) criterion for both drinking water and consumption of fish/shellfish from inland and nearshore waters combined and a separate human health criterion based on ingestion of fish/shellfish from inland and nearshore waters alone. This latter criterion applies in cases where the designated uses of a waterbody include supporting fish/shellfish for human consumption but not drinking water supply sources (*e.g.,* in non-potable estuarine waters).

The criteria are based on two types of biological endpoints: (1) Carcinogenicity and (2) systemic toxicity (*i.e.,* all adverse effects other than cancer). EPA takes an integrated approach and considers both cancer and non-cancer effects when deriving human health criteria. Where sufficient data are available, EPA derives criteria using both carcinogenic and non-carcinogenic toxicity endpoints and recommends the lower value. Human health criteria for carcinogenic effects are calculated using the following input parameters: Cancer slope factor, cancer risk level, body weight, drinking water intake rate, fish consumption rate, and a bioaccumulation factor(s). Human health criteria for non-carcinogenic and nonlinear carcinogenic effects are calculated using a reference dose in place of a cancer slope factor and cancer risk level, as well as a relative source contribution (RSC), which is intended to ensure that an individual's total exposure from all sources does not exceed the criteria. Each of these inputs is discussed in more detail below and in

Final 2015 Updated National Recommended Human Health Criteria. U.S. Environmental Protection Agency, Office of Water, Washington, DC. *http://water.epa.gov/scitech/swguidance/standards/criteria/current/hhfinal.cfm.*

[3] Washington adopted criteria for the protection of aquatic life from toxic pollutants at WAC 173–201A–240. On January 12, 2015, Washington proposed statewide human health criteria and new and revised implementation provisions. In July 2015, Governor Inslee directed Washington to reconsider its proposed human health criteria and implementation tool revisions. See *http://www.ecy.wa.gov/programs/wq/ruledev/wac173201A/1203ov.html.*

EPA's 2000 Human Health Methodology.[4]

a. Cancer Risk Level

EPA's 304(a) national recommended human health criteria generally assume that carcinogenicity is a "non-threshold phenomenon," which means that there are no "safe" or "no-effect" levels because even extremely small doses are assumed to cause a finite increase in the incidence of cancer. Therefore, EPA calculates 304(a) human health criteria for carcinogenic effects as pollutant concentrations corresponding to lifetime increases in the risk of developing cancer.[5] EPA calculates its 304(a) human health criteria values at a 10^{-6} (one in one million) cancer risk level and recommends cancer risk levels of 10^{-6} or 10^{-5} (one in one hundred thousand) for the general population.[6] EPA notes that states and authorized tribes can also choose a more stringent risk level, such as 10^{-7} (one in ten million), when deriving human health criteria.

If the pollutant is not considered to have the potential for causing cancer in humans (*i.e.,* systemic toxicants), EPA assumes that the pollutant has a threshold below which a physiological mechanism exists within living organisms to avoid or overcome the adverse effects of the pollutant.

b. Cancer Slope Factor and Reference Dose

A dose-response assessment is required to understand the quantitative relationships between the amount of exposure to a pollutant and the onset of human health effects. EPA evaluates dose-response relationships derived from animal toxicity and human epidemiological studies to derive dose-response metrics for regulatory purposes. To evaluate carcinogenic effects, the dose-response metric used to characterize a chemical's human cancer-causing potential is referred to as a cancer slope factor (CSF). For non-carcinogenic effects, EPA uses the reference dose (RfD) to calculate human health criteria. Doses that are below the RfD are less likely to be associated with health risks. EPA's Integrated Risk Information System (IRIS)[7] was the primary source of toxicity values (*i.e.,* RfD and CSF) for EPA's 2015 updated 304(a) human health criteria.[8] For some pollutants, however, more recent peer-reviewed and publicly available toxicological data were available from other EPA program offices (*e.g.,* Office of Pesticide Programs, Office of Water, Office of Solid Waste and Emergency Response), other national and international programs, and state programs.

c. Exposure Assumptions

Per EPA's latest 304(a) national human health criteria, EPA uses a default drinking water intake rate of 2.4 liters per day (L/day) and default rate of 22 g/day for consumption of fish and shellfish from inland and nearshore waters, multiplied by pollutant-specific bioaccumulation factors (BAFs) to account for the amount of the pollutant in the edible portions of the ingested species. EPA's methodology for deriving human health criteria emphasizes using, when possible, measured or estimated BAFs, which account for chemical accumulation in aquatic organisms from all potential exposure routes.[9] In the 2015 national 304(a) human health criteria update, EPA primarily used field-measured BAFs and laboratory-measured bioconcentration factors (BCFs) available from peer-reviewed, publicly available databases to develop national BAFs for three trophic levels of fish.[10] If this information was not available, EPA selected octanol-water partition coefficients (K_{ow} values) from peer-reviewed sources for use in calculating national BAFs.

EPA's national default drinking water intake rate of 2.4 L/day represents the per capita estimate of combined direct and indirect community water ingestion at the 90th percentile for adults ages 21 and older.[11] EPA's national FCR of 22 g/day represents the 90th percentile consumption rate of fish and shellfish from inland and nearshore waters for the U.S. adult population 21 years of age and older, based on National Health and Nutrient Examination Survey (NHANES) data from 2003 to 2010.[12] [13] EPA calculates human health criteria using a default body weight of 80 kilograms (kg), the average weight of a U.S. adult age 21 and older, based on NHANES data from 1999 to 2006.

Although EPA uses these values to calculate national 304(a) recommended criteria, EPA's methodology notes a preference for the use of local data to calculate human health criteria (*e.g.,* locally derived FCRs, drinking water intake rates and body weights, and waterbody-specific bioaccumulation rates) over national default values, to better represent local conditions.[14] EPA also generally recommends, where sufficient data are available, selecting a FCR that reflects consumption that is not suppressed by fish availability or concerns about the safety of available fish.[15] Deriving criteria using an unsuppressed FCR furthers the restoration goals of the CWA, and ensures protection of human health as pollutant levels decrease, fish habitats

[5] As noted above, EPA recommends the criteria derived for non-carcinogenic effects if it is more protective (lower) than that derived for carcinogenic effects.

[6] EPA's 2000 Human Health Methodology also states: "Criteria based on a 10^{-5} risk level are acceptable for the general population as long as states and authorized tribes ensure that the risk to more highly exposed subgroups (sport fishers or subsistence fishers) does not exceed the 10^{-4} level." Since EPA is proposing criteria to protect the target general population in Washington (tribes with reserved rights in Washington waters), the applicable EPA-recommended cancer risk levels are those for the general population. See section IV for additional discussion.

[13] EPA's national FCR is based on the total rate of consumption of fish and shellfish from inland and nearshore waters (including fish and shellfish from local, commercial, aquaculture, interstate, and international sources). This is consistent with a principle that each state does its share to protect people who consume fish and shellfish that originate from multiple jurisdictions. USEPA. January 2013. *Human Health Ambient Water Quality Criteria and Fish Consumption Rates: Frequently Asked Questions. http://water.epa.gov/scitech/swguidance/standards/criteria/health/methodology/upload/hhfaqs.pdf.*

are restored, and fish availability increases. While EPA encourages doing so in general, where tribal treaty or other reserved fishing rights apply, selecting a FCR that reflects unsuppressed fish consumption could be necessary in order to satisfy such rights. If sufficient data regarding unsuppressed fish consumption levels are unavailable, consultation with tribes is important in deciding which fish consumption data should be used. See section IV.C.a.

d. Relative Source Contribution

When deriving human health criteria for non-carcinogens and nonlinear carcinogens, EPA recommends including a RSC factor to account for sources of exposure other than drinking water and fish and shellfish from inland and nearshore waters, so that the pollutant effect threshold (*i.e.*, RfD) is not apportioned to drinking water and fish consumption alone. These other exposures include exposure to a particular pollutant from ocean fish consumption (which is not included in EPA's default national FCR), non-fish food consumption (*e.g.*, fruits, vegetables, grains, meats, poultry), dermal exposure, and respiratory exposure. EPA's guidance includes a procedure for determining an appropriate RSC for a given pollutant ranging in value from 0.2 to 0.8.

III. Necessity Determination for Washington

A. Existing Criteria Are Not Protective of Designated Uses of Waters in the State of Washington

In the NTR, 40 CFR 131.36(d)(14), EPA stated that the federal human health criteria applied to all waters assigned to Washington's use classifications identified at WAC 173–201–045, including fish and shellfish, fish, water supply (domestic), and recreation. As currently defined in Washington's WQS (WAC 173–201A–600 and WAC 173–201A–610), the uses subject to federal human health criteria in Washington include the following: Fresh waters—Harvesting (fish harvesting), Domestic Water (domestic water supply), and Recreational Uses; Marine waters—Shellfish Harvesting (shellfish—clam, oyster, and mussel—harvesting), Harvesting (salmonid and other fish harvesting, and crustacean and other shellfish—crabs, shrimp, scallops, etc.—harvesting), and Recreational Uses.

Per EPA's regulations at § 131.11(a), water quality criteria must contain sufficient parameters or constituents to protect the designated use, and for waters with multiple use designations, the criteria must support the most sensitive use. In determining whether WQS comply with the CWA and EPA's regulations, when setting criteria to support the most sensitive use in Washington, it is necessary to consider other applicable laws, including federal treaties.[16] In Washington, many tribes hold reserved rights to take fish for subsistence, ceremonial, religious, and commercial purposes, including treaty-reserved rights to fish at all usual and accustomed fishing grounds and stations in waters under state jurisdiction, which cover the majority of waters in the state. Such rights include not only a right to take those fish, but necessarily include an attendant right to not be exposed to unacceptable health risks by consuming those fish.

In 1992, EPA selected input values based on available national data to derive protective human health criteria in the NTR. To ensure protection of human health in waters where fish and shellfish are caught and consumed, EPA used data available at the time on the average per-capita consumption rate of fish from inland and nearshore waters for the U.S. population. This average rate was 6.5 g/day.

Surveys of local residents in the Pacific Northwest, including tribes and recreational anglers, reflect high consumption levels of fish and shellfish—much higher than the 6.5 g/day rate that EPA used in 1992 to derive Washington's human health criteria in the NTR. Since that time, data have become available that better represent regional and local fish consumption in Washington, including:

- *A Fish Consumption Survey of the Umatilla, Nez Perce, Yakama, and Warm Springs Tribes of the Columbia River Basin* (Columbia River Inter-Tribal Fish Commission (CRITFC), 1994).
- *A Fish Consumption Survey of the Tulalip and Squaxin Island Tribes of the Puget Sound Region* (Toy et al., 1996).
- *Fish Consumption Survey of the Suquamish Indian Tribe of the Port Madison Indian Reservations, Puget Sound Region* (Suquamish Tribe, 2000).
- *Asian and Pacific Islander Seafood Consumption Study* (Sechena et al., 1999).

The average FCRs[17] from these surveys range from 63 to 214 g/day, far in excess of 6.5 g/day. The 90th percentile FCRs from these surveys range from 113 to 489 g/day, also far in excess of EPA's current national FCR of 22 g/day, which represents the 90th percentile national FCR (see section II.B.c). The 6.5 g/day FCR that EPA used to derive the current human health criteria applicable to Washington does not account for these more recent local data, nor suppression in fish consumption (as discussed earlier).[18] In addition, the 6.5 g/day FCR does not account for EPA's 2000 recommendation to use an upper percentile of fish consumption data for the target general population (as with EPA's current national FCR of 22 g/day) rather than an average. EPA considered the fish consumption data cited above, in conjunction with Washington's current designated uses as informed by tribal reserved rights in Washington (as discussed in section IV.A), and determined that the federal human health criteria in the NTR as applied to Washington no longer protect the relevant designated uses of Washington's waters.

B. CWA 303(c)(4)(B) Determination of Necessity

Because Washington's existing human health criteria, as promulgated by EPA in the NTR, are no longer protective of the applicable designated uses per the CWA and EPA's regulations at 40 CFR 131.11, EPA determines under CWA section 303(c)(4)(B) that new or revised WQS for the protection of human health are necessary to meet the requirements of the CWA for Washington. EPA, therefore, proposes the revised human health criteria for Washington in this rule in accordance with this 303(c)(4)(B) determination. EPA's determination is not itself a final action, nor part of a final action, at this time. After consideration of comments on the

[16] In addition to treaties, executive orders and federal statutes, such as land claim settlement acts, could also apply.

[17] Cited FCRs are based on total fish consumption regardless of source.

[18] Historical or heritage FCRs could be of relevance to establishing unsuppressed FCRs for Washington tribes. Extensively researched historical average FCRs for the Columbia River Basin Tribes range from 401 to 995 g/day (Craig and Hacker (1940) & Hewes (1947); Swindell (1942); Marshall (1977); Walker (1967)). More limited average historic FCRs for Washington Tribes range from 454 to 746 g/day (Hewes 1973). In *United States* v. *Washington* (1974), the court accepted a heritage FCR of 620 g/day. A number of factors could cause these FCRs to be underestimates (Schalk 1986), including the fact that, with the exception of Craig and Hacker (1940), they only include consumption of salmon. Upper percentile values are not reported in these historical studies but would be higher than the reported average values. The highest estimated current FCRs in Washington come from the Suquamish Tribal survey (Suquamish 2000), with a reported FCR as high as 1,600 g/day (Table C5). The 95th percentile Suquamish FCR is 767 g/day (Ecology 2013). Recent publications by Harper and Walker (2015) comprehensively summarize and further support these heritage and contemporary fish consumption rates.

proposed rule, EPA will take final agency action on this rulemaking. It is at that time that any change to the water quality standards applicable to Washington would occur.

IV. Derivation of Human Health Criteria for Washington

A. Tribal Reserved Fishing Rights and Washington's Designated Uses

A majority of waters under Washington's jurisdiction are covered by reserved rights, including tribal treaty-reserved rights (see section III.A). Many areas where reserved rights are exercised cannot be directly protected or regulated by the tribal governments and, therefore, the responsibility falls to the state and federal governments to ensure their protection.[19] In order to effectuate and harmonize these reserved rights, including treaty rights, with the CWA, EPA determined that such rights appropriately must be considered when determining which criteria are necessary to adequately protect Washington's fish and shellfish harvesting designated uses (see sections IV.C.a and IV.C.b).

Protecting Washington's fish and shellfish harvesting designated uses, which include consumption of such fish and shellfish, necessitates protecting the population exercising those uses. Where a population exercising such uses has a legal right to do so, the criteria protecting such uses must be consistent with such right. Thus, EPA proposes to consider the tribal population exercising their reserved fishing rights in Washington as the target general population for the purposes of deriving protective criteria that allow the tribes to harvest and consume fish consistent with their reserved rights.

Although treaties do not cover all waters in Washington, they cover the vast majority of the state's waters. Additionally, where treaty and non-treaty reserved rights apply on waters downstream of waters without reserved fishing rights, upstream WQS must provide for the attainment and maintenance of downstream WQS in accordance with EPA's regulations at 40 CFR 131.10(b). For any remaining waters in Washington where reserved rights do not apply and that are not upstream of waters with such rights or waters in Oregon (see section IV.C.a), it would be administratively burdensome and difficult to implement separate criteria because it would create a patchwork of protection among these areas leading to potential difficulties in administering the WQS, NPDES permitting, and other programs. In addition, delineating the precise boundaries could itself be complicated. Therefore, EPA proposes to apply these criteria to all waters under Washington's jurisdiction.

B. Scope of EPA's Proposal

In 1992, EPA did not establish human health criteria in the NTR for some priority toxic pollutants for reasons articulated in the preamble to the final rule at 57 FR 60848, December 22, 1992. EPA had no 304(a) recommendations for those pollutants at the time. EPA now has 304(a) recommendations for 99 priority toxic pollutants listed pursuant to CWA section 307(a)(1) (85 for which EPA established criteria in the NTR, plus 14 additional pollutants). Therefore, EPA proposes to derive Washington-specific criteria for all 99 priority toxic pollutants in this rule. For those priority pollutants for which EPA does not have 304(a) national recommended criteria, and are thus not included in this proposed rule, EPA expects that Washington will continue to apply their existing narrative toxics criterion in the state's WQS at WAC 173–201A–260(2)(a).

This rule proposes to change the criteria that EPA promulgated for Washington in the NTR and establish new human health criteria for the 14 additional chemicals for which EPA now has 304(a) recommended criteria: Copper, Selenium, Zinc, 1,2-Dichloropropane, 1,2-Trans-Dichloroethylene, 2-Chlorophenol, 2,4-Dimethylphenol, Acenaphthene, Butylbenzyl Phthalate, 2-Chloronaphthalene, N-Nitrosodi-n-Propylamine, 1,1,1-Trichloroethane, 3-Methyl-4-Chlorophenol, and 1,2,4-Trichlorobenzene. Since 1992, EPA replaced its recommended human health criteria for mercury with a fish tissue-based human health criterion for methylmercury. EPA proposes to replace the criteria for mercury that EPA promulgated for Washington in the NTR with a methylmercury fish tissue criterion, adjusted for the FCR that EPA proposes to use to derive human health criteria in Washington.[20] This proposed rule would not change or supersede any criteria that EPA previously promulgated for other states in the NTR, nor does it change any other elements of the NTR such as EPA's original basis for promulgation. EPA proposes to remove Washington from the NTR at 40 CFR 131.36 and incorporate the Washington-specific criteria proposed in this rule into proposed 40 CFR 131.45 so there is a single comprehensive rule for Washington.

This proposed rule would apply to waters under the state of Washington's jurisdiction, and not to waters within Indian Country[21], unless otherwise specified in federal law. Some waters located within Indian Country already have CWA-effective human health criteria, while others do not.[22] Several tribes are working with EPA to either revise their existing CWA-effective WQS, or obtain treatment in a similar manner as a state (TAS) status in order to adopt their own WQS in the near future. EPA will continue to work closely with tribes in Washington to ensure that they adopt human health criteria that are scientifically supported and protective of designated uses, in accordance with the CWA and EPA's regulations.

C. Washington-Specific Human Health Criteria Inputs

a. Fish Consumption Rate

EPA proposes to derive human health criteria for Washington using a FCR of 175 g/day as this FCR accounts for local data (consistent with EPA's methodology), reflects input received during consultation with tribes, and appropriately addresses protection of Oregon's downstream WQS, per EPA's regulations at 40 CFR 131.10(b).

EPA considered the input received during consultation with tribes when selecting which fish consumption data would be used to estimate a FCR for calculating human health criteria to protect the designated uses. A FCR of 175 g/day approximates the 95th percentile consumption rate of surveyed tribal members from the CRITFC study.[23] Although EPA's national default FCR only includes consumption of fish from inland and nearshore waters, 175 g/day in this case includes anadromous fish, which is appropriate given that anadromous species reside in

[19] Note that for formal and informal reservation lands, eligible tribes can obtain treatment in a similar manner as a state (TAS) status and set their own WQS under the CWA, including human health criteria.

[20] USEPA. 2001. Water Quality Criterion for the Protection of Human Health: Methylmercury. U.S. Environmental Protection Agency, Office of Water, Washington, DC EPA–823–R–01–001. *http://water.epa.gov/scitech/swguidance/standards/criteria/health/upload/2009_01_15_criteria_methylmercury_mercury-criterion.pdf.*

[21] *See* 18 U.S.C. 1151 for definition of Indian Country.

[22] Indian Country waters with CWA-effective WQS are (a) those Indian Country waters where EPA explicitly found that a tribe has jurisdiction to adopt WQS under the CWA, and where the tribe adopted standards in accordance with EPA regulations, and (b) where EPA promulgated federal WQS.

[23] *Fish Consumption Survey of the Umatilla, Nez Perce, Yakama, and Warm Springs Tribes of the Columbia River Basin* (Columbia River Inter-Tribal Fish Commission (CRITFC), 1994)

Washington's nearshore waters, especially Puget Sound, and accumulate pollutants discharged to these waters.[24] A FCR of 175 g/day, therefore, accounts for local fish consumption data. Additionally, Oregon, much of which is downstream from Washington, used this FCR to derive statewide human health criteria, which EPA approved in 2011. Use of this FCR to derive Washington's criteria should thus help provide for the attainment and maintenance of downstream WQS in Oregon.

After consideration of the full range of available local fish consumption data and after consultation with Washington tribes and Columbia River Basin tribes in Oregon and Idaho, EPA determined that a FCR of 175 g/day very likely does not reflect unsuppressed consumption rates of tribes within the state (see section II.B.c). EPA considered this fact as well as tribal input in selecting a cancer risk level of 10^{-6} to account for this uncertainty and ensure that EPA's proposed criteria protect Washington's fishing uses, including the tribes' reserved fishing rights. See discussion in section IV.C.b.

b. Cancer Risk Level

Based on Washington's longstanding use of a cancer risk level of 10^{-6}, along with EPA's consideration of tribal reserved rights, EPA guidance, and downstream protection, EPA proposes to derive human health criteria for carcinogens in Washington using a 10^{-6} cancer risk level.

To derive final human health criteria for each state in the NTR, EPA selected a cancer risk level based on each state's policy or practice regarding what risk level should be used when regulating carcinogens in surface waters. In its official comments on EPA's proposed NTR, Washington asked EPA to promulgate human health criteria using a cancer risk level of 10^{-6}, stating, "The State of Washington supports adoption of a risk level of one in one million for carcinogens. If EPA decides to promulgate a risk level below one in one million, the rule should specifically address the issue of multiple contaminants so as to better control overall site risks." (57 FR 60848, December 22, 1992). Accordingly, in the NTR, EPA used a cancer risk level of 10^{-6} (one in one million) to derive human health criteria for Washington. Subsequently, Washington adopted and EPA approved a provision in the state's WQS that reads: "Risk-based criteria for carcinogenic substances shall be selected such that the upper-bound excess cancer risk is less than or equal to one in a million" (WAC 173–201A–240(6)). This provision has been in effect in Washington's WQS since 1993.

In order to effectuate reserved fishing rights, including the rights that federal treaties afford to tribes in Washington, EPA proposes to derive criteria that will protect the tribe's reserved fishing rights in Washington, treating the tribal population exercising those rights as the target general population (see section IV.A). EPA's selection of a 10^{-6} cancer risk level for the tribal target general population is consistent with EPA's 2000 Human Health Methodology, which states that when promulgating water quality criteria for states and tribes, EPA intends to use the 10^{-6} level, which reflects an appropriate risk for the general population.[25] EPA's 2000 Human Health Methodology did not consider how CWA decisions should account for applicable reserved fishing rights, including treaty-reserved rights. As discussed in section IV.C.a, because a FCR of 175 g/day very likely does not reflect unsuppressed consumption, using a cancer risk level of 10^{-6} ensures protection of tribal members' unsuppressed consumption. Independently, the treaties themselves could require higher levels of protection. The treaties themselves could be interpreted to require a certain level of risk; *e.g.*, a *de minimis* level of risk that would most reasonably approximate conditions at the time the treaties were signed and the fishing rights were reserved. In policy development regarding management of cancer risks, EPA often uses 10^{-6} as a *de minimis* risk level.[26] In this case, EPA considers 10^{-6} to be sufficiently protective, and the tribes have supported this during consultation.

Finally, many of Washington's rivers are in the Columbia River basin, upstream of Oregon's portion of the Columbia River. Oregon's criteria are based on a FCR of 175 g/day and a cancer risk level of 10^{-6}. EPA's proposal to derive human health criteria for Washington using a cancer risk level of 10^{-6} along with a FCR of 175 g/day helps ensure that Washington's criteria will provide for the attainment and maintenance of Oregon's downstream WQS as required by 40 CFR 131.10(b).

c. Relative Source Contribution

EPA recommends using a RSC for non-carcinogens and nonlinear carcinogens to account for sources of exposure other than drinking water and consumption of inland and nearshore fish and shellfish (see section II.B.d). In 2015, after evaluating information on chemical uses, properties, occurrences, releases to the environment and regulatory restrictions, EPA developed chemical-specific RSCs for non-carcinogens and nonlinear carcinogens ranging from 0.2 (20 percent) to 0.8 (80 percent) following the Exposure Decision Tree approach described in EPA's 2000 Human Health Methodology.[27] [28] EPA proposes to use these same RSCs to derive human health criteria for Washington. Where EPA did not update the nationally recommended criteria for certain pollutants in 2015, EPA proposes to use a RSC of 0.2 to derive human health criteria for those pollutants in Washington to ensure protectiveness. See Table 1, column B2 for a list of EPA's proposed RSCs by pollutant.

d. Body Weight

EPA proposes to calculate human health criteria for Washington using a body weight of 80 kg, which represents the average weight of a U.S. adult. In 2015, EPA updated its national adult body weight to 80 kg based on national survey data (see section II.B.c).[29] Local

tribal survey data relevant to Washington are consistent with EPA's national adult body weight of 80 kg.[30]

e. Drinking Water Intake

EPA proposes to calculate human health criteria for Washington using a rate of 2.4 L/day. In 2015, EPA updated its national default drinking water intake rate to 2.4 L/day based on national survey data (see section II.B.c).[31] EPA is not aware of any local data applicable to Washington that suggest a more appropriate rate.

f. Pollutant-Specific Reference Doses and Cancer Slope Factors

As part of EPA's 2015 updates to its 304(a) recommended human health criteria, EPA conducted a systematic search of eight peer-reviewed, publicly available sources to obtain the most current toxicity values for each pollutant (RfDs for non-carcinogenic effects and CSFs for carcinogenic effects).[32] EPA proposes to calculate human health criteria for Washington using the same toxicity values that EPA used in its 2015 304(a) criteria updates, to ensure that the resulting criteria are based on a sound scientific rationale. Where EPA did not update criteria for certain pollutants in 2015, EPA proposes to use the toxicity values that the Agency used the last time it updated its 304(a) criteria for those pollutants as the best available scientific information. See Table 1, columns B1 and B3 for a list of EPA's proposed toxicity factors by pollutant.

g. Pollutant-Specific Bioaccumulation Factors

For the 2015 national 304(a) human health criteria update, EPA estimated chemical-specific BAFs using a framework for deriving national BAFs described in EPA's 2000 Human Health Methodology.[33] Because the surveyed population upon which the 175 g/day FCR is based consumed almost exclusively trophic level four fish (*i.e.,* predator fish species), EPA proposes to apply the trophic level four BAF from the 2015 304(a) human health criteria updates in conjunction with the 175 g/day FCR, in order to ensure protectiveness.[34] Where EPA did not update criteria for certain pollutants in 2015, EPA proposes to use the BCFs that the Agency used the last time it updated its 304(a) criteria for those pollutants as the best available scientific information. See Table 1, columns B4 and B5 for a list of EPA's proposed bioaccumulation factors by pollutant.

D. Proposed Human Health Criteria for Washington

EPA proposes 195 human health criteria for 99 different pollutants (97 organism-only criteria and 98 water-plus-organism criteria) to protect the applicable designated uses of Washington's waters (see Table 1). The water-plus-organism criteria in column C1 of Table 1 are the applicable criteria for any waters that include the Domestic Water (domestic water supply) use defined in Washington's WQS (WAC 173–201A–600). The organism-only criteria in column C2 of Table 1 apply to waters that do not include the Domestic Water (domestic water supply) use and that Washington defines at WAC 173–201A–600 and 173–201A–610 as the following: Fresh waters—Harvesting (fish harvesting), and Recreational Uses; Marine waters—Shellfish Harvesting (shellfish—clam, oyster, and mussel—harvesting), Harvesting (salmonid and other fish harvesting, and crustacean and other shellfish—crabs, shrimp, scallops, etc.—harvesting), and Recreational Uses.

EPA solicits comment on the criteria, the inputs EPA used to derive these criteria, and specifically solicits additional Washington-specific information such as data from local fish or drinking water consumption rate studies, or bioaccumulation field studies from Washington waters.

[a] This criterion refers to the inorganic form of arsenic only.
[b] This criterion is expressed as fibers per liter (fibers/L). The criterion for asbestos is the Maximum Contaminant Level Goal (MCLG) developed under the Safe Drinking Water Act (SDWA) (56 FR 3526, January 30, 1991).
[c] EPA's national 304(a) recommended criteria for benzene use a CSF range of 0.015 to 0.055 per mg/kg-day. EPA proposes to use the higher end of the CSF range (0.055 per mg/kg-day) to derive the proposed benzene criteria for Washington.
[d] The criterion for copper is the Maximum Contaminant Level Goal (MCLG) developed under the Safe Drinking Water Act (SDWA) (40 CFR 141.80, June 7, 1991).
[e] This criterion is expressed as the fish tissue concentration of methylmercury (mg methylmercury/kg fish). See *Water Quality Criterion for the Protection of Human Health: Methylmercury* (EPA–823–R–01–001, January 3, 2001) for how this value is calculated using the criterion equation in EPA's 2000 Human Health Methodology rearranged to solve for a protective concentration in fish tissue rather than in water.
[f] This criterion applies to total PCBs (*e.g.,* the sum of all congener or isomer or homolog or Aroclor analyses).
* Bis(2-Chloro-1-Methylethyl) Ether was previously listed as Bis(2-Chloroisopropyl) Ether.

E. Applicability of Criteria When Final

The EPA does not propose to revise or replace any existing criteria (related to human health or otherwise) that were already adopted and submitted to EPA by Washington (and for those adopted after May 30, 2000, approved by EPA), such as the state's narrative toxics criteria statement at WAC 173–201A–260(2)(a). Rather, EPA proposes to revise the current federal human health criteria applicable to waters in the state of Washington, as promulgated in the NTR, and establish new criteria for 14 additional priority pollutants. These new and revised human health criteria would apply for CWA purposes in addition to any existing criteria already applicable to Washington's waters.

EPA proposes to replicate in 40 CFR 131.45 the same general rules of applicability for human health criteria as in 40 CFR 131.36(c), with one exception. For waters suitable for the establishment of low flow return frequencies (*i.e.,* streams and rivers), EPA proposes that Washington must not use a low flow value below which numeric standards can be exceeded that is less stringent than the harmonic mean flow (a long-term mean flow value calculated by dividing the number of daily flows analyzed by the sum of the reciprocals of those daily flows). Per 65 FR 66444, November 3, 2000, EPA now recommends harmonic mean flow be used to implement human health criteria for both carcinogens and non-carcinogens.[35]

Under the CWA, Congress gave states primary responsibility for developing and adopting WQS for their navigable waters (CWA section 303(a)–(c)). Although EPA proposes human health criteria for Washington to update the existing federally promulgated criteria, Washington continues to have the option to adopt and submit to EPA human health criteria for the state's waters consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131. EPA encourages Washington to expeditiously adopt protective human health criteria. Consistent with CWA section 303(c)(4), if Washington adopts and submits human health criteria and EPA approves such criteria before finalizing this proposed rule, EPA would not proceed with the final rulemaking for those waters and/or pollutants for which EPA approves Washington's criteria.

If EPA finalizes this proposed rule, and Washington subsequently adopts and submits human health criteria, EPA proposes that once EPA approves Washington's WQS, the pollutant-specific or site-specific EPA-approved criteria in Washington's WQS would become effective for CWA purposes and EPA's promulgated criteria for those pollutants or for that site would no longer apply. EPA would still undertake a rulemaking to withdraw the federal criteria for those pollutants, but any delay in that process would not delay Washington's approved criteria from becoming the sole applicable criteria for CWA purposes. EPA solicits comment on this approach.

F. Alternative Regulatory Approaches and Implementation Mechanisms

Once finalized, Washington will have considerable discretion to implement these revised federal human health criteria through various water quality control programs including the NPDES program, which limits discharges to waters except in compliance with a NPDES permit. EPA's regulations at 40 CFR 131.14, once effective, authorize states and authorized tribes to adopt WQS variances to provide time to achieve the applicable WQS. 40 CFR part 131 defines WQS variances at 131.3(o) as time-limited designated uses and supporting criteria for a specific pollutant(s) or water quality parameter(s) that reflect the highest attainable conditions during the term of the WQS variance. WQS variances adopted in accordance with 40 CFR part 131 allow states and authorized tribes to

[35] See also USEPA. 2014. Water Quality Standards Handbook—Chapter 5: General Policies. U.S. Environmental Protection Agency. Office of Water. Washington, D.C. EPA–820–B–14–004. *http://water.epa.gov/scitech/swguidance/standards/handbook/chapter05.cfm#section52.*

address water quality challenges in a transparent and predictable way. Variances help states and authorized tribes focus on making incremental progress in improving water quality, rather than pursuing a downgrade of the underlying water quality goals through a designated use change, when the current designated use is difficult to attain. EPA's regulations at 40 CFR 122.47 and 40 CFR 131.15, once effective, allow states and authorized tribes to include permit compliance schedules in their NPDES permits if dischargers need additional time to meet their water quality based limits based on the applicable WQS. EPA's updated regulations at 40 CFR part 131 also include provisions authorizing the use of permit compliance schedules to ensure that a decision to allow permit compliance schedules includes public engagement and transparency. (80 FR 51022, August 21, 2015).

40 CFR 131.10 specifies how states and authorized tribes establish, modify or remove designated uses for their waters. 40 CFR 131.11 specifies the requirements for establishing criteria to protect designated uses, including criteria modified to reflect site-specific conditions. In the context of this rulemaking, a site-specific criterion (SSC) is an alternative value to the federal human health criteria that would be applied on a watershed, area-wide, or waterbody-specific basis that meets the regulatory test of protecting the designated use, being scientifically defensible, and ensuring the protection and maintenance of downstream WQS. A SSC may be more or less stringent than the otherwise applicable federal criteria. A SSC may be appropriate when further scientific data and analyses can bring added precision to express the concentration of a particular pollutant that protects the human health-related designated use in a particular waterbody.

EPA does not propose to change any of the flexibilities afforded to Washington by EPA's regulations to modify or remove designated uses, adopt variances, issue compliance schedules or establish site-specific criteria. Washington may continue to use any of these regulatory flexibilities when implementing the revised federal human health criteria.

a. Designating Uses

EPA's proposed human health criteria apply to waters that Washington has designated for the following: Fresh waters—Harvesting (fish harvesting), Domestic Water (domestic water supply), and Recreational Uses; Marine waters—Shellfish Harvesting (shellfish—clam, oyster, and mussel—harvesting), Harvesting (salmonid and other fish harvesting, and crustacean and other shellfish—crabs, shrimp, scallops, etc.—harvesting), and Recreational Uses (see WAC 173–201A–600 and WAC 173–201A–610). If Washington removes the Domestic Water use but retains any of the other above designated uses for any particular waterbody ultimately affected by this rule, and EPA finds that removal to be consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131, then the federal organism-only criteria would apply in place of the federal water-plus-organism criteria. If Washington removes designated uses such that none of the above uses apply to any particular waterbody ultimately affected by this rule and adopts the highest attainable use, as defined by 40 CFR 131.3(m), consistent with 40 CFR 131.10(g), and EPA finds that removal to be consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131, then the federal human health criteria would no longer apply to that waterbody. Instead, any criteria associated with the newly designated highest attainable use would apply to that waterbody.

b. Variances and Compliance Schedules

EPA is proposing human health criteria that apply to use designations that Washington has already established. Washington has sufficient authority to use variances when implementing the human health criteria as long as such variances are adopted consistent with 40 CFR 131.14. Washington may use its currently EPA-approved variance procedures with respect to a temporary modification of its uses as it pertains to any federal criteria (see WAC 173–201A–420) when adopting such variances. Similarly, Washington already has an EPA-approved regulation authorizing the use of permit compliance schedules (see WAC 173–201A–510), consistent with 40 CFR 131.15. That state regulation is not affected by this rule, and Washington is authorized to grant compliance schedules, as appropriate, based on the federal criteria.

c. Site-Specific Criteria

As discussed in section IV.E, EPA proposes that once EPA approves human health criteria that Washington adopts and submits after EPA finalizes this proposed rule, the pollutant-specific or site-specific EPA-approved criteria in Washington's WQS would become effective for CWA purposes and EPA's promulgated criteria for those pollutants or for that site would no longer apply.

V. Economic Analysis

These WQS may serve as a basis for development of NPDES permit limits. Washington has NPDES permitting authority, and retains considerable discretion in implementing standards. EPA evaluated the potential costs to NPDES dischargers associated with state implementation of EPA's proposed criteria. This analysis is documented in "Economic Analysis for the Revision of Certain Federal Water Quality Criteria Applicable to Washington," which can be found in the record for this rulemaking.

Any NPDES-permitted facility that discharges pollutants for which the revised human health criteria are more stringent than the applicable aquatic life criteria (or for which human health criteria are the only applicable criteria) could potentially incur compliance costs. The types of affected facilities could include industrial facilities and POTWs discharging wastewater to surface waters (*i.e.*, point sources). Once in compliance with water quality-based effluent limitations (WQBELs) reflective of existing federal human health criteria applicable to Washington (hereafter referred to as "baseline criteria"), EPA expects that dischargers will continue to use the same types of controls to come into compliance with the revised criteria; EPA did not attribute compliance with WQBELs reflective of baseline criteria to the proposed rule. EPA did not fully evaluate the potential for costs to nonpoint sources, such as agricultural runoff, for this preliminary analysis.

EPA recognizes that the permitting authority may require controls for nonpoint sources (*e.g.*, agricultural runoff). However, it is difficult to model and evaluate the potential cost impacts of this proposed rule to nonpoint sources because they are intermittent, variable, and occur under hydrologic or climatic conditions associated with precipitation events. Also, data on instream and discharge levels of the pollutants of concern after dischargers have implemented controls to meet current WQS, total maximum daily loads (TMDLs) for impaired waters, or other water quality improvement plans, are not available. Therefore, trying to determine which sources would not achieve WQS based on the revised human health criteria after complying with existing regulations and policies may not be possible.

Finally, legacy contamination (*e.g.*, in sediment) may be a source of ongoing loading. Atmospheric deposition may

also contribute loadings of the pollutants of concern (*e.g.*, mercury). EPA did not estimate sediment remediation costs, or air pollution controls costs, for this preliminary analysis.

A. Identifying Affected Entities

EPA identified 406 point source facilities that could ultimately be affected by this proposed rule. Of these potentially affected facilities, 73 are major dischargers and 333 are minor dischargers. EPA did not include general permit facilities in its analysis because data for such facilities are limited, and flows are usually negligible. Of the potentially affected facilities, EPA evaluated a sample of 17 major facilities. Minor facilities are unlikely to incur costs as a result of implementation of the rule. Minor facilities are typically those that discharge less than 1 million gallons per day (mgd) and do not discharge toxics in toxic amounts. Although lower human health criteria could potentially change this categorization, EPA did not have effluent data on toxic pollutants to evaluate minor facilities for this preliminary analysis. Table 2 summarizes these potentially affected facilities by type and category.

TABLE 2—POTENTIALLY AFFECTED FACILITIES

Category	Minor	Major	All
Municipal	184	48	232
Industrial	149	25	174
Total	333	73	406

B. Method for Estimating Costs

EPA evaluated the 2 major municipal facilities with design flows greater than 100 mgd and the largest industrial facility, to attempt to capture the facilities with the potential for the largest costs. For the remaining major facilities, EPA evaluated a random sample of facilities to represent discharger type and category. For all sample facilities, EPA evaluated existing baseline permit conditions, reasonable potential to exceed human health criteria based on the proposed rule, and potential to exceed projected effluent limitations based on the last three years of effluent monitoring data (if available). In instances of baseline effluent limitations not being reflective of baseline criteria, EPA estimated baseline effluent limitations, compliance actions, and costs. In instances of exceedances of projected effluent limitations under the proposed criteria, EPA determined the likely compliance scenarios and costs. Only compliance actions and costs that would be needed above the baseline level of controls are attributable to the proposed rule.

EPA assumed that dischargers will pursue the least cost means of compliance with WQBELs. Incremental compliance actions attributable to the proposed rule may include pollution prevention, end-of-pipe treatment, and alternative compliance mechanisms (*e.g.*, variances). EPA annualized capital costs, including study (*e.g.*, variance) and program (*e.g.*, pollution prevention) costs, over 20 years using a 7% discount rate to obtain total annual costs per facility. For the random sample, EPA extrapolated the annualized costs based on the sampling weight for each sample facility. To obtain an estimate of total costs to point sources, EPA added the results for the certainty sample to the extrapolated random sample costs.

C. Results

Based on the results for 17 sample facilities across 8 industrial and municipal categories,[36] EPA estimated a total annual cost of approximately $13.0 million to $13.1 million for all major dischargers in the state. The low end of the range reflects the assumption that the compliance actions will result in compliance with projected effluent limits through pollution prevention programs and end-of-pipe treatment, whereas the high scenario reflects the assumption that these actions will not result in compliance with very low limits and dischargers will also need to apply for variances. All of the incremental costs are attributable to industrial dischargers, primarily for treatment of arsenic. Overall, compliance with revised human health criteria for arsenic accounts for 99% of the costs, while compliance with revised human health criteria for mercury accounts for the remaining 1% of costs.

If the revised criteria result in an incremental increase in impaired waters, resulting in the need for TMDL development, there could also be some costs to nonpoint sources of pollution. Using available ambient monitoring data, EPA compared pollutant concentrations to the baseline and proposed criteria, identifying waterbodies that may be incrementally impaired (*i.e.*, impaired under the proposed criteria but not under the baseline). For the 26 parameters and stations for which EPA had sufficient monitoring data available to evaluate, there were 205 impairments under the baseline criteria and 254 under the proposed criteria, for a total of 49 potential incremental impairments (or a 24% increase relative to the baseline; including for mercury and DDT). This increase indicates the potential for nonpoint sources to bear some compliance costs, although data are not available to estimate the magnitude of these costs. The control of nonpoint sources such as in the context of a TMDL could result in less stringent requirements, and thus lower costs, for point sources.

[36] Seven industrial categories (mining, food and kindred products, paper and allied products, chemicals and allied products, petroleum refining and related industries, primary metal industries, and transportation and public utilities (except POTWs)) and municipal POTWs.

VI. Statutory and Executive Order Reviews

A. Executive Order 12866 (Regulatory Planning and Review) and Executive Order 13563 (Improving Regulation and Regulatory Review)

It has been determined that this proposed rule is not a "significant regulatory action" under the terms of Executive Order 12866 (58 FR 51735, October 4, 1993) and is, therefore, not subject to review under Executive Orders 12866 and 13563 (76 FR 3821, January 21, 2011). The proposed rule does not establish any requirements directly applicable to regulated entities or other sources of toxic pollutants. However, these WQS may serve as a basis for development of NPDES permit limits. Washington has NPDES permitting authority, and retains considerable discretion in implementing standards. In the spirit of Executive Order 12866, EPA evaluated the potential costs to NPDES dischargers associated with state implementation of EPA's proposed criteria. This analysis,

Economic Analysis for the Revision of Certain Federal Water Quality Criteria Applicable to Washington, is summarized in section V of the preamble and is available in the docket.

B. Paperwork Reduction Act

This action does not impose any direct new information collection burden under the provisions of the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.* Actions to implement these WQS could entail additional paperwork burden. Burden is defined at 5 CFR 1320.3(b). This action does not include any information collection, reporting, or record-keeping requirements.

C. Regulatory Flexibility Act

This action will not have a significant economic impact on a substantial number of small entities under the Regulatory Flexibility Act (RFA). Small entities, such as small businesses or small governmental jurisdictions, are not directly regulated by this rule. This proposed rule will thus not impose any requirements on small entities. We continue to be interested, however, in the potential impacts of the proposed rule on small entities and welcome comments on issues related to such impacts.

D. Unfunded Mandates Reform Act

This action contains no federal mandates under the provisions of Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), 2 U.S.C. 1531–1538 for state, local, or tribal governments or the private sector. As these water quality criteria are not self-implementing, EPA's action imposes no enforceable duty on any state, local or tribal governments or the private sector. Therefore, this action is not subject to the requirements of sections 202 or 205 of the UMRA.

This action is also not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that could significantly or uniquely affect small governments.

E. Executive Order 13132 (Federalism)

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national government and the states, or on the distribution of power and responsibilities among the various levels of government. This rule does not alter Washington's considerable discretion in implementing these WQS, nor would it preclude Washington from adopting WQS that EPA concludes meet the requirements of the CWA, either before or after promulgation of the final rule, which would eliminate the need for federal standards. Thus, Executive Order 13132 does not apply to this action.

In the spirit of Executive Order 13132 and consistent with EPA policy to promote communications between EPA and state and local governments, EPA specifically solicits comments on this proposed action from state and local officials.

F. Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments)

This action has tribal implications. However, it will neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. In the state of Washington, there are 29 federally recognized Indian tribes. To date, nine of these Indian tribes have been approved for TAS for CWA sections 303 and 401.[37] Of these nine tribes, seven have EPA-approved WQS in their respective jurisdictions.[38] This rule could affect federally recognized Indian tribes in Washington because the numeric criteria for Washington will apply to waters adjacent to (or upstream or downstream of) the tribal waters, and because the proposed Washington criteria are informed by tribal reserved rights. Additionally, there are ten federally recognized Indian tribes in the Columbia River Basin located in the states of Oregon and Idaho that this rule could affect because their waters could affect or be affected by the water quality of Washington's downstream or upstream waters.

EPA consulted with federally recognized tribal officials under EPA's Policy on Consultation and Coordination with Indian tribes early in the process of developing this proposed rule to permit them to have meaningful and timely input into its development. In February and March 2015, EPA held tribes-only technical staff and leadership consultation sessions to hear their views and answer questions of all interested tribes on the proposed rule. Representatives from approximately 23 tribes and four tribal consortia participated in two leadership meetings held in March 2015. EPA and tribes have also met regularly since November 2012 to discuss Washington's human health criteria at both the tribal leadership level and technical staff level. The tribes have repeatedly asked EPA to promulgate federal human health criteria for Washington if the state did not do so in a timely and protective manner. At these meetings, the tribes consistently emphasized that the human health criteria should be derived using at least a minimum FCR value of 175 g/day, a cancer risk level of 10^{-6}, and the latest scientific information from EPA's 304(a) recommended criteria. EPA considered the input received during consultation with tribes when developing this proposal (see section IV for additional discussion of how EPA considered tribal input).

G. Executive Order 13045 (Protection of Children From Environmental Health and Safety Risks)

This rule is not subject to Executive Order 13045, because it is not economically significant as defined in Executive Order 12866, and because the environmental health or safety risks addressed by this action do not present a disproportionate risk to children.

The public is invited to submit comments or identify peer-reviewed studies and data that assess effects of early life exposure.

H. Executive Order 13211 (Actions That Significantly Affect Energy Supply, Distribution, or Use)

This action is not a "significant energy action" because it is not likely to have a significant adverse effect on the supply, distribution, or use of energy.

I. National Technology Transfer and Advancement Act of 1995

This proposed rulemaking does not involve technical standards.

J. Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations)

This action will not have disproportionately high and adverse human health or environmental effects on minority or low-income populations. Conversely, this action identifies and ameliorates disproportionately high and adverse human health effects on minority populations and low-income populations in Washington. EPA developed the human health criteria included in this proposed rule specifically to protect Washington's designated uses, using the most current science, including local and regional information on fish consumption. Applying these criteria to waters in the state of Washington will afford a greater

[37] *http://water.epa.gov/scitech/swguidance/standards/wqslibrary/approvtable.cfm.*

[38] *http://yosemite.epa.gov/r10/water.nsf/34090d07b77d50bd88256b79006529e8/dd2a4df00fd7ae1a88256e0500680e86!OpenDocument.* Note that this number does not include the Confederated Tribes of the Colville Reservation, which has federally-promulgated WQS from 1989. EPA is currently reviewing the Colville Tribe's application for TAS.

level of protection to both human health and the environment.

List of Subjects in 40 CFR Part 131

Environmental protection, Indians-lands, Intergovernmental relations, Reporting and recordkeeping requirements, Water pollution control.

Dated: August 31, 2015.

Gina McCarthy,

Administrator.

For the reasons set forth in the preamble, EPA proposes to amend 40 CFR part 131 as follows:

PART 131—WATER QUALITY STANDARDS

■ 1. The authority citation for part 131 continues to read as follows:

Authority: 33 U.S.C. 1251 *et seq.*

Subpart D—Federally Promulgated Water Quality Standards

§ 131.36 [Amended]

■ 2. In § 131.36, remove paragraph (d)(14).

■ 3. Add § 131.45 to read as follows:

§ 131.45 Revision of certain Federal water quality criteria applicable to Washington.

(a) *Scope.* This section promulgates human health criteria for priority toxic pollutants in surface waters in Washington.

(b) *Criteria for priority toxic pollutants in Washington.* The applicable human health criteria are shown in Table 1.

TABLE 1—PROPOSED HUMAN HEALTH CRITERIA FOR WASHINGTON

A		B					C

99. Zinc	7440666	.....	0.20	0.3	.....	47	450	580

[a] This criterion refers to the inorganic form of arsenic only.
[b] This criterion is expressed as fibers per liter (fibers/L). The criterion for asbestos is the Maximum Contaminant Level Goal (MCLG) developed under the Safe Drinking Water Act (SDWA) (56 FR 3526, January 30, 1991).
[c] EPA's national 304(a) recommended criteria for benzene use a CSF range of 0.015 to 0.055 per mg/kg-day. EPA proposes to use the higher end of the CSF range (0.055 per mg/kg-day) to derive the proposed benzene criteria for Washington.
[d] The criterion for copper is the Maximum Contaminant Level Goal (MCLG) developed under the Safe Drinking Water Act (SDWA) (40 CFR 141.80, June 7, 1991).
[e] This criterion is expressed as the fish tissue concentration of methylmercury (mg methylmercury/kg fish). See *Water Quality Criterion for the Protection of Human Health: Methylmercury* (EPA–823–R–01–001, January 3, 2001) for how this value is calculated using the criterion equation in EPA's 2000 Human Health Methodology rearranged to solve for a protective concentration in fish tissue rather than in water.
[f] This criterion applies to total PCBs (*e.g.*, the sum of all congener or isomer or homolog or Aroclor analyses).
* Bis(2-Chloro-1-Methylethyl) Ether was previously listed as Bis(2-Chloroisopropyl) Ether.

(c) *Applicability.* (1) The criteria in paragraph (b) of this section apply to waters with Washington's designated uses cited in paragraph (d) of this section and apply concurrently with any water quality criteria adopted by the state, except where pollutant- or waterbody-specific state human health criteria regulations determined by EPA to meet the requirements of Clean Water Act section 303(c) and 40 CFR part 131 apply, in which case Washington's pollutant- or waterbody-specific criteria will apply and not the criteria in paragraph (b) of this section.

(2) The criteria established in this section are subject to Washington's general rules of applicability in the same way and to the same extent as are other federally promulgated and state-adopted numeric criteria when applied to the same use classifications in paragraph (d) of this section.

(i) For all waters with mixing zone regulations or implementation procedures, the criteria apply at the appropriate locations within or at the boundary of the mixing zones; otherwise the criteria apply throughout the waterbody including at the end of any discharge pipe, conveyance or other discharge point.

(ii) The state must not use a low flow value below which numeric non-carcinogen and carcinogen human health criteria can be exceeded that is less stringent than the harmonic mean flow for waters suitable for the establishment of low flow return frequencies (*i.e.*, streams and rivers). Harmonic mean flow is a long-term mean flow value calculated by dividing the number of daily flows analyzed by the sum of the reciprocals of those daily flows.

(iii) If the state does not have such a low flow value for numeric criteria, then none will apply and the criteria in paragraph (b) of this section herein apply at all flows.

(d) *Applicable use designations.* (1) All waters in Washington assigned to the following use classifications are subject to the criteria identified in paragraph (d)(2) of this section:

(i) Fresh waters—

(A) Miscellaneous uses: Harvesting (Fish harvesting);

(B) Recreational uses;

(C) Water supply uses: Domestic water (Domestic water supply);

(ii) Marine waters—

(A) Miscellaneous uses: Harvesting (Salmonid and other fish harvesting, and crustacean and other shellfish (crabs, shrimp, scallops, etc.) harvesting);

(B) Recreational uses;

(C) Shellfish harvesting: Shellfish harvest (Shellfish (clam, oyster, and mussel) harvesting)

Note to paragraph (d)(1): The source of these uses is Washington Administrative Code 173–201A–600 for Fresh waters and 173–201A–610 for Marine waters.

(2) For Washington waters that include the use classification of Domestic Water, the criteria in column C1 of Table 1 in paragraph (b) of this section apply. For Washington waters that include any of the following use classifications but do not include the use classification of Domestic Water, the criteria in column C2 of Table 1 in paragraph (b) of this section apply: Harvesting (fresh and marine waters), Recreational Uses (fresh and marine waters), and Shellfish Harvesting.

ENVIRONMENTAL PROTECTION AGENCY

40 CFR Part 271

[EPA–R06–RCRA 2015–0070; FRL–9933–78–Region 6]

Louisiana: Final Authorization of State Hazardous Waste Management Program Revisions

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The State of Louisiana has applied to the Environmental Protection Agency (EPA) for Final authorization of the changes to its hazardous waste program under the Resource Conservation and Recovery Act (RCRA). EPA proposes to grant Final authorization to the State of Louisiana. In the "Rules and Regulations" section of this **Federal Register**, EPA is authorizing the changes by direct final rule. EPA did not make a proposal prior to the direct final rule because we believe this action is not controversial and do not expect comments that oppose it. We have explained the reasons for this authorization in the preamble to the direct final rule. Unless we get written comments which oppose this authorization during the comment period, the direct final rule will become effective 60 days after publication and we will not take further action on this proposal. If we receive comments that oppose this action, we will withdraw the direct final rule and it will not take effect. We will then respond to public comments in a later final rule based on this proposal. You may not have another opportunity for comment. If you want to comment on this action, you must do so at this time.

DATES: Send your written comments by October 14, 2015.

ADDRESSES: Submit any comments identified by Docket ID No. EPA–R06–RCRA–2015–0070, by one of the following methods:

1. *Federal eRulemaking Portal: http://www.regulations.gov.* Follow the on-line instructions for submitting comments.

2. *Email: patterson.alima@epa.gov.*

3. *Mail:* Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733.

4. *Hand Delivery or Courier:* Deliver your comments to Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733.

Instructions: Do not submit information that you consider to be CBI or otherwise protected through regulations.gov, or email. Direct your comment to Docket No. EPA–R06–RCRA–2015–0070. The Federal regulations.gov Web site is an "anonymous access" system, which means the EPA will not know your identity or contact information unless you provide it in the body of your comment. If you send an email comment directly to the EPA without going through regulations.gov, your email address will be automatically captured and included as part of the comment that is placed in the public docket and made available on the Internet. If you submit an electronic comment, the EPA recommends that you include your name and other contact information in the body of your comment and with any disk or CD–ROM you submit. If the EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, the EPA may not be able to consider your comment. Electronic files should avoid the use of special characters, any form of encryption, and be free of any defects or viruses. You can view and copy Louisiana's application and associated publicly available materials from 8:30 a.m. to 4 p.m. Monday through Friday at the following locations: Louisiana Department of Environmental Quality, 602 N. Fifth Street, Baton Rouge, Louisiana 70884–2178, phone number (225) 219–3559 and EPA, Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733, phone number (214) 665–8533. Interested persons wanting to examine these documents should make an appointment with the office at least two weeks in advance.

FOR FURTHER INFORMATION CONTACT: Alima Patterson, Region 6, Regional Authorization Coordinator, State/Tribal Oversight Section (6PD–O), Multimedia Planning and Permitting Division, EPA Region 6, 1445 Ross Avenue, Dallas, Texas 75202–2733, (214) 665–8533) and Email address *patterson.alima@epa.gov.*

SUPPLEMENTARY INFORMATION: For additional information, please see the direct final published in the "Rules and Regulations" section of this **Federal Register**.

Dated: August 21, 2015.

Ron Curry,

Regional Administrator, Region 6.

Clean Vessel Act Grant Program

AGENCY: Fish and Wildlife Service, Interior.

ACTION: Advance notice of proposed rulemaking; notice of intent.

SUMMARY: The U.S. Fish and Wildlife Service (Service) is seeking comments to assist us in developing a proposed rule for the Clean Vessel Act Grant Program (CVA). The proposed rule will use plain language to clarify topics that have led to varying interpretations and will incorporate changes in legislation and technology. We seek public input to advise us on topics of interest to the boating community in regard to projects funded through CVA. We ask for response from anyone having an interest in CVA and associated topics, but particularly from members of the public having experience, expertise, or both in administering CVA; entities receiving services from CVA-funded facilities; entities manufacturing, selling, or installing CVA-funded facilities and equipment; or persons possessing other professional or practical knowledge of the subjects we present in this document. We present topics of interest, but encourage comments on any topic relevant to CVA and the proposed rulemaking. The terms *you* or *your* in this document refer to those members of the public from whom we seek response. The terms *we, us,* and *our* refer to the U.S. Fish and Wildlife Service.

DATES: Submit comments on or before November 13, 2015.

ADDRESSES: You may submit comments, identified by docket number FWS–R9–WSR–2015–0006, by any of the following methods:

- Federal eRulemaking Portal: *http://www.regulations.gov.* Follow the instructions for submitting comments.
- U.S. mail: Public Comments Processing, Attn: Docket No. FWS–R9–WSR–2015–0006; U.S. Fish and Wildlife Service; Division of Policy, Performance, and Management Programs; MS: BPHC; 5275 Leesburg Pike, Falls Church, VA 22041–4501.
- Hand Delivery/Courier: U.S. Fish and Wildlife Service; Division of Policy, Performance, and Management Programs; 5275 Leesburg Pike, Falls Church, VA 22041–4501.

We will not accept email or faxes. All submissions received must include the agency name and docket number for this rulemaking. We will post all comments received without change to *http://www.regulations.gov,* including any personal information provided. For detailed instructions on submitting comments and other information on the rulemaking process, see the "Public Participation" heading in **SUPPLEMENTARY INFORMATION.**

Docket: For access to the docket to read background documents or comments received, go to *http://www.regulations.gov* and search for FWS–R9–WSR–2015–0006.

FOR FURTHER INFORMATION CONTACT: Lisa E. Van Alstyne, Wildlife and Sport Fish Restoration Program, Division of Policy and Programs, U.S. Fish and Wildlife Service, 703–358–1942.

SUPPLEMENTARY INFORMATION:

Background

The Clean Vessel Act of 1992 (Act) (Pub. L. 102–587, title V, subtitle F) amends the Sport Fish Restoration Act (16 U.S.C. 777c) and establishes a program that provides matching grants to States for projects that address septic waste from recreational vessels. Grants may be used to conduct coastal surveys and establish plans; construct, renovate, operate, and maintain pumpout and other waste reception facilities for recreational vessels; and conduct programs to educate boaters about the environmental and health issues associated with improperly disposing of human waste. Priority consideration was established in the Act for projects that are in coastal States, include public/private partnerships, and include innovative ways to increase project availability and use. The Sportfishing and Recreational Boating Safety Act of 2005 (SAFETEA–LU) (Pub. L. 109–59, Title X, section 10131) amends the Clean Vessel Act to remove the preference for projects in coastal States.

Since inception, the Clean Vessel Act grant program (CVA) has awarded more than $246 million. The projects funded have helped States to build an infrastructure that links services within and between States and raised awareness of the benefits of properly disposing of septic waste. As a result, States have experienced a reduction in beach and shellfish bed closures, enhanced boater awareness and satisfaction, and improved water quality in recreational areas.

In the 1990s, we published in the **Federal Register** three documents related to CVA: Clean Vessel Act Pumpout Grant Program, Final rule (59 FR 11204, March 10, 1994); Clean Vessel Act: Pumpout Station and Dump Station Technical Guidelines, Notice of final guidelines (59 FR 11290, March 10, 1994); and Clean Vessel Act Pumpout Symbol, Slogan, and Program Crediting, Final rule (62 FR 45344, August 27, 1997). The CVA regulations are located in title 50 of the Code of Federal Regulations (CFR) in part 85 (50 CFR part 85).

As we move forward in the program, we propose not only to build on the success of CVA to date, but also to seek new and innovative ways to serve the boating public into the future. We hosted four open forum discussions between October 2014 and February 2015 in which we asked States and other stakeholders to share their knowledge and opinions on topics associated with implementing CVA nationally. Participants informed us on challenges to implementation and consistency that have arisen since the program began, changes in focus that have evolved as the program has matured, and successful approaches they would like to continue. These discussions prompted us to seek input on certain topics from a larger audience.

Information Requested

With this advance notice of proposed rulemaking (ANPR), the Service is seeking information, comments, and suggestions that will help us to consider how best to address updating the CVA regulations and Technical Guidelines. We ask for your help in identifying significant issues that interfere with participation in CVA, administration of CVA, services provided under CVA, or successful implementation of CVA projects. We ask for your responses on successful approaches or foundational benefits that you suggest we should preserve in future rulemaking. We intend to use your input to develop updated regulations and guidelines in one location at 50 CFR part 85. After receiving and considering your responses to our requests in this ANPR, we will publish a proposed rule in the **Federal Register** for public review and comment. In particular, we encourage you to give comments and suggestions on the issues described in the body of the ANPR. When commenting, please indicate which of the listed issues your comment addresses and to which question you are responding. If your comments cover issues outside of those listed, please identify them as *Other.*

There are several topics where your response may reference a State or local law, regulation, standard, or other legal

reference. When your comments include a legal reference, please specifically cite the legal document. We recommend you use citation formats in *Association of Legal Writing Directors (ALWD) Guide to Legal Citation* or *Bluebook: A Uniform System of Citation* as your guide. If possible, please give a location where we may access the document electronically.

Issue 1: Technical information

(a) The Technical Guidelines (Guidelines) issued on March 10, 1994, reflect a collaborative effort between the Service and various entities that have expertise or interest in boating, clean water, waste disposal equipment, and other associated topics. We consulted with the Environmental Protection Agency (EPA), the U.S. Coast Guard (USCG), and the National Oceanic and Atmospheric Administration (NOAA) when developing the guidelines. We also asked for advice and input from States, local municipalities, boat users, manufacturers of pumpout equipment, marina operators, conservation groups, interest organizations, and the public. The resulting document reflects the best available knowledge at that time and informs the public on basic principles that were foundational to the grant program in the beginning stages of development.

(b) We are aware that advances have been made in technology, technique, and approach since we published the Guidelines. Through this notice, we ask for those same groups and any new user and interest groups, technical experts, and practitioners to advise us on some specific and some general technology issues. When responding to a topic, please address to the extent possible the following regarding the technology, technique, or approach:

(1) For technology, if it is currently available or would need to be developed;

(2) Cost;

(3) Expertise needed;

(4) Supporting infrastructure or other technology needed;

(5) Long-term personnel investment; and

(6) Any known obstacles.

(c) We ask that if you have knowledge of such advancements, you discuss developments that have been made since 1994, or are anticipated in the next few years, that improve, support, or otherwise affect CVA. Discuss how you suggest we should use this information to inform new guidelines.

(d) We ask your comments on these specific topics:

(1) States that experience seasonal cold weather likely have pumpout facility operators that choose to close for the season, winterize their pumpout equipment, or both. However, boaters may travel to those areas seeking pumpout services. What technology, technique, or approach would address the need to provide pumpout services in cold weather areas?

(2) How important is it for States to monitor the amount of waste removed through pumpouts? Should the guidelines strongly recommend meters or other "add-on" equipment to accomplish this? Should the regulations require it? If so, when should the new requirement be effective?

(3) Floating restrooms are eligible for CVA funding. However, with the emphasis of the program on providing facilities that benefit boaters, the current regulations state they cannot be connected to land or anything else that is connected to land, restricting floating restrooms to water-only access. Therefore, floating restrooms connected to an attached dock cannot be funded through CVA. (Land-based restrooms are currently ineligible.) We have received requests to revisit this restriction and consider the possibility of allowing floating restrooms to be attached to a dock and to allow piping to run directly from the floating restroom to a land connection for waste disposal. We ask you to comment on:

(i) Whether we should allow floating restrooms to be connected to land or docks. What are the advantages and disadvantages? Should there be limitations?

(ii) Are you aware of legal issues that affect floating restrooms, such as State or local regulations, permit restrictions, or building standards? If so, please discuss the effect and cite the regulation, code, or standard.

(iii) There are concerns with protecting floating restrooms from vandalism and other damage. If floating restrooms are allowed to be connected to land or docks, the potential for vandalism may increase with easier land-side access. Do you have any suggestions for how to address these concerns?

(iv) Is it important to maintain the emphasis on floating restrooms serving only the boating public? If we were to allow floating restrooms to be connected to docks, what approaches would restrict use to serve only the boating public?

(v) What approaches would ensure that floating restrooms are designed to limit land-side access and potential over-use by the non-boating public?

(vi) Should we participate in efforts to develop standards or best management practices for floating restrooms?

Issue 2: State Participation in Offering Operation and Maintenance (O&M) Funds for CVA Projects

(a) Some States offer CVA O&M, and some do not. We suggest that offering O&M greatly benefits CVA by:

(1) Increasing the number of pumpout facilities by supporting operators that otherwise might not be able to financially support ongoing service;

(2) Providing a mechanism to reimburse operators when they respond to equipment failures, increasing pumpout facility availability and functionality; and

(3) Helping to extend the useful life of the investment.

(b) The Service does not have a comprehensive list of how many and which States do not participate in offering O&M for pumpout projects, or the reasons why these States have chosen this approach. We would like to know more about those States that participate, and those that do not, in order to identify if changes in regulations or guidelines could improve this aspect of CVA. We ask States to respond telling us:

(1) Does your State offer O&M grant funding to subgrantees and operators?

(2) If your State does offer O&M funding, describe your program, including:

(i) Any restrictions on the type of projects that may receive O&M funds;

(ii) Any limits on O&M funds;

(iii) How you administer O&M processing; and

(iv) Any obstacles you currently experience that you suggest we may alleviate either through regulation or other means.

(3) If your State does not offer O&M funding, describe the reasons why your State has chosen not to offer O&M funding. If the reasons include laws or regulations, please cite as directed under Information Requested. Include in your comments changes you suggest we consider that might assist your State to begin a CVA O&M program.

Issue 3: Do any existing or proposed State or local laws affect CVA?

(a) Please cite, as directed under Information Requested, and discuss any State or local laws or regulations that either support or impede CVA projects. When available, include web links to the law or regulation.

(b) Discuss specifically how the law or regulation affects CVA projects. If it is a positive effect, tell us if you believe the Service should consider adopting similar principles. If it is a negative effect, tell us how it restricts your ability to complete successful projects. Please

suggest any changes in the CVA regulation that would increase your ability to complete successful projects within the parameters of current or proposed State and local laws and regulations.

Issue 4: User Fees

(a) The current regulations at 50 CFR 85.44 allow operators of facilities constructed, operated, or maintained with CVA grant funds to charge users a maximum $5 fee, with no justification. If an operator chooses to charge a higher fee, it must be justified. The proceeds must be accounted for and used by the operator to defray the operation and maintenance costs of the facility as long as the facility is needed and serves its intended purpose. The Service was to evaluate the maximum fee each year for inflation and other potential considerations. The Service has not taken this action to date.

(b) During an open forum discussion at the States Organization for Boating Access Conference on October 6, 2014, we asked States to comment on the following questions:

(1) Should the maximum fee be increased? Decreased?

(2) What are the pros and cons of higher fees?

(3) What alternatives do you suggest other than a maximum fee (Ex: sliding scale)?

(4) Should fees correspond to usage (Ex: gallons pumped, holding tank size)?

(5) Should the method of service influence the fees charged (Ex: self-serve vs. pumpout assistance)?

(c) We received a range of responses that fall into five general categories:

(1) Support no change to the current regulations. The $5 maximum fee works well, and boaters are used to it.

(2) Suggest the regulations be changed to mandate or encourage free pumpout services. Offering free pumpout services increases the number of boaters using pumpouts, decreases the amount of inappropriately disposed boater septic waste, and reduces the burden for operators in States that offer CVA O&M funding.

(3) Suggest the regulations be changed to allow a sliding scale with a $5 maximum for boats with smaller holding tanks, increasing fees with the size of the holding tank. An issue with this option is that not all pumpout equipment is installed with monitoring capability to gauge the number of gallons pumped.

(4) Address the fee issue by maintaining a similar approach as in the current regulations, but increase the fee.

(5) Allow operators to charge a fee according to the prevailing market rate for the area they serve.

(d) We are interested in comments from States, boaters, operators, and interest organizations that address the questions and responses above. When responding, please consider:

(1) The maximum fee that boaters will accept as reasonable for the service they receive;

(2) How the fee schedule may influence boater usage;

(3) How the fee schedule may affect water quality;

(4) If we need to consider State and local laws or codes when establishing a fee schedule; and

(5) How reduced fees may affect operators that incur additional costs for:

(i) Removing septic waste via a waste hauler from an on-site holding tank where municipal sewer service is not available;

(ii) Disposing of boater waste via municipal sewer connections where the municipality charges an additional fee for boater waste (Ex: hazardous waste disposal fee); or

(iii) Other actions to process or dispose of boater waste.

Issue 5: Defining "Recreational Vessel" and Access to CVA-Funded Services

(a) We have received many comments requesting clarity on how to define "recreational vessel" in the context of CVA and whether we should consider allowing CVA-funded facilities to be available to non-recreational vessels (Ex: house boats, commercial vessels). We ask your comments on the following:

(1) How should we define "recreational vessel" for CVA? Should the term include vessels that are not for personal use, but that transport the public to recreational opportunities? (Ex: dive boats, fishing charters)

(2) What criteria might we use that would clearly separate a recreational vessel from a non-recreational vessel?

(b) We have considered that the ultimate benefit of CVA is clean recreational waters that benefit all users. We have engaged in discussions that ask us to consider allowing CVA-funded pumpouts to be available for use by other than what we define as a "recreational vessel." We ask for comments on the following:

(1) Should CVA-funded facilities be available to serve all vessels, regardless of their designation as recreational or non-recreational? What are the advantages and disadvantages?

(2) If CVA-funded facilities are used to service other than non-recreational vessels, should operators be allowed to charge a higher fee for non-recreational use? (The rationale is that the higher fees would help pay for replacement/repairs of the equipment that will have a reduced useful life due to the additional burden on the equipment.)

(3) Are there any user groups or vessel types that should be fully excluded from consideration for expanding availability of CVA-funded pumpouts? Why or why not?

(4) If we choose to expand eligible use, what restrictions, if any, should be imposed on non-recreational vessels using CVA-funded pumpouts?

Issue 6: Definition of "Useful Life"

(a) The term "useful life" as used in the current CVA regulations was intended to relate to the functional longevity of the equipment. Using this approach, there are multiple considerations that could influence the useful life of a pumpout project, such as environmental effects (marine vs. freshwater environment, weather), biological effects (quagga mussels), amount and type of usage, adequate maintenance, boater education on proper use, and equipment components that are more vulnerable to wear or failure. In addition, it is likely that more than one of these considerations are present at one time, compounding potential impacts. Many States indicate that they have moved away from looking at the operational longevity of the equipment and instead have set a contractual requirement for the number of years the operator must maintain the equipment.

The above information has led us to reconsider our regulatory approach for how long a pumpout facility must be maintained and operational for its intended purpose. We also consider that a primary goal of CVA is to have sufficient available and functional pumpout facilities and that they contribute to a network of pumpout facilities for continued boater access and use.

(b) We typically employ useful life consideration for capital improvements. We define a "capital improvement" as: (1) a new structure that costs at least $25,000 to build; or (2) altering, renovating, or repairing an existing structure if it increases the structure's useful life by 10 years or if it costs at least $25,000. The focus is on structures attached to real property.

The cost of a typical land-based pumpout facility is below the threshold for a capital improvement. Mobile or movable pumpout facilities, such as boats and floating restrooms, we consider personal property and not a capital improvement. We, therefore, must consider that using useful life to

measure obligation for a pumpout facility may not benefit the consistency and viability of the CVA program mission.

We suggest the alternative approach of applying in regulation an obligation for a minimum number of years that an operator must maintain an operational pumpout for its intended purpose. After this time, an operator may choose to continue the obligation for another period under the CVA grant program, continue operation outside the CVA grant program, or cease operation of the pumpout facility.

The majority of States responding to an inquiry suggested 10 years, but other suggestions ranged from 4 to 20 years.

(c) We ask for your comments on the following:

(1) Which approach do you suggest is the best for the continued success of CVA, and why do you prefer it?

(2) What obligation do you suggest an operator assume when participating in CVA, including how long an operator must maintain a CVA-funded pumpout facility?

(3) If a State offers O&M funding for existing facilities, should participation in O&M extend the obligation to maintain and operate the facility? For example, if we assume a fixed-year obligation for maintaining a pumpout facility, for each year that the operator receives O&M funding should it extend the obligation an additional year?

(4) What CVA-funded actions would you suggest we identify that, if completed, will restart the fixed-year obligation period? (Ex: replacement, major renovation, etc.)

(5) We discussed in Issue 5 the possibility of expanding the type of vessels that could be serviced by CVA-funded facilities. If we choose the approach to require a fixed-year obligation for a CVA-funded facility, the CVA-funded facility would be obligated to be maintained and functional for the designated period regardless of use, so additional wear and tear would be the responsibility of the operator to address during that period. What advantages, disadvantages, or other effects should we consider regarding this combined approach?

Public Participation

We seek comments from you in response to the topics and questions above. We also seek any relevant comments on other issues related to this proposed rulemaking. We especially seek recommendations for effective and efficient approaches to CVA. After analyzing the comments received from this ANPR, we will proceed with a proposed rulemaking.

All submissions received must include the Service docket number for this notice. Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal information—may be made publicly available. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

The Service supports a collaborative process as we develop the proposed rule. After the comment period ends for the ANPR, we will post information on other opportunities to comment prior to the proposed rule, background, and past comments received at: *http://fawiki.fws.gov/display/CR5C8/CVA+Review+50+CFR+85+Home.*

Dated: August 31, 2015.

Karen Hyun,

Acting Principal Deputy Assistant Secretary for Fish and Wildlife and Parks.

Notices

Federal Register
Vol. 80, No. 177
Monday, September 14, 2015

This section of the FEDERAL REGISTER contains documents other than rules or proposed rules that are applicable to the public. Notices of hearings and investigations, committee meetings, agency decisions and rulings, delegations of authority, filing of petitions and applications and agency statements of organization and functions are examples of documents appearing in this section.

DEPARTMENT OF AGRICULTURE

Forest Service

Ketchikan Resource Advisory Committee

AGENCY: Forest Service, USDA.

ACTION: Notice of meeting.

SUMMARY: The Ketchikan Resource Advisory Committee (RAC) will meet in Ketchikan, Alaska. The committee is authorized under the Secure Rural Schools and Community Self-Determination Act (the Act) and operates in compliance with the Federal Advisory Committee Act. The purpose of the committee is to improve collaborative relationships and to provide advice and recommendations to the Forest Service concerning projects and funding consistent with title II of the Act. The meeting is open to the public. Additional RAC information, including the meeting agenda and the meeting summary/minutes can be found at the following Web site: *https://www.fs.usda.gov/main/pts.*

DATES: The meeting will be held October 14, 2015, at 4:00 p.m. All RAC meetings are subject to cancellation. For status of meeting prior to attendance, please contact the person listed under **FOR FURTHER INFORMATION CONTACT.**

ADDRESSES: The meeting will be held at the Ketchikan Misty Fiords Ranger District, 3031 Tongass Avenue, Ketchikan, Alaska. A conference line has been set up for those wishing to listen in by telephone, for the conference call number, please contact the person listed under **FOR FURTHER INFORMATION CONTACT.**

Written comments may be submitted as described under **SUPPLEMENTARY INFORMATION** All comments, including names and addresses when provided, are placed in the record and are available for public inspection and copying. The public may inspect comments received at Ketchikan Misty Fiords Ranger District. Please call ahead to facilitate entry into the building.

FOR FURTHER INFORMATION CONTACT: Diane L. Olson, RAC Coordinator, by phone at 907–228–4105 or via email at *dianelolson@fs.fedus.*

Individuals who use telecommunication devices for the deaf (TDD) may call the Federal Information Relay Service (FIRS) at 1–800–877–8339 between 8:00 a.m. and 8:00 p.m., Eastern Standard Time, Monday through Friday.

SUPPLEMENTARY INFORMATION: The purpose of the meeting is:

1. To update members on past RAC projects, and
2. Propose new RAC projects.

The meeting is open to the public. The agenda will include time for people to make oral statements of three minutes or less. Individuals wishing to make an oral statement should request in writing by October 9, 2015, to be scheduled on the agenda. Anyone who would like to bring related matters to the attention of the committee may file written statements with the committee staff before or after the meeting. Written comments and requests for time to make oral comments must be sent to Diane L. Olson, RAC Coordinator, Ketchikan Misty Fiords Ranger District, 3031 Tongass Avenue, Ketchikan, Alaska 99901; by email to *dianelolson@fsled.us,* or via facsimile to 907–225–8738.

Meeting Accommodations: If you are a person requiring reasonable accommodation, please make requests in advance for sign language interpreting, assistive listening devices or other reasonable accomodation for access to the facility or proceedings by contacting the person listed in the section titled **FOR FURTHER INFORMATION CONTACT.** All reasonable accommodation requests are managed on a case by case basis.

Dated: September 1, 2015.

Jeffrey DeFreest,

District Ranger.

BILLING CODE M

COMMISSION ON CIVIL RIGHTS

Agenda and Notice of Public Meeting of the Delaware Advisory Committee

AGENCY: Commission on Civil Rights.

ACTION: Announcement of meeting.

SUMMARY: Notice is hereby given, pursuant to the provisions of the rules and regulations of the U.S. Commission on Civil Rights (Commission), and the Federal Advisory Committee Act (FACA) that a briefing meeting of the Delaware Advisory Committee to the Commission will convene at 1:00 p.m. (EDT) on Thursday, October 8, 2015, by teleconference. The purpose of the meeting is to hear from experts who will share information about the impact that discriminatory public school disciplinary practices and policies have on children of color. This presentation will inform the DE Advisory Committee's civil rights review of discriminatory school discipline in the state's public schools and whether the Supportive School Discipline Initiative is employed by Delaware schools.

Interested members of the public may listen to the discussion by calling the following toll-free conference call number 1–888–359–3624 and conference call code: 2977026#. Please be advised that before placing them into the conference call, the conference call operator will ask callers to provide their names, their organizational affiliations (if any), and email addresses (so that callers may be notified of future meetings). Callers can expect to incur charges for calls they initiate over wireless lines, and the Commission will not refund any incurred charges. Callers will incur no charge for calls they initiate over land-line connections to the toll-free telephone number.

Persons with hearing impairments may also follow the discussion by first calling the Federal Relay Service at 1–800–977–8339 and providing the operator with the above conference call number and conference call code.

Members of the public are invited to submit written comments; the comments must be received in the regional office by Monday, October 9, 2015. Written comments may be mailed to the Eastern Regional Office, U.S. Commission on Civil Rights, 1331 Pennsylvania Avenue, Suite 1150, Washington, DC 20425, faxed to (202) 376–7548, or emailed to Evelyn Bohor at *ero@usccr.gov.* Persons who desire additional information may contact the Eastern Regional Office at (202) 376–7533.

The activities of this advisory committee, including records and

documents discussed during the meeting, will be available for public viewing, as they become available at: *https://database.faca.gov/committee/meetings.aspx?cid=240.* Records generated from this meeting may also be inspected and reproduced at the Eastern Regional Office, as they become available, both before and after the meeting. Persons interested in the work of this advisory committee are advised to go to the Commission's Web site, *www.usccr.gov,* or to contact the Eastern Regional Office at the above phone number, email or street address.

BILLING CODE 6335–01–P

COMMISSION ON CIVIL RIGHTS

Agenda and Notice of Public Meeting of the Virginia Advisory Committee

AGENCY: Commission on Civil Rights.

ACTION: Announcement of meeting.

SUMMARY: Notice is hereby given, pursuant to the provisions of the rules and regulations of the U.S. Commission on Civil Rights (Commission), and the Federal Advisory Committee Act (FACA) that both an orientation and planning meeting of the Virginia Advisory Committee to the Commission will convene at 2:00 p.m. (EDT) on Thursday, October 1, 2015, by teleconference. The purpose of the orientation meeting is to inform the newly appointed members about the rules of operation for the advisory committee. The purpose of the planning meeting is to begin discussing possible topics for the advisory committee's expected civil rights review.

Interested members of the public may listen to the discussion by calling the following toll-free conference call number 1–888–437–9445 and conference call code: 8116017#. Please be advised that before placing them into the conference call, the conference call operator will ask callers to provide their names, their organizational affiliations (if any), and email addresses (so that callers may be notified of future meetings). Callers can expect to incur charges for calls they initiate over wireless lines, and the Commission will not refund any incurred charges. Callers will incur no charge for calls they initiate over land-line connections to the toll-free telephone number.

Persons with hearing impairments may also follow the discussion by first calling the Federal Relay Service at 1–800–977–8339 and providing the operator with the above conference call number and conference call code.

Members of the public are invited to submit written comments; the comments must be received in the regional office by Monday, November 2, 2015. Written comments may be mailed to the Eastern Regional Office, U.S. Commission on Civil Rights, 1331 Pennsylvania Avenue, Suite 1150, Washington, DC 20425, faxed to (202) 376–7548, or emailed to Evelyn Bohor at *ero@usccr.gov.* Persons who desire additional information may contact the Eastern Regional Office at (202) 376–7533.

The activities of this advisory committee, including records and documents discussed during the meeting, will be available for public viewing, as they become available at: *https://database.faca.gov/committee/meetings.aspx?cid=279.* Records generated from this meeting may also be inspected and reproduced at the Eastern Regional Office, as they become available, both before and after the meeting. Persons interested in the work of this advisory committee are advised to go to the Commission's Web site, *www.usccr.gov,* or to contact the Eastern Regional Office at the above phone number, email or street address.

BILLING CODE 6335–01–P

DEPARTMENT OF COMMERCE

Submission for OMB Review; Comment Request

The Department of Commerce will submit to the Office of Management and Budget (OMB) for clearance the following proposal for collection of information under the provisions of the Paperwork Reduction Act (44 U.S.C. Chapter 35).

Agency: Bureau of Economic Analysis (BEA).

Title: Annual Survey of U.S. Direct Investment Abroad.

OMB Control Number: 0608–0053.

Form Number: BE–11.

Type of Request: Regular submission.

Number of Respondents: An estimated 1,900 U.S. parents will file data for their U.S. operations on the A form; 21,800 foreign affiliates, which include 20,500 B forms, 1,150 C forms, and 150 D forms; and 500 Claim for Exemption forms.

Estimated Total Annual Burden Hours: 262,250 hours. Total annual burden is calculated by multiplying the estimated number of submissions of each form by the average hourly burden

per form, which is 7 hours for the A form, 12 hours for the B form, 2 hours for the C form, 1 hour for the D form, and 1 hour for the Claim for Exemption forms.

Estimated Time per Respondent: 138.0 hours per respondent (262,250 hours/1,900 U.S. parents) is the average, but may vary considerably among respondents because of differences in company structure, size, and complexity.

Needs and Uses: The Annual Survey of U.S. Direct Investment Abroad (Form BE–11) collects financial and operating data covering the operations of U.S. parents and their foreign affiliates, including their balance sheets, income statements, property, plant, and equipment, employment and employee compensation, merchandise trade, sales of goods and services, taxes, and research and development activity. The survey is a sample survey that covers all foreign affiliates above a size-exemption level and their U.S. parents. The sample data are used to derive universe estimates in nonbenchmark years by extrapolating forward similar data reported in the BE–10, Benchmark Survey of U.S. Direct Investment Abroad, which is conducted every five years. The data are needed to measure the size and economic significance of direct investment abroad, measure changes in such investment, and assess its impact on the U.S. and foreign economies.

The data from the survey are primarily intended as general purpose statistics. They should be readily available to answer any number of research and policy questions related to U.S. direct investment abroad.

Affected Public: Businesses or other for-profit organizations.

Frequency: Annual.

Respondent's Obligation: Mandatory.

This information collection request may be viewed at *www.reginfo.gov.* Follow the instructions to view Department of Commerce collections currently under review by OMB.

Written comments and recommendations for the proposed information collection should be sent within 30 days of publication of this notice to *OIRASubmission@omb.eop.gov* or fax to (202) 395–5806.

Dated: September 9, 2015.

Glenna Mickelson,

Management Analyst, Office of the Chief Information Officer.

[FR Doc. 2015–23014 Filed 9–11–15; 8:45 am]

BILLING CODE 3510–06–P

DEPARTMENT OF COMMERCE

Submission for OMB Review; Comment Request

The Department of Commerce will submit to the Office of Management and Budget (OMB) for clearance the following proposal for collection of information under the provisions of the Paperwork Reduction Act (44 U.S.C. chapter 35).

Agency: U.S. Census Bureau.

Title: 2016 Government Units Survey.

OMB Control Number: 0607–0930.

Form Number(s): GUS–1.

Type of Request: Reinstatement, with change, of an expired collection.

Number of Respondents: 77,000.

Average Hours per Response: 15 minutes.

Burden Hours: 19,250.

Needs and Uses: This information request covers the questionnaire needed to conduct the directory survey component of the 2017 Census of Governments. The 2016 Government Units Survey (GUS) will be used to update the universe list of public sector entities for the 2017 Census of Governments. Each of the estimated 77,000 non-school governments will be sent a questionnaire. Respondents will be encouraged to respond to the survey on the Internet but will have the option to answer the questions and return the questionnaire by paper mail. Respondents will be asked to verify or correct the name and mailing address of the government and answer five questions to complete the survey.

The GUS is mailed to all municipalities, townships, counties, and special districts. The 2011 GUS, conducted in advance of the 2012 Census of Governments, consisted of nine broad content areas: Background information, debt, license and permit fees, taxes, retirement/pension plan, government activity, public services, judicial or legal activities, and finance. The 2016 GUS will differ from the former version by shortening the number of content areas. The 2016 GUS consists of only two broad content areas: Background and employee information. Both the 2011 and 2016 GUS also include(d) both remarks and contact information sections. The first content area for the 2016 GUS consists predominately of yes/no questions and is designed to determine the existence of a government. The employees section of the questionnaire requests the number of paid employees of a government. A notice published in the **Federal Register** on April 1, 2015 stated our intent to ask respondents detailed questions on defined-contribution plans, defined-benefit and post-employment healthcare plans. However, we will not be asking these questions for this collection.

The GUS serves multiple purposes. The GUS will be used to obtain descriptive information on the basic characteristics of governments; to identify and delete inactive units from the official list of public entities maintained by the Census Bureau; to identify file duplicates and units that were dependent on other governments; to update and verify the mailing addresses of governments; and to produce the official count of non-school government units in the United States.

Federal legislation relevant to the American workforce, the Fair Labor Standards Act (FLSA) and the Family Medical Leave Act, refer to the list of governments maintained by the Census Bureau for purposes of administering provisions of these laws. The Bureau of Justice Statistics maintains an interest in the list of active governments and their activities for purposes of administering grant programs. The Bureau of Economic Analysis (BEA) uses the products of the Census of Governments including the counts of state and local governments; and state and local government employment and payroll data. BEA also uses revenue, expenditures, debt, and financial assets data from the Census of Governments for principal inputs to the local government portion of their Gross Domestic Product publication. In addition, users from academia, research organizations, governments, public interest groups, and various businesses provide evidence of their interest through requests for information and requests for assistance in accessing universe information available on the Census Bureau Internet Web site.

Affected Public: State, local or tribal government.

Frequency: Every 5 years.

Respondent's Obligation: Voluntary.

Legal Authority: Title 13 U.S.C., Sections 161 and 193.

This information collection request may be viewed at *www.reginfo.gov.* Follow the instructions to view Department of Commerce collections currently under review by OMB.

Written comments and recommendations for the proposed information collection should be sent within 30 days of publication of this notice to *OIRA_Submission@omb.eop.gov* or fax to (202) 395–5806.

Dated: September 8, 2015.

Glenna Mickelson,

Management Analyst, Office of the Chief Information Officer.

[FR Doc. 2015–22958 Filed 9–11–15; 8:45 am]

BILLING CODE 3510–07–P

DEPARTMENT OF COMMERCE

Census Bureau

Submission for OMB Review; Comment Request

The Department of Commerce will submit to the Office of Management and Budget (OMB) for clearance the following proposal for collection of information under the provisions of the Paperwork Reduction Act (44 U.S.C. chapter 35).

Agency: U.S. Census Bureau, Commerce.

Title: Geographic Partnership Programs.

OMB Control Number: 0607–0795.

Form Number(s): Not applicable.

Type of Request: Regular Submission.

Number of Respondents: 9,900.

Fiscal Year (FY) 2015: 1,900.

FY 2016: 4,000.

FY 2017: 4,000.

Average Hours per Response: 13.5.

Burden Hours: 133,650.

FY 2015: 25,650.

FY 2016: 54,000.

FY 2017: 54,000.

Needs and Uses: The mission of GEO within the U.S. Census Bureau is to plan, coordinate, and administer all geographic and cartographic activities needed to facilitate Census Bureau statistical programs throughout the United States and its territories. GEO manages programs to continuously update geographic data including addresses, spatial features, boundaries, and geographic entities in the Master Address File/Topologically Integrated Geographic Encoding and Referencing (MAF/TIGER) System. GEO also conducts research into geographic concepts, methods, and standards needed to facilitate Census Bureau data collection and dissemination programs. Geographic Partnership Programs (GPPs) encourages participants, following Census Bureau guidelines, to review, update, and suggest modifications to geographic data to maintain MAF/TIGER and to ensure the accurate reporting of data from censuses and surveys. Because state, local, and tribal governments have geographic data and current knowledge about where growth and change are occurring in their jurisdictions, their input into the overall development of a continually maintained address list for censuses and surveys makes a vital contribution. The Census Bureau recognizes that state, local, and tribal governments have authoritative geographic data for their jurisdictions. The benefits to local governments in sharing that information as part of the Census Bureaus GPPs are realized with quality data for more accurate results of censuses and surveys. This notice is for a generic clearance that will cover a number of activities required for updating MAF/TIGER with participant-provided address and other geographic information, or obtain address and spatial data for research and evaluation purposes. The information collected in these programs in cooperation with state, local, and tribal governments and other partners is essential to the mission of the Census Bureau and directly contributes to the successful outcome of censuses and surveys conducted by the Census Bureau. The generic clearance allows the Census Bureau to focus its resources on actual operational planning, development of procedures, and implementation of programs to update and improve the geographic data maintained in MAF/TIGER.

Geographic Support System Initiative (GSS–I)

The GSS–I is an integrated program designed to improve geographic data and enhance the quality assessment and measurement for MAF/TIGER. The GSS–I builds on the accomplishments of the last decade's MAF/TIGER Enhancement Program (MTEP), which redesigned MAF/TGER, improved the positional accuracy of TIGER spatial features, and emphasized quality measurement. The Census Bureau plans on a continual update process for MAF/TIGER throughout the decade to support current surveys, including the American Community Survey (ACS). Major participants are the Census Bureau with state, local, and tribal governments. The Census Bureau will contact state, local, and tribal governments to obtain files containing their geographic data to explore data exchange opportunities, and share best practices on maintaining quality geographic data. Governments can provide a file of their geographic data or provide data through a web-based application sponsored by the Census Bureau. Governments can choose the format and medium to provide their data directly to the Census Bureau, or may elect to standardize their data using Community TIGER.

Affected Public: State, local, and tribal governments.

Frequency: Annually.

Respondent's Obligation: Voluntary.

Legal Authority: Title 13 U.S.C. Sections 16, 141, and 193.

This information collection request may be viewed at *www.reginfo.gov.* Follow the instructions to view Department of Commerce collections currently under review by OMB.

Written comments and recommendations for the proposed information collection should be sent within 30 days of publication of this notice to *OIRA_Submission@omb.eop.gov* or fax to (202) 395–5806.

Dated: September 8, 2015.

Glenna Mickelson,

Management Analyst, Office of the Chief Information Officer.

DEPARTMENT OF COMMERCE

Economic Development Administration

Notice of Petitions by Firms for Determination of Eligibility To Apply for Trade Adjustment Assistance

AGENCY: Economic Development Administration, Department of Commerce.

ACTION: Notice and opportunity for public comment.

Pursuant to Section 251 of the Trade Act 1974, as amended (19 U.S.C. 2341 *et seq.*), the Economic Development Administration (EDA) has received petitions for certification of eligibility to apply for Trade Adjustment Assistance from the firms listed below. Accordingly, EDA has initiated investigations to determine whether increased imports into the United States of articles like or directly competitive with those produced by each of these firms contributed importantly to the total or partial separation of the firm's workers, or threat thereof, and to a decrease in sales or production of each petitioning firm.

LIST OF PETITIONS RECEIVED BY EDA FOR CERTIFICATION ELIGIBILITY TO APPLY FOR TRADE ADJUSTMENT ASSISTANCE
(9/1/2015 through 9/8/2015)

Firm name	Firm address	Date accepted for investigation	Product(s)
Northridge Gardens, Inc. d/b/a PUREfactory Naturals.	3380 Town Point Drive, #330, Kennesaw, GA 30144	9/4/2015	The firm manufactures lotion bars, hand cream, lip balm, body wash and other body care products.
United Lens	259 Worcester Street, Southbridge, MA 01550	9/3/2015	The firm manufactures finished mirrors, prisms, windows, and other optical components.
The Old Wood Company, LLC	99 Riverside Drive, Asheville, NC 28801	9/3/2015	The firm manufactures tabletops, tables with bases, stools, and other furniture items.
Machining Concepts, Inc.	1304 Industrial Drive, Erie, PA 16505	9/8/2015	The firm manufactures precision component parts comprised of stainless steel and other metals.
Palmetto Plating Company, Inc..	510 Saco Lowell Road Easley SC 29640	9/8/2015	The firm manufactures protective metal coatings and finishes.

Any party having a substantial interest in these proceedings may request a public hearing on the matter. A written request for a hearing must be submitted to the Trade Adjustment Assistance for Firms Division, Room 71030, Economic Development Administration, U.S. Department of Commerce, Washington, DC 20230, no later than ten (10) calendar days following publication of this notice.

Please follow the requirements set forth in EDA's regulations at 13 CFR 315.9 for procedures to request a public hearing. The Catalog of Federal Domestic Assistance official number and title for the program under which these petitions are submitted is 11.313, Trade Adjustment Assistance for Firms.

Dated: September 8, 2015.

Michael S. DeVillo,

Eligibility Examiner.

Foreign-Trade Zones Board

[B–31–2015]

Foreign-Trade Zone 44—Mount Olive, New Jersey, Authorization of Production Activity, Robertet, Inc., (Fragrance Compounds), Mount Olive, New Jersey

On May 6, 2015, Robertet, Inc. submitted a notification of proposed production activity to the Foreign-Trade Zones (FTZ) Board for its facility within FTZ 44-Site 1 in Mount Olive, New Jersey.

The notification was processed in accordance with the regulations of the FTZ Board (15 CFR part 400), including notice in the **Federal Register** inviting public comment (80 FR 27628–27631, 05–14–2015). The FTZ Board has determined that no further review of the activity is warranted at this time. The production activity described in the notification is authorized, subject to the FTZ Act and the Board's regulations, including Section 400.14.

Dated: September 4, 2015.

DEPARTMENT OF COMMERCE

Foreign-Trade Zones Board

[B–59–2015]

Foreign-Trade Zone (FTZ) 29—Louisville, Kentucky; Notification of Proposed Production Activity; Custom Quality Services (Liquor Kitting); Louisville, Kentucky

Custom Quality Services submitted a notification of proposed production activity to the FTZ Board for its facility in Louisville, Kentucky within FTZ 29. The notification conforming to the requirements of the regulations of the FTZ Board (15 CFR 400.22) was received on September 2, 2015.

The Custom Quality Services facility is located within Site 1 of FTZ 29. The facility is used for the warehousing, distribution and kitting of liquor and glassware. Pursuant to 15 CFR 400.14(b), FTZ activity would be limited to the specific foreign-status materials and components and specific finished products described in the submitted notification (as described below) and subsequently authorized by the FTZ Board.

Production under FTZ procedures could exempt Custom Quality Services from customs duty payments on the foreign status components used in export production. On its domestic sales, Custom Quality Services would be able to choose the duty rates during customs entry procedures that apply to: Whiskey liquor kits; vodka kits; tequila kits; and, wine kits (duty rate ranges from duty-free to 6.3¢/liter) for the foreign status inputs noted below. Customs duties also could possibly be deferred or reduced on foreign status production equipment.

The components and materials sourced from abroad include: Whiskey, bourbon; tequila; wine; whiskey and cola; vodka; liqueur; specialty-tempered glassware; cut or engraved glassware;

lead crystal glasses; non-lead crystal glasses; and, drinking glasses (duty rate ranges from duty-free to 28.5%).

Public comment is invited from interested parties. Submissions shall be addressed to the Board's Executive Secretary at the address below. The closing period for their receipt is October 26, 2015.

A copy of the notification will be available for public inspection at the Office of the Executive Secretary, Foreign-Trade Zones Board, Room 21013, U.S. Department of Commerce, 1401 Constitution Avenue NW., Washington, DC 20230–0002, and in the "Reading Room" section of the Board's Web site, which is accessible via *www.trade.gov/ftz.*

For further information, contact Elizabeth Whiteman at *Elizabeth.Whiteman@trade.gov* or (202) 482–0473.

Dated: September 4, 2015.

BILLING CODE 3510–DS–P

DEPARTMENT OF COMMERCE

Foreign-Trade Zones Board

[B–60–2015]

Foreign-Trade Zone (FTZ) 84—Houston, Texas; Notification of Proposed Production Activity; Mitsubishi Caterpillar Forklift America Inc. (Forklift Trucks); Houston, Texas

Mitsubishi Caterpillar Forklift America Inc. (MCFA), an operator of FTZ 84, submitted a notification of proposed production activity to the FTZ Board for its facility in Houston, Texas. The notification conforming to the requirements of the regulations of the FTZ Board (15 CFR 400.22) was received on August 13, 2015.

MCFA already has authority to produce forklift trucks (Class I through Class V) powered by gasoline, propane or electric motors within Site 27 of FTZ 84. The current request would add certain foreign-status components to the scope of authority. Pursuant to 15 CFR 400.14(b), additional FTZ authority would be limited to the specific foreign-status materials and components and specific finished products described in the submitted notification (as described below) and subsequently authorized by the FTZ Board.

Production under FTZ procedures could exempt MCFA from customs duty payments on the foreign status components used in export production. On its domestic sales, MCFA would be able to choose the duty rates during customs entry procedures that apply to forklift trucks (free) for the foreign status materials and components noted below and in the existing scope of authority. Customs duties also could possibly be deferred or reduced on foreign status production equipment.

The components sourced from abroad include: Acrylonitrile-butadiene rubber sheets; alloy/non-alloy steel angles/shapes/sections/pipes/tubes; steel liquid/compressed petroleum gas tanks and cylinders; steel wires; and, liquid crystal display video monitors (duty rate ranges from free to 5.0%).

Public comment is invited from interested parties. Submissions shall be addressed to the FTZ Board's Executive Secretary at the address below. The closing period for their receipt is October 26, 2015.

A copy of the notification will be available for public inspection at the Office of the Executive Secretary, Foreign-Trade Zones Board, Room 21013, U.S. Department of Commerce, 1401 Constitution Avenue NW., Washington, DC 20230–0002, and in the "Reading Room" section of the FTZ Board's Web site, which is accessible via *www.trade.gov/ftz.*

BILLING CODE 3510–DS–P

DEPARTMENT OF COMMERCE

Bureau of Industry and Security

[Docket No. 150902803–5803–01]

Effects of Extending Foreign Policy-Based Export Controls

AGENCY: Bureau of Industry and Security, Commerce.

ACTION: Request for comments.

SUMMARY: The Bureau of Industry and Security (BIS) is seeking public comments on the effect of existing foreign policy-based export controls in the Export Administration Regulations. Section 6 of the Export Administration Act requires BIS to consult with industry on the effect of such controls and to report the results of the consultations to Congress. BIS is conducting the consultations through this request for public comments. Comments from all interested persons are welcome. All comments will be made available for public inspection and copying and included in a report to be submitted to Congress.

DATES: Comments must be received by October 14, 2015.

ADDRESSES: Comments may be submitted through the Federal e-Rulemaking portal (*www.regulations.gov*). The regulations.gov ID for this notice is: BIS–2015–0029. Comments may also be sent by email to *publiccomments@bis.doc.gov* or on paper to Regulatory Policy Division, Bureau of Industry and Security, Department of Commerce, 14th Street & Pennsylvania Avenue NW., Room 2099B, Washington, DC 20230. Include the phrase "FPBEC Comment" in the subject line of the email message or on the envelope if submitting comments on paper. All comments must be in writing (either submitted to regulations.gov, by email or on paper). All comments, including Personal Identifying Information (*e.g.,* name, address) voluntarily submitted by the commenter will be a matter of public record and will be available for public inspection and copying. Do not submit Confidential Business Information or otherwise sensitive or protected information.

FOR FURTHER INFORMATION CONTACT: Elan Mitchell, Foreign Policy Division, Office of Nonproliferation Controls and Treaty Compliance, Bureau of Industry and Security, telephone 202–482–4777. Copies of the current Annual Foreign Policy Report to the Congress are available at *http://www.bis.doc.gov/index.php/about-bis/newsroom/archives/27-about-bis/502-foreign-policy-reports,* and copies may also be requested by calling the Office of Nonproliferation and Treaty Compliance at the number listed above.

SUPPLEMENTARY INFORMATION: Foreign policy-based controls in the Export Administration Regulations (EAR) are implemented pursuant to section 6 of the Export Administration Act of 1979, as amended, (50 U.S.C. app. sections 2401–2420 (2000)) (EAA). The current foreign policy-based export controls maintained by the Bureau of Industry and Security (BIS) are set forth in the EAR (15 CFR parts 730–774), including in parts 742 (CCL Based Controls), 744 (End-User and End-Use Based Controls) and 746 (Embargoes and Other Special Controls). These controls apply to a range of countries, items, activities and persons, including:

- Entities acting contrary to the national security or foreign policy interests of the United States (§ 744.11);

- Certain general purpose microprocessors for "military end-uses" and "military end-users" (§ 744.17);
- Significant items (SI): Hot section technology for the development, production, or overhaul of commercial aircraft engines, components, and systems (§ 742.14);
- Encryption items (§ 742.15);
- Crime control and detection items (§ 742.7);
- Specially designed implements of torture (§ 742.11);
- Certain firearms and related items based on the Organization of American States Model Regulations for the Control of the International Movement of Firearms, their Parts and Components and Ammunition included within the Inter-American Convention Against the Illicit Manufacturing of and Trafficking in Firearms, Ammunition, Explosives, and Other Related Materials (§ 742.17);
- Regional stability items (§ 742.6);
- Equipment and related technical data used in the design, development, production, or use of certain rocket systems and unmanned air vehicles (§§ 742.5 and 744.3);
- Chemical precursors and biological agents, associated equipment, technical data, and software related to the production of chemical and biological agents (§§ 742.2 and 744.4) and various chemicals included on the list of those chemicals controlled pursuant to the Chemical Weapons Convention (§ 742.18);
- Communication intercepting devices, software and technology (§ 742.13);
- Nuclear propulsion (§ 744.5);
- Aircraft and vessels (§ 744.7);
- Restrictions on exports and reexports to certain persons designated as proliferators of weapons of mass destruction (§ 744.8);
- Certain cameras to be used by military end-users or incorporated into a military commodity (§ 744.9);
- Countries designated as Supporters of Acts of International Terrorism (§§ 742.8, 742.9, 742.10, 742.19, 746.4, 746.7, and 746.9);
- Certain entities in Russia (§ 744.10);
- Individual terrorists and terrorist organizations (§§ 744.12, 744.13 and 744.14);
- Certain persons designated by Executive Order 13315 ("Blocking Property of the Former Iraqi Regime, Its Senior Officials and Their Family Members") (§ 744.18);
- Certain sanctioned entities (§ 744.20);
- Embargoed countries (Part 746); and
- U.S. and U.N. arms embargoes (§ 746.1 and Country Group D:5 of Supplement No. 1 to Part 740).

In addition, the EAR impose foreign policy-based export controls on certain nuclear related commodities, technology, end-uses and end-users (§§ 742.3 and 744.2), in part, implementing section 309(c) of the Nuclear Non-Proliferation Act (42 U.S.C. 2139a).

Under the provisions of section 6 of the EAA, export controls maintained for foreign policy purposes require annual extension. Section 6 of the EAA requires a report to Congress when foreign policy-based export controls are extended. The EAA expired on August 20, 2001. Executive Order 13222 of August 17, 2001 (3 CFR, 2001 Comp., p. 783 (2002)), as amended by Executive Order 13637 of March 8, 2013, 78 FR 16129 (March 13, 2013), which has been extended by successive Presidential Notices, the most recent being that of August 7, 2015 (80 FR 48233 (Aug. 11, 2015)), continues the EAR and, to the extent permitted by law, the provisions of the EAA, in effect under the International Emergency Economic Powers Act (50 U.S.C. 1701–1706 (2000)). The Department of Commerce, as appropriate, follows the provisions of section 6 of the EAA by reviewing its foreign policy-based export controls, conducting consultations with industry on such controls through public comments and preparing a report to be submitted to Congress. In January 2015, the Secretary of Commerce, on the recommendation of the Secretary of State, extended for one year all foreign policy-based export controls then in effect. BIS is now soliciting public comment on the effects of extending the existing foreign policy-based export controls from January 21, 2016 to January 20, 2017. Among the criteria considered in determining whether to extend U.S. foreign policy-based export controls are the following:

1. The likelihood that such controls will achieve their intended foreign policy purposes, in light of other factors, including the availability from other countries of the goods, software or technology proposed for such controls;

2. Whether the foreign policy objective of such controls can be achieved through negotiations or other alternative means;

3. The compatibility of the controls with the foreign policy objectives of the United States and with overall U.S. policy toward the country subject to the controls;

4. Whether the reaction of other countries to the extension of such controls is not likely to render the controls ineffective in achieving the intended foreign policy objective or be counterproductive to U.S. foreign policy interests;

5. The comparative benefits to U.S. foreign policy objectives versus the effect of the controls on the export performance of the United States, the competitive position of the United States in the international economy, the international reputation of the United States as a supplier of goods and technology; and

6. The ability of the United States to effectively enforce the controls.

BIS is particularly interested in receiving comments on the economic impact of proliferation controls. BIS is also interested in industry information relating to the following:

1. Information on the effect of foreign policy-based export controls on sales of U.S. products to third countries (*i.e.*, those countries not targeted by sanctions), including the views of foreign purchasers or prospective customers regarding U.S. foreign policy-based export controls.

2. Information on controls maintained by U.S. trade partners. For example, to what extent do U.S. trade partners have similar controls on goods and technology on a worldwide basis or to specific destinations?

3. Information on licensing policies or practices by our foreign trade partners that are similar to U.S. foreign policy based export controls, including license review criteria, use of conditions, and requirements for pre- and post-shipment verifications (preferably supported by examples of approvals, denials and foreign regulations).

4. Suggestions for bringing foreign policy-based export controls more into line with multilateral practice.

5. Comments or suggestions to make multilateral controls more effective.

6. Information that illustrates the effect of foreign policy-based export controls on trade or acquisitions by intended targets of the controls.

7. Data or other information on the effect of foreign policy-based export controls on overall trade at the level of individual industrial sectors.

8. Suggestions for measuring the effect of foreign policy-based export controls on trade.

9. Information on the use of foreign policy-based export controls on targeted countries, entities, or individuals. BIS is also interested in comments relating generally to the extension or revision of existing foreign policy-based export controls.

Parties submitting comments are asked to be as specific as possible. All comments received before the close of the comment period will be considered by BIS in reviewing the controls and in

developing the report to Congress. All comments received in response to this notice will be displayed on BIS's Freedom of Information Act (FOIA) Web site at *http://efoia.bis.doc.gov/* and on the Federal e-Rulemaking portal at *www.Regulations.gov.* All comments will also be included in a report to Congress, as required by section 6 of the EAA, which directs that BIS report to Congress the results of its consultations with industry on the effects of foreign policy-based controls.

Dated: September 8, 2015.

Kevin J. Wolf,

Assistant Secretary for Export Administration.

BILLING CODE 3510–33–P

DEPARTMENT OF COMMERCE

International Trade Administration

[A–427–818]

Low-Enriched Uranium From France: Final Results of Antidumping Duty Administrative Review; 2013–2014

AGENCY: Enforcement and Compliance, International Trade Administration, Department of Commerce.

SUMMARY: On March 9, 2015, the Department of Commerce (the Department) published the preliminary results of the administrative review of the antidumping duty order on low-enriched uranium (LEU) from France.[1] The review covers one producer or exporter of the subject merchandise, Eurodif S.A., AREVA NC, and AREVA NC, Inc. (collectively AREVA). The Department determines that AREVA made no shipments of subject merchandise during the POR. The Department also determines that we will issue revised certifications required from the importer and end-user.

DATES: *Effective Date:* September 14, 2015.

FOR FURTHER INFORMATION CONTACT: Andrew Huston, AD/CVD Operations, Office VII, Enforcement and Compliance, International Trade Administration, U.S. Department of Commerce, 14th Street and Constitution Avenue NW., Washington, DC 20230; telephone: (202) 482–4261.

SUPPLEMENTARY INFORMATION:

Background

For a complete description of the events that followed the *Preliminary Results,* see the Issues and Decision Memorandum.[2] The Issues and Decision Memorandum is a public document and is available electronically via Enforcement and Compliance's Antidumping and Countervailing Duty Centralized Electronic Services System (ACCESS). ACCESS is available to registered users at *http://acess.trade.gov,* and it is available to all parties in the Central Records Unit of the main Commerce Building, room B8024. In addition, a complete version of the Issues and Decision Memorandum is also accessible on the internet at *http://enforcement.trade.gov/frn/index.html.* The signed Issues and Decision Memorandum and the electronic versions of the Issues and Decision Memorandum are identical in content.

Period of Review

The period of review (POR) is February 1, 2013, through January 31, 2014.

Scope of the Order

The product covered by the order is all low-enriched uranium. Low-enriched uranium is enriched uranium hexafluoride (UF_6) with a U^{235} product assay of less than 20 percent that has not been converted into another chemical form, such as UO_2, or fabricated into nuclear fuel assemblies, regardless of the means by which the LEU is produced (including low-enriched uranium produced through the down-blending of highly enriched uranium).[3]

Analysis of Comments Received

All issues raised by the parties in the case and rebuttal briefs are addressed in the Issues and Decision Memorandum. A list of the issues addressed in the Issues and Decision Memorandum is appended to this notice.

Changes Since the Preliminary Results

In the *Preliminary Results* the Department determined that AREVA did have shipments of merchandise subject to the antidumping order on LEU from France during the POR. Upon review of the comments received from parties, the Department finds that AREVA had no shipments subject to the antidumping duty order. We have also determined to allow revised the re-export certifications required under the scope of the order to allow replenishment of LEU that has been re-exported and to address the issue of samples in future entries.[4]

Determination of No Shipments

We determine that AREVA had no shipments of merchandise subject to the antidumping duty order on LEU from France during the POR.

Determination of Revised Certifications

The Department will issue customs instructions with revised certifications to U.S. Customs and Border Protection (CBP). These instructions will be posted on CBP's Antidumping and Countervailing Duty Online Search System, available at *http://adcvd.cbp.dhs.gov/adcvdweb/,* and the Department will release the customs instructions with revised certifications via ACCESS. The revised certifications are effective when posted on the CBP's Antidumping and Countervailing Duty Online Search System.

Assessment Rates

Since the Department found that AREVA had no shipments subject to the order during the POR, we did not calculate importer-specific assessment rates for these final results.

The Department clarified its "automatic assessment" regulation on May 6, 2003. This clarification will apply to entries of subject merchandise during the POR produced by companies included in the final results of review for which these companies did not know that the merchandise was destined for the United States. In such instances, we will instruct CBP to liquidate un-reviewed entries at the all-others rate if there is no rate for the intermediate company(ies) involved in the transaction.[5]

We intend to issue instructions to CBP 15 days after publication of the final results of this review.

Cash Deposit Requirements

The following deposit requirements will be effective for all shipments of LEU from France entered, or withdrawn from warehouse, for consumption on or after the date of publication of the final results of this administrative review, as provided for by section 751(a)(2)(C) of the Act: (1) The cash deposit rate for AREVA will remain unchanged from the

[1] *See Low Enriched Uranium from France; Preliminary Results of Antidumping Duty Administrative Review; 2013–2014,* 80 FR 12434 (March 9, 2015) (*Preliminary Results*).

[2] *See* "Decision Memorandum for the Final Results of Antidumping Duty Administrative Review: Low-Enriched Uranium From France: 2013–2014" from Gary Taverman, Associate Deputy Assistant Secretary for Antidumping and Countervailing Duty Operations to Paul Piquado, Assistant Secretary for Enforcement and Compliance (Issues and Decision Memorandum), dated concurrently with these results and herby adopted by this notice.

[3] For a full description of the scope of the order, *see* the Issues and Decision Memorandum.

[4] *See* Issue 2: Re-export Certifications section of the Issues and Decision Memorandum.

[5] *See Antidumping and Countervailing Duty Proceedings: Assessment of Antidumping Duties,* 68 FR 23954 (May 6, 2003).

rate assigned to the company in the most recently completed review of that company, except for entries for which the importer claims to be excluded from the order under the re-export provision of the scope, which will require a cash deposit rate of zero percent; (2) for previously reviewed or investigated companies not listed above, the cash deposit rate will continue to be the company-specific rate published for the most recent period with a completed segment of this proceeding; (3) if the exporter is not a firm covered in this review, a prior review, or the less-than-fair-value investigation, but the manufacturer is, the cash deposit rate will be the rate established for the most recent period with a completed segment of this proceeding for the manufacturer of the merchandise; and (4) the cash deposit rate for all other manufacturers or exporters will continue to be 19.95 percent, the all-others rate established in the investigation.[6] Entries accompanied by certifications from the exporter, the importer, and the end user, indicating that the LEU will be re-exported within 18 months will be subject to a cash deposit requirement of zero percent *ad valorem*. These cash deposit requirements, when imposed, shall remain in effect until further notice.

Notification Regarding Administrative Protective Orders

This notice is the only reminder to parties subject to the administrative protective order (APO) of their responsibility concerning the return or destruction of proprietary information disclosed under the APO in accordance with 19 CFR 351.305(a)(3), which continues to govern business proprietary information in this segment of the proceeding. Timely written notification of the return or destruction of APO materials, or conversion to judicial protective order, is hereby requested. Failure to comply with the regulations and the terms of an APO is a sanctionable violation.

Notification to Importers

This notice serves as a final reminder to the importers of their responsibility under 19 CFR 351.402(f)(2) to file a certificate regarding the reimbursement of antidumping duties prior to liquidation of the relevant entries during this review period. Failure to comply with this requirement could result in the Secretary's presumption that reimbursement of antidumping duties occurred and the subsequent assessment of double antidumping duties.

Notification to Interested Parties

These final results of administrative review are issued and published in accordance with sections 751(a)(1) and 777(i)(1) of the Act.

Dated: September 4, 2015.

Paul Piquado,

Assistant Secretary for Enforcement and Compliance.

Crystalline Silicon Photovoltaic Cells, Whether or Not Assembled Into Modules, From the People's Republic of China: Rescission of Antidumping Duty New Shipper Review; 2013–2014

AGENCY: Enforcement and Compliance, International Trade Administration, Department of Commerce.

SUMMARY: The Department of Commerce ("Department") published its *Preliminary Rescission* for the new shipper review ("NSR") of the antidumping duty order on crystalline silicon photovoltaic cells, whether or not assembled into modules, from the People's Republic of China ("PRC") on April 21, 2015.[1] The period of review ("POR") is December 1, 2013, through May 31, 2014. As discussed below, we preliminarily found that the sale made by Hengdian Group DMEGC Magnetics Co., Ltd. ("DMEGC") was non-*bona fide*, and announced our preliminary intent to rescind its NSR. For the final results of this review, we continue to find DMEGC's sale to be non-*bona fide*. Therefore, we are rescinding this NSR.

DATES: *Effective Date:* September 14, 2015.

FOR FURTHER INFORMATION CONTACT: Jeffrey Pedersen, AD/CVD Operations, Office IV, Enforcement and Compliance, International Trade Administration, Department of Commerce, 1401 Constitution Avenue NW., Washington, DC 20230; telephone: (202) 482–2769.

SUPPLEMENTARY INFORMATION:

Background

For a complete description of the events that following the publication of the *Preliminary Results*, see the Issues and Decision Memorandum.[2] The Issues and Decision Memorandum is a public document and is on file electronically via Enforcement and Compliance's AD and Countervailing Duty (CVD) Centralized Electronic Service System (ACCESS). ACCESS is available to registered users at *http://access.trade.gov* and in the Central Records Unit, Room B8024 of the main Department of Commerce building. In addition, a complete version of the Issues and Decision Memorandum can be accessed directly at *http://enforcement.trade.gov/frn/index.html*. The signed Issues and Decision Memorandum and the electronic version of the Issues and Decision Memorandum are identical in content.

Scope of the Order

The merchandise covered by the order is crystalline silicon photovoltaic cells, and modules, laminates, and panels, consisting of crystalline silicon photovoltaic cells, whether or not partially or fully assembled into other products, including, but not limited to, modules, laminates, panels and building integrated materials.[3] Merchandise covered by the order is classifiable under subheadings 8501.61.0000, 8507.20.80, 8541.40.6020, 8541.40.6030,

[1] *See Crystalline Silicon Photovoltaic Cells, Whether or Not Assembled Into Modules, From the People's Republic of China: Preliminary Rescission of 2013–2014 Antidumping Duty New Shipper Review*, 80 FR 22164 (April 21, 2015) ("*Preliminary Rescission*"); *see also* Memorandum to Howard Smith, Acting Director, Office 4, AD/CVD Operations, from Jeffrey Pedersen, International Trade Analyst, titled "2013–2014 Antidumping Duty New Shipper Review of Crystalline Silicon Photovoltaic Cells, Whether or Not Assembled Into Modules, From the People's Republic of China: Preliminary Bona Fide Sales Analysis for Hengdian Group DMEGC Magnetics Co., Ltd.," dated April 7, 2015.

[2] *See* Memorandum from Edward Yang, Senior Director, Office VII, Antidumping and Countervailing Operations, to Paul Piquado, Assistant Secretary for Enforcement and Compliance, entitled "Issues and Decision Memorandum for the Final Results of the Antidumping Duty New Shipper Review: Crystalline Silicon Photovoltaic Cells, Whether or Not Assembled Into Modules, From the People's Republic of China" issued concurrently with and hereby adopted by this notice ("Issues and Decision Memorandum").

[3] For a complete description of the scope of the order, *see* the Issues and Decision Memorandum.

and 8501.31.8000 of the Harmonized Tariff Schedule of the United States ("HTSUS"). Although the HTSUS subheadings are provided for convenience and customs purposes, our written description of the scope of the order is dispositive.

Analysis of Comments Received

All issues raised in the case and rebuttal briefs by parties are addressed in the Issues and Decision Memorandum.[4] A list of the issues which parties raised is attached to this notice as an Appendix.

Bona Fide Analysis

For the *Preliminary Rescission*, the Department analyzed the *bona fides* of DMEGC's single sale and preliminarily found it to be a non-*bona fide* sale.[5] Based on the Department's complete analysis of all of the information and comments on the record of this review, the Department continues to find DMEGC's sale to be a non-*bona fide* sale. The Department reached this conclusion based on the totality of circumstances, namely: (a) The atypical nature of the price and sale quantity; (b) DMEGC's failure to demonstrate that its first unaffiliated customer resold the merchandise at a profit; (c) the timing of the sale; and (d) issues concerning payment.[6] For a complete discussion, *see* the Issues and Decision Memorandum.[7]

Rescission of New Shipper Review

For the foregoing reasons, the Department finds that DMEGC's sale is a non-*bona fide* sale and that this sale does not provide a reasonable or reliable basis for calculating a dumping margin. Because this non-*bona fide* sale was DMEGC's only sale of subject merchandise during the POR, the Department is rescinding this NSR.

Assessment

As the Department is rescinding this NSR, we have not calculated a company-specific dumping margin for DMEGC. DMEGC remains part of the PRC-wide entity and, accordingly, its entries will be assessed at the PRC-wide rate.

Cash Deposit Requirements

Effective upon publication of this notice of final rescission of the NSR of DMEGC, the Department will instruct U.S. Customs and Border Protection to discontinue the option of posting a bond or security in lieu of a cash deposit for entries of subject merchandise from DMEGC. Because we did not calculate a dumping margin for DMEGC or grant DMEGC a separate rate in this review, DMEGC continues to be part of the PRC-wide entity. The cash deposit rate for the PRC-wide entity is 238.95 percent. These cash deposit requirements shall remain in effect until further notice.

Administrative Protective Order

This notice also serves as a reminder to parties subject to Administrative Protective Order ("APO") of their responsibility concerning the return or destruction of proprietary information disclosed under APO in accordance with 19 CFR 351.305, which continues to govern business proprietary information in these segments of the proceeding. Timely written notification of the return or destruction of APO materials, or conversion to judicial protective order, is hereby requested. Failure to comply with the regulations and terms of an APO is a violation which is subject to sanction.

We are issuing and publishing this notice in accordance with sections 751(a)(2)(B) and 777(i) of the Tariff Act of 1930, as amended, and 19 CFR 351.214.

Dated: September 4, 2015.

Paul Piquado,

Assistant Secretary for Enforcement and Compliance.

Large Residential Washers From the Republic of Korea: Partial Rescission of Antidumping Duty Administrative Review; 2014–2015

AGENCY: Enforcement and Compliance, International Trade Administration, Department of Commerce.

SUMMARY: The Department of Commerce (the Department) is partially rescinding its administrative review of the antidumping duty order on large residential washers (LRW) from the Republic of Korea (Korea) for the period of review February 1, 2014, through January 31, 2015 (POR).

DATES: *Effective Date:* September 14, 2015.

FOR FURTHER INFORMATION CONTACT: David Goldberger or Reza Karamloo, Enforcement and Compliance, International Trade Administration, U.S. Department of Commerce, 14th Street and Constitution Avenue NW., Washington, DC 20230; telephone: (202) 482–4136 or (202) 482–4470, respectively.

SUPPLEMENTARY INFORMATION:

Background

On February 2, 2015, the Department published in the **Federal Register** a notice of "Opportunity to Request Administrative Review" of the antidumping duty order on LRW from Korea for the POR.[1]

On February 11, 2015, in accordance with section 751(a) of the Tariff Act of 1930, as amended (the Act), and 19 CFR 351.213(b), the Department received a timely request from LG Electronics, Inc. and its affiliate LG Electronics USA, Inc. (collectively, LG) to conduct a review of LG's sales and shipments to the United States during the POR. On February 26, 2015, Whirlpool Corporation, the petitioner, requested that the Department conduct an administrative review of the sales of LG, Samsung Electronics Co., Ltd. (Samsung), and Daewoo Electronics Corporation (Daewoo).[2]

On April 3, 2015, the Department published in the **Federal Register** a notice of initiation of an administrative review of the antidumping duty order

[1] *See Antidumping or Countervailing Duty Order, Finding, or Suspended Investigation; Opportunity to Request Administrative Review,* 80 FR 5509 (February 2, 2015).

[2] *See* February 11 and 26, 2015, letters from LG and the petitioner, respectively, regarding request for administrative review.

on LRW from Korea with respect to the above-named companies.[3]

On May 29, 2015, the petitioner timely withdrew its request for a review of Samsung and Daewoo.[4]

Partial Rescission of Review

Pursuant to 19 CFR 351.213(d)(1), the Department will rescind an administrative review, in whole or in part, if the parties that requested a review withdraw the request within 90 days of the date of publication of notice of initiation of the requested review. The petitioner's withdrawal request was filed before the 90-day deadline. Therefore, in response to the withdrawal of request for review of Samsung and Daewoo, and pursuant to 19 CFR 351.213(d)(1), we are rescinding this review with regard to these companies. The instant review will continue with respect to LG.

Assessment

The Department will instruct U.S. Customs and Border Protection (CBP) to assess antidumping duties on all appropriate entries. For the companies for which this review is rescinded, antidumping duties shall be assessed at rates equal to the cash deposit of estimated antidumping duties required at the time of entry, or withdrawal from warehouse, for consumption, in accordance with 19 CFR 351.212(c)(1)(i). The Department intends to issue appropriate assessment instructions directly to CBP 15 days after the date of publication of this notice in the **Federal Register**.

Notification to Importers

This notice serves as the only reminder to importers of their responsibility, under 19 CFR 351.402(f)(2), to file a certificate regarding the reimbursement of antidumping and/or countervailing duties prior to liquidation of the relevant entries during this review period. Failure to comply with this requirement may result in the presumption that reimbursement of antidumping and/or countervailing duties occurred and the subsequent assessment of double antidumping duties.

Notification Regarding Administrative Protective Order

This notice serves as the only reminder to parties subject to administrative protective order (APO) of their responsibility concerning the disposition of proprietary information disclosed under APO in accordance with 19 CFR 351.305(a)(3). Timely written notification of return/destruction of APO materials or conversion to judicial protective order is hereby requested. Failure to comply with the regulations and the terms of an APO is a sanctionable violation.

This notice is published in accordance with section 751 of the Act and 19 CFR 351.213(d)(4).

Dated: September 8, 2015.

Christian Marsh,

Deputy Assistant Secretary for Antidumping and Countervailing Duty Operations.

International Trade Administration

[A–552–801]

Certain Frozen Fish Fillets From the Socialist Republic of Vietnam: Preliminary Results and Partial Rescission of the Antidumping Duty Administrative Review; 2013–2014

AGENCY: Enforcement and Compliance, International Trade Administration, Department of Commerce.

SUMMARY: The Department of Commerce ("the Department") is conducting the 11th administrative review of the antidumping duty order on certain frozen fish fillets ("fish fillets") from the Socialist Republic of Vietnam ("Vietnam").[1] The Department preliminarily determines that the Hung Vuong Group ("HVG")[2] and Thuan An Production Trading and Service Co., Ltd. ("TAFISHCO") sold subject merchandise in the United States at prices below normal value ("NV") during the period of review ("POR") August 1, 2013, through July 31, 2014. If these preliminary results are adopted in the final results, the Department will instruct U.S. Customs and Border Protection ("CBP") to assess antidumping duties on all appropriate entries of subject merchandise during the POR. Interested parties are invited to comment on these preliminary results.

DATES: *Effective date:* September 14, 2015.

FOR FURTHER INFORMATION CONTACT: Javier Barrientos or Jerry Huang, AD/CVD Operations, Office V, Enforcement and Compliance, International Trade Administration, U.S. Department of Commerce, 14th Street and Constitution Avenue NW., Washington, DC 20230; telephone 202–482–2243 or 202–482–4047, respectively.

SUPPLEMENTARY INFORMATION:

Background

On September 30, 2014, the Department initiated the 11th administrative review of the antidumping duty order on fish fillets from Vietnam for the period August 1, 2013, through July 31, 2014.[3] On April 8, 2015, the Department partially extended the deadline for issuing the preliminary results by 106 days.[4] On August 11, 2015, the Department further extended the deadline for issuing the preliminary results by 14 days.[5] The revised deadline for the preliminary results of this administrative is now August 31, 2015.

Scope of the Order

The product covered by the order is frozen fish fillets, including regular, shank, and strip fillets and portions thereof, whether or not breaded or marinated, of the species *Pangasius Bocourti, Pangasius Hypophthalmus* (also known as *Pangasius Pangasius*) and *Pangasius Micronemus.* These products are classifiable under tariff article codes 0304.29.6033, 0304.62.0020, 0305.59.0000, 0305.59.4000, 1604.19.2000, 1604.19.2100, 1604.19.3000, 1604.19.3100, 1604.19.4000, 1604.19.4100, 1604.19.5000,

[1] *See Notice of Antidumping Duty Order: Certain Frozen Fish Fillets from the Socialist Republic of Vietnam,* 68 FR 47909 (August 12, 2003) ("*Order*").

[2] The Department previously found that An Giang Fisheries Import & Export Joint Stock Company ("Agifish") is a member of the Hung Vuong Group, which also includes Asia Pangasius Company Limited, Europe Joint Stock Company, Hung Vuong Joint Stock Company, Hung Vuong Mascato Company Limited, Hung Vuong—Vinh Long Co., Ltd. and Hung Vuong—Sa Dec Co., Ltd. *See Certain Frozen Fish Fillets From the Socialist Republic of Vietnam: Final Results of the Antidumping Duty Administrative Review and New Shipper Review; 2011–2012,* 79 FR 19053 (April 7, 2014).

[3] *See Initiation of Antidumping and Countervailing Duty Administrative Reviews,* 79 FR 58729 (September 30, 2014) ("*Initiation Notice*").

[4] *See* Memorandum to James P. Maeder, Senior Director, Office I, Antidumping and Countervailing Duty Operations, through James C. Doyle, Director, Office V, Antidumping and Countervailing Duty Operations regarding "Certain Frozen Fish Fillets from the Socialist Republic of Vietnam: Extension of Deadline for Preliminary Results of 2013–2014 Antidumping Duty Administrative Review," dated April 8, 2015.

[5] *See* Memorandum to Gary Taverman, Associate Deputy Assistant Secretary for Antidumping and Countervailing Duty Operations, through James C. Doyle, Director, Office V, Antidumping and Countervailing Duty Operations regarding "Certain Frozen Fish Fillets from the Socialist Republic of Vietnam: Second Extension of Deadline for Preliminary Results of 2013–2014 Antidumping Duty Administrative Review," dated August 11, 2015.

1604.19.5100, 1604.19.6100 and 1604.19.8100 (Frozen Fish Fillets of the species *Pangasius* including basa and tra) of the Harmonized Tariff Schedule of the United States ("HTSUS").[6] Although the HTSUS subheading is provided for convenience and Customs purposes, our written description of the scope of the order is dispositive.[7]

Partial Rescission of Administrative Review

Pursuant to 19 CFR 351.213(d)(1), the Department will rescind an administrative review, in whole or in part, if the parties that requested a review withdraw the request within 90 days of the date of publication of the notice of initiation. On November 25, 2014, Vinh Hoan Corporation ("Vinh Hoan") withdrew its review request.[8] On November 25, 2014, Petitioner[9] withdrew its review request with respect to Vinh Hoan.[10] On December 23, 2014, Bien Dong Seafood Co., Ltd ("Bien Dong") withdrew its review request,[11] and Petitioner withdrew its review request with respect to Bien Dong Seafood on the same date.[12] On December 29, 2014, Petitioner withdrew its review request with respect to Hung Vuong Seafood Joint Stock Company ("Hung Vuong Seafood"), Thanh Hung Co., Ltd. (also known as Thanh Hung Frozen Seafood Processing Import Export Co., Ltd. or Thanh Hung) ("Thanh Hung"), Vinh Long Import-Export Company (also known as Vinh Long or Imex Cuu Long) ("Vinh Long").[13] No other party requested an administrative review of Vinh Hoan, Bien Dong, Hung Vuong Seafood, Thanh Hung, and Vinh Long. Therefore, in accordance with 19 CFR 351.213(d)(1), the Department is rescinding this review of the antidumping duty order on certain frozen fish fillets from the Socialist Republic of Vietnam with respect to Vinh Hoan, Bien Dong, Hung Vuong Seafood, Thanh Hung, and Vinh Long. The review will continue with respect to the other firms for which a review was requested and initiated.

Preliminary Determination of No Shipments

The following companies filed no-shipment certifications indicating that they did not export subject merchandise to the United States during the POR: An Giang Agriculture and Food Import-Export Joint Stock Company, Anvifish Joint Stock Company, Asia Commerce Fisheries Joint Stock Company, Binh An Seafood Joint Stock Company, Dai Thanh Seafoods Company Limited, Fatifish Company Limited, Golden Quality Seafood Corporation, Hiep Thanh Seafood Joint Stock Company, Hoa Phat Seafood Import-Export and Processing JSC, Ngoc Ha Co., Ltd. Food Processing and Trading, Quang Minh Seafood Company, Limited, QVD Food Company, Ltd., Saigon-Mekong Fishery Co., Ltd., Southern Fisheries Industries Company, Ltd., TG Fishery Holdings Corporation, and To Chau Joint Stock Company (collectively "No Shipment Companies"). Based on the certifications submitted by the above companies, and our analysis of the CBP information, we preliminarily determine that the No Shipment Companies did not have any reviewable transactions during the POR. The Department finds that consistent with its practice in non-market economy ("NME") cases, it is appropriate not to rescind the review in part in this circumstance but, rather, to complete the review with respect to the No Shipment Companies and issue appropriate instructions to CBP based on the final results of the review.[14]

Vietnam-Wide Entity

A review was requested, but not rescinded, for Asia Pangasius Company Limited, Nam Phuong Seafood Co., Ltd., NTACO Corporation, Thien Ma Seafood Co., Ltd., Thuan Hung Co., Ltd. (collectively, "No Response Companies").[15] The No Response Companies are not eligible for separate rate status because they did not submit completed separate rate applications or certifications.[16] Accordingly, the Department finds that these No Response Companies are a part of the Vietnam-wide entity.

The Department's change in policy regarding conditional review of the NME-wide entity applies to this administrative review.[17] Under this policy, the Vietnam-wide entity will not be under review unless a party specifically requests, or the Department self-initiates, a review of the entity. Because no party requested a review of the Vietnam-wide entity in this review, the entity is not under review and the entity's rate is not subject to change.

Methodology

The Department conducted this review in accordance with sections 751(a)(1)(B) and 751(a)(2)(A) of the Tariff Act of 1930, as amended ("the Act"). Constructed export prices and export prices have been calculated in accordance with section 772 of the Act. Because Vietnam is an NME within the meaning of section 771(18) of the Act, NV has been calculated in accordance with section 773(c) of the Act.

For a full description of the methodology underlying our conclusions, *see* the Preliminary Decision Memorandum. The Preliminary Decision Memorandum is a public document and is on file electronically via Enforcement and Compliance's Antidumping and Countervailing Duty Centralized Electronic Service System ("ACCESS"). ACCESS is available to registered users at *http://access.trade.gov,* and is

[6] Until July 1, 2004, these products were classifiable under HTSUS 0304.20.6030 (Frozen Catfish Fillets), 0304.20.6096 (Frozen Fish Fillets, NESOI), 0304.20.6043 (Frozen Freshwater Fish Fillets) and 0304.20.6057 (Frozen Sole Fillets). Until February 1, 2007, these products were classifiable under HTSUS 0304.20.6033 (Frozen Fish Fillets of the species *Pangasius,* including basa and tra). On March 2, 2011, the Department added two HTSUS numbers at the request of U.S. Customs and Border Protection ("CBP"): 1604.19.2000 and 1604 19.3000. On January 30, 2012, the Department added eight HTSUS numbers at the request of CBP: 0304.62.0020, 0305.59.0000, 1604.19.2100, 1604.19.3100, 1604.19.4100, 1604.19.5100, 1604.19.6100 and 1604.19.8100.

Preliminary Results of Review

The Department preliminarily determines that the following weighted-average dumping margins exist for the period August 1, 2013, through July 31, 2014:

Exporter	Weighted-average margin (dollars/kilogram) [18]
Hung Vuong Group [19]	0.36
Thuan An Production Trading and Services Co., Ltd	0.84
Basa Joint Stock Company	0.60
Cadovimex II Seafood Import-Export and Processing Joint Stock Company	0.60
Cafatex Corporation	0.60
Can Tho Import-Export Joint Stock Company	0.60
C.P. Vietnam Corporation	0.60
Cuu Long Fish Joint Stock Company	0.60
East Sea Seafoods LLC	0.60
GODACO Seafood Joint Stock Company	0.60
Green Farms Seafood Joint Stock Company	0.60
Hoang Long Seafood Processing Company Limited	0.60
International Development and Investment Corporation	0.60
Nam Viet Corporation	0.60
NTSF Seafoods Joint Stock Company	0.60
Seafood Joint Stock Company No. 4—Branch Dong Tam Fisheries Processing Company	0.60
Viet Phu Foods and Fish Corporation	0.60
Vinh Quang Fisheries Joint-Stock Company	0.60

Disclosure, Public Comment and Opportunity To Request a Hearing

The Department will disclose the calculations used in our analysis to parties in this review within five days of the date of publication of this notice in accordance with 19 CFR 351.224(b).

Interested parties may submit case briefs within 30 days after the date of publication of these preliminary results of review in the **Federal Register**.[20] Rebuttals to case briefs, which must be limited to issues raised in the case briefs, must be filed within five days after the time limit for filing case briefs.[21] Parties who submit arguments are requested to submit with the argument (a) a statement of the issue, (b) a brief summary of the argument, and (c) a table of authorities.[22] Parties submitting briefs should do so pursuant to the Department's electronic filing system, ACCESS.

Pursuant to 19 CFR 351.310(c), interested parties who wish to request a hearing must submit a written request to the Assistant Secretary for Enforcement and Compliance within 30 days of the date of publication of this notice. Requests should contain: (1) The party's name, address and telephone number; (2) the number of participants; and (3) a list of issues parties intend to discuss. Issues raised in the hearing will be limited to those raised in the respective case and rebuttal briefs. If a request for a hearing is made, the Department intends to hold the hearing at the U.S. Department of Commerce, 14th Street and Constitution Avenue NW., Washington, DC 20230, at a date and time to be determined. *See* 19 CFR 351.310(d). Parties should confirm by telephone the date, time, and location of the hearing two days before the scheduled date.

The Department intends to issue the final results of this administrative review, which will include the results of our analysis of all issues raised in the case briefs, within 120 days of publication of these preliminary results in the **Federal Register**, pursuant to section 751(a)(3)(A) of the Act.

Assessment Rates

Upon issuance of the final results, the Department will determine, and CBP shall assess, antidumping duties on all appropriate entries covered by this review.[23] The Department intends to issue assessment instructions to CBP 15 days after the publication date of the final results of this review.

For any individually examined respondent whose weighted average dumping margin is above *de minimis* (*i.e.*, 0.50 percent) in the final results of this review, the Department will calculate importer-specific assessment rates on the basis of the ratio of the total amount of dumping calculated for the importer's examined sales to the total entered value of sales, in accordance with 19 CFR 351.212(b)(1). Where an importer- (or customer-) specific *ad valorem* rate is greater than *de minimis*, the Department will instruct CBP to collect the appropriate duties at the time of liquidation.[24] Where either a respondent's weighted average dumping margin is zero or *de minimis*, or an importer- (or customer-) specific *ad valorem* is zero or *de minimis*, the Department will instruct CBP to liquidate appropriate entries without regard to antidumping duties.[25]

Cash Deposit Requirements

The following cash deposit requirements will be effective upon publication of the final results of this review for shipments of the subject

[18] In the third administrative review of this order, the Department determined that it would calculate per-unit assessment and cash deposit rates for all future reviews. *See Certain Frozen Fish Fillets from the Socialist Republic of Vietnam: Final Results of Antidumping Duty Administrative Review and Partial Rescission*, 73 FR 15479 (March 24, 2008).

[19] This rate is applicable to the Hung Vuong Group, which includes: An Giang Fisheries Import and Export Joint Stock Company, Asia Pangasius Company Limited, Europe Joint Stock Company, Hung Vuong Joint Stock Company, Hung Vuong Mascato Company Limited, Hung Vuong—Vinh Long Co., Ltd., and Hung Vuong—Sa Dec Co., Ltd.

[20] *See* 19 CFR 351.309(c)(1)(ii).

[21] *See* 19 CFR 351.309(d)(1)–(2).

[22] *See* 19 CFR 351.309(c)(2), (d)(2).

[23] *See* 19 CFR 351.212(b).

[24] *See* 19 CFR 351.212(b)(1).

[25] *See* 19 CFR 351.106(c)(2).

merchandise from Vietnam entered, or withdrawn from warehouse, for consumption on or after the publication date, as provided by sections 751(a)(2)(C) of the Act: (1) For the companies listed above that have a separate rate, the cash deposit rate will be that established in the final results of this review (except, if the rate is zero or *de minimis,* then zero cash deposit will be required); (2) for previously investigated or reviewed Vietnam and non-Vietnam exporters not listed above that received a separate rate in a prior segment of this proceeding, the cash deposit rate will continue to be the existing exporter-specific rate; (3) for all Vietnam exporters of subject merchandise that have not been found to be entitled to a separate rate, the cash deposit rate will be that for the Vietnam -wide entity; and (4) for all non-Vietnam exporters of subject merchandise which have not received their own rate, the cash deposit rate will be the rate applicable to the Vietnam exporter that supplied that non-Vietnam exporter. These deposit requirements, when imposed, shall remain in effect until further notice.

Notification to Importers

This notice also serves as a preliminary reminder to importers of their responsibility under 19 CFR 351.402(f)(2) to file a certificate regarding the reimbursement of antidumping duties prior to liquidation of the relevant entries during the POR. Failure to comply with this requirement could result in the Department's presumption that reimbursement of antidumping duties occurred and the subsequent assessment of double antidumping duties.

This preliminary determination is issued and published in accordance with sections 751(a)(1) and 777(i)(1) of the Act.

Dated: August 21, 2015.

Paul Piquado,

Assistant Secretary for Enforcement and Compliance.

BILLING CODE 3510–DS–P

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

RIN 0648–XE154

Endangered Species; File No. 18926

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice; receipt of application.

SUMMARY: Notice is hereby given that Jane Provancha, Mail Code: IHA–005 OHF, Room 1104, Kennedy Space Center, FL 32815 has applied in due form for a permit to take green sea (*Chelonia mydas*), loggerhead (*Caretta caretta*), Kemp's ridley (*Lepidochelys kempii*), and hawksbill (*Eretmochelys imbricata*) sea turtles for purposes of scientific research.

DATES: Written, telefaxed, or email comments must be received on or before October 14, 2015.

ADDRESSES: The application and related documents are available for review by selecting "Records Open for Public Comment" from the "Features" box on the Applications and Permits for Protected Species (APPS) home page, *https://apps.nmfs.noaa.gov,* and then selecting File No. 18926 from the list of available applications.

These documents are also available upon written request or by appointment in the Permits and Conservation Division, Office of Protected Resources, NMFS, 1315 East-West Highway, Room 13705, Silver Spring, MD 20910; phone (301) 427–8401; fax (301) 713–0376.

Written comments on this application should be submitted to the Chief, Permits and Conservation Division, at the address listed above. Comments may also be submitted by facsimile to (301) 713–0376, or by email to *NMFS.Pr1Comments@noaa.gov.* Please include the File No. in the subject line of the email comment.

Those individuals requesting a public hearing should submit a written request to the Chief, Permits and Conservation Division at the address listed above. The request should set forth the specific reasons why a hearing on this application would be appropriate.

FOR FURTHER INFORMATION CONTACT: Brendan Hurley or Amy Hapeman, (301) 427–8401.

SUPPLEMENTARY INFORMATION: The subject permit is requested under the authority of the Endangered Species Act of 1973, as amended (ESA; 16 U.S.C. 1531 *et seq.*) and the regulations governing the taking, importing, and exporting of endangered and threatened species (50 CFR parts 222–226).

The applicant requests a five-year permit to continue monitoring the abundance and distribution of sea turtles inhabiting the waters of the northern Indian River Lagoon and Mosquito Lagoon system (in Volusia and Brevard Counties), Florida. The purpose of this project is to provide NASA-Kennedy Space Center with updates on the status of marine turtles within its boundaries and nearby waters. This area also will continue to be used as an index site to document distribution and movement of individuals in these waters. The applicant requests to capture by hand, tangle, or dip net up to 50 green, one Kemp's ridley, 1 hawksbill, and 50 loggerhead turtles, each year. Turtles will be placed onboard a research vessel for morphometric measures, tagging, photographs, tissue and blood sampling, and/or possible lavage, before release. A subset of captured turtles may also be released with sonic transmitters glued to the carapace.

Dated: September 8, 2015.

Julia Harrison,

Chief, Permits and Conservation Division, Office of Protected Resources, National Marine Fisheries Service.

RIN 0648–XE172

Endangered Species; File No. 19528

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice; receipt of application.

SUMMARY: Notice is hereby given that Michael Bresette, Inwater Research Group Inc., 4160 NE Hyline Dr., Jensen Beach, FL 34957, has applied in due form for a permit to take green (*Chelonia mydas*), hawksbill (*Eretmochelys*

imbricata), Kemp's ridley (*Lepidochelys kempii*), leatherback (*Dermochelys coriacea*), and loggerhead (*Caretta caretta*) sea turtles for purposes of scientific research.

DATES: Written, telefaxed, or email comments must be received on or before October 14, 2015.

ADDRESSES: The application and related documents are available for review by selecting "Records Open for Public Comment" from the "Features" box on the Applications and Permits for Protected Species (APPS) home page, *https://apps.nmfs.noaa.gov,* and then selecting File No. 19528 from the list of available applications.

These documents are also available upon written request or by appointment in the Permits and Conservation Division, Office of Protected Resources, NMFS, 1315 East-West Highway, Room 13705, Silver Spring, MD 20910; phone (301) 427–8401; fax (301) 713–0376.

Written comments on this application should be submitted to the Chief, Permits and Conservation Division, at the address listed above. Comments may also be submitted by facsimile to (301) 713–0376, or by email to *NMFS.Pr1Comments@noaa.gov.* Please include the File No. in the subject line of the email comment.

Those individuals requesting a public hearing should submit a written request to the Chief, Permits and Conservation Division at the address listed above. The request should set forth the specific reasons why a hearing on this application would be appropriate.

FOR FURTHER INFORMATION CONTACT: Amy Hapeman, (301) 427–8401.

SUPPLEMENTARY INFORMATION: The subject permit is requested under the authority of the Endangered Species Act of 1973, as amended (ESA; 16 U.S.C. 1531 *et seq.*) and the regulations governing the taking, importing, and exporting of endangered and threatened species (50 CFR parts 222–226).

The applicant requests a five-year permit to investigate habitat preference, species abundance, size frequencies, diet composition, genetic origin, disease occurrence and sex ratios of sea turtles in waters of the Indian River and Miami-Dade Counties in southeastern Florida. During vessel surveys, up to 250 greens, 100 loggerheads, 50 hawksbills, 10 Kemp's ridleys, and one leatherback sea turtle would be sighted and pursued for capture by hand, dip net or tangle net annually. Once captured, the following procedures may be performed on sea turtles: Measurements, flipper and passive integrated transponder tagging, temporary marking, photography/video, lavage, blood and tissue sampling, and/or attachment of a transmitter. In addition, up to 1,400 green, 100 loggerhead, 280 hawksbill, and 10 Kemp's ridley sea turtles could be harassed during vessel approaches.

Dated: September 8, 2015.

BILLING CODE 3510–22–P

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

Proposed Information Collection; Comment Request; A Creel Survey of the Recreational (Non-Commercial), Boat Ramp Based Fisheries in the United States Virgin Islands

AGENCY: National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice.

SUMMARY: The Department of Commerce, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995.

DATES: Written comments must be submitted on or before November 13, 2015.

ADDRESSES: Direct all written comments to Jennifer Jessup, Departmental Paperwork Clearance Officer, Department of Commerce, Room 6616, 14th and Constitution Avenue NW., Washington, DC 20230 (or via the Internet at *JJessup@doc.gov*).

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the information collection instrument and instructions should be directed to Dr. Brent Stoffle, Fishery Anthropologist, SEFSC, NMFS, 75 Virginia Beach Drive, Miami FL 33149, (305) 361–4276 or *Brent.Stoffle@noaa.gov.*

SUPPLEMENTARY INFORMATION:

I. Abstract

This request is for a new information collection.

The National Marine Fisheries Service (NMFS) proposes to collect landings and socioeconomic data from recreational anglers in the U.S. Virgin Islands. This data collection will assist in creating and utilizing an appropriate methodology for future sampling of this segment of these fisheries and to assist in the development of management proposals. In addition, the information will be used to satisfy legal mandates under Executive Order 12898, the Magnuson-Stevens Fishery Conservation and Management Act (U.S.C. 1801 *et seq.*), the Regulatory Flexibility Act, the Endangered Species Act, and the National Environmental Policy Act, and other pertinent statues.

II. Method of Collection

The information will be collected on paper using face to face interviews.

III. Data

OMB Control Number: 0648–xxxx.

Form Number(s): None.

Type of Review: Regular (request for a new information collection).

Affected Public: Business or other for-profit organizations; individuals or households.

Estimated Number of Respondents: 250.

Estimated Time per Response: 15 minutes.

Estimated Total Annual Burden Hours: 63.

Estimated Total Annual Cost to Public: $0 in recordkeeping/reporting costs.

IV. Request for Comments

Comments are invited on: (a) Whether the proposed collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; (b) the accuracy of the agency's estimate of the burden (including hours and cost) of the proposed collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; and (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology.

Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval of this information collection; they also will become a matter of public record.

Dated: September 9, 2015.

Sarah Brabson,

NOAA PRA Clearance Officer.

RIN 0648–XE153

Advisory Committee to the U.S. Section of the International Commission for the Conservation of Atlantic Tunas; Fall Meeting

AGENCY: National Marine Fisheries Service (NMFS), National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice of public meeting.

SUMMARY: In preparation for the 2015 International Commission for the Conservation of Atlantic Tunas (ICCAT) meeting, the Advisory Committee to the U.S. Section to ICCAT is announcing the convening of its fall meeting.

DATES: The meeting will be held October 8–9, 2015. There will be an open session on Thursday, October 8, 2015, from 9 a.m. through approximately 12:30 p.m. The remainder of the meeting will be closed to the public and is expected to end by 1 p.m. on October 9. Interested members of the public may present their views during the public comment session on October 8, 2015.

ADDRESSES: The meeting will be held at the Sheraton Hotel, 8777 Georgia Ave., Silver Spring, MD 20910. Written comments should be sent via email (*Rachel.O'Malley@noaa.gov*). Comments may also be sent via mail to Rachel O'Malley at NMFS, Office of International Affairs and Seafood Inspection, Room 10653, 1315 East-West Highway, Silver Spring, MD 20910.

FOR FURTHER INFORMATION CONTACT: Rachel O'Malley, Office of International Affairs and Seafood Inspection, 301–427–8373.

SUPPLEMENTARY INFORMATION: The Advisory Committee to the U.S. Section to ICCAT will meet October 8–9, 2015, first in an open session to consider management-and research-related information on stock status of Atlantic highly migratory species and then in a closed session to discuss sensitive matters. The open session will be from 9 a.m. through 12:30 p.m. on October 8, 2015, including an opportunity for public comment beginning at approximately 12 p.m. Comments may also be submitted in writing for the Advisory Committee's consideration. Interested members of the public can submit comments by mail or email; use of email is encouraged. All written comments must be received by October 6, 2015 (see **ADDRESSES**).

NMFS expects members of the public to conduct themselves appropriately at the open session of the Advisory Committee meeting. At the beginning of the public comment session, an explanation of the ground rules will be provided (*e.g.*, alcohol in the meeting room is prohibited, speakers will be called to give their comments in the order in which they registered to speak, each speaker will have an equal amount of time to speak and speakers should not interrupt one another). The session will be structured so that all attending members of the public are able to comment, if they so choose, regardless of the degree of controversy of the subject(s). Those not respecting the ground rules will be asked to leave the meeting.

After the open session, the Advisory Committee will meet in closed session to discuss sensitive information relating to upcoming international negotiations regarding the conservation and management of Atlantic highly migratory species.

Special Accommodations

The meeting location is physically accessible to people with disabilities. Requests for sign language interpretation or other auxiliary aids should be directed to Rachel O'Malley at (301) 427–8373 or *Rachel.O'Malley@noaa.gov* at least 5 days prior to the meeting date.

Dated: September 9, 2015.

John Henderschedt,

Director, Office of International Affairs and Seafood Inspection, National Marine Fisheries Service.

BILLING CODE 3510–22–P

DEPARTMENT OF COMMERCE

National Oceanic and Atmospheric Administration

Proposed Information Collection; Comment Request; International Billfish Angler Survey

AGENCY: National Oceanic and Atmospheric Administration (NOAA), Commerce.

ACTION: Notice.

SUMMARY: The Department of Commerce, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995.

DATES: Written comments must be submitted on or before November 13, 2015.

ADDRESSES: Direct all written comments to Jennifer Jessup, Departmental Paperwork Clearance Officer, Department of Commerce, Room 6616, 14th and Constitution Avenue NW., Washington, DC 20230 (or via the Internet at *JJessup@doc.gov*).

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the information collection instrument and instructions should be directed to James Wraith, Southwest Fisheries Science Center, 8901 La Jolla Shores Drive, La Jolla, CA 92037, (858) 546 7087 or *james.wraith@noaa.gov.*

SUPPLEMENTARY INFORMATION:

I. Abstract

The International Billfish Angler Survey began in 1969 and is an integral part of the Billfish Research Program at the National Oceanic and Atmospheric Administration's (NOAA) Southwest Fisheries Science Center (SWFSC). The survey tracks recreational angler fishing catch and effort for billfish in the Pacific and Indian Oceans in support of the Pacific and Western Pacific Fishery Management Councils, authorized under the Magnuson-Stevens Fishery Conservation and Management and Act (MSA). The data are used by scientists and fishery managers to assist with assessing the status of billfish stocks. The survey is intended for anglers cooperating in the Billfish Program and is entirely voluntary. This survey is specific to recreational anglers fishing for Istiophorid and Xiphiid billfish in the Pacific and Indian Oceans; as such it provides the only estimates of catch per unit of effort for recreational billfish fishing in those areas.

II. Method of Collection

The paper form is sent to anglers with recent participation in the SWFSC Billfish Research Program and is also available for downloading on the SWFSC Billfish Program Web site. Completed forms are submitted by mail.

III. Data

OMB Number: 0648–0020.

Form Number: NOAA Form 88–10.

Type of Review: Regular (extension of a current information collection).

Affected public: Individuals or households.

Estimated Number of Respondents: 600.

Estimated Time per Response: 5 minutes.

Estimated Total Annual Burden Hours: 50.

Estimated Total Annual Cost to Public: $0 in recordkeeping/reporting costs.

IV. Request for Comments

Comments are invited on: (a) Whether the proposed collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; (b) the accuracy of the agency's estimate of the burden (including hours and cost) of the proposed collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; and (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology.

Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval of this information collection; they also will become a matter of public record.

COMMODITY FUTURES TRADING COMMISSION

Public Alert—Registration Deficient List

AGENCY: Commodity Futures Trading Commission.

ACTION: Notice; request for comment.

SUMMARY: The Commodity Futures Trading Commission ("CFTC" or "Commission") is announcing a new program, the Registration Deficient List ("RED List"), that will post on the Commission's Web site and distribute to the public certain factual information about foreign entities that are soliciting or accepting funds from U.S. residents and are acting in a manner that requires registration but are not appropriately registered with the CFTC.

DATES: Comments must be received on or before October 14, 2015.

ADDRESSES: You may submit comments, identified by "Registration Deficient List," by any of the following methods:

- *The agency's Web site, at http://comments.cftc.gov.* Follow the instructions for submitting comments through the Web site.
- *Mail:* Christopher Kirkpatrick, Secretary of the Commission, Commodity Futures Trading Commission, Three Lafayette Centre, 1155 21st Street NW., Washington, DC 20581.
- *Hand Delivery/Courier:* Same as Mail above.
- *Federal eRulemaking Portal: http://www.regulations.gov.* Follow the instructions for submitting comments.

Please submit your comments using only one method.

All comments must be submitted in English, or if not, accompanied by an English translation. Comments will be posted as received to *www.cftc.gov.* You should submit only information that you wish to make available publicly. If you wish the Commission to consider information that you believe is exempt from disclosure under the Freedom of Information Act, a petition for confidential treatment of the exempt information may be submitted according to the procedures established in § 145.9 of the Commission's regulations.[1]

The Commission reserves the right, but shall have no obligation, to review, pre-screen, filter, redact, refuse or remove any or all of your submission from *www.cftc.gov* that it may deem to be inappropriate for publication, such as obscene language. All submissions that have been redacted or removed that contain comments on the merits of the rulemaking will be retained in the public comment file and will be considered as required under the Administrative Procedure Act and other applicable laws, and may be accessible under the Freedom of Information Act.

FOR FURTHER INFORMATION CONTACT: Rick Glaser, Deputy Director, Division of Enforcement, Commodity Futures Trading Commission, Three Lafayette Centre, 1151 21st Street NW., Washington, DC 20581, phone: (202) 418–5358, email: *rglaser@cftc.gov.*

SUPPLEMENTARY INFORMATION: The CFTC today is announcing a new program, effective immediately, for informing the public about unregistered foreign entities engaged in the solicitation or acceptance of funds from U.S. residents at a retail level. These entities solicit and/or accept funds for investments in, among other things, foreign currency ("forex") and binary options. Through this new program, the Registration Deficient List ("RED List"), the Commission will publish on its Web site the names of unregistered foreign entities that the Commission has reason to believe may be required to register with the CFTC but are not, in fact, registered. Publication does not represent final Commission disposition or a final Commission order. By making this information publicly available, the Commission expects investors to make more informed decisions whether to trade with or through such an entity. The more U.S. investors trade with and through registered entities, the more likely that their funds have a better chance of being protected.

I. Background

The Commission often receives investigative leads relating to foreign entities that solicit and/or accept funds from U.S. residents at a retail level. For example, the CFTC's Division of Enforcement ("Enforcement") has investigated approximately 60 such cases in the past twenty-four months. These cases involve unregistered foreign entities that engage in, among other things, forex in a capacity similar to Retail Foreign Exchange Dealers, Introducing Brokers, Commodity Trading Advisors or Commodity Pool Operators and binary options.[2] Almost all, if not all, of these foreign entities are acting in a capacity that requires them to be registered with the Commission.

In many cases, there are obstacles to bringing an effective enforcement action against these types of entities. For example, the Commission spends considerable resources investigating these matters. Even if Enforcement is able to develop a legal case against one of these entities, international service of process is cumbersome, often takes a very long time to effectuate and is not always successful. Even if service of process is successful, many of these entities are judgment proof.

The Commission believes that a consumer protection approach has a better chance of success than continuing to spend resources on Enforcement investigations and litigations that have a limited chance of success. The proposed RED List would disseminate information about certain foreign entities into the marketplace so that U.S. residents would be able to make more informed choices about how they trade their money. This approach is used by other regulators, including the Securities and Exchange Commission.[3]

[1] 17 CFR 145.9 (2014).

[2] The Commission uses forex and binary options merely as illustrative examples. Any entity that meets the criteria set forth below is a candidate for inclusion on the RED list.

[3] There are approximately 47 countries that issue, or have issued, lists, warning letters, or public statements, including Belgium, Brazil, British Virgin Islands, Canada (Ontario, British Columbia and the Quebec provincial regulators), Croatia, Denmark, Hong Kong, Ireland, Malaysia, Panama, Poland, Cyprus, Singapore, Spain, Sweden, Switzerland, Thailand, The Netherlands, the United Kingdom and the U.S.

The International Organization of Securities Commissions ("IOSCO") has established an

II. The RED List

In light of the challenges associated with taking enforcement action against such entities, the Commission believes it useful to educate and empower prospective investors. The goal of the RED List is to provide prospective investors with information regarding unregistered soliciting entities before they invest. For a foreign entity to be listed on the CFTC's RED List, reasonable grounds must exist to believe that the entity meets the following six criteria:

1. The entity is foreign;
2. The foreign entity has no or limited presence in the United States;[4]
3. The foreign entity is soliciting and/or accepting funds from U.S. residents;
4. The foreign entity is offering a product within the Commission's jurisdiction (*e.g.* "forex");
5. The foreign entity is required to be registered; and
6. The foreign entity is not registered.[5]

If the foreign entity meets these criteria, Enforcement will propose that it be included on a publicly disclosed list stating that the foreign entity is acting in a capacity that appears to require registration but is not registered with the Commission. This list will then be publicized by the Commission's Office of Consumer Outreach by a variety of different methods and media.

The RED List process contains three separate levels of review before a recommendation is made to the Commission for inclusion on the RED List. First the Intake Officer reviews the complaint and makes an initial determination of whether a foreign entity should potentially be included in the RED List. This initial determination is passed to a Triage Officer who will conduct a limited investigation and then make a recommendation to an Enforcement Deputy Director. The Deputy Director will, based on the information before him/her, make a decision as to whether to recommend to the Commission that it include a foreign entity on the RED List. These levels of review are to ensure that only those foreign entities that should be included on the RED List are included on the RED List.

The CFTC is committed to providing accurate information to investors using the RED List. Before listing an entity on the RED List, Commission staff will notify the entity by Notice Letter of the Commission's intent to list the entity. The entity will have the opportunity to respond to the Commission and provide relevant documentation. If the foreign entity does not respond to the notice letter or provides an unsatisfactory response, Enforcement will recommend to the Commission that a foreign entity should be included on the RED List.

To implement the RED List, the Commission will post on its public Web sites, *http://www.SmartCheck.gov/REDList,* the names, and only the names, of unregistered soliciting foreign entities that have been subject of complaints received by the CFTC. The RED list will contain the following information:

RED (Registration Deficient) LIST

List of Foreign Entities That Have Been Identified as Acting in a Capacity That Appears To Require Registration but Are Not Appropriately Registered With the Commission

The Commodity Futures Trading Commission ("CFTC") frequently receives investigative leads and questions from the public about foreign entities that solicit and/or accept funds from U.S. residents at a retail level. For example these leads and questions can relate to, among things, foreign entities that engage in foreign currency ("Forex") in a capacity similar to Retail Foreign Exchange Dealers ("RFEDs"), Introducing Brokers, Commodity Trading Advisors or Commodity Pool Operators *http://www.cftc.gov/ConsumerProtection/FraudAwarenessPrevention/ForeignCurrencyTrading/index.htm;* and binary options *http://www.cftc.gov/PressRoom/PressReleases/fraudadv_binaryoptions.* Many of these foreign entities are acting in a capacity that requires them to be registered with the CFTC.

If a foreign entity is registered with the CFTC, then it is subject to CFTC regulations and oversight that apply to registrants. Generally, foreign entities that solicit you to trade are required to register with the CFTC. For this reason, it is important for you to consider whether the foreign entity that solicits you is, in fact, registered with the CFTC.

In certain cases, a preliminary review by the CFTC reveals that foreign entities that solicit and/or accept funds from U.S. residents at a retail level have no or limited U.S. presence, and act in a capacity that requires registration, but are not in fact registered. In an effort to warn the public about these entities, the CFTC is publishing the names of those foreign entities.

The goal of this list is to provide information to U.S. consumers about foreign entities that are acting in an unregistered capacity and to help them make more informed decisions about whether to trade with or through such an entity. The more that U.S. consumers trade with and through registered entities, the more likely that their funds will have a greater chance of being protected.

The named foreign entities currently appear to be acting in a capacity that requires registration with the CFTC but are NOT registered with the CFTC.

[Inserted will be a list of all of the foreign entities that have met the criteria, as approved by the Commission.]

The inclusion of an entity's name on the RED list does not mean that the CFTC or a Court has concluded that a violation of any provision of the Commodity Exchange Act or the Commission's Regulations has occurred.

III. Review of RED List

Twice annually, on or about June 30 and December 31, the Triage Officer will review the RED List and, if it appears that a minimum of 12 months have elapsed during which no complaints have been received regarding the a foreign entity and the foreign entity's Web site is either inactive or taken down, Enforcement will submit a recommendation for Commission consideration to move the foreign entity from the active portion of the RED List homepage to the archival portion of such page.

Issued in Washington, DC, on September 9, 2015, by the Commission.

Robert N. Sidman,

Deputy Secretary of the Commission.

[FR Doc. 2015–23040 Filed 9–11–15; 8:45 am]

BILLING CODE 6351–01–P

investor Alert Portal on its Web site to receive and publish alerts and warnings from its members about firms which are not authorized to provide investment services in the jurisdiction that issued the alert or warning.

[4] Merely registering a Web site with a U.S. based domain name registrar does not constitute physical presence.

[5] If the foreign entity offers binary options there is one additional criterion: Whether the entity is a foreign board of trade. If it is a foreign board of trade, then the entity would not be eligible for the RED list.

BUREAU OF CONSUMER FINANCIAL PROTECTION

AGENCY: Bureau of Consumer Financial Protection.

ACTION: Notice and request for comment.

SUMMARY: In accordance with the Paperwork Reduction Act of 1995 (PRA), the Consumer Financial Protection Bureau (Bureau) is proposing a new information collection titled, "Regulation F: Fair Debt Collection Practices Act, State Application for Exemption (12 CFR 1006.2)".

DATES: Written comments are encouraged and must be received on or before October 14, 2015 to be assured of consideration.

ADDRESSES: You may submit comments, identified by the title of the information collection, OMB Control Number (see

below), and docket number (see above), by any of the following methods:

• *Electronic: http://www.regulations.gov.* Follow the instructions for submitting comments.

• *OMB:* Office of Management and Budget, New Executive Office Building, Room 10235, Washington, DC 20503 or fax to (202) 395–5806. Mailed or faxed comments to OMB should be to the attention of the OMB Desk Officer for the Bureau of Consumer Financial Protection.

Please note that comments submitted after the comment period will not be accepted. In general, all comments received will become public records, including any personal information provided. Sensitive personal information, such as account numbers or social security numbers, should not be included.

FOR FURTHER INFORMATION CONTACT: Documentation prepared in support of this information collection request is available at *www.reginfo.gov* (this link active on the day following publication of this notice). Select "Information Collection Review," under "Currently under review, use the dropdown menu "Select Agency" and select "Consumer Financial Protection Bureau" (recent submissions to OMB will be at the top of the list). The same documentation is also available at *http://www.regulations.gov.* Requests for additional information should be directed to the Consumer Financial Protection Bureau, (Attention: PRA Office), 1700 G Street NW., Washington, DC 20552, (202) 435–9575, or email: *PRA@cfpb.gov. Please do not submit comments to this email box.*

SUPPLEMENTARY INFORMATION:

Title of Collection: Regulation F: Fair Debt Collection Practices Act, State Application for Exemption (12 CFR 1006.2).

OMB Control Number: 3170–XXXX.

Type of Review: Request for a new OMB Control Number.

Affected Public: State and Tribal governments and the five (5) inhabited U.S. Territories.

Estimated Number of Respondents: 1.

Estimated Total Annual Burden Hours: 2.

Abstract: This Rule establishes procedures and criteria whereby states may apply to the Bureau for exemption of a class of debt collection practices within the applying state from the provisions of the Fair Debt Collection Practices Act (FDCPA) as provided in section 817 of the Act, 15 U.S.C. 1692. The information collection request seeks OMB approval for the state application for exemption from the provisions of FDCPA as contained in 12 CFR 1006.2.

Request for Comments: The Bureau issued a 60-day **Federal Register** notice on June 15, 2015, (80 FR 34148). Comments were solicited and continue to be invited on: (a) Whether the collection of information is necessary for the proper performance of the functions of the Bureau, including whether the information will have practical utility; (b) The accuracy of the Bureau's estimate of the burden of the collection of information, including the validity of the methods and the assumptions used; (c) Ways to enhance the quality, utility, and clarity of the information to be collected; and (d) Ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology. Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval. All comments will become a matter of public record.

Dated: September 9, 2015.

Linda F. Powell,

Chief Data Officer, Bureau of Consumer Financial Protection.

[FR Doc. 2015–23070 Filed 9–11–15; 8:45 am]

BILLING CODE 4810–AM–P

BUREAU OF CONSUMER FINANCIAL PROTECTION

[Docket No: CFPB–2015–0039]

Agency Information Collection Activities: Comment Request

AGENCY: Bureau of Consumer Financial Protection.

ACTION: Notice and request for comment.

SUMMARY: In accordance with the Paperwork Reduction Act of 1995 (PRA), the Consumer Financial Protection Bureau (Bureau) is requesting to renew the Office of Management and Budget (OMB) approval for an existing information collection, titled, "High-Cost Mortgage and Homeownership Counseling Amendments to the Truth in Lending Act (Regulation Z)."

DATES: Written comments are encouraged and must be received on or before November 13, 2015 to be assured of consideration.

ADDRESSES: You may submit comments, identified by the title of the information collection, OMB Control Number (see below), and docket number (see above), by any of the following methods:

• *Electronic: http://www.regulations.gov.* Follow the instructions for submitting comments.

• *Mail:* Consumer Financial Protection Bureau (Attention: PRA Office), 1700 G Street NW., Washington, DC 20552.

• *Hand Delivery/Courier:* Consumer Financial Protection Bureau (Attention: PRA Office), 1275 First Street NE., Washington, DC 20002.

Please note that comments submitted after the comment period will not be accepted. In general, all comments received will become public records, including any personal information provided. Sensitive personal information, such as account numbers or social security numbers, should not be included.

FOR FURTHER INFORMATION CONTACT: Documentation prepared in support of this information collection request is available at *www.regulations.gov.* Requests for additional information should be directed to the Consumer Financial Protection Bureau, (Attention: PRA Office), 1700 G Street NW., Washington, DC 20552, (202) 435–9575, or email: *PRA@cfpb.gov. Please do not submit comments to this mailbox.*

SUPPLEMENTARY INFORMATION:

Title of Collection: High-Cost Mortgage and Homeownership Counseling Amendments to the Truth in Lending Act (Regulation Z).

OMB Control Number: 3170–0023.

Type of Review: Extension without change of a currently approved collection.

Affected Public: Businesses and other for- and non-profit institutions.

Estimated Number of Respondents: 49.

Estimated Total Annual Burden Hours: 317.

Abstract: The Truth in Lending Act (TILA), 15 U.S.C. 1601 *et seq.,* was enacted to foster comparison credit shopping and informed credit decision making by requiring accurate disclosure of the costs and terms of credit to consumers. Creditors are subject to disclosure and other requirements that apply to open-end credit (*e.g.,* revolving credit or credit lines) and closed-end credit (*e.g.,* installment financing). TILA imposes disclosure requirements on all types of creditors in connection with consumer credit, including mortgage companies, finance companies, retailers, and credit card issuers, to ensure that consumers are fully apprised of the terms of financing prior to consummation of the transaction and, in some instances, during the loan term. It also imposes advertising disclosure requirements on advertisers of consumer credit. TILA also establishes billing error resolution procedures for open-end credit and limits consumer

liability for the unauthorized use of credit cards. An amendment to TILA, the Home Ownership and Equity Protection Act (HOEPA), imposes, among other things, various disclosure and other requirements on certain creditors offering high-cost mortgages to consumers. The CFPB promulgated its Regulation Z to implement TILA, as required by the statute. The CFPB enforces TILA as to certain creditors and advertisers. TILA also contains a private right of action for consumers and provides enhanced remedies to consumers in high-cost mortgages for violations of HOEPA.

Request for Comments: Comments are invited on: (a) Whether the collection of information is necessary for the proper performance of the functions of the Bureau, including whether the information will have practical utility; (b) The accuracy of the CFPB's estimate of the burden of the collection of information, including the validity of the methods and the assumptions used; (c) Ways to enhance the quality, utility, and clarity of the information to be collected; and (d) Ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology. Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval. All comments will become a matter of public record.

Dated: September 9, 2015.

BILLING CODE 4810–AM–P

DEPARTMENT OF DEFENSE

Office of the Secretary

National Commission on the Future of the Army; Notice of Federal Advisory Committee Meeting

AGENCY: Deputy Chief Management Officer, Department of Defense (DoD).

ACTION: Notice of Federal advisory committee meeting.

SUMMARY: The DoD is publishing this notice to announce an open meeting of the National Commission on the Future of the Army ("the Commission").

DATES: Date of the open meeting: Thursday, September 24, 2015, from 3 p.m. to 5 p.m.

ADDRESSES: Address of open meeting, September 24, 2015: Red Lion Hotel Conference Room, Red Lion Hotel—Tacoma, 8402 S. Hosmer Street, Tacoma, WA 98444.

FOR FURTHER INFORMATION CONTACT: Mr. Don Tison, Designated Federal Officer, National Commission on the Future of the Army, 700 Army Pentagon, Room 3E406, Washington, DC 20310–0700, Email: *dfo.public@ncfa.ncr.gov.* Desk (703) 692–9099. Facsimile (703) 697–8242.

SUPPLEMENTARY INFORMATION:

Due to circumstances beyond the control of the Designated Federal Officer and the Department of Defense, the National Commission on the Future of the Army was unable to provide public notification of its meeting of September 24, 2015, as required by 41 CFR 102–3.150(a). Accordingly, the Advisory Committee Management Officer for the Department of Defense, pursuant to 41 CFR 102–3.150(b), waives the 15-calendar day notification requirement. This meeting will be held under the provisions of the Federal Advisory Committee Act (FACA) of 1972 (5 U.S.C., Appendix, as amended), the Government in the Sunshine Act of 1976 (5 U.S.C. 552b, as amended), and 41 CFR 102–3.150.

Purpose of Meetings: During the open meeting on Thursday, September 24, 2015, the Commission will hear verbal comments from the public.

Agenda: September 24, 2015, 3 p.m. to 5 p.m.—Open Hearing: The public will have the opportunity to make verbal comments.

Meeting Accessibility: Pursuant to 41 CFR 102–3.140 through 102–3.165 and the availability of space, the meeting scheduled for September 24, 2015 from 3 p.m. to 5 p.m. at the Red Lion Hotel Conference Room is open to the public. Seating is limited and pre-registration is strongly encouraged. Media representatives are also encouraged to register. Members of the media must comply with the rules of photography and video filming published by the Red Lion Hotel. The closest public parking facility is located on the property. Visitors should keep their belongings with them at all times.

Written Comments: Pursuant to section 10(a)(3) of the FACA and 41 CFR 102–3.105(j) and 102–3.140, the public or interested organizations may submit written comments to the Commission in response to the stated agenda of the open and/or closed meeting or the Commission's mission. The Designated Federal Officer (DFO) will review all submitted written statements. Written comments should be submitted to Mr. Donald Tison, DFO, via facsimile or electronic mail, the preferred modes of submission. Each page of the comment must include the author's name, title or affiliation, address, and daytime phone number. All comments received before Wednesday, September 23, 2015, will be provided to the Commission before the September 24, 2015, meeting. Comments received after Wednesday, September 23, 2015, will be provided to the Commission before its next meeting. All contact information may be found in the **FOR FURTHER INFORMATION CONTACT** section.

Oral Comments: In addition to written statements, one hour and forty minutes will be reserved for individuals or interest groups to address the Commission on September 24, 2015. Those interested in presenting oral comments to the Commission must summarize their oral statement in writing and submit with their registration. The Commission's staff will assign time to oral commenters at the meeting; no more than five minutes each for individuals. While requests to make an oral presentation to the Commission will be honored on a first come, first served basis, other opportunities for oral comments will be provided at future meetings.

Registration: Individuals and entities who wish to attend the public hearing and meeting on Thursday, September 24, 2015 are encouraged to register for the event with the DFO using the electronic mail and facsimile contact information found in the **FOR FURTHER INFORMATION CONTACT** section. The communication should include the registrant's full name, title, affiliation or employer, email address, day time phone number. This information will assist the Commission in contacting individuals should it decide to do so at a later date. If applicable, include written comments and a request to speak during the oral comment session. (Oral comment requests must be accompanied by a summary of your presentation.) Registrations and written comments should be typed.

Additional Information

The DoD sponsor for the Commission is the Deputy Chief Management Officer. The Commission is tasked to submit a report, containing a comprehensive study and recommendations, by February 1, 2016 to the President of the United States and the Congressional defense committees. The report will contain a detailed statement of the findings and conclusions of the Commission, together with its recommendations for such legislation and administrative actions it may consider appropriate in light of the results of the study. The comprehensive

study of the structure of the Army will determine whether, and how, the structure should be modified to best fulfill current and anticipated mission requirements for the Army in a manner consistent with available resources.

Dated: September 8, 2015.

Aaron Siegel,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

[FR Doc. 2015–22983 Filed 9–11–15; 8:45 am]

BILLING CODE 5001–06–P

DEPARTMENT OF DEFENSE

Office of the Secretary

Charter Establishment of Department of Defense Federal Advisory Committees

AGENCY: Department of Defense.

ACTION: Establishment of Federal advisory committee.

SUMMARY: The Department of Defense is publishing this notice to announce that it is establishing the charter for the Lake Eufaula Advisory Committee ("the Committee").

FOR FURTHER INFORMATION CONTACT: Jim Freeman, Advisory Committee Management Officer for the Department of Defense, 703–692–5952.

SUPPLEMENTARY INFORMATION: This committee's charter is being established in accordance with the Federal Advisory Committee Act (FACA) of 1972 (5 U.S.C., Appendix, as amended) and 41 CFR 102–3.50(a).

The Committee is a statutory Federal advisory committee that provides information and recommendations to the Secretary of Defense through the Secretary of the Army, the Assistant Secretary of the Army for Civil Works, and the U.S. Army Corps of Engineers ("the Corps"), regarding the operations of Lake Eufaula for the project purposes for Lake Eufaula.

According to section 3133(a) of the 2007 WRDA, the Lake Eufaula project goal is to maximize the use of available storage in a balanced approach that incorporates advice from representatives from all the project purposes to ensure that the full value of the reservoir is realized by the United States. To achieve this goal, recreation is recognized as a project purpose at Lake Eufaula, pursuant to section 4 of the Flood Control Act of December 22, 1944 (58 Stat. 889). The recommendations of the Committee shall be considered by the Secretary of the Army and the Corp in performing a reallocation study and developing an interim management plan as required by sections 3133(c) and (d) of the 2007 WRDA. The Department of Defense (DoD), through the Department of the Army and the Corps, shall provide support for the Committee and shall ensure compliance with the requirements of the FACA, the Government in the Sunshine Act of 1976 ("the Sunshine Act") (5 U.S.C. 552b, as amended), governing Federal statutes and regulations, and established DoD policies and procedures.

Pursuant to section 3133(b) of the 2007 WRDA, the Committee shall be composed of members that equally represent the project purposes for Lake Eufaula, identified as flood control, water supply, hydroelectric power, navigation, fish and wildlife, and recreation. The Committee shall consist of no more than 12 members. Committee members will serve a two-year term of service, with annual renewals, on the Committee. Members may be appointed to no more than two terms of service (four years total) without prior approval of the Secretary of Defense or Deputy Secretary of Defense. Members may subsequently be reappointed to the Committee but only after being off the Committee for at least two years.

The Committee will be comprised of a mix of regular government employee (RGE) members, special government employee (SGE) members, and representative members. Those individuals who are full-time or permanent part-time Federal officers or employees will be appointed pursuant to 41 CFR 102–3.130(a) to serve as RGE members. Those individuals who are not full-time or permanent part-time Federal officers or employees and provide their own best independent judgment based on their individual expertise will be appointed as experts or consultants pursuant to 5 U.S.C. 3109 to serve as SGE members. Those individuals who are not full-time or permanent part-time Federal officers or employees and are selected for the purpose of obtaining the point of view or perspective of an outside interest group or stakeholder interest will be appointed pursuant to 41 CFR 102–3.130(a) to serve as representative members.

The Secretary of the Army will appoint the Chair and the Vice Chair of the Committee and the leadership for any approved subcommittees from the respective Committee and subcommittee membership previously approved by the Secretary of Defense or Deputy Secretary of Defense.

With the exception of reimbursement for official travel and per diem, Committee members shall serve without compensation.

The DoD, when necessary and consistent with the Committee's mission and DoD policies and procedures, may establish subcommittees, task groups, or working groups to support the Committee. Establishment of subcommittees will be based upon a written determination, to include terms of reference, by the Secretary of Defense, the Deputy Secretary of Defense, or the Secretary of the Army. Currently, the Committee does not use subcommittees. If the DoD determines that the establishment of subcommittees is warranted, the Committee's charter and membership balance plan must be amended prior to such establishment.

The Designated Federal Officer (DFO) shall be a full-time or permanent part-time DoD officer or employee designated in accordance with governing DoD policies and procedures.

The Committee's DFO is required to be in attendance at all meetings of the Committee and any subcommittees for the entire duration of each and every meeting. However, in the absence of the Committee's DFO, a properly approved Alternate DFO, duly designated to the Committee according to DoD policies and procedures, shall attend the entire duration of the meetings of the Committee or any subcommittees.

The DFO, or the Alternate DFO, shall call all meetings of the Committees and any subcommittees; prepare and approve all meeting agendas; and adjourn any meeting when the DFO, or the Alternate DFO, determines adjournment to be in the public's interest or required by governing regulations or DoD policies and procedures.

Pursuant to 41 CFR 102–3.105(j) and 102–3.140, the public or interested organizations may submit written statements to Committee membership about the Committee's mission and functions. Written statements may be submitted at any time or in response to the stated agenda of planned meeting of the Committee.

All written statements shall be submitted to the DFO for the Committee, and this individual will ensure that the written statements are provided to the membership for their consideration. Contact information for the Committee's DFO can be obtained from the GSA's FACA Database—*http://www.facadatabase.gov/.*

The DFO, pursuant to 41 CFR 102–3.150, will announce planned meetings of the Committee. The DFO, at that time, may provide additional guidance on the submission of written statements that are in response to the stated agenda for the planned meeting in question.

Dated: September 8, 2015.

Aaron Siegel,

Alternate OSD Federal Register Liaison Officer, Department of Defense.

BILLING CODE 5001–06–P

DEPARTMENT OF DEFENSE

Department of the Army, Corps of Engineers

Intent To Prepare an Integrated Draft Feasibility Report and Environmental Impact Statement To Investigate Hydrologic and Hydraulic Problems Threatening Navigation, Aquatic Ecosystem Habitat, Recreation, Flood Damage Reduction and Existing Infrastructure at the Three Rivers Study Site in Arkansas and Desha Counties in Southeast Arkansas

AGENCY: Department of the Army, U.S. Army Corps of Engineers, DoD.

ACTION: Notice of intent.

SUMMARY: The study is being conducted under the authority contained in the River and Harbor Act of 1946 (Pub. L. 79–525), as amended, which authorized the development of the Arkansas River and its tributaries for the purposes of navigation, flood control, hydropower, water supply, recreation, and fish and wildlife. Public Law 91–649 stated that the project would be known as the McClellan-Kerr Arkansas River navigation system. Additional authorization is included by the Flood Control Act of 1970, (Pub. L. 91–611), as amended, under Section 216 and under guidance provided in ER 1105–2–100. Pursuant to the National Environmental Policy Act (NEPA), the USACE, Little Rock District, will prepare a Draft Environmental Impact Statement (EIS) for the Three Rivers Study. The EIS will evaluate potential impacts (beneficial and adverse) to the natural, physical, and human environment as a result of implementing any of the proposed project alternatives developed during the process.

ADDRESSES: Submit written comments to Mr. Craig Hilburn, Biologist, U.S. Army Corps of Engineers, Planning and Environmental Division, Environmental Branch, Little Rock District, P.O. Box 867, Little Rock, AR 72203–0867. Comments will be accepted through October 15, 2015.

FOR FURTHER INFORMATION CONTACT: For questions or comments regarding the Three Rivers Draft Feasibility Report or EIS, please contact Mr. Craig Hilburn, (501) 324–5735 or email: *david.c.hilburn@usace.army.mil.*

SUPPLEMENTARY INFORMATION:

1. MKARNS: The McClellan-Kerr Arkansas River Navigation System consists of a series of 18 locks and dams that provide navigation from the Mississippi River to the Port of Catoosa near Tulsa, Oklahoma. River flow in the Arkansas River is modified primarily by 11 reservoirs in Oklahoma.

2. Study Location: The study is located at the confluence of the Mississippi, White, and Arkansas Rivers in Desha and Arkansas Counties, in southeast Arkansas. Prominent features include the McClellan-Kerr Arkansas River Navigation System (MKARNS) Post Canal and the 160,000-acre Dale Bumpers National Wildlife Refuge (U.S. Fish and Wildlife Service). The Arkansas Post Canal connects the Arkansas River to the White River for navigation onto the Mississippi River to complete the 445-mile navigation system. The study area is downstream of Lock No. 1 of the MKARNS and upstream of the Montgomery Point Lock & Dam and includes any adjacent landmasses that are presently being impacted or could be potentially impacted by the alternatives.

3. Study History: Studies in the area have occurred since the mid-1960's. Structures were placed along the White River and between the White and Arkansas River to regulate hydrologic flow between the two systems in the 1960's, 1970's and late 1980's.

4. Scoping/Public Involvement. The Public Scoping process provides information about the study to the public, serves as a mechanism to solicit agency and public input on alternatives and issues of concern, and ensures full and open participation in Scoping and review of the Draft EIS. Comments received as a result of this notice and news releases will be used to assist the preparers in identifying potential impacts to the quality of the human or natural environment. The Corps invites other Federal agencies, Native American Tribes, State and local agencies and officials, private organizations, and interested individuals to participate in the Scoping process by forwarding written comments to (see **ADDRESSES**). Interested parties may also request to be included on the mailing list for public distribution of announcements and documents.

5. Issues/Alternatives: The EIS will evaluate effects from a range of alternatives developed to address navigation and environmental concerns of the area. Anticipated significant issues to be addressed in the EIS include impacts on: (1) Navigation, (2) flooding, (3) recreation, (4) river hydraulics, (5) fish and wildlife resources and habitats, (6) wetlands, (7) timber and forestry management, and (8) other impacts identified by the Public, agencies or USACE studies.

The hydrology of the two rivers is strongly influenced by high water in the Mississippi River. Significant hydrologic and hydraulic problems currently threaten the Corps' mission areas of Navigation, Recreation, Flood Risk Management, as well as aquatic ecosystem habitat and existing infrastructure. Possible solutions may include increasing detention upstream, raising the height of the containment structure, removal of the control structure, or construction of a passive or active weir to restore a more natural hydrology between the two rivers. The study will evaluate opportunities for ecosystem restoration. Proposed improvements resulting from the study could impact (positively or negatively) navigation, agriculture, silviculture, hydropower, recreation, flood risk management, and fish and wildlife.

6. Availability of the Draft EIS: The Draft Environmental Impact Statement is anticipated to be available for public review in the spring of 2017, subject to the receipt of Federal funding.

Courtney W. Paul,

Colonel, U.S. Army, District Engineer.

[FR Doc. 2015–23032 Filed 9–11–15; 8:45 am]

BILLING CODE 3720–58–P

DEPARTMENT OF DEFENSE

Department of the Army, Corps of Engineers

National Wetland Plant List

AGENCY: U.S. Army Corps of Engineers, DoD.

ACTION: Notice.

SUMMARY: The National Wetland Plant List (NWPL) is used to delineate wetlands for purposes of the Clean Water Act and the Wetland Conservation Provisions of the Food Security Act. Other applications of the list include wetland restoration, establishment, and enhancement projects. To update the NWPL, the U.S. Army Corps of Engineers (Corps), as part of an interagency effort with the U.S. Environmental Protection Agency (EPA), the U.S. Fish and Wildlife Service (FWS) and the U.S. Department of Agriculture, Natural Resources Conservation Service (NRCS), is announcing the availability of the draft National Wetland Plant List (NWPL) 2015 and its Web address to solicit public comments. The public will now be provided the opportunity to

comment and vote on the proposed update of wetland indicator status ratings for 186 plants species in select Corps wetland regions.

DATES: Comments must be submitted on or before November 13, 2015.

ADDRESSES: U.S. Army Corps of Engineers, Attn: CECW–CO (Ms. Karen Mulligan), 441 G Street NW., Washington, DC 20314–1000.

FOR FURTHER INFORMATION CONTACT: Ms. Karen Mulligan, Headquarters, Operations and Regulatory Community of Practice, Washington, DC at 202–761–4664.

SUPPLEMENTARY INFORMATION: The U.S. Army Corps of Engineers (Corps) administers the National Wetland Plant List (NWPL) for the United States (U.S.) and its territories. Responsibility for the NWPL was transferred to the Corps from the U.S. Fish and Wildlife Service (FWS) in 2006. The Corps led interagency efforts to update the list in 2012, 2013, and 2014. The 2012 list contained 7,828 species, the 2013 update contained 7,937 species, and the 2014 update contained 8,061 species. Additions to these lists represent new records, range extensions, nomenclatural changes, and newly proposed species.

During the latest review process the ratings of two groups of plant species were reevaluated. The first consisted of a group of plants for which the public submitted rating changes on the NWPL Web site from November 10, 2014 to January 31, 2015. A total of 60 suggested rating changes for 42 species were submitted for eight Corps regions and two subregions. Twenty-two ratings and 14 species of these were not evaluated because (1) the proposed rating and the current rating were the same (nine species), (2) crops and epiphytic species were removed from the NWPL in the 2012 update (four species), and (3) insufficient information (one species). This leaves a total of 38 ratings for 28 species which were evaluated in seven Corps regions and two subregions. Of the 28 species evaluated, seven of these were suggested additions to the NWPL. The second group consisted of species with highly variable ratings, which were reexamined because they spanned more than three ratings categories, nationally (*i.e.,* rated FACW in the Arid West and UPL in the Caribbean). This group contained 885 ratings of 169 species. Three species were included in both groups. As a result of the process, 923 ratings of 194 species, in ten Corps regions were reviewed by the regional and national panels and a draft NWPL 2015, containing 8,056 species, has been compiled.

In group one, 71% percent of the public requests resulted in potential changes to the NWPL (resulting in 27 rating changes for 21 species). The ratings of the remaining species are unchanged, including one proposed addition that was determined to be an upland plant. Six new plants were recommended to be added to the NWPL. In group two, 30% percent of the highly variable ratings resulted in proposed changes to the NWPL (267 proposed rating changes for 168 species). One species was removed from the NWPL because it does not grow in soil. Removal of ten additional species is proposed because they were determined to be rated UPL in every region in which they occur. The overall net change between the 2014 list and the proposed 2015 list would be five species (6 proposed additions and 11 proposed removals).

Together, the proposed changes based on public requests and highly variable ratings total 1% of the ratings (294) and 2% (186) of the species on the 2014 NWPL. These proposed changes are nearly an equal split between species that received wetter ratings and those that received drier ratings. The specific break-down of proposed changes are: 51 percent (151 ratings for 116 species) rated wetter and 49 percent (143 ratings for 111 species) rated drier. The number of species above (227) exceeds the number of species included in the update (186) because 41 species were included in each category (*e.g.,* proposed to go drier in one region and wetter in another). Most of the rating changes are proposed in the Atlantic and Gulf Coastal Plain (55) and the Caribbean Islands (53) regions. The fewest changes are proposed in the Hawaii and Pacific Islands (12) and the Northcentral and Northeast (13) regions. Complete lists of changes by region, resources used to evaluate ratings and species, and newly submitted literature references are located at: *http://wetland_plants.usace.army.mil/nwpl2015_update/proposed_changes/.*

Indicator Status Ratings

On the NWPL, there are five categories of indicator status ratings, used to describe a plant's likelihood for occurrence in a wetland versus and upland: Obligate Wetland (OBL), Facultative Wetland (FACW), Facultative (FAC), Facultative Upland (FACU), and Obligate Upland (UPL). These rating categories are defined by the National Panel as follows: OBL—almost always is a hydrophyte, rarely in uplands; FACW—usually is a hydrophyte but occasionally found in uplands; FAC—commonly occurs as either a hydrophyte or non-hydrophyte; FACU—occasionally is a hydrophyte but usually occurs in uplands; UPL—rarely is a hydrophyte, almost always in uplands. These category definitions are qualitative descriptions that better reflect the qualitative supporting information, rather than numeric frequency ranges. The percentage frequency categories used in the older definitions are only used for testing problematic or contested species being recommended for indicator status changes. Plus and minus designations and wetland indicator designations such as No Indicator (NI), No Occurrence (NO), and No Agreement (NA) are no longer used on the NWPL. When assigning wetland indicator statuses, commenters should use the rating definitions described above and developed by the National Panel for updating the NWPL.

Wetlands are defined as those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions (33 CFR 328.3 and 40 CFR 230.3). Such wetlands are identified using the Corps 1987 Wetland Delineation Manual or relevant regional supplements, whichever is more recent. Wetlands are identified using the three factor approach. Because each species being evaluated occurs as part of a vegetation assemblage, examining the other species present may be useful in assessing hydrophytic vegetation.

Instructions for Providing Comments Online

Reviewers may consider the ecological information on the NWPL Web site, which includes prior information obtained by the FWS and others. Links to prior rating votes and maps of Corps wetland regions can be accessed from the NWPL *homepage.* To access regional voting records during the recent NWPL updates, click the *"Voting History (Rounds/Algos)"* link. To find ratings from the 1988 or 1996 Plant Lists, click *"National Wetland Plant List", "NWI 1988/1996 Lists"* and then either *"1996 National Summary"* or *"1988 National Summary (Reed 1988)."* The Corps wetland regions and subregions are based on Land Resource Regions (LRRs) and Major Land Resource Areas (MLRAs) (*http://soils.usda. gov/survey/geography/mlra/).* To display regional maps click the *"Wetland Regions and Rating Info"* link on the NWPL homepage. To view subregional maps, click the link under the "NWPL Viewer Tool" heading in the

upper left of the homepage. Once the viewer tool opens in a new window, click the "*Custom Plant List,*" "*Geographic Area,*" and "*USACE subregions*" links. The viewer tool is also used to access individual species pages. To find a species, type the scientific name into the search box in the upper right corner. Users are automatically redirected to the currently accepted name when a synonym is entered. Each species page includes scientific and common names, synonyms, and maps of distributions by county. Habitat descriptions from the literature can be displayed in the center of the page by clicking on "*Species Detail,*" "*Center Page View,*" and "*FWS or CRREL Literature.*"

The Corps is requesting assistance in the form of data, comments, literature references, or field experiences, to help clarify the status of the 186 species in the 2015 NWPL update. Comments may be made on one or more species in any of the wetland supplement regions or subregions where a rating change is proposed. A list of these species by region and the details of how their rating was evaluated by Regional and National Panel members can be viewed at the NWPL homepage, *http://wetland_plants. usace.army.mil/* by clicking on the "*Proposed FR NWPL2015 Update*" and "*Proposed Changes*" links. Recently submitted literature references are also shown here. Comments on these proposed changes to the NWPL are being accepted at the same Web site. To add input, commenters should click on the "*Federal Register Comments*" link underneath the "*Proposed Changes*" link. Commenters will be redirected to an online form for submitting comments. Literature citations, experiential references, monitoring data, and other relevant reports may be submitted through this form. In all cases, the most useful comments are from specific knowledge or studies related to individual species. Commenters should use their regional botanical and ecological expertise, field observations, reviews of the most recent indicator status information, appropriate botanical literature, floras, herbarium specimens with notation of habitat and associated species, habit data, relevant studies, and historic list information. Guessing ratings is inappropriate. The commenter can also submit general comments on the 2015 NWPL update that are not related to a specific species. General comments can be submitted by clicking on the email contact link titled "*Questions or Comments? Contact us!*" on the NWPL homepage. All votes and comments will be compiled and sent to the National Panel for their consideration.

Future Actions

Future updates to the NWPL will occur biennially according to the following proposed procedures. A change in indicator status may be requested at any time at *http://wetland_plants.usace.army.mil/* by clicking on the "Submit a NWPL *Change Request*" link and submitting the appropriate data. Data includes ecological data, literature reviews, testing descriptions, geographic data, and frequency and abundance data for the taxon in wetlands and uplands in the Corps wetland region or subregion for which the change is proposed. The regions and subregions are based on Land Resource Regions (LRRs) and Major Land Resource Areas (MLRAs) (*http://soils.usda.gov/survey/geography/mlra/*) and are shown for each wetland supplement region on the NWPL Web site. If the commenter believes that a wetland supplement region needs a subregion that has not yet been developed, the commenter should identify the MLRAs involved and provide a list of species from within that region that need their own wetland ratings.

Proposed rating changes will be compiled in January of odd years (*i.e.* 2017, 2019) and sent to the Regional Panels for input in February. The National Panel will assign wetland ratings to non-consensus species and will review all regional lists in April. The proposed changes will be compiled over the summer and published in the **Federal Register** for public comment in September. In October, public comments will be summarized and the National Panel will review and respond to comments. The final changes will be published in the **Federal Register** in December of odd years.

Dated: September 4, 2015.

Edward E. Belk, Jr.

Chief, Operations and Regulatory Division, Directorate of Civil Works.

BILLING CODE 3720–58–P

DEPARTMENT OF EDUCATION

[Docket No.: ED–2015–ICCD–0074]

Agency Information Collection Activities; Submission to the Office of Management and Budget for Review and approval; Comment Request; Mandatory Civil Rights Data Collection

AGENCY: Office of Civil Rights (OCR), Department of Education (ED).

ACTION: Notice.

SUMMARY: In accordance with the Paperwork Reduction Act of 1995 (44 U.S.C. chapter 3501 *et seq.*), ED is proposing a revision of an existing information collection.

DATES: Interested persons are invited to submit comments on or before October 14, 2015.

ADDRESSES: To access and review all the documents related to the information collection listed in this notice, please use *http://wwww.regulations.gov* by searching the Docket ID number ED–2015–ICCD–0074. Comments submitted in response to this notice should be submitted electronically through the Federal eRulemaking Portal at *http://www.regulations.gov* by selecting the Docket ID number or via postal mail, commercial delivery, or hand delivery. *Please note that comments submitted by fax or email and those submitted after the comment period will not be accepted.* Written requests for information or comments submitted by postal mail or delivery should be addressed to the Director of the Information Collection Clearance Division, U.S. Department of Education, 400 Maryland Avenue SW., LBJ, Room 2E105, Washington, DC 20202–4537.

FOR FURTHER INFORMATION CONTACT: For specific questions related to collection activities, please contact Rosa Olmeda, 202–453–5968.

SUPPLEMENTARY INFORMATION: The Department of Education (ED), in accordance with the Paperwork Reduction Act of 1995 (PRA) (44 U.S.C. 3506(c)(2)(A)), provides the general public and Federal agencies with an opportunity to comment on proposed, revised, and continuing collections of information. This helps the Department assess the impact of its information collection requirements and minimize the public's reporting burden. It also helps the public understand the Department's information collection requirements and provide the requested data in the desired format. ED is soliciting comments on the proposed information collection request (ICR) that is described below. The Department of Education is especially interested in public comment addressing the following issues: (1) Is this collection necessary to the proper functions of the Department; (2) will this information be processed and used in a timely manner; (3) is the estimate of burden accurate; (4) how might the Department enhance the quality, utility, and clarity of the information to be collected; and (5) how might the Department minimize the burden of this collection on the

respondents, including through the use of information technology. Please note that written comments received in response to this notice will be considered public records.

Title of Collection: Mandatory Civil Rights Data Collection

OMB Control Number: 1870–0504

Type of Review: A revision of an existing information collection.

Respondents/Affected Public: State, Local and Tribal Governments

Total Estimated Number of Annual Responses: 17, 620

Total Estimated Number of Annual Burden Hours: 1,520,260

Abstract: The collection, use and reporting of education data is an integral component of the mission of the U.S. Department of Education (ED). EDFacts, an ED initiative to put performance data at the center of ED's policy, management, and budget decision-making processes for all K–12 education programs, has transformed the way in which ED collects and uses data. For school years 2009–10 and 2011–12, the Civil Rights Data Collection (CRDC) was approved by OMB as part of the EDFacts information collection (1875–0240). For school years 2013–14 and 2015–16, the Office for Civil Rights (OCR) cleared the CRDC as a separate collection from EDFacts. OCR used the most current EDFacts information collection approved by OMB (1875–0240) as a model for the 2013–14 and 2015–16 CRDC information collection that was approved by OMB (1870–0504) in February 2014. Similarly, the currently proposed revised CRDC information collection for school year 2015–16 is modeled after the most recent OMB-approved EDFacts information collection. Except for a few data elements that were revised based on recommendations received from various school districts and advice received from experts across ED, the currently proposed CRDC information collection for school year 2015–16 is identical to the information collection for school year 2015–16 that was approved by OMB in February 2014. As with previous CRDC collections, the purpose of the 2015–16 CRDC is to obtain vital data related to the civil rights laws' requirement that public local educational agencies and elementary and secondary schools provide equal educational opportunity. ED seeks OMB approval under the Paperwork Reduction Act to collect from school districts, the elementary and secondary education data described in the sections of Attachment A.

Dated: September 9, 2015.

Stephanie Valentine,

Acting Director, Information Collection Clearance Division, Office of the Chief Privacy Officer, Office of Management.

BILLING CODE 4000–01–P

DEPARTMENT OF EDUCATION

National Advisory Council on Indian Education; Public Teleconference Meeting

AGENCY: National Advisory Council on Indian Education (NACIE or Council), U.S. Department of Education.

ACTION: Announcement of an open public teleconference meeting.

SUMMARY: This notice sets forth the schedule of an upcoming public meeting conducted by the National Advisory Council on Indian Education NACIE). Notice of the meeting is required by section 10(a)(2) of the Federal Advisory Committee Act and intended to notify the public of its opportunity to attend.

DATES: The NACIE teleconference meeting will be held via conference call on September 25, 2015—2:00 p.m.–2:30 p.m. Eastern Daylight Saving Time. Up to 20 dial-in, listen only phone lines will be made available to the public on a first come, first served basis. The conference call number is 1–800–857–9682 and the participant code is 5273162.

FOR FURTHER INFORMATION CONTACT: Tina Hunter, Designated Federal Official, Office of Elementary and Secondary Education, U.S. Department of Education, 400 Maryland Avenue SW., Washington, DC 20202. Telephone: 202–205–8527. Fax: 202–205–0310.

SUPPLEMENTARY INFORMATION: NACIE's Statutory Authority and Function: The National Advisory Council on Indian Education is authorized by § 7141 of the Elementary and Secondary Education Act. The Council is established within the Department of Education to advise the Secretary of Education on the funding and administration (including the development of regulations, and administrative policies and practices) of any program over which the Secretary has jurisdiction and includes Indian children or adults as participants or programs that may benefit Indian children or adults, including any program established under title VII, part A of the Elementary and Secondary Education Act. The Council submits to the Congress, not later than June 30 of each year, a report on the activities of the Council that includes recommendations the Council considers appropriate for the improvement of Federal education programs that include Indian children or adults as participants or that may benefit Indian children or adults, and recommendations concerning the funding of any such program.

One of the Council's responsibilities is to develop and provide recommendations to the Secretary of Education on the funding and administration (including the development of regulations, and administrative policies and practices) of any program over which the Secretary has jurisdiction that can benefit Indian children or adults participating in any program which could benefit Indian children.

Meeting Agenda: The purpose of the meeting is to convene the Council to conduct the following business: (1) Final discussion, review and approval of the annual report to Congress; and, (2) Discuss schedule to submit recommendations to the Secretary of Education on funding and administration of programs.

Access to Records of the Meeting: The Department will post the official report of the meeting on the Office of Elementary and Secondary Education (OESE) Web site at: *http://www2.ed.gov/about/offices/list/oese/index.html?src=oc* 21 days after the meeting. Pursuant to the FACA, the public may also inspect the materials at the Office of Indian Education, United States Department of Education, 400 Maryland Avenue SW., Washington, DC 20202, Monday-Friday, 8:30 a.m. to 5:00 p.m. Eastern Daylight Saving Time or by emailing *TribalConsultation@ed.gov* or by calling Terrie Nelson on (202) 401–0424 to schedule an appointment.

Reasonable Accommodations: The teleconference is accessible to individuals with disabilities. If you will need an auxiliary aid or service to participate in the meeting (*e.g.,* interpreting service, assistive listening device, or materials in an alternate format), notify Brandon Dent on (202) 453–6450 no later than September 18, 2015. Although we will attempt to meet a request received after request due date, we may not be able to make available the requested auxiliary aid or service because of insufficient time to make arrangements.

Electronic Access to this Document: The official version of this document is the document published in the **Federal Register.** Free Internet access to the official edition of the **Federal Register** and the Code of Federal Regulations is available via the Federal Digital System at: *www.gpo.gov/fdsys.* At this site you

can view this document, as well as all other documents of this Department published in the **Federal Register**, in text or Adobe Portable Document Format (PDF). To use PDF, you must have Adobe Acrobat Reader, which is available free at the site.

You may also access documents of the Department published in the **Federal Register** by using the article search feature at: *www.federalregister.gov.* Specifically, through the advanced search feature at this site, you can limit your search to documents published by the Department.

Authority: The National Advisory Council on Indian Education is authorized by section 7141 of the Elementary and Secondary Education Act.

Ann Whalen,

Senior Advisor to the Secretary Delegated the Duties of Assistant Secretary for Elementary and Secondary Education.

Agency Information Collection Activities; Comment Request; Pell for Students Who Are Incarcerated Experimental Site Initiative

AGENCY: Federal Student Aid (FSA), Department of Education (ED).

ACTION: Notice.

SUMMARY: In accordance with the Paperwork Reduction Act of 1995 (44 U.S.C. chapter 3501 *et seq.*), ED is proposing a new information collection.

DATES: Interested persons are invited to submit comments on or before November 13, 2015.

ADDRESSES: To access and review all the documents related to the information collection listed in this notice, please use *http://wwww.regulations.gov* by searching the Docket ID number ED–2015–ICCD–0110. Comments submitted in response to this notice should be submitted electronically through the Federal eRulemaking Portal at *http://www.regulations.gov* by selecting the Docket ID number or via postal mail, commercial delivery, or hand delivery. *Please note that comments submitted by fax or email and those submitted after the comment period will not be accepted.* Written requests for information or comments submitted by postal mail or delivery should be addressed to the Director of the Information Collection Clearance Division, U.S. Department of Education, 400 Maryland Avenue SW., LBJ, Room 2E103, Washington, DC 20202–4537.

FOR FURTHER INFORMATION CONTACT: For specific questions related to collection activities, please contact Beth Grebeldinger, 202–377–4018.

SUPPLEMENTARY INFORMATION: The Department of Education (ED), in accordance with the Paperwork Reduction Act of 1995 (PRA) (44 U.S.C. 3506(c)(2)(A)), provides the general public and Federal agencies with an opportunity to comment on proposed, revised, and continuing collections of information. This helps the Department assess the impact of its information collection requirements and minimize the public's reporting burden. It also helps the public understand the Department's information collection requirements and provide the requested data in the desired format. ED is soliciting comments on the proposed information collection request (ICR) that is described below. The Department of Education is especially interested in public comment addressing the following issues: (1) Is this collection necessary to the proper functions of the Department; (2) will this information be processed and used in a timely manner; (3) is the estimate of burden accurate; (4) how might the Department enhance the quality, utility, and clarity of the information to be collected; and (5) how might the Department minimize the burden of this collection on the respondents, including through the use of information technology. Please note that written comments received in response to this notice will be considered public records.

Title of Collection: Pell for Students who are Incarcerated Experimental Site Initiative.

OMB Control Number: 1845—NEW.

Type of Review: A new information collection.

Respondents/Affected Public: Private Sector, State, Local and Tribal Governments.

Total Estimated Number of Annual Responses: 100.

Total Estimated Number of Annual Burden Hours: 7,500.

Abstract: Through the Pell for Students who are Incarcerated experiment (also known as Second Chance Pell) the Department of Education will provide selected eligible postsecondary institutions with a waiver to the current statutory ban on incarcerated individuals, who are otherwise eligible, from receiving Federal Pell Grant funds to attend eligible postsecondary programs. The experiment aims to test whether participation in high-quality educational opportunities increases after access to financial aid for incarcerated adults is expanded and to examine how waiving the restriction influences individual academic and life outcomes.

Dated: September 8, 2015.

Kate Mullan,

Acting Director, Information Collection Clearance Division, Office of the Chief Privacy Officer, Office of Management.

BILLING CODE 4000–01–P

DEPARTMENT OF EDUCATION

National Committee on Foreign Medical Education and Accreditation

AGENCY: Office of Postsecondary Education, U.S. Department of Education, National Committee on Foreign Medical Education and Accreditation.

ACTION: Announcement of a Committee meeting.

SUMMARY: The purpose of this notice is to announce the upcoming meeting of the National Committee on Foreign Medical Education and Accreditation (NCFMEA). Parts of this meeting will be open to the public, and the public is invited to attend those portions.

Meeting Date and Place: The meeting will be held on October 28, 29, and 30, 2015, from 8:30 a.m. until approximately 5:00 p.m., at the U.S. Department of Education, Eighth Floor Conference Center, Office of Postsecondary Education, 1990 K Street NW., Washington, DC 20006. The Committee will meet in Executive Session on October 30, 2015. The entire October 30th session will be devoted to training sessions for the Committee; and, therefore, is closed to the public.

FOR FURTHER INFORMATION CONTACT: Jennifer Hong, Executive Director for the NCFMEA, U.S. Department of Education, 1990 K Street NW., Room 8073, Washington, DC 20006–8129; telephone: 202 502–7696; fax: 202 502–7874, or email: *Jennifer.Hong@ed.gov*

SUPPLEMENTARY INFORMATION: *Statutory Authority and Function:* The NCFMEA was established by the Secretary of Education under § 102 of the Higher Education Act of 1965, as amended. The NCFMEA's responsibilities are to:

- Evaluate the standards of accreditation applied to foreign medical schools and,
- Determine the comparability of those standards to standards for accreditation applied to United States medical schools.

A determination of comparability of accreditation standards by the NCFMEA is an eligibility requirement for foreign medical schools to participate in the William D. Ford Federal Direct Student Loan Program, 20 U.S.C. 1087a *et seq.*

Meeting Agenda: The NCFMEA will review the standards of accreditation applied to medical schools to determine whether those standards are comparable to the standards of accreditation applied to medical schools in the United States. The NCFMEA will also review previously requested reports from accrediting entities that accredit medical schools. Discussion of the standards of accreditation will be held in sessions open to the public. Discussions resulting in specific determinations of comparability are closed to the public until proper notification of the NCFMEA's decision is provided to the medical school by the Department.

The countries which are scheduled to be discussed are Antigua and Barbuda, Canada, Cayman Islands, Dominica, Dominican Republic, and Hungary. The meeting agenda, as well as the staff analyses pertaining to the meeting, will be posted on the Department of Education's Web site prior to the meeting at *http://www2.ed.gov/about/bdscomm/list/ncfmea.html.*

Reasonable Accommodations: The meeting site is accessible to individuals with disabilities. If you will need an auxiliary aid or service to participate in the meeting (*e.g.,* interpreting service, assistive listening device, or materials in an alternate format), notify the contact person listed in this notice by September 28, 2015, although we will attempt to meet a request received after that date.

Electronic Access To This Document: The official version of this document is the document published in the **Federal Register.** Free Internet access to the official edition of the **Federal Register** and the Code of Federal Regulations is available via the Federal Digital System at: *www.gpo.gov/fdsys.* At this site you can view this document, as well as all other documents of this Department published in the **Federal Register,** in text or Adobe Portable Document Format (PDF). To use PDF, you must have Adobe Acrobat Reader, which is available free at the site.

You may also access documents of the Department published in the **Federal Register** by using the article search feature at: *www.federalregister.gov.* Specifically, through the advanced search feature at this site, you can limit your search to documents published by the Department.

Delegation of Authority: The Secretary of Education has delegated authority to Jamienne S. Studley, Deputy Under Secretary, to perform the functions and duties of the Assistant Secretary for Postsecondary Education.

Authority: § 102 of the Higher Education Act of 1965, as amended.

Jamienne S. Studley,

Deputy Under Secretary.

BILLING CODE 6717–01–P

DEPARTMENT OF ENERGY

Federal Energy Regulatory Commission

[Docket No. EL15–100–000]

Northwest Power Pool Members' Market, Assessment and Coordination Committee; Notice of Petition for Declaratory Order

Take notice that on September 4, 2015, pursuant to Rule 207(a)(2) of the Federal Energy Regulatory Commission's (Commission) Rules of Practice and Procedure, 18 CFR 385.207(a)(2), the Northwest Power Pool Members' Market Assessment and Coordination Committee (Petitioner), filed a petition for a declaratory order (petition) on limited threshold issues critical to the development of a subhourly energy market in the Northwest Power Pool footprint, all as more fully explained in the petition.

Any person desiring to intervene or to protest this filing must file in accordance with Rules 211 and 214 of the Commission's Rules of Practice and Procedure (18 CFR 385.211, 385.214). Protests will be considered by the Commission in determining the appropriate action to be taken, but will not serve to make protestants parties to the proceeding. Any person wishing to become a party must file a notice of intervention or motion to intervene, as appropriate. Such notices, motions, or protests must be filed on or before the comment date. Anyone filing a motion to intervene or protest must serve a copy of that document on the Petitioner.

The Commission encourages electronic submission of protests and interventions in lieu of paper using the "eFiling" link at *http://www.ferc.gov.* Persons unable to file electronically should submit an original and 5 copies of the protest or intervention to the Federal Energy Regulatory Commission, 888 First Street NE., Washington, DC 20426.

This filing is accessible on-line at *http://www.ferc.gov,* using the "eLibrary" link and is available for review in the Commission's Public Reference Room in Washington, DC. There is an "eSubscription" link on the Web site that enables subscribers to receive email notification when a document is added to a subscribed docket(s). For assistance with any FERC Online service, please email *FERCOnlineSupport@ferc.gov,* or call (866) 208–3676 (toll free). For TTY, call (202) 502–8659.

Comment Date: 5:00 p.m. Eastern time on October 5, 2015.

Dated: September 8, 2015.

Coleman Hydro LLC; Notice of Teleconference

a. Project Name and Number: Coleman Hydroelectric Project No. 13629.

b. Date and Time of Meeting: September 22, 2015; 10:00 a.m. Pacific Daylight Time (11:00 a.m. Mountain Daylight Time).

c. FERC Contact: Jim Hastreiter, *james.hastreiter@ferc.gov* or (503) 552–2760.

d. Purpose of Meeting: U.S. Fish and Wildlife Service has requested the teleconference to discuss the scope of the proposed Coleman Hydroelectric Project and its effects on federally-listed bull trout, as it relates to the Commission staff's request for formal consultation under section 7 of the Endangered Species Act.

e. All local, state, and federal agencies, Indian tribes, and other interested parties are invited to participate by phone. Please call Jim Hastreiter at (503) 552–2760 by September 15, 2015, to RSVP and to receive specific instructions on how to participate.

Dated: September 8, 2015.

Kimberly D. Bose,

Secretary.

[Docket No. RM98–1–000]

Records Governing Off-the-Record Communications; Public Notice

This constitutes notice, in accordance with 18 CFR 385.2201(b), of the receipt of prohibited and exempt off-the-record communications.

Order No. 607 (64 FR 51222, September 22, 1999) requires Commission decisional employees, who make or receive a prohibited or exempt off-the-record communication relevant to the merits of a contested proceeding, to deliver to the Secretary of the Commission, a copy of the communication, if written, or a summary of the substance of any oral communication.

Prohibited communications are included in a public, non-decisional file associated with, but not a part of, the decisional record of the proceeding. Unless the Commission determines that the prohibited communication and any responses thereto should become a part of the decisional record, the prohibited off-the-record communication will not be considered by the Commission in reaching its decision. Parties to a proceeding may seek the opportunity to respond to any facts or contentions made in a prohibited off-the-record communication, and may request that the Commission place the prohibited communication and responses thereto in the decisional record. The Commission will grant such a request only when it determines that fairness so requires. Any person identified below as having made a prohibited off-the-record communication shall serve the document on all parties listed on the official service list for the applicable

proceeding in accordance with Rule 2010, 18 CFR 385.2010.

Exempt off-the-record communications are included in the decisional record of the proceeding, unless the communication was with a cooperating agency as described by 40 CFR 1501.6, made under 18 CFR 385.2201(e)(1)(v).

The following is a list of off-the-record communications recently received by the Secretary of the Commission. The communications listed are grouped by docket numbers in ascending order. These filings are available for electronic review at the Commission in the Public Reference Room or may be viewed on the Commission's Web site at *http://www.ferc.gov* using the eLibrary link. Enter the docket number, excluding the last three digits, in the docket number field to access the document. For assistance, please contact FERC Online Support at *FERCOnlineSupport@ferc.gov* or toll free at (866)208–3676, or for TTY, contact (202)502–8659.

[Docket No. ER15–2534–000]

Saddleback Ridge Wind, LLC; Supplemental Notice That Initial Market-Based Rate Filing Includes Request for Blanket Section 204 Authorization

This is a supplemental notice in the above-referenced proceeding of Saddleback Ridge Wind, LLC's application for market-based rate authority, with an accompanying rate tariff, noting that such application includes a request for blanket authorization, under 18 CFR part 34, of future issuances of securities and assumptions of liability.

Any person desiring to intervene or to protest should file with the Federal Energy Regulatory Commission, 888 First Street NE., Washington, DC 20426, in accordance with Rules 211 and 214 of the Commission's Rules of Practice and Procedure (18 CFR 385.211 and 385.214). Anyone filing a motion to intervene or protest must serve a copy of that document on the Applicant.

Notice is hereby given that the deadline for filing protests with regard to the applicant's request for blanket authorization, under 18 CFR part 34, of future issuances of securities and assumptions of liability, is September 28, 2015.

The Commission encourages electronic submission of protests and interventions in lieu of paper, using the FERC Online links at *http://www.ferc.gov.* To facilitate electronic service, persons with Internet access who will eFile a document and/or be listed as a contact for an intervenor must create and validate an eRegistration account using the eRegistration link. Select the eFiling link to log on and submit the intervention or protests.

Persons unable to file electronically should submit an original and 5 copies of the intervention or protest to the Federal Energy Regulatory Commission, 888 First Street NE., Washington, DC 20426.

The filings in the above-referenced proceeding are accessible in the Commission's eLibrary system by clicking on the appropriate link in the above list. They are also available for electronic review in the Commission's Public Reference Room in Washington, DC. There is an eSubscription link on the Web site that enables subscribers to receive email notification when a document is added to a subscribed docket(s). For assistance with any FERC Online service, please email *FERCOnlineSupport@ferc.gov.* or call (866) 208–3676 (toll free). For TTY, call (202) 502–8659.

Dated: September 8, 2015.

BILLING CODE 6717–01–P

ENVIRONMENTAL PROTECTION AGENCY

[EPA–HQ–OGC–2015–0612; FRL 9933–93–OGC]

Proposed Consent Decree, Clean Air Act Citizen Suit

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice of proposed settlement agreement; request for public comment.

SUMMARY: In accordance with section 113(g) of the Clean Air Act, as amended ("CAA"), notice is hereby given of a proposed settlement agreement to settle lawsuits filed by Sinclair Wyoming Refining Company and Sinclair Casper Refining Company ("Petitioners"), in the United States Courts of Appeal for the Tenth and District of Columbia Circuits: *Sinclair Wyoming Refining Co. et al.* v. *EPA,* No. 14–9594 (10th Cir.) and *Sinclair Wyoming Refining Co. et al.* v. *EPA,* No. 14–1209 (D.C. Cir.). On October 24, 2014, Petitioners filed petitions for review challenging EPA's August 29, 2014 denials of Sinclair's requests for extensions of its small refinery temporary exemptions for its refineries in Evansville and Sinclair, Wyoming (collectively, the "Small Refinery Temporary Exemptions"). Under the terms of the proposed settlement agreement, Petitioners may submit a request for an extension of their Small Refinery Temporary Exemptions with respect to Petitioners' 2014 obligations under the Renewable Fuel Standards ("RFS") Program (the "2014 Exemption Request"). After EPA determines that the 2014 Exemption Request is complete, EPA will issue its decision to Petitioners on the 2014 Extension Request within 90 calendar days.

DATES: Written comments on the proposed settlement agreement must be received by October 14, 2015.

ADDRESSES: Submit your comments, identified by Docket ID number EPA–HQ–OGC–2015–0612, online at *www.regulations.gov* (EPA's preferred method); by email to *oei.docket@epa.gov;* mailed to EPA Docket Center, Environmental Protection Agency, Mailcode: 2822T, 1200 Pennsylvania Ave. NW., Washington, DC 20460–0001; or by hand delivery or courier to EPA Docket Center, EPA West, Room 3334, 1301 Constitution Ave. NW., Washington, DC, between 8:30 a.m. and 4:30 p.m. Monday through Friday, excluding legal holidays. Comments on a disk or CD–ROM should be formatted in Word or ASCII file, avoiding the use of special characters and any form of encryption, and may be mailed to the mailing address above.

FOR FURTHER INFORMATION CONTACT: Susan Stahle, Air and Radiation Law Office (2344A), Office of General Counsel, U.S. Environmental Protection Agency, 1200 Pennsylvania Ave. NW., Washington, DC 20460; telephone: (202) 564–1272; fax number (202) 564–5603; email address: *stahle.susan@epa.gov.*

SUPPLEMENTARY INFORMATION:

I. Additional Information About the Proposed Consent Decree

The proposed settlement agreement would settle Petitioners' petitions for review in the United States Courts of Appeal for the Tenth and District of Columbia Circuits challenging, under

section 307(b)(1) of the Clean Air Act, EPA's August 29, 2014 denials of Petitioners' requests for extensions of their Small Refinery Temporary Exemptions (*see Sinclair Wyoming Refining Co. et al.* v. *EPA,* No. 14–9594 (10th Cir.) and *Sinclair Wyoming Refining Co. et al.* v. *EPA,* No. 14–1209 (D.C. Cir.) (jointly, the "Pending Cases"). The proposed settlement agreement provides that after Petitioners submit their 2014 Exemption Request, EPA will, within 14 business days after receiving the 2014 Exemption Request, either make a determination that the Request is complete or advise Sinclair in writing of any additional information needed to make the Request complete (an Incompleteness Determination). After EPA determines that the 2014 Exemption Request is complete, EPA will issue its decision to Petitioners on the 2014 Exemption Request within 90 calendar days. Within five business days of EPA issuing its decision on the 2014 Exemption Request, Petitioners will (1) voluntarily dismiss the Pending Cases with prejudice and (2) send a letter to EPA withdrawing its January 13, 2015 "Request for Reconsideration of Petition for Partial Extension of Small Refinery RFS Exemptions" regarding EPA's August 29, 2014 denials of Petitioners' requests for extensions of the Small Refinery Temporary Exemptions.

For a period of 30 days following the date of publication of this notice, the Agency will receive written comments relating to the proposed settlement agreement from persons who were not named as parties or intervenors to the litigation in question. EPA or the Department of Justice may withdraw or withhold consent to the proposed settlement agreement if the comments disclose facts or considerations that indicate that such consent is inappropriate, improper, inadequate, or inconsistent with the requirements of the Act. Unless EPA or the Department of Justice determines that consent to the agreement should be withdrawn, the terms of the agreement will be affirmed.

II. Additional Information About Commenting on the Proposed Consent Decree

A. How can I get a copy of the consent decree?

Direct your comments to the official public docket for this action under Docket ID No. EPA–HQ–OGC–2015–0612 which contains a copy of the settlement agreement. The official public docket is available for public viewing at the Office of Environmental Information (OEI) Docket in the EPA Docket Center, EPA West, Room 3334, 1301 Constitution Ave. NW., Washington, DC. The EPA Docket Center Public Reading Room is open from 8:30 a.m. to 4:30 p.m., Monday through Friday, excluding legal holidays. The telephone number for the Public Reading Room is (202) 566–1744, and the telephone number for the OEI Docket is (202) 566–1752.

An electronic version of the public docket is available through *www.regulations.gov.* You may use the *www.regulations.gov* to submit or view public comments, access the index listing of the contents of the official public docket, and to access those documents in the public docket that are available electronically. Once in the system, key in the appropriate docket identification number then select "search".

It is important to note that EPA's policy is that public comments, whether submitted electronically or in paper, will be made available for public viewing online at *www.regulations.gov* without change, unless the comment contains copyrighted material, CBI, or other information whose disclosure is restricted by statute. Information claimed as CBI and other information whose disclosure is restricted by statute is not included in the official public docket or in the electronic public docket. EPA's policy is that copyrighted material, including copyrighted material contained in a public comment, will not be placed in EPA's electronic public docket but will be available only in printed, paper form in the official public docket. Although not all docket materials may be available electronically, you may still access any of the publicly available docket materials through the EPA Docket Center.

B. How and to whom do I submit comments?

You may submit comments as provided in the **ADDRESSES** section. Please ensure that your comments are submitted within the specified comment period. Comments received after the close of the comment period will be marked "late." EPA is not required to consider these late comments.

If you submit an electronic comment, EPA recommends that you include your name, mailing address, and an email address or other contact information in the body of your comment and with any disk or CD ROM you submit. This ensures that you can be identified as the submitter of the comment and allows EPA to contact you in case EPA cannot read your comment due to technical difficulties or needs further information on the substance of your comment. Any identifying or contact information provided in the body of a comment will be included as part of the comment that is placed in the official public docket, and made available in EPA's electronic public docket. If EPA cannot read your comment due to technical difficulties and cannot contact you for clarification, EPA may not be able to consider your comment.

Use of the *www.regulations.gov* Web site to submit comments to EPA electronically is EPA's preferred method for receiving comments. The electronic public docket system is an "anonymous access" system, which means EPA will not know your identity, email address, or other contact information unless you provide it in the body of your comment. In contrast to EPA's electronic public docket, EPA's electronic mail (email) system is not an "anonymous access" system. If you send an email comment directly to the Docket without going through *www.regulations.gov,* your email address is automatically captured and included as part of the comment that is placed in the official public docket, and made available in EPA's electronic public docket.

Dated: September 3, 2015.

Gautam Srinivasan,

Acting Associate General Counsel.

ENVIRONMENTAL PROTECTION AGENCY

[FRL–9933–83–Region 9]

Samoa Pulp Mill Removal Site, Samoa, CA; Notice of Proposed CERCLA Settlement Agreement for Recovery of Past Response Costs

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice; request for comment.

SUMMARY: In accordance with Section 122(i) of the Comprehensive Environmental Response, Compensation and Liability Act of 1980, as amended (CERCLA), 42 U.S.C. 9622(i), notice is hereby given of a proposed administrative settlement with Humboldt Bay Harbor, Conservation and Recreation District for recovery of response costs concerning the Samoa Pulp Mill Superfund Site in Samoa, California. The settlement is entered into pursuant to Section 122(h)(1) of CERCLA, 42 U.S.C. 9622(h)(1), and it requires the settling party to reimburse EPA based on any salvage of fixtures at the site, including the pulp mill boiler,

or on any sale of the real property that is the site. The settlement includes a covenant not to sue the settling party pursuant to Sections 106 or 107(a) of CERCLA, 42 U.S.C. 9606 or 9607(a). For thirty (30) days following the date of publication of this Notice in the **Federal Register**, the Agency will receive written comments relating to the settlement. The Agency will consider all comments received and may modify or withdraw its consent to the settlement if comments received disclose facts or considerations that indicate the proposed settlement is inappropriate, improper, or inadequate. The Agency's response to any comments received will be available for public inspection at 75 Hawthorne Street, San Francisco, CA 94105.

DATES: Pursuant to Section 122(i) of CERCLA, EPA will receive written comments relating to this proposed settlement until October 14, 2015.

ADDRESSES: The proposed settlement is available for public inspection at EPA Region IX, 75 Hawthorne Street, San Francisco, California. A copy of the proposed settlement may be obtained from J. Andrew Helmlinger, EPA Region IX, 75 Hawthorne Street, ORC–3, San Francisco, CA 94105, telephone number 415–972–3904. Comments should reference the Samoa Pulp Mill Superfund Site, Samoa, California and should be addressed to Mr. Helmlinger at the above address.

FOR FURTHER INFORMATION CONTACT: J. Andrew Helmlinger, Assistant Regional Counsel (ORC–3), Office of Regional Counsel, U.S. EPA Region IX, 75 Hawthorne Street, San Francisco, CA 94105; phone: (415) 972–3904; fax: (417) 947–3570; email: *helmlinger.andrew@epa.gov.*

SUPPLEMENTARY INFORMATION: *Parties to the Proposed Settlement:* Humboldt Bay Harbor, Conservation and Recreation District.

Dated: August 31, 2015.

Enrique Manzanilla,

Director, Superfund Division, U.S. EPA, Region IX.

BILLING CODE 6715–01–P

FEDERAL RESERVE SYSTEM

Formations of, Acquisitions by, and Mergers of Bank Holding Companies

The companies listed in this notice have applied to the Board for approval, pursuant to the Bank Holding Company Act of 1956 (12 U.S.C. 1841 *et seq.*) (BHC Act), Regulation Y (12 CFR part 225), and all other applicable statutes and regulations to become a bank holding company and/or to acquire the assets or the ownership of, control of, or the power to vote shares of a bank or bank holding company and all of the banks and nonbanking companies owned by the bank holding company, including the companies listed below.

The applications listed below, as well as other related filings required by the Board, are available for immediate inspection at the Federal Reserve Bank indicated. The applications will also be available for inspection at the offices of the Board of Governors. Interested persons may express their views in writing on the standards enumerated in the BHC Act (12 U.S.C. 1842(c)). If the proposal also involves the acquisition of a nonbanking company, the review also includes whether the acquisition of the nonbanking company complies with the standards in section 4 of the BHC Act (12 U.S.C. 1843). Unless otherwise noted, nonbanking activities will be conducted throughout the United States.

Unless otherwise noted, comments regarding each of these applications must be received at the Reserve Bank indicated or the offices of the Board of Governors not later than October 9, 2015.

A. Federal Reserve Bank of Richmond (Adam M. Drimer, Assistant Vice President) 701 East Byrd Street, Richmond, Virginia 23261–4528:

1. *Old Line Bancshares, Inc.,* Bowie, Maryland; to acquire 100 percent of the voting shares of Regal Bancorp, Inc., and thereby indirectly acquire voting shares of Regal Bank & Trust, both in Owings Mill, Maryland.

Board of Governors of the Federal Reserve System, September 9, 2015.

Michael J. Lewandowski,

Associate Secretary of the Board.

BILLING CODE 6210–01–P

FEDERAL RESERVE SYSTEM

Change in Bank Control Notices; Acquisitions of Shares of a Bank or Bank Holding Company

The notificants listed below have applied under the Change in Bank Control Act (12 U.S.C. 1817(j)) and § 225.41 of the Board's Regulation Y (12 CFR 225.41) to acquire shares of a bank or bank holding company. The factors that are considered in acting on the notices are set forth in paragraph 7 of the Act (12 U.S.C. 1817(j)(7)).

The notices are available for immediate inspection at the Federal Reserve Bank indicated. The notices also will be available for inspection at the offices of the Board of Governors. Interested persons may express their views in writing to the Reserve Bank indicated for that notice or to the offices of the Board of Governors. Comments must be received not later than September 29, 2015.

A. Federal Reserve Bank of Chicago (Colette A. Fried, Assistant Vice President) 230 South LaSalle Street, Chicago, Illinois 60690–1414:

1. *Ronald G. Gerken and Karol S. Gerken,* both of Sterling, Illinois, as a group acting in concert, to retain voting shares of SV Financial, Inc., and thereby indirectly retain voting shares of Sauk Valley Bank & Trust Company, both in Sterling, Illinois.

Board of Governors of the Federal Reserve System, September 9, 2015.

Michael J. Lewandowski,

Associate Secretary of the Board.

BILLING CODE 6210–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Disease Control and Prevention

Safety and Occupational Health Study Section, National Institute for Occupational Safety and Health

In accordance with section 10(a)(2) of the Federal Advisory Committee Act (Pub. L. 92–463), the Centers for Disease Control and Prevention (CDC) announces the following committee meeting.

Times and Dates: 8 a.m.–5 p.m., October 14, 2015 (Closed), 8 a.m.–5 p.m., October 15, 2015 (Closed).

Place: Embassy Suites, 1900 Diagonal Road, Alexandria, Virginia 22314, Telephone: 703–684–5900, Fax: 703–684–0653.

Purpose: The Safety and Occupational Health Study Section (SOHSS) will review, discuss, and evaluate grant application(s) received in response to the National Institute for Occupational Safety and Health (NIOSH or Institute) standard grants review and funding cycles pertaining to research issues in occupational safety and health, and allied areas.

It is the intent of NIOSH to support broad-based research endeavors in keeping with the Institute's program goals. This will lead to improved understanding and appreciation for the magnitude of the aggregate health burden associated with occupational injuries and illnesses, as well as to support more focused research projects, which will lead to improvements in the delivery of occupational safety and health services, and the prevention of work-related injury and illness. It is anticipated that research funded will promote these program goals.

Matters for Dicussion: The meeting will convene to address matters related to the conduct of Study Section business and for the study section to consider safety and occupational health-related grant applications.

These portions of the meeting will be closed to the public in accordance with provisions set forth in Section 552b(c)(4) and (6), Title 5 U.S.C., and the Determination of the Director, Management Analysis and Services Office, Centers for Disease Control and Prevention, pursuant to Section 10(d) Pub. L. 92–463.

Agenda items are subject to change as priorities dictate.

Contact Person for More Information: Joanne Fairbanks, Committee Management Specialist, NIOSH, CDC, 1095 Willowdale Road, Morgantown, WV, 26506, Mailstop L1119, Telephone: (304) 285–6143.

The Director, Management Analysis and Services Office, has been delegated the authority to sign **Federal Register** notices pertaining to announcements of meetings and other committee management activities for both the Centers for Disease Control and Prevention and the Agency for Toxic Substances and Disease Registry.

Elaine L. Baker,

Director, Management Analysis and Services Office, Centers for Disease Control and Prevention.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Disease Control and Prevention

Board of Scientific Counselors, Office of Public Health Preparedness and Response

In accordance with section 10(a)(2) of the Federal Advisory Committee Act (Pub. L. 92–463), the Centers for Disease Control and Prevention (CDC), announces the following meeting of the aforementioned committee:

Times and Dates: 9:30 a.m.–5:15 p.m., EDT, October 7, 2015; 8:15 a.m.–3:45 p.m., EDT, October 8, 2015.

Place: Centers for Disease Control and Prevention (CDC), Global Communications Center, Building 19, Auditorium B3, 1600 Clifton Road NE., Atlanta, Georgia 30333.

Status: Open to the public limited only by the space available. The meeting room will accommodate up to 90 people. Members of the public that wish to attend this meeting should pre-register by submitting the following information by email, facsimile, or phone (see *Contact Person For More Information*) no later than 12 noon (EDT) on Tuesday, September 29, 2015:

- Full Name
- Organizational Affiliation
- Complete Mailing Address
- Citizenship
- Phone Number or Email Address

Purpose: The Board of Scientific Counselors (BSC), OPHPR is charged with providing advice and guidance to the Secretary, Department of Health and Human Services (HHS), the Assistant Secretary for Health (ASH), the Director, Centers for Disease Control and Prevention (CDC), and the Director, Office of Public Health Preparedness and Response (OPHPR), concerning strategies and goals for the programs and research within OPHPR, monitoring the overall strategic direction and focus of the OPHPR Divisions and Offices, and administration and oversight of peer review of OPHPR scientific programs. For additional information about the Board, please visit: *http://www.cdc.gov/phpr/science/counselors.htm.*

Matters for Discussion: Day one of the meeting will cover briefings and BSC deliberation on the following topics: interval updates from OPHPR Divisions and Offices; key issues associated with CDC's Incident Management Training and Development Program (IMTP); healthcare preparedness and public health interface during the Ebola response; and BSC liaison representative updates to the Board highlighting organizational activities relevant to the OPHPR mission.

Day two of the meeting will cover briefings and BSC deliberation on the following topics: OPHPR strategic priorities; OPHPR impact measurement; Public Health Emergency Preparedness (PHEP) review and impact; intramural portfolio initiative; select agent regulations; and mental and behavioral health and emergency preparedness and response.

Agenda items are subject to change as priorities dictate.

Contact Person for More Information: Sparklé Buissereth, Office of Science and Public Health Practice, Executive Assistant, Centers for Disease Control and Prevention, 1600 Clifton Road NE., Mailstop D–44, Atlanta, Georgia 30333, Telephone: (404) 639–7325; Facsimile: (404)639–7977; Email: *OPHPR.BSC.Questions@cdc.gov.*

The Director, Management Analysis and Services Office, has been delegated the authority to sign **Federal Register** notices pertaining to announcements of meetings and other committee management activities for both the Centers for Disease Control and Prevention, and Agency for Toxic Substances and Disease Registry.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Medicare & Medicaid Services

[Document Identifiers: CMS–10526]

Agency Information Collection Activities: Proposed Collection; Comment Request

AGENCY: Centers for Medicare & Medicaid Services, HHS.

ACTION: Notice.

SUMMARY: The Centers for Medicare & Medicaid Services (CMS) is announcing an opportunity for the public to comment on CMS' intention to collect information from the public. Under the Paperwork Reduction Act of 1995 (the PRA), federal agencies are required to publish notice in the **Federal Register** concerning each proposed collection of information (including each proposed extension or reinstatement of an existing collection of information) and to allow 60 days for public comment on the proposed action. Interested persons are invited to send comments regarding our burden estimates or any other aspect of this collection of information, including any of the following subjects: (1) The necessity and utility of the proposed information collection for the proper performance of the agency's functions; (2) the accuracy of the estimated burden; (3) ways to enhance the quality, utility, and clarity of the information to be collected; and (4) the use of automated collection techniques or other forms of information technology to minimize the information collection burden.

DATES: Comments must be received by November 13, 2015.

ADDRESSES: When commenting, please reference the document identifier or OMB control number. To be assured consideration, comments and recommendations must be submitted in any one of the following ways:

1. *Electronically.* You may send your comments electronically to *http://www.regulations.gov.* Follow the instructions for "Comment or Submission" or "More Search Options" to find the information collection document(s) that are accepting comments.

2. *By regular mail.* You may mail written comments to the following address: CMS, Office of Strategic Operations and Regulatory Affairs, Division of Regulations Development, Attention: Document Identifier/OMB Control Number _____, Room C4–26–05, 7500 Security Boulevard, Baltimore, Maryland 21244–1850.

To obtain copies of a supporting statement and any related forms for the proposed collection(s) summarized in this notice, you may make your request using one of following:

1. Access CMS' Web site address at *http://www.cms.hhs.gov/PaperworkReductionActof1995.*

2. Email your request, including your address, phone number, OMB number, and CMS document identifier, to *Paperwork@cms.hhs.gov.*

3. Call the Reports Clearance Office at (410) 786–1326.

FOR FURTHER INFORMATION CONTACT: Reports Clearance Office at (410) 786–1326.

SUPPLEMENTARY INFORMATION:

Contents

This notice sets out a summary of the use and burden associated with the following information collections. More detailed information can be found in each collection's supporting statement and associated materials (see **ADDRESSES**).

CMS–10526 Cost-Sharing Reduction Reconciliation

Under the PRA (44 U.S.C. 3501–3520), federal agencies must obtain approval from the Office of Management and Budget (OMB) for each collection of

information they conduct or sponsor. The term "collection of information" is defined in 44 U.S.C. 3502(3) and 5 CFR 1320.3(c) and includes agency requests or requirements that members of the public submit reports, keep records, or provide information to a third party. Section 3506(c)(2)(A) of the PRA requires federal agencies to publish a 60-day notice in the **Federal Register** concerning each proposed collection of information, including each proposed extension or reinstatement of an existing collection of information, before submitting the collection to OMB for approval. To comply with this requirement, CMS is publishing this notice.

Information Collection

1. *Type of Information Collection Request:* Revision of a currently approved collection; *Title of Information Collection:* Cost-Sharing Reduction Reconciliation; *Use:* Under established Department of Health and Human Services (HHS) regulations, qualified health plan (QHP) issuers will receive estimated advance payments of cost-sharing reductions throughout the year. Each issuer will then be subject to a reconciliation process at the end of the benefit year to ensure that HHS reimburses each issuer only for actual cost sharing. This revised collection eliminates some data elements and requires summary plan level reporting and reporting in the 2016 reconciliation cycle on the dollar amount of 2014 cost-sharing reductions used in calculations for medical loss ratio and risk corridors programs reporting. *Form Number:* CMS–10526 (OMB Control Number: 0938–1266); *Frequency:* Annually; *Affected Public:* Private Sector, Not-for-profit institutions; *Number of Respondents:* 295; *Total Annual Responses:* 4,000,000; *Total Annual Hours:* 6,939. (For policy questions regarding this collection contact Pat Meisol at 410–786–1917.)

Dated: September 8, 2015.

William N. Parham, III,

Director, Paperwork Reduction Staff, Office of Strategic Operations and Regulatory Affairs.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Centers for Medicare & Medicaid Services

[Document Identifier: CMS–10398 (#43)]

Agency Information Collection Activities: Submission for OMB Review; Comment Request

ACTION: Notice.

SUMMARY: The Centers for Medicare & Medicaid Services (CMS) is announcing an opportunity for the public to comment on CMS' intention to collect information from the public. Under the Paperwork Reduction Act of 1995 (PRA), federal agencies are required to publish notice in the **Federal Register** concerning each proposed collection of information, including each proposed extension or reinstatement of an existing collection of information, and to allow a second opportunity for public comment on the notice. Interested persons are invited to send comments regarding the burden estimate or any other aspect of this collection of information, including any of the following subjects: (1) The necessity and utility of the proposed information collection for the proper performance of the agency's functions; (2) the accuracy of the estimated burden; (3) ways to enhance the quality, utility, and clarity of the information to be collected; and (4) the use of automated collection techniques or other forms of information technology to minimize the information collection burden.

DATES: Comments on the collection(s) of information must be received by the OMB desk officer by October 14, 2015:

ADDRESSES: When commenting, please reference the document identifier or OMB control number. To be assured consideration, comments and recommendations must be submitted in any one of the following ways:

1. *Electronically.* You may send your comments electronically to *http://www.regulations.gov.* Follow the instructions for "Comment or Submission" or "More Search Options" to find the information collection document(s) that are accepting comments.

2. *By regular mail.* You may mail written comments to the following address: CMS, Office of Strategic Operations and Regulatory Affairs, Division of Regulations Development, Attention: Document Identifier/OMB Control Number _____, Room C4–26–05, 7500 Security Boulevard, Baltimore, Maryland 21244–1850.

To obtain copies of a supporting statement and any related forms for the proposed collection(s) summarized in this notice, you may make your request using one of following:

1. Access CMS' Web site address at *http://www.cms.hhs.gov/PaperworkReductionActof1995.*

2. Email your request, including your address, phone number, OMB number, and CMS document identifier, to *Paperwork@cms.hhs.gov.*

3. Call the Reports Clearance Office at (410) 786–1326.

FOR FURTHER INFORMATION CONTACT: Reports Clearance Office at (410) 786–1326.

SUPPLEMENTARY INFORMATION: Under the Paperwork Reduction Act of 1995 (PRA) (44 U.S.C. 3501–3520), federal agencies must obtain approval from the Office of Management and Budget (OMB) for each collection of information they conduct or sponsor. The term "collection of information" is defined in 44 U.S.C. 3502(3) and 5 CFR 1320.3(c) and includes agency requests or requirements that members of the public submit reports, keep records, or provide information to a third party. Section 3506(c)(2)(A) of the PRA (44 U.S.C. 3506(c)(2)(A)) requires federal agencies to publish a 30-day notice in the **Federal Register** concerning each proposed collection of information, including each proposed extension or reinstatement of an existing collection of information, before submitting the collection to OMB for approval. To comply with this requirement, CMS is publishing this notice that summarizes the following proposed collection(s) of information for public comment:

1. *Type of Information Collection Request:* Revision of a currently approved collection; *Title of Information Collection:* Demonstration Programs to Improve Community Mental Health Services; *Use:* The Centers for Medicare and Medicaid Services (CMS), the Substance Abuse and Mental Health Services Administration (SAMHSA), and the Assistant Secretary of Planning and Evaluation (ASPE) intend to collect information from states selected to participate in the Section 223 Demonstration Programs to Improve Community Mental Health Services. To be completed annually by each certified community behavioral health clinic (CCBHC), the information collection's cost report would be used to determine each CCBHC's prospective payment system (PPS) rate, effective January 1, 2017, for the payment of demonstration services. The cost report would facilitate rate determinations for both PPS–1 and

PPS–2 (the two methodologies allowed by CMS and specified in CCBHC PPS guidance previously issued by CMS). The cost report would assist states in meeting the requirement for annual reporting of CCBHC cost to CMS in a manner that is consistent with the guidance's cost reporting and documentation requirements.

Information collections approved under this package's control number are reviewed/approved under OMB's generic process. As such, they are usually not subject to formal public review and comment. In this instance, however, CMS is interested in receiving public input and is posting the cost report, cost report instructions, and Supporting Statement on its Web site for public review (see **ADDRESSES** and **DATES**).

Form Number: CMS–10398 (#43) (OMB control number 0938–1148); *Frequency:* Yearly; *Affected Public:* Private sector (not-for-profits institutions) and State, Local, or Tribal Governments; *Number of Respondents:* 24; *Total Annual Responses:* 24; *Total Annual Hours:* 1,832. (For policy questions regarding this collection contact Mary Cieslicki at 410–786–4576).

Dated: September 9, 2015.

William N. Parham, III,

Director, Paperwork Reduction Staff, Office of Strategic Operations and Regulatory Affairs.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Administration for Children and Families

Submission for OMB Review; Comment Request

Title: Child Care Quarterly Case Record Report—ACF–801.

OMB No.: 0970–0167.

Description: Section 658K of the Child Care and Development Block Grant (CCDBG) Act (42 U.S.C. 9858, as amended by Pub. L. 113–186) requires that States and Territories submit monthly case-level data on the children and families receiving direct services under the Child Care and Development Fund (CCDF). The implementing regulations for the statutorily required reporting are at 45 CFR 98.70 and 98.71. Case-level reports, submitted quarterly or monthly (at grantee option), include monthly sample or full population case-level data. The data elements to be included in these reports are represented in the ACF–801. ACF uses disaggregate data to determine program and participant characteristics as well as costs and levels of child care services provided. This provides ACF with the information necessary to make reports to Congress, address national child care needs, offer technical assistance to grantees, meet performance measures, and conduct research.

Consistent with the recent reauthorization of the CCDBG statute, ACF requests extension of the ACF–801 including a number of changes and clarifications to the reporting requirements and instructions as set forth below.

- *Homeless Status:* Section 658K(a)(1)(B)(xi) of the CCDBG Act now requires States to report whether children receiving assistance under this subchapter are homeless children. Specifically, this data element will be required with the reporting period beginning October 2015.
- *Child Disability:* ACF proposes to add a new data element effective October 2016 indicating whether or not each child receiving services is a child with a disability, in part to track State implementation of priority for services requirements at section 658E(c)(3)(B) of the CCDBG Act (which includes children with special needs as defined by the State).
- *Military Status:* ACF proposes to add a new data element effective October 2016 to the ACF–801 to determine the family's status related to military service.
- *Family Zip Code and Provider Zip Code:* ACF proposes to add zip codes effective October 2016 to both the family and the provider records to identify the communities where CCDF families and providers are located, in part to support implementation of sections 658E(a)(2)(M) and 658E(a)(2)(Q) of the CCDBG Act that require States to address the supply and access to high-quality child care services for certain areas and populations.
- *Quality of Child Care Providers:* The existing ACF–801 allows States several ways of reporting information on the quality of each child's provider(s)—including: Quality Rating and Improvement System (QRIS) participation and rating, accreditation status, State pre-K standards, and other State-defined quality measure. To date, States have been required to report on at least one of the quality elements for a portion of the provider population. ACF is proposing that, effective with the October 2017 report, States must report quality information for every child care provider. States with a QRIS, at a minimum, would be required to report QRIS participation and rating for every provider. States without QRIS would be required to report quality information for every provider using one or more of the quality elements on the form. ACF is proposing to add a new option to indicate whether or not the provider is subject to Head Start or Early Head Start standards.
- *Inspection Date:* Section 658E(c)(2)(J) of the reauthorized CCDBG Act requires States to monitor both licensed and license-exempt CCDF providers. ACF proposes to add a data element effective October 2017 indicating, for each child care provider delivering services to a CCDF child, the date of the most recent inspection for compliance with health, safety, and fire standards (including licensing standards for licensed providers).
- *Personally Identifiable Information:* Section 658K(a)(1)(E) of the CCDBG Act now prohibits the ACF–801 report from containing personally identifiable information. As a result, ACF proposes to delete Social Security Numbers (SSNs) from the report. Specifically, this change will be required with the reporting period beginning October 2015. Note that the form will still require a unique identifying number, other than the SSN, that is assigned by the State for each family.
- *Language:* ACF proposes to add a data element effective October 2016 indicating, the primary language spoken in the home consistent with a Head Start Program Information Report question, *i.e.,* Primary Language of Family at Home.

Respondents: States, the District of Columbia, and Territories including Puerto Rico, Guam, the Virgin Islands, American Samoa, and the Northern Marianna Islands.

ANNUAL BURDEN ESTIMATES

Instrument	Number of respondents	Number of responses per respondent	Average burden hours per response	Total burden hours
ACF–801	56	4	25	5,600

Estimated Total Annual Burden Hours: 5,600.

Additional Information: Copies of the proposed collection may be obtained by writing to the Administration for Children and Families, Office of Planning, Research and Evaluation, 370 L'Enfant Promenade SW., Washington, DC 20447, Attn: ACF Reports Clearance Officer. All requests should be identified by the title of the information collection. Email address: *infocollection@acf.hhs.gov.*

OMB Comment: OMB is required to make a decision concerning the collection of information between 30 and 60 days after publication of this document in the **Federal Register.** Therefore, a comment is best assured of having its full effect if OMB receives it within 30 days of publication. Written comments and recommendations for the proposed information collection should be sent directly to the following: Office of Management and Budget, Paperwork Reduction Project, Email: *OIRA_SUBMISSION@OMB.EOP.GOV.* Attn: Desk Officer for the Administration for Children and Families.

BILLING CODE 4184–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Administration for Children and Families

Submission for OMB Review; Comment Request

Title: Study of Early Head Start-Child Care Partnerships.

OMB No.: New Collection.

Description: The Administration for Children and Families (ACF) in the Department of Health and Human Services (HHS) has awarded 275 Early Head Start expansion and Early Head Start-child care partnership grants in 50 states; Washington, DC; Puerto Rico; and the Northern Mariana Islands. These grants will allow new or existing Early Head Start programs to partner with local child care centers and family child care providers to expand high-quality early learning opportunities for infants and toddlers from low-income families.

ACF is proposing to conduct a descriptive study of the new partnership grantees to document the characteristics and features of partnerships and the activities that aim to improve professional development and quality of services and better meet the needs of families. The study will focus on the grantees that have received funds for Early Head Start-child care partnership grants.

The proposed data collection for the descriptive Study of Early Head Start-Child Care Partnerships will include two components: (1) Surveys of 311 partnership grantee and delegate agency directors and a randomly selected sample of 933 child care partners, and (2) in-depth follow-up case studies of 12 purposively selected partnerships.

The goal of this work is to collect descriptive information about partnership grantees and delegate agencies, child care partners, and services and quality improvement activities implemented as part of the partnerships and explore how particular partnership models operate. These data will be used to describe the national landscape of partnerships, fill a knowledge gap about partnership models implemented in the field, lay the groundwork for future research, and provide information to inform technical assistance and actions aimed at informing the Early Head Start-child care partnerships grant initiative.

Respondents: Partnership grantee and delegate agency directors; child care partner managers/owners; partnership staff who focus on coordinating activities among partners, monitoring compliance with the Head Start Program Performance Standards, and providing technical assistance and training; frontline staff; parents; and other state and local stakeholders (such as staff from child care resource and referral agencies or child care subsidy administrators).

ANNUAL BURDEN ESTIMATES

Instrument	Total number of respondents	Annual number of respondents	Number of responses per respondent	Average burden hours per response	Annual burden hours
1. Partnership grantee and delegate agency director survey	311	156	1	1	156
2. Child care partner survey	933	467	1	0.50	234
3. Interview topic guide:					
Partnership grantee and delegate agency directors	12	6	1	1.5	9
Partnership staff	36	18	1	1	18
State and local stakeholders	48	24	1	1	24
4. Parent focus group guide	96	48	1	1.5	72
5. Child care center director focus group guide	96	48	1	1.5	72
6. Child care center teacher focus group guide	96	48	1	1.5	72
7. Family child care provider focus group guide	48	24	1	1.5	36
8. Partnership grantee and delegate agency director questionnaire	12	6	1	2	12
9. Child care partner questionnaire	180	90	1	0.33	30

Estimated Total Annual Burden Hours: 735.

Additional Information: Copies of the proposed collection may be obtained by writing to the Administration for Children and Families, Office of Planning, Research and Evaluation, 370 L'Enfant Promenade SW., Washington, DC 20447, Attn: OPRE Reports Clearance Officer. All requests should be identified by the title of the information collection. Email address: *OPREinfocollection@acf.hhs.gov.*

OMB Comment: OMB is required to make a decision concerning the collection of information between 30 and 60 days after publication of this document in the **Federal Register**. Therefore, a comment is best assured of having its full effect if OMB receives it within 30 days of publication. Written comments and recommendations for the proposed information collection should be sent directly to the following: Office of Management and Budget, Paperwork Reduction Project, *Email: OIRA_SUBMISSION@OMB.EOP.GOV, Attn:* Desk Officer for the Administration for Children and Families.

BILLING CODE 4184–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Administration for Children and Families

[CFDA Number: 93.612]

Announcement of the Award of a Single Source Emergency Grant to the Oglala Sioux Tribe in Pine Ridge, SD

AGENCY: Administration for Native Americans, ACF, HHS.

ACTION: Announcement of the award of a single source, emergency grant to the Oglala Sioux Tribe in Pine Ridge, SD to address the critically high levels of youth suicide on the reservation since December 2014.

SUMMARY: The Administration for Children and Families (ACF), Administration for Native Americans (ANA) announces the award of a single source emergency grant in the amount of $400,000 to the Oglala Sioux Tribe to provide empowerment activities for youth in order to address the critically high levels of youth suicide on the reservation since December 2014.

DATES: The timeframe for the initial award is July 31, 2015 to July 30, 2016.

FOR FURTHER INFORMATION CONTACT: Carmelia Strickland, Director, Division of Program Operations, Administration for Native Americans, 370 L'Enfant Promenade SW., Washington, DC 20047. Telephone: 877–922–9262; Email: *Carmelia.strickland@acf.hhs.gov.*

SUPPLEMENTARY INFORMATION: The Administration for Native Americans (ANA), Administration for Children and Families, has awarded an emergency single source grant to the Oglala Sioux Tribe (OST) for programs whose goal is to empower youth ages 8 to 24 to make changes in their communities, to be proud of their heritage, and to inspire them to celebrate life so that they may see that there is a positive future for them. It is intended that this program will have a 24-month project period so that another 12-month budget period will be funded noncompetitively for $400,000 in FY 2016. In testimony before the Senate Committee on Indian Affairs on June 24, 2015, Oglala Sioux Tribe President John Yellowbird Steele's testimony stated that 11 young people on the Pine Ridge Reservation have been lost to suicide since December. In addition, at least another 176 of the youth have attempted suicide in that period, according to the Indian Health Service, and 229 more were treated for suicidal ideation.

The awarded project is designed to increase positive youth empowerment activities in all nine districts on the Pine Ridge Indian Reservation through the development of Student Youth Councils, peer to peer mentoring, and Lakota cultural awareness activities. The award was made under ANA's program for Social and Economic Development Strategies (SEDS). The OST has been designated as a Federal government Promise Zone, because of the severe financial and economic status in the area in which they live. The Pine Ridge Reservation is also located in Shannon County, which is often referred to as the poorest county in the United States.

Statutory Authority: This program is authorized under § 803(a) of the Native American Programs Act of 1974 (NAPA), 42 U.S.C. 2991b.

Christopher Beach,

Senior Grants Policy Specialist, Division of Grants Policy, Office of Administration.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Administration for Community Living

Delegation of Authority

Notice is hereby given that I have delegated to the Administrator of the Administration for Community Living, or his or her successor, the following authorities vested in the Secretary:

- The authorities vested under 42 U.S.C. 300d–52 and 300d–53, as amended by Sections 3 and 4 of the Traumatic Brain Injury Reauthorization Act of 2014 (P.L. 113–196), titled "State Grants for Projects Regarding Traumatic Brain Injury" and "State Grants for Protection and Advocacy Services."

(Prior to the passage of the Traumatic Brain Injury Reauthorization Act of 2014, exercise of these authorities was vested by statute with the Administrator, Health Resources and Services Administration.)

These authorities may be redelegated.

This delegation excludes the authority to issue regulations, to establish advisory committees and councils, and appoint their members, and to submit reports to Congress, and shall be exercised in accordance with the Department's applicable policies, procedures, and guidelines.

This delegation will concurrently supersede all existing delegations of these authorities.

I hereby affirm and ratify any actions taken by agency officials which involved the exercise of the authorities delegated herein prior to the effective date of this delegation.

This delegation is effective October 1, 2015.

Dated: August 31, 2015.

Sylvia M. Burwell,

Secretary.

BILLING CODE 4154–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

[Docket No. FDA–2015–N–0007]

Fee for Using a Tropical Disease Priority Review Voucher in Fiscal Year 2016

AGENCY: Food and Drug Administration, HHS.

ACTION: Notice.

SUMMARY: The Food and Drug Administration (FDA or the Agency) is announcing the fee rates for using a

tropical disease priority review voucher for fiscal year (FY) 2016. The Federal Food, Drug, and Cosmetic Act (the FD&C Act), as amended by the Food and Drug Administration Amendments Act of 2007 (FDAAA), authorizes FDA to determine and collect priority review user fees for certain applications for approval of drug or biological products when those applications use a tropical disease priority review voucher awarded by the Secretary of Health and Human Services. These vouchers are awarded to the sponsors of certain tropical disease product applications, submitted after September 27, 2007, upon FDA approval of such applications. The amount of the fee submitted to FDA with applications using a tropical disease priority review voucher is determined each fiscal year based on the difference between the average cost incurred by FDA in the review of a human drug application subject to priority review in the previous fiscal year, and the average cost incurred in the review of an application that is not subject to priority review in the previous fiscal year. This notice establishes the tropical disease priority review fee rate for FY 2016.

FOR FURTHER INFORMATION CONTACT: Robert J. Marcarelli, Office of Financial Management, Food and Drug Administration, 8455 Colesville Rd., COLE–14202F, Silver Spring, MD, 20993–0002, 301–796–7223.

SUPPLEMENTARY INFORMATION:

I. Background

Section 1102 of FDAAA (Pub. L. 110–85) added section 524 to the FD&C Act (21 U.S.C. 360n). In section 524, Congress encouraged development of new drug and biological products for prevention and treatment of certain tropical diseases by offering additional incentives for obtaining FDA approval of such products. Under section 524, the sponsor of an eligible human drug application submitted after September 27, 2007, for a qualified tropical disease (as defined in section 524(a)(3) of the FD&C Act), shall receive a priority review voucher upon approval of the tropical disease product application. The recipient of a tropical disease priority review voucher may either use the voucher with a future submission to FDA under section 505(b)(1) of the FD&C Act (21 U.S.C. 355(b)(1)) or section 351 of the Public Health Service Act (42 U.S.C. 262), or transfer (including by sale) the voucher to another party that may then use it. A priority review is a review conducted with a Prescription Drug User Fee Act (PDUFA) goal date of 6 months after the receipt or filing date, depending upon the type of application. Information regarding the PDUFA goals is available at: *http://www.fda.gov/downloads/forindustry/userfees/prescriptiondruguserfee/ucm270412.pdf.*

The applicant that uses a priority review voucher is entitled to a priority review but must pay FDA a priority review user fee in addition to any other fee required by PDUFA. FDA published a draft guidance on its Web site about how this tropical disease priority review voucher program operates (available at: *http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/ucm080599.pdf).*

This notice establishes the tropical disease priority review fee rate for FY 2016 as $2,727,000 and outlines FDA's process for implementing the collection of the priority review user fees. This rate is effective on October 1, 2015, and will remain in effect through September 30, 2016, for applications submitted with a tropical disease priority review voucher. The payment of this priority review user fee is required in addition to the payment of any other fee that would normally apply to such an application under PDUFA before FDA will consider the application complete and acceptable for filing.

II. Tropical Disease Priority Review User Fee for FY 2016

Under section 524(c)(2) of the FD&C Act, the amount of the tropical disease priority review user fee is determined each fiscal year based on the difference between the average cost incurred by FDA in the review of a human drug application subject to priority review in the previous fiscal year, and the average cost incurred by FDA in the review of a human drug application that is not subject to priority review in the previous fiscal year. The priority review voucher fee is intended to cover the incremental costs for FDA to do a priority review on a product that would otherwise get a standard review. The formula provides the Agency with the added resources to conduct a priority review while still ensuring a robust priority review voucher program that is consistent with the Agency's public health goal of encouraging the development of new drug and biological products.

A priority review is a review conducted with a PDUFA goal date of 6 months after the receipt or filing date, depending on the type of application. Under the PDUFA goals letter, FDA has committed to reviewing and acting on 90 percent of the applications granted priority review status within this expedited timeframe. Normally, an application for a human drug or biological product will qualify for priority review if the product is intended to treat a serious condition and, if approved, would provide a significant improvement in safety or effectiveness. An application that does not receive a priority designation will receive a standard review. Under the PDUFA goals letter, FDA committed to reviewing and acting on 90 percent of standard applications within 10 months of the receipt or filing date, depending on the type of application. A priority review involves a more intensive level of effort and a higher level of resources than a standard review.

Section 524 of the FD&C Act specifies that the fee amount should be based on the difference between the average cost incurred by the Agency in the review of a human drug application subject to a priority review in the previous fiscal year, and the average cost incurred by FDA in the review of a human drug application that is not subject to priority review in the previous fiscal year. FDA is setting fees for FY 2016, and the previous fiscal year is FY 2015. However, the FY 2015 submission cohort has not been closed out yet, and the cost data for FY 2015 are not complete. The latest year for which FDA has complete cost data is FY 2014. Furthermore, because FDA has never tracked the cost of reviewing applications that get priority review as a separate cost subset, FDA estimated this cost based on other data that the Agency has tracked. FDA uses data that the Agency estimates and publishes on its Web site each year—standard costs for review. FDA does not publish a standard cost for "the review of a human drug application subject to priority review in the previous fiscal year." However, we expect all such applications would contain clinical data. The standard cost application categories with clinical data that FDA does publish each year are: (1) New drug applications (NDAs) for a new molecular entity (NME) with clinical data and (2) biologics license applications (BLAs).

The worksheets for standard costs for FY 2014, show a standard cost (rounded to the nearest thousand dollars) of $5,646,000 for a NME NDA and $5,533,000 for a BLA. Based on these standard costs, the total cost to review the 48 applications in these two categories in FY 2014 (30 NME NDAs with clinical data and 18 BLAs) was $268,974,000. (Note: these numbers exclude the President's Emergency Plan for AIDS Relief NDAs; no

investigational new drug review costs are included in this amount.) Twenty-nine of these applications (20 NDAs and 9 BLAs) received priority review, which would mean that the remaining 19 received standard reviews. Because a priority review compresses a review that ordinarily takes 10 months into 6 months, FDA estimates that a multiplier of 1.67 (10 months divided by 6 months) should be applied to non-priority review costs in estimating the effort and cost of a priority review as compared to a standard review. This multiplier is consistent with published research on this subject. In the article "Developing Drugs for Developing Countries," published in "Health Affairs," Volume 25, Number 2, in 2006, the comparison of historical average review times by David B. Ridley, Henry G. Grabowski, and Jeffrey L. Moe, supports a priority review multiplier in the range of 1.48 to 2.35. The multiplier derived by FDA falls well below the midpoint of this range. Using FY 2014 figures, the costs of a priority and standard review are estimated using the following formula:

$(29\ \alpha \times 1.67) + (19\ \alpha) = \$268{,}974{,}000$

where "α" is the cost of a standard review and "$\alpha \times 1.67$" is the cost of a priority review. Using this formula, the cost of a standard review for NME NDAs and BLAs is calculated to be $3,989,000 (rounded to the nearest thousand dollars) and the cost of a priority review for NME NDAs and BLAs is 1.67 times that amount, or $6,662,000 (rounded to the nearest thousand dollars). The difference between these two cost estimates, or $2,673,000, represents the incremental cost of conducting a priority review rather than a standard review.

For the FY 2016 fee, FDA will need to adjust the FY 2014 incremental cost by the average amount by which FDA's average costs increased in the 3 years prior to FY 2015, to adjust the FY 2014 amount for cost increases in FY 2015. That adjustment, published in the **Federal Register** on August 3, 2015 (see 80 FR 46028 at 46029), setting FY 2016 PDUFA fees, is 2.0266 percent for the most recent year, not compounded. Increasing the FY 2014 incremental priority review cost of $2,673,000 by 2.0266 percent results in an estimated cost of $2,727,000 (rounded to the nearest thousand dollars). This is the priority review user fee amount for FY 2016 that must be submitted with a priority review voucher in FY 2016, in addition to any PDUFA fee that is required for such an application.

III. Fee Schedule for FY 2016

The fee rate for FY 2016 is set out in table 1:

TABLE 1—TROPICAL DISEASE PRIORITY REVIEW SCHEDULE FOR FY 2016

Fee category	Fee rate for FY 2016
Application submitted with a tropical disease priority review voucher in addition to the normal PDUFA fee	$2,727,000

IV. Implementation of Tropical Disease Priority Review User Fee

Under section 524(c)(4)(A) of the FD&C Act, the priority review user fee is due upon submission of a human drug application for which the priority review voucher is used. Section 524(c)(4)(B) of the FD&C Act specifies that the application will be considered incomplete if the priority review user fee and all other applicable user fees are not paid in accordance with FDA payment procedures. In addition, FDA may not grant a waiver, exemption, reduction, or refund of any fees due and payable under this section of the FD&C Act and FDA may not collect priority review voucher fees prior to a relevant appropriation for fees for that fiscal year. Beginning with FDA's appropriation for FY 2009, the annual appropriation language states specifically that "priority review user fees authorized by 21 U.S.C. 360n (section 524 of the FD&C Act) may be credited to this account, to remain available until expended." (Pub. L. 111–8, Section 5, Division A, Title VI).

The tropical disease priority review fee established in the new fee schedule must be paid for any application that is received on or after October 1, 2015, and submitted with a priority review voucher. This fee must be paid in addition to any other fee due under PDUFA. Payment must be made in U.S. currency by check, bank draft, or U.S. postal money order payable to the order of the Food and Drug Administration. The user fee identification (ID) number should be included on the check, followed by the words "Tropical Disease Priority Review." Payments can be mailed to: Food and Drug Administration, P.O. Box 979107, St. Louis, MO 63197–9000.

If checks are sent by a courier that requests a street address, the courier can deliver the checks to: U.S. Bank, Attention: Government Lockbox 979107, 1005 Convention Plaza, St. Louis, MO 63101. (Note: This U.S. Bank address is for courier delivery only.) The FDA post office box number (P.O. Box 979107) must be written on the check. The tax identification number of FDA is 53–0196965.

Wire transfer payments may also be used. Please reference your unique user fee ID number when completing your transfer. The originating financial institution may charge a wire transfer fee. Please ask your financial institution about the fee and include it with your payment to ensure that your fee is fully paid. The account information is as follows: New York Federal Reserve Bank, U.S. Dept. of Treasury, TREAS NYC, 33 Liberty St., New York, NY 10045, Account Number: 75060099, Routing Number: 021030004, SWIFT: FRNYUS33, Beneficiary: FDA, 8455 Colesville Rd., Silver Spring, MD 20993–0002.

Dated: September 8, 2015.

Leslie Kux,

Associate Commissioner for Policy.

BILLING CODE 4164–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

[Docket No. FDA–2015–N–0001]

Anesthetic and Analgesic Drug Products Advisory Committee; Notice of Meeting

AGENCY: Food and Drug Administration, HHS.

ACTION: Notice.

This notice announces a forthcoming meeting of a public advisory committee of the Food and Drug Administration (FDA). The meeting will be open to the public.

Name of Committee: Anesthetic and Analgesic Drug Products Advisory Committee.

General Function of the Committee: To provide advice and recommendations to the Agency on FDA's regulatory issues.

Date and Time: The meeting will be held on November 6, 2015, from 8 a.m. to 5 p.m.

Location: FDA White Oak Campus, 10903 New Hampshire Ave., Bldg. 31 Conference Center, the Great Room (Rm. 1503), Silver Spring, MD 20993–0002. Answers to commonly asked questions including information regarding special accommodations due to a disability, visitor parking, and transportation may be accessed at: *http://www.fda.gov/AdvisoryCommittees/*

AboutAdvisoryCommittees/ucm408555.htm.

Contact Person: Stephanie L. Begansky, Center for Drug Evaluation and Research, Food and Drug Administration, 10903 New Hampshire Ave., Bldg. 31, Rm. 2417, Silver Spring, MD 20993–0002, 301–796–9001, FAX: 301–847–8533, *AADPAC@fda.hhs.gov,* or FDA Advisory Committee Information Line, 1–800–741–8138 (301–443–0572 in the Washington, DC area). A notice in the **Federal Register** about last minute modifications that impact a previously announced advisory committee meeting cannot always be published quickly enough to provide timely notice. Therefore, you should always check the Agency's Web site at *http://www.fda.gov/AdvisoryCommittees/default.htm* and scroll down to the appropriate advisory committee meeting link, or call the advisory committee information line to learn about possible modifications before coming to the meeting.

Agenda: The committee will discuss new drug application (NDA) 022225, sugammadex sodium injection, submitted by Organon USA Inc., a subsidiary of Merck & Co., Inc., for the proposed indication of reversal of moderate or deep neuromuscular blockade (NMB) induced by rocuronium or vecuronium.

FDA intends to make background material available to the public no later than 2 business days before the meeting. If FDA is unable to post the background material on its Web site prior to the meeting, the background material will be made publicly available at the location of the advisory committee meeting, and the background material will be posted on FDA's Web site after the meeting. Background material is available at *http://www.fda.gov/AdvisoryCommittees/Calendar/default.htm.* Scroll down to the appropriate advisory committee meeting link.

Procedure: Interested persons may present data, information, or views, orally or in writing, on issues pending before the committee. Written submissions may be made to the contact person on or before October 23, 2015. Oral presentations from the public will be scheduled between approximately 1 p.m. and 2 p.m. Those individuals interested in making formal oral presentations should notify the contact person and submit a brief statement of the general nature of the evidence or arguments they wish to present, the names and addresses of proposed participants, and an indication of the approximate time requested to make their presentation on or before October 15, 2015. Time allotted for each presentation may be limited. If the number of registrants requesting to speak is greater than can be reasonably accommodated during the scheduled open public hearing session, FDA may conduct a lottery to determine the speakers for the scheduled open public hearing session. The contact person will notify interested persons regarding their request to speak by October 16, 2015.

Persons attending FDA's advisory committee meetings are advised that the Agency is not responsible for providing access to electrical outlets.

FDA welcomes the attendance of the public at its advisory committee meetings and will make every effort to accommodate persons with disabilities. If you require accommodations due to a disability, please contact Stephanie L. Begansky at least 7 days in advance of the meeting.

FDA is committed to the orderly conduct of its advisory committee meetings. Please visit our Web site at *http://www.fda.gov/AdvisoryCommittees/AboutAdvisoryCommittees/ucm111462.htm* for procedures on public conduct during advisory committee meetings.

Notice of this meeting is given under the Federal Advisory Committee Act (5 U.S.C. app. 2).

Dated: September 8, 2015.

Jill Hartzler Warner,

Associate Commissioner for Special Medical Programs.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

[Docket No. FDA–2013–D–1600]

Enforcement Policy for Certain (Provisional) Tobacco Products That the Food and Drug Administration Finds Not Substantially Equivalent; Guidance for Industry and Tobacco Retailers; Availability

AGENCY: Food and Drug Administration, HHS.

ACTION: Notice.

SUMMARY: The Food and Drug Administration (FDA) is announcing the availability of a guidance for industry entitled "Enforcement Policy for Certain (Provisional) Tobacco Products that FDA Finds Not Substantially Equivalent." This guidance provides information to tobacco retailers on FDA's enforcement policy regarding certain so-called provisional tobacco products that become subject to not substantially equivalent (NSE) orders issued under the Federal Food, Drug, and Cosmetic Act (the FD&C Act).

DATES: Submit either electronic or written comments on Agency guidances at any time.

ADDRESSES: Submit written requests for single copies of this guidance to the Center for Tobacco Products, Food and Drug Administration, Document Control Center, 10903 New Hampshire Ave., Bldg. 71, Rm. G335, Silver Spring, MD 20993–2000. Send one self-addressed adhesive label to assist that office in processing your request or include a fax number to which the guidance document may be sent. See the **SUPPLEMENTARY INFORMATION** section for information on electronic access to the guidance.

Submit electronic comments on the guidance to *http://www.regulations.gov.* Submit written comments to the Division of Dockets Management (HFA–305), Food and Drug Administration, 5630 Fishers Lane, Rm. 1061, Rockville, MD 20852. Identify comments with the docket number found in brackets in the heading of this document.

FOR FURTHER INFORMATION CONTACT: Annette Marthaler, Center for Tobacco Products, Food and Drug Administration, Document Control Center, 10903 New Hampshire Ave., Bldg. 71, Rm. G335, Silver Spring, MD 20993–2000, email: *CTPRegulations@fda.hhs.gov.*

SUPPLEMENTARY INFORMATION:

I. Background

FDA is announcing the availability of a guidance for industry entitled "Enforcement Policy for Certain (Provisional) Tobacco Products that FDA Finds Not Substantially Equivalent." This guidance provides information to tobacco retailers on FDA's enforcement policy regarding certain so-called provisional tobacco products that become subject to NSE orders issued under the FD&C Act. We received several comments to the draft guidance (79 FR 10534, February 25, 2014), and those comments were considered as the guidance was finalized.

II. Significance of Guidance

This guidance is being issued consistent with FDA's good guidance practices regulation (21 CFR 10.115). The guidance represents the current thinking of FDA on "Enforcement Policy for Certain (Provisional) Tobacco Products that FDA Finds Not Substantially Equivalent." It does not

establish any rights for any person and is not binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the applicable statutes and regulations.

III. Comments

A. General Information About Submitting Comments

Interested persons may submit either electronic comments regarding this document to *http://www.regulations.gov* or written comments to the Division of Dockets Management (see **ADDRESSES**). It is only necessary to send one set of comments. Identify comments with the docket number found in brackets in the heading of this document.

B. Public Availability of Comments

Received comments may be seen in the Division of Dockets Management between 9 a.m. and 4 p.m., Monday through Friday, and will be posted to the docket at *http://www.regulations.gov*. As a matter of Agency practice, FDA generally does not post comments submitted by individuals in their individual capacity on *http://www.regulations.gov*. This is determined by information indicating that the submission is written by an individual, for example, the comment is identified with the category "Individual Consumer" under the field titled "Category (Required)," on the "Your Information" page on *www.regulations.gov*. For this docket, however, FDA will not be following this general practice. Instead, FDA will post on *http://www.regulations.gov* comments to this docket that have been submitted by individuals in their individual capacity. If you wish to submit any information under a claim of confidentiality, please refer to 21 CFR 10.20.

C. Information Identifying the Person Submitting the Comment

Please note that your name, contact information, and other information identifying you will be posted on *http://www.regulations.gov* if you include that information in the body of your comments. For electronic comments submitted to *http://www.regulations.gov*, FDA will post the body of your comment on *http://www.regulations.gov* along with your State/province and country (if provided), the name of your representative (if any), and the category identifying you (*e.g.*, individual, consumer, academic, industry). For written submissions submitted to the Division of Dockets Management, FDA will post the body of your comments on *http://www.regulations.gov*, but you can put your name and/or contact information on a separate cover sheet and not in the body of your comments.

IV. Electronic Access

Persons with access to the Internet may obtain an electronic version of the guidance at either *http://www.regulations.gov* or *http://www.fda.gov/TobaccoProducts/GuidanceComplianceRegulatoryInformation/default.htm*.

Dated: September 9, 2015.

Leslie Kux,

Associate Commissioner for Policy.

BILLING CODE 4164–01–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

[Docket No. FDA–2014–N–1206]

Authorization of Emergency Use of an In Vitro Diagnostic Device for Detection of Ebola Zaire Virus; Availability

AGENCY: Food and Drug Administration, HHS.

ACTION: Notice.

SUMMARY: The Food and Drug Administration (FDA) is announcing the issuance of an Emergency Use Authorization (EUA) (the Authorization) for an in vitro diagnostic device for detection of the Ebola Zaire virus in response to the Ebola virus outbreak in West Africa. FDA issued this Authorization under the Federal Food, Drug, and Cosmetic Act (the FD&C Act), as requested by OraSure Technologies, Inc. The Authorization contains, among other things, conditions on the emergency use of the authorized in vitro diagnostic device. The Authorization follows the September 22, 2006, determination by then-Secretary of the Department of Homeland Security (DHS), Michael Chertoff, that the Ebola virus presents a material threat against the U.S. population sufficient to affect national security. On the basis of such determination, the Secretary of Health and Human Services (HHS) declared on August 5, 2014, that circumstances exist justifying the authorization of emergency use of in vitro diagnostic devices for detection of Ebola virus subject to the terms of any authorization issued under the FD&C Act. The Authorization, which includes an explanation of the reasons for issuance, is reprinted in this document.

DATES: The Authorization is effective as of July 31, 2015.

ADDRESSES: Submit written requests for single copies of the EUA to the Office of Counterterrorism and Emerging Threats, Food and Drug Administration, 10903 New Hampshire Ave., Bldg. 1, Rm. 4338, Silver Spring, MD 20993–0002. Send one self-addressed adhesive label to assist that office in processing your request or include a fax number to which the Authorization may be sent. See the **SUPPLEMENTARY INFORMATION** section for electronic access to the Authorization.

FOR FURTHER INFORMATION CONTACT: Carmen Maher, Acting Assistant Commissioner for Counterterrorism Policy and Acting Director, Office of Counterterrorism and Emerging Threats, Food and Drug Administration, 10903 New Hampshire Ave., Bldg. 1, Rm. 4347, Silver Spring, MD 20993–0002, 301–796–8510 (this is not a toll free number).

SUPPLEMENTARY INFORMATION:

I. Background

Section 564 of the FD&C Act (21 U.S.C. 360bbb–3) as amended by the Project BioShield Act of 2004 (Pub. L. 108–276) and the Pandemic and All-Hazards Preparedness Reauthorization Act of 2013 (Pub. L. 113–5) allows FDA to strengthen the public health protections against biological, chemical, nuclear, and radiological agents. Among other things, section 564 of the FD&C Act allows FDA to authorize the use of an unapproved medical product or an unapproved use of an approved medical product in certain situations. With this EUA authority, FDA can help assure that medical countermeasures may be used in emergencies to diagnose, treat, or prevent serious or life-threatening diseases or conditions caused by biological, chemical, nuclear, or radiological agents when there are no adequate, approved, and available alternatives.

Section 564(b)(1) of the FD&C Act provides that, before an EUA may be issued, the Secretary of HHS must declare that circumstances exist justifying the authorization based on one of the following grounds: (1) A determination by the Secretary of Homeland Security that there is a domestic emergency, or a significant potential for a domestic emergency, involving a heightened risk of attack with a biological, chemical, radiological, or nuclear agent or agents; (2) a determination by the Secretary of Defense that there is a military emergency, or a significant potential for a military emergency, involving a

heightened risk to U.S. military forces of attack with a biological, chemical, radiological, or nuclear agent or agents; (3) a determination by the Secretary of HHS that there is a public health emergency, or a significant potential for a public health emergency, that affects, or has a significant potential to affect, national security or the health and security of U.S. citizens living abroad, and that involves a biological, chemical, radiological, or nuclear agent or agents, or a disease or condition that may be attributable to such agent or agents; or (4) the identification of a material threat by the Secretary of Homeland Security under section 319F–2 of the Public Health Service (PHS) Act (42 U.S.C. 247d–6b) sufficient to affect national security or the health and security of U.S. citizens living abroad.

Once the Secretary of HHS has declared that circumstances exist justifying an authorization under section 564 of the FD&C Act, FDA may authorize the emergency use of a drug, device, or biological product if the Agency concludes that the statutory criteria are satisfied. Under section 564(h)(1) of the FD&C Act, FDA is required to publish in the **Federal Register** a notice of each authorization, and each termination or revocation of an authorization, and an explanation of the reasons for the action. Section 564 of the FD&C Act permits FDA to authorize the introduction into interstate commerce of a drug, device, or biological product intended for use when the Secretary of HHS has declared that circumstances exist justifying the authorization of emergency use. Products appropriate for emergency use may include products and uses that are not approved, cleared, or licensed under sections 505, 510(k), or 515 of the FD&C Act (21 U.S.C. 355, 360(k), and 360e) or section 351 of the PHS Act (42 U.S.C. 262). FDA may issue an EUA only if, after consultation with the HHS Assistant Secretary for Preparedness and Response, the Director of the National Institutes of Health, and the Director of the Centers for Disease Control and Prevention (to the extent feasible and appropriate given the applicable circumstances), FDA [1] concludes: (1) That an agent referred to in a declaration of emergency or threat can cause a serious or life-threatening disease or condition; (2) that, based on the totality of scientific evidence available to FDA, including data from adequate and well-controlled clinical trials, if available, it is reasonable to believe that: (A) The product may be effective in diagnosing, treating, or preventing (i) such disease or condition; or (ii) a serious or life-threatening disease or condition caused by a product authorized under section 564, approved or cleared under the FD&C Act, or licensed under section 351 of the PHS Act, for diagnosing, treating, or preventing such a disease or condition caused by such an agent; and (B) the known and potential benefits of the product, when used to diagnose, prevent, or treat such disease or condition, outweigh the known and potential risks of the product, taking into consideration the material threat posed by the agent or agents identified in a declaration under section 564(b)(1)(D) of the FD&C Act, if applicable; (3) that there is no adequate, approved, and available alternative to the product for diagnosing, preventing, or treating such disease or condition; and (4) that such other criteria as may be prescribed by regulation are satisfied.

No other criteria for issuance have been prescribed by regulation under section 564(c)(4) of the FD&C Act. Because the statute is self-executing, regulations or guidance are not required for FDA to implement the EUA authority.

II. EUA Request for an In Vitro Diagnostic Device for Detection of the Ebola Zaire Virus

On September 22, 2006, then-Secretary of DHS, Michael Chertoff, determined that the Ebola virus presents a material threat against the U.S. population sufficient to affect national security.[2] On August 5, 2014, under section 564(b)(1) of the FD&C Act, and on the basis of such determination, the Secretary of HHS declared that circumstances exist justifying the authorization of emergency use of in vitro diagnostics for detection of Ebola virus, subject to the terms of any authorization issued under section 564 of the FD&C Act. Notice of the declaration of the Secretary was published in the **Federal Register** on August 12, 2014 (79 FR 47141). On July 20, 2015, OraSure Technologies, Inc. requested, and on July 31, 2015, FDA issued, an EUA for the OraQuick® Ebola Rapid Antigen Test, subject to the terms of the Authorization.

III. Electronic Access

An electronic version of this document and the full text of the Authorization are available on the Internet at *http://www.regulations.gov.*

IV. The Authorization

Having concluded that the criteria for issuance of the Authorization under section 564(c) of the FD&C Act are met, FDA has authorized the emergency use of an in vitro diagnostic device for detection of the Ebola Zaire virus (detected in the West Africa outbreak in 2014) subject to the terms of the Authorization. The Authorization in its entirety (not including the authorized versions of the fact sheets and other written materials) follows and provides an explanation of the reasons for its issuance, as required by section 564(h)(1) of the FD&C Act:

BILLING CODE 4164–01–P

[1] The Secretary of HHS has delegated the authority to issue an EUA under section 564 of the FD&C Act to the Commissioner of Food and Drugs.

[2] Under section 564(b)(1) of the FD&C Act, the HHS Secretary's declaration that supports EUA issuance must be based on one of four determinations, including the identification by the DHS Secretary of a material threat under section 319F–2 of the PHS Act sufficient to affect national security or the health and security of U.S. citizens living abroad (section 564(b)(1)(D) of the FD&C Act).

DEPARTMENT OF HEALTH & HUMAN SERVICES

Food and Drug Administration
Silver Spring, MD 20993

July 31, 2015

Tiffany Miller
Director, Regulatory Affairs
OraSure Technologies, Inc.
220 East First Street
Bethlehem, PA 18015

Dear Ms. Miller:

This letter is in response to your request that the Food and Drug Administration (FDA) issue an Emergency Use Authorization (EUA) for emergency use of the OraQuick® Ebola Rapid Antigen Test[1] for the presumptive detection of Ebola Zaire virus (detected in the West Africa outbreak in 2014)[2] in venipuncture whole blood or fingerstick whole blood specimens from individuals with signs and symptoms of Ebola virus infection in conjunction with epidemiological risk factors (including geographic locations with high prevalence of Ebola infection), by laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics), pursuant to section 564 of the Federal Food, Drug, and Cosmetic Act (the Act) (21 U.S.C. § 360bbb-3). The OraQuick® Ebola Rapid Antigen Test is intended for circumstances when the use of a rapid Ebola virus test is determined to be more appropriate than the use of an authorized Ebola virus nucleic acid test, which has been demonstrated to be more sensitive in detecting the Ebola Zaire virus. The OraQuick® Ebola Rapid Antigen Test is not intended for use for general Ebola virus infection screening, such as airport screening or contact tracing of individuals without signs and symptoms of Ebola infection.

On September 22, 2006, then-Secretary of the Department of Homeland Security (DHS), Michael Chertoff, determined, pursuant to section 319F-2 of the Public Health Service (PHS) Act (42 U.S.C. § 247d-6b), that the Ebola virus presents a material threat against the United States population sufficient to affect national security.[3] Pursuant to section 564(b)(1) of the Act (21 U.S.C. § 360bbb-3(b)(1)), and on the basis of such determination, the Secretary of the

[1] For purposes of this authorization, the term "OraQuick® Ebola Rapid Antigen Test" includes, in addition to the OraQuick® Ebola Rapid Antigen Test Kit, the OraQuick® Ebola Rapid Antigen Test Kit Controls (quality control reagents intended for use only with the OraQuick® Ebola Rapid Antigen Test) and the OraQuick® Ebola Visual Reference Panel (intended to assist new operators in becoming proficient at reading specimens with antigen levels near the limit of detection of the device). While the OraQuick® Ebola Rapid Antigen Test Kit Controls and OraQuick® Ebola Visual Reference Panel are both sold separately, under this authorization they must be used in conjunction with the OraQuick® Ebola Rapid Antigen Test Kit.

[2] This assay is intended for the qualitative detection of antigens from Zaire Ebola virus (detected in the West Africa outbreak in 2014), but may also detect antigens from Sudan Ebola virus and Bundibugyo Ebola virus; however, it does not distinguish between these different Ebola virus species.

[3] Pursuant to section 564(b)(1) of the Act (21 U.S.C. § 360bbb-3(b)(1)), the HHS Secretary's declaration that supports EUA issuance must be based on one of four determinations, including the identification by the DHS Secretary of a material threat pursuant to section 319F-2 of the PHS Act sufficient to affect national security or the health and security of United States citizens living abroad (section 564(b)(1)(D) of the Act).

Department of Health and Human Services (HHS) declared on August 5, 2014, that circumstances exist justifying the authorization of emergency use of *in vitro* diagnostics for detection of Ebola virus, subject to the terms of any authorization issued under section 564(a) of the Act (21 U.S.C. § 360bbb-3(a)).[4]

Having concluded that the criteria for issuance of this authorization under section 564(c) of the Act (21 U.S.C. § 360bbb-3(c)) are met, I am authorizing the emergency use of the OraQuick® Ebola Rapid Antigen Test (as described in the Scope of Authorization section of this letter (section II)) in individuals with signs and symptoms of Ebola virus infection in conjunction with epidemiological risk factors (including geographic locations with high prevalence of Ebola infection) (as described in the Scope of Authorization section of this letter (section II)) for the presumptive detection of Ebola Zaire virus (detected in the West Africa outbreak in 2014).

I. Criteria for Issuance of Authorization

I have concluded that the emergency use of the OraQuick® Ebola Rapid Antigen Test for the presumptive detection of Ebola Zaire virus (detected in the West Africa outbreak in 2014) in the specified population meets the criteria for issuance of an authorization under section 564(c) of the Act, because I have concluded that:

1. The Ebola Zaire virus (detected in the West Africa outbreak in 2014) can cause Ebola virus disease, a serious or life-threatening disease or condition to humans infected with this virus;

2. Based on the totality of scientific evidence available to FDA, it is reasonable to believe that the OraQuick® Ebola Rapid Antigen Test may be effective in diagnosing Ebola Zaire virus (detected in the West Africa outbreak in 2014) infection, and that the known and potential benefits of the OraQuick® Ebola Rapid Antigen Test for diagnosing Ebola Zaire virus (detected in the West Africa outbreak in 2014) infection, outweigh the known and potential risks of such product; and

3. There is no adequate, approved, and available alternative to the emergency use of the OraQuick® Ebola Rapid Antigen Test for diagnosing Ebola Zaire virus (detected in the West Africa outbreak in 2014) infection.[5]

II. Scope of Authorization

I have concluded, pursuant to section 564(d)(1) of the Act, that the scope of this authorization is limited to the use of the authorized OraQuick® Ebola Rapid Antigen Test by laboratories and facilities adequately equipped, trained, and capable of such testing (including treatment centers and public health clinics) for the presumptive detection of Ebola Zaire virus (detected in the

[4] U.S. Department of Health and Human Services. *Declaration Regarding Emergency Use of In Vitro Diagnostics for Detection of Ebola Virus.* 79 Fed. Reg. 47141 (August 12, 2014).

[5] No other criteria of issuance have been prescribed by regulation under section 564(c)(4) of the Act.

West Africa outbreak in 2014) in individuals with signs and symptoms of Ebola virus infection in conjunction with epidemiological risk factors (including geographic locations with high prevalence of Ebola infection). The authorized OraQuick® Ebola Rapid Antigen Test is intended for circumstances when use of a rapid Ebola virus test is determined to be more appropriate than use of an authorized Ebola virus nucleic acid test, which has been demonstrated to be more sensitive in detecting the Ebola Zaire virus. The authorized OraQuick® Ebola Rapid Antigen Test is not intended for use for general Ebola infection screening, such as airport screening or contact tracing of individuals without signs and symptoms of Ebola infection.

The Authorized OraQuick® Ebola Rapid Antigen Test
