The OraQuick® Ebola Rapid Antigen Test is a rapid single-use chromatographic lateral flow immunoassay contained within a rigid plastic device housing that is intended for the *in vitro* qualitative detection of antigens from the Ebola Zaire virus (detected in the West Africa outbreak 2014) in venipuncture whole blood, fingerstick whole blood, and other authorized specimen types from individuals with signs and symptoms of Ebola virus infection in conjunction with epidemiological risk factors (including geographic locations with high prevalence of Ebola infection). The OraQuick® Ebola Rapid Antigen Test is a point-of-care test.

The OraQuick® Ebola Rapid Antigen Test utilizes a sandwich capture lateral flow immunoassay method to detect Ebola virus antigens. This lateral flow test is composed of an assay strip with several components: the flat pad, the blocker pad, the conjugate pad, the nitrocellulose membrane (with a Test Line ("T") and a Control ("C") line), and the absorbent pad. The clinical specimen is applied to the device followed by insertion of the device into the developer solution. The execution of the assay occurs as reagents are hydrated and liquid is transported along with the specimen across the strip towards the test zone.

If Ebola viral antigens are present in the patient sample they will be bound by biotinylated anti-Ebola polyclonal antibodies eluting from the blocker pad. These complexed Ebola antigens will then form immunological sandwiches with signal generating colloidal gold labeled Ebola antibodies that are eluting from the conjugate pad. The immunological sandwich complex is subsequently captured through reaction of the biotinylated anti-Ebola antibody with the biotin binding protein streptavidin that is immobilized at the Test Line ("T") of the test strip.

The OraQuick® Ebola Rapid Antigen Test Kit is comprised of an OraQuick® Ebola Rapid Antigen Test device, a filled, capped and labeled Developer Vial, a device stand (used to hold the device during the running of the test following specimen collection), micropipettes, a quick reference guide and the package insert. The test kit has a built-in procedural control that demonstrates assay validity. A purple line in the Control ("C") area of the Result Window indicates that the fluid migrated appropriately through the Test Device. The Control line will appear on all valid tests, whether or not the sample is positive (i.e., reactive) or negative (i.e., non-reactive).

The OraQuick® Ebola Rapid Antigen Test Kit Controls must be used with the OraQuick® Ebola Rapid Antigen Test. The OraQuick® Ebola Rapid Antigen Test Kit Controls contain two vials,

one Ebola positive control vial (orange capped) and one Ebola negative control vial (white capped).

The OraQuick® Ebola Visual Reference Panel is intended to assist new operators in becoming proficient at reading specimens with antigen levels near the limit of detection of the device. It consists of three devices that have been specifically formulated and manufactured to represent positive results near the limit of detection, low positive, and negative test results. New operators must be able to correctly interpret all devices of the OraQuick® Ebola Visual Reference Panel prior to using the OraQuick® Ebola Rapid Antigen Test device with patient samples.

The above described OraQuick® Ebola Rapid Antigen Test, when labeled consistently with the labeling authorized by FDA entitled "OraQuick® Ebola Rapid Antigen Test Instructions for Use" (available at http://www.fda.gov/MedicalDevices/Safety/EmergencySituations/ucm161496.htm), which may be revised by OraSure Technologies, Inc. in consultation with FDA, is authorized to be distributed to laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics), despite the fact that it does not meet certain requirements otherwise required by federal law.

The above described OraQuick® Ebola Rapid Antigen Test is authorized to be accompanied by the following information pertaining to the emergency use, which is authorized to be made available to health care professionals and patients:

- Fact Sheet for Health Care Providers: Interpreting OraQuick® Ebola Rapid Antigen Test Results
- Fact Sheet for Patients: Understanding Results from the OraQuick® Ebola Rapid Antigen Test

As described in section IV below, OraSure Technologies, Inc. and any authorized distributor(s) are also authorized to make available additional information relating to the emergency use of the authorized OraQuick® Ebola Rapid Antigen Test that is consistent with, and does not exceed, the terms of this letter of authorization.

I have concluded, pursuant to section 564(d)(2) of the Act, that it is reasonable to believe that the known and potential benefits of the authorized OraQuick® Ebola Rapid Antigen Test in the specified population, when used for presumptive detection of Ebola Zaire virus (detected in the West Africa outbreak in 2014), outweigh the known and potential risks of such a product.

I have concluded, pursuant to section 564(d)(3) of the Act, based on the totality of scientific evidence available to FDA, that it is reasonable to believe that the authorized OraQuick® Ebola Rapid Antigen Test may be effective in the diagnosis of Ebola Zaire virus (detected in the West Africa outbreak in 2014) infection pursuant to section 564(c)(2)(A) of the Act. FDA has reviewed the scientific information available to FDA including the information supporting the conclusions described in section I above, and concludes that the authorized OraQuick® Ebola Rapid Antigen Test, when used to diagnose Ebola Zaire virus (detected in the West Africa

outbreak in 2014) infection in the specified population, meets the criteria set forth in section 564(c) of the Act concerning safety and potential effectiveness.

The emergency use of the authorized OraQuick® Ebola Rapid Antigen Test under this EUA must be consistent with, and may not exceed, the terms of this letter, including the Scope of Authorization (section II) and the Conditions of Authorization (section IV). Subject to the terms of this EUA and under the circumstances set forth in the Secretary of DHS's determination described above and the Secretary of HHS's corresponding declaration under section 564(b)(1), the OraQuick® Ebola Rapid Antigen Test described above is authorized to diagnose Ebola Zaire virus (detected in the West Africa outbreak in 2014) infection in individuals with signs and symptoms of Ebola virus infection in conjunction with epidemiological risk factors (including geographic locations with high prevalence of Ebola infection).

This EUA will cease to be effective when the HHS declaration that circumstances exist to justify the EUA is terminated under section 564(b)(2) of the Act or when the EUA is revoked under section 564(g) of the Act.

III. Waiver of Certain Requirements

I am waiving the following requirements for the OraQuick® Ebola Rapid Antigen Test during the duration of this EUA:

- Current good manufacturing practice requirements, including the quality system requirements under 21 CFR Part 820 with respect to the design, manufacture, packaging, labeling, storage, and distribution of the OraQuick® Ebola Rapid Antigen Test.

- Labeling requirements for cleared, approved, or investigational devices, including labeling requirements under 21 CFR 809.10 and 21 CFR 809.30, except for the intended use statement (21 CFR 809.10(a)(2), (b)(2)), adequate directions for use (21 U.S.C. 352(f)), (21 CFR 809.10(b)(5), (7), and (8)), any appropriate limitations on the use of the device including information required under 21 CFR 809.10(a)(4), and any available information regarding performance of the device, including requirements under 21 CFR 809.10(b)(12).

IV. Conditions of Authorization

Pursuant to section 564 of the Act, I am establishing the following conditions on this authorization:

OraSure Technologies, Inc. and Any Authorized Distributor(s)

A. OraSure Technologies, Inc. and any authorized distributor(s) will distribute the authorized OraQuick® Ebola Rapid Antigen Test with the authorized labeling, as may be revised by OraSure Technologies, Inc. in consultation with FDA, to laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics).

B. OraSure Technologies, Inc. and any authorized distributor(s) will provide to laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics), the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Health Care Providers and the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Patients.

C. OraSure Technologies, Inc. and any authorized distributor(s) will make available on their websites the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Health Care Providers and the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Patients.

D. OraSure Technologies, Inc. and any authorized distributor(s) will inform laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) and relevant public health authority(ies) of this EUA, including the terms and conditions herein.

E. OraSure Technologies, Inc. and any authorized distributor(s) will ensure that first time users of the OraQuick® Ebola Rapid Antigen Test Kit will be informed about the requirement for use of the control material and the visual reference panel.

F. OraSure Technologies, Inc. and any authorized distributor(s) will ensure that laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) using the authorized OraQuick® Ebola Rapid Antigen Test have a process in place for reporting test results to health care professionals and relevant public health authorities, as appropriate.

G. Through a process of inventory control, OraSure Technologies, Inc. and any authorized distributor(s) will maintain records of device usage.

H. OraSure Technologies, Inc. and any authorized distributor(s) will collect information on the performance of the assay, and report to FDA any suspected occurrence of false positive or false negative results of which OraSure Technologies, Inc. and any authorized distributor(s) become aware.

I. OraSure Technologies, Inc. and any authorized distributor(s) are authorized to make available additional information relating to the emergency use of the authorized OraQuick® Ebola Rapid Antigen Test that is consistent with, and does not exceed, the terms of this letter of authorization.

OraSure Technologies, Inc.

J. OraSure Technologies, Inc. will notify FDA of any authorized distributor(s) of the OraQuick® Ebola Rapid Antigen Test, including the name, address, and phone number of any authorized distributor(s).

K. OraSure Technologies, Inc. will provide any authorized distributor(s) with a copy of this EUA, and communicate to any authorized distributor(s) any subsequent amendments that might be made to this EUA and its authorized accompanying materials (e.g., fact sheets, instructions for use).

L. OraSure Technologies, Inc. only may request changes to the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Health Care Providers or the authorized OraQuick® Ebola Rapid Antigen Test Fact Sheet for Patients. Such requests will be made only by OraSure Technologies, Inc. in consultation with FDA.

M. OraSure Technologies, Inc. may request the addition of other specimen types for use with the authorized OraQuick® Ebola Rapid Antigen Test. Such requests will be made by OraSure Technologies, Inc. in consultation with, and require concurrence of, FDA.

N. OraSure Technologies, Inc. will track adverse events and report to FDA under 21 CFR Part 803.

Laboratories and Facilities Adequately Equipped, Trained, and Capable of Testing for Ebola Infection (Including Treatment Centers and Public Health Clinics)

O. Laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) will include with reports of the results of the OraQuick® Ebola Rapid Antigen Test the authorized Fact Sheet for Health Care Providers and the authorized Fact Sheet for Patients. Under exigent circumstances, other appropriate methods for disseminating these Fact Sheets may be used, which may include mass media.

P. Laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) will have a process in place for reporting test results to health care professionals and relevant public health authorities, as appropriate.

Q. Laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) will collect information on the performance of the assay, and report to OraSure Technologies, Inc. and any authorized distributor(s) any suspected occurrence of false positive or false negative results of which they become aware.

R. All personnel from laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) using the assay will be appropriately trained on the OraQuick® Ebola Rapid Antigen Test and use appropriate laboratory and personal protective equipment when handling this kit.

OraSure Technologies, Inc., Any Authorized Distributor(s), and Laboratories and Facilities Adequately Equipped, Trained, and Capable of Testing for Ebola Infection (Including Treatment Centers and Public Health Clinics)

S. OraSure Technologies, Inc., any authorized distributor(s), and laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics) will ensure that any records associated with this EUA are maintained until notified by FDA. Such records will be made available to FDA for inspection upon request.

Conditions Related to Advertising and Promotion

T. All advertising and promotional descriptive printed matter relating to the use of the authorized OraQuick® Ebola Rapid Antigen Test shall be consistent with the Fact Sheets and authorized labeling, as well as the terms set forth in this EUA and the applicable requirements set forth in the Act and FDA regulations.

U. All advertising and promotional descriptive printed matter relating to the use of the authorized OraQuick® Ebola Rapid Antigen Test shall clearly and conspicuously state that:

- This test has not been FDA cleared or approved;
- This test has been authorized by FDA under an EUA for use by laboratories and facilities adequately equipped, trained, and capable of testing for Ebola infection (including treatment centers and public health clinics);
- This test has been authorized only for the detection of Ebola Zaire virus (detected in the West Africa outbreak in 2014); and
- This test is authorized only for the duration of the declaration that circumstances exist justifying the authorization of the emergency use of *in vitro* diagnostics for detection of Ebola virus under section 564(b)(1) of the Act, 21 U.S.C. § 360bbb-3(b)(1), unless the authorization is terminated or revoked sooner.

No advertising or promotional descriptive printed matter relating to the use of the authorized OraQuick® Ebola Rapid Antigen Test may represent or suggest that this test is safe or effective for the diagnosis of Ebola Zaire virus (detected in the West Africa outbreak in 2014).

The emergency use of the authorized OraQuick® Ebola Rapid Antigen Test described in this letter of authorization must comply with the conditions and all other terms of this authorization.

V. Duration of Authorization

This EUA will be effective until the declaration that circumstances exist justifying the authorization of the emergency use of *in vitro* diagnostics for detection of Ebola virus is terminated under section 564(b)(2) of the Act or the EUA is revoked under section 564(g) of the Act.

Sincerely,

Stephen M. Ostroff, M.D.
Acting Commissioner of Food and Drugs

Enclosures

Dated: September 8, 2015.

Leslie Kux,

Associate Commissioner for Policy.

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Health Resources and Services Administration

Administration for Children and Families

Agency Information Collection Activities: Submission to OMB for Review and Approval; Public Comment Request

AGENCY: Health Resources and Services Administration, HHS. Administration for Children and Families, HHS.

ACTION: Notice.

SUMMARY: In compliance with Section 3507(a)(1)(D) of the Paperwork Reduction Act of 1995, the Health Resources and Services Administration (HRSA) and the Administration for Children and Families (ACF) has submitted an Information Collection Request (ICR) to the Office of Management and Budget (OMB) for review and approval. Comments submitted during the first public review of this ICR will be provided to OMB. OMB will accept further comments from the public during the review and approval period.

DATES: Comments on this ICR should be received no later than October 14, 2015.

ADDRESSES: Submit your comments, including the Information Collection Request Title, to the desk officer for HRSA, either by email to *OIRA_submission@omb.eop.gov* or by fax to 202–395–5806.

FOR FURTHER INFORMATION CONTACT: To request a copy of the clearance requests submitted to OMB for review, email the HRSA Information Collection Clearance Officer at *paperwork@hrsa.gov* or call (301) 594–4306.

SUPPLEMENTARY INFORMATION:

Information Collection Request Title: The Maternal, Infant, and Early Childhood Home Visiting Program Quarterly Data Request.

OMB No. 0906–xxxx—NEW.

Abstract: The Maternal, Infant, and Early Childhood Home Visiting Program (MIECHV), administered by HRSA in close partnership with the Administration for Children and Families (ACF), supports voluntary, evidence-based home visiting services during pregnancy and to parents with young children up to kindergarten entry. States, Territories, nonprofit organizations (in some circumstances), and Tribal entities are eligible to receive funding from the MIECHV Program and have the flexibility to tailor the program to serve the specific needs of the communities that they serve.

Need and Proposed Use of the Information: In order to continuously monitor and provide oversight, quality improvement guidance, and technical assistance to MIECHV grantees, HHS is seeking to collect two categories of information: Service Utilization Data and Corrective Action Benchmark Data. This information will be used to monitor and provide continued oversight for grantee performance and to target technical assistance resources to grantees.

Service Utilization Data is made up of four data categories:

(1) *Program Capacity:* HHS is seeking to collect information related to the overall home visiting service capacity (*i.e.,* number of families) that grantees are able to provide to the communities they work in, the actual capacity being utilized at certain points in time, as well as updates of home visiting enrollment in number of families.

(2) *Place-Based Services:* HHS is seeking to collect information to identify the geographic areas where home visiting services are being provided. Specifically, data on zip code and locally defined communities are being requested from MIECHV grantees in order to allow grantees an opportunity to provide data that identifies geographic areas that are most salient to their respective programs. Currently, HHS collects information related to service area zip code on an annual basis (OMB–0915–0357, expiration 7/31/2017). HHS plans to allow the grantee to describe the service community at the neighborhood, town, or city level where services are provided based on their judgment of local salience, rather than solely at the county level, which is how geographic services are currently reported.

(3) *Family Engagement:* Currently HHS collects information related to family engagement (attrition) on an annual basis (OMB–0915–0357, expiration 7/31/2017). However, HHS has learned through grants monitoring and technical assistance efforts that family engagement is an ongoing and complex issue for home visiting service providers. In order to monitor grantee performance and target technical assistance efforts most effectively, HHS proposes that, in addition to annual reporting, MIECHV grantees will report quarterly on the existing family engagement metrics they are currently required to submit to HHS. These metrics are currently defined as the number of participants currently receiving services who have completed the program, who stopped services before completion, and other participants.

(4) *Staff Recruitment and Retention:* HHS is seeking to collect information related to the number of home visitors and other support staff who are currently employed directly or through sub-contracted grant funds. Staff recruitment and retention is a key component to the successful delivery of home visiting services and to maximizing the number of cases each local implementing agency can reach. MIEHCV grantees will report quarterly on the actual number of staff and current vacancies in three categories: home visitors, home visiting supervisors, and other staff.

Corrective Action Benchmark Data (Improvement Action Benchmark Data): *Corrective Action Constructs consist of one category of data.* MIECHV grantees that have not shown improvement in four of six Benchmark areas identified in the authorizing legislation after 3 years of grant funding are required to complete corrective action plans (Improvement Action Technical Assistance Plans), subject to approval by the Secretary, in order to show how they plan to achieve improvement in deficient areas. Currently HHS collects information related to selected Benchmark areas from all MIECHV grantees on an annual basis (OMB–0915–0357, expiration 7/31/2017). In order to monitor grantee improvement toward meeting these Benchmarks, HHS is seeking to collect information from grantees on implementation of their Improvement Action Plans on a more frequent basis. HHS proposes that state, territory, and nonprofit organization grantees with Improvement Action Plans report the Benchmark measures for which they were deemed as not showing improvement on a quarterly basis. It is estimated that approximately 9 grantees per year will require this more frequent reporting. Tribal grantees that did not demonstrate improvement after 3 years will continue to develop program improvement plans as currently required.

Likely Respondents: MIECHV grantees.

Burden Statement: Burden in this context means the time expended by persons to generate, maintain, retain, disclose or provide the information requested. This includes the time needed to review instructions; to develop, acquire, install and utilize technology and systems for the purpose of collecting, validating and verifying information, processing and maintaining information, and disclosing and providing information; to train personnel and to be able to respond to

a collection of information; to search data sources; to complete and review the collection of information; and to transmit or otherwise disclose the information. The total annual burden hours estimated for this ICR are summarized in the table below.

TOTAL ESTIMATED ANNUALIZED BURDEN—HOURS

Form name	Number of respondents	Number of responses per respondent	Total responses	Average burden per response (in hours)	Total burden hours
Service Utilization Form—State, Territory, and Tribal MIECHV Grantees	[1] 125	4	500	24	12,000
Improvement Action Benchmark Form—State and Territory MIECHV Grantees	[2] 9	4	36	40	1,440
Total	125		536		13,440

[1] This figures includes two responses for jurisdictions which received both formula and competitive funding in FY 2015.
[2] Only includes MIECHV state, territory, and non-profit grantees that did not demonstrate improvement in 4 of 6 Benchmark areas after 3 years of grant funding.

Dated: September 2, 2015.

Jackie Painter,

Director, Division of the Executive Secretariat, Health Resources and Services Administration.

Robert Sargis,

Reports Clearance Officer, Administration for Children and Families.

BILLING CODE 4165–15–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Health Resources and Services Administration

Agency Information Collection Activities: Submission to OMB for Review and Approval; Public Comment Request

AGENCY: Health Resources and Services Administration, HHS.

ACTION: Notice.

SUMMARY: In compliance with Section 3507(a)(1)(D) of the Paperwork Reduction Act of 1995, the Health Resources and Services Administration (HRSA) has submitted an Information Collection Request (ICR) to the Office of Management and Budget (OMB) for review and approval. Comments submitted during the first public review of this ICR will be provided to OMB. OMB will accept further comments from the public during the review and approval period.

DATES: Comments on this ICR should be received no later than October 14, 2015.

ADDRESSES: Submit your comments, including the Information Collection Request Title, to the desk officer for HRSA, either by email to *OIRA_submission@omb.eop.gov* or by fax to 202–395–5806.

FOR FURTHER INFORMATION CONTACT: To request a copy of the clearance requests submitted to OMB for review, email the HRSA Information Collection Clearance Officer at *paperwork@hrsa.gov* or call (301) 594–4306.

SUPPLEMENTARY INFORMATION: Information Collection Request Title: Maternal, Infant, and Childhood Home Visiting (Home Visiting) Program for Non-Competing Continuation Progress Report OMB No. 0915–0356—Extension

A 30-day notice was previously published on July 22, 2015 for this information collection request but it contained incorrect burden figures.

Abstract: The Maternal, Infant, and Early Childhood Home Visiting (MIECHV) Program, administered by the Health Resources and Services Administration (HRSA) in close partnership with the Administration for Children and Families (ACF), supports voluntary, evidence-based home visiting services during pregnancy and to parents with young children up to kindergarten entry. Competitive grants support the efforts of eligible entities that have already made significant progress towards establishing a high quality home visiting program or embedding their home visiting program into a comprehensive, high-quality early childhood system. All fifty states, the District of Columbia, five territories, and nonprofit organizations that would provide services in jurisdictions that have not directly applied for or been approved for a grant are eligible for competitive grants and if awarded, are required to submit non-competing continuation progress reports annually. There are currently 48 entities with competitive grant awards. Some eligible entities have been awarded more than one competitive grant.

Need and Proposed Use of the Information: This information collection is needed for eligible entities to report progress under the Home Visiting Program annually. On March 23, 2010, the President signed into law the Patient Protection and Affordable Care Act (ACA). Section 2951 of the ACA amended Title V of the Social Security Act by adding a new section, 511, which authorized the creation of the Home Visiting Program (*http://frwebgate.access.gpo.gov/cgi-bin/getdoc.cgi?dbname=111_cong_bills&docid=f:h3590enr.txt.pdf*, pages 216–2250). A portion of funding under this program is awarded to participating states and eligible jurisdictions competitively. The purpose of the competitive funding is to provide additional support to entities that have already made significant progress towards establishing a high-quality home visiting program and also want to implement innovative home visiting strategies in their states and jurisdictions.

The information collected will be used to review grantee progress on proposed project plans sufficient to permit project officers to assess whether the project is performing adequately to achieve the goals and objectives that were previously approved. This report will also provide implementation plans for the upcoming year, which project officers can assess to determine whether the plan is consistent with the grant as approved, and will result in implementation of a high-quality project that will complement the home visiting program as a whole. Progress Reports are submitted to project officers through the Electronic HandBooks (EHB). Failure to collect this information would result in the inability of the project officers to exercise due diligence in monitoring and overseeing the use of grant funds in keeping with legislative, policy, and programmatic requirements.

Grantees are required to provide a performance narrative with the following sections: Project identifier information, accomplishments and barriers, state home visiting program goals and objectives, an update on the state home visiting innovative approach and evaluations conducted under the competitive grant, implementation of the program in targeted at-risk communities, progress toward meeting legislatively-mandated reporting on benchmark areas, state home visiting quality improvement efforts, and updates on the administration of state home visiting innovation program.

Since federal fiscal year 2011, 48 eligible entities have received competitive grant awards. Grantees of the competitive grant program need to complete annual reports in order to comply with HRSA reporting requirements.

Likely Respondents: Grantees with Home Visiting Competitive Expansion Grants Awarded in Federal Fiscal Years 2011–2015

Burden Statement: Burden in this context means the time expended by persons to generate, maintain, retain, disclose or provide the information requested. This includes the time needed to review instructions; to develop, acquire, install and utilize technology and systems for the purpose of collecting, validating and verifying information, processing and maintaining information, and disclosing and providing information; to train personnel and to be able to respond to a collection of information; to search data sources; to complete and review the collection of information; and to transmit or otherwise disclose the information. The total annual burden hours estimated for this ICR are summarized in the table below.

TOTAL ESTIMATED ANNUALIZED BURDEN—HOURS

Summary progress on the following activities	Number of respondents	Number of responses per respondent	Total responses	Hours per response	Total burden hours
Home Visiting Competitive Grant Progress Report—FY 2012, FY 2013, FY 2014	37	1	37	25	925
Home Visiting Competitive Grant Progress Report—FY 2015	35	1	35	20	700
Home Visiting Competitive Grant Progress Report—FY 2016	56	1	56	20	1,120
Home Visiting Competitive Grant Progress Report—FY 2017	56	1	56	20	1,120
Total	184	4	184		3,865

BILLING CODE 4165–15–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Office of the Secretary

[Document Identifier: HHS–OS–0937–0166–30D]

Agency Information Collection Activities; Submission to OMB for Review and Approval; Public Comment Request

AGENCY: Office of the Secretary, HHS.

ACTION: Notice.

SUMMARY: In compliance with section 3507(a)(1)(D) of the Paperwork Reduction Act of 1995, the Office of the Secretary (OS), Department of Health and Human Services, has submitted an Information Collection Request (ICR), described below, to the Office of Management and Budget (OMB) for review and approval. The ICR is for renewal of the approved information collection assigned OMB control number 0937–0166, scheduled to expire on October 31, 2015. Comments submitted during the first public review of this ICR will be provided to OMB. OMB will accept further comments from the public on this ICR during the review and approval period.

DATES: Comments on the ICR must be received on or before October 14, 2015.

ADDRESSES: Submit your comments to *OIRA_submission@omb.eop.gov* or via facsimile to (202) 395–5806.

FOR FURTHER INFORMATION CONTACT: Information Collection Clearance staff, *Information.CollectionClearance@hhs.gov* or (202) 690–6162.

SUPPLEMENTARY INFORMATION: When submitting comments or requesting information, please include the OMB control number 0937–0166 and document identifier.

Information Collection Request Title: HHS 42 CFR part 50, subpart B; Sterilization of Persons in Federally Assisted Family Planning Projects—OMB No. 0937–0166–Extension–OASH, Office of Population Affairs—Office of Family Planning.

Abstract: This is a request for extension of a currently approved collection for the disclosure and record-keeping requirements codified at 42 CFR part 50, subpart B ("Sterilization of Persons in Federally Assisted Family Planning Projects"). The consent form solicits information to assure voluntary and informed consent to persons undergoing sterilization in programs of health services which are supported by federal financial assistance administered by the Public Health Service (PHS). Consent forms are signed by individuals undergoing a federally funded sterilization procedure and certified by necessary medical authorities. Forms are incorporated into the patient's medical records and the agency's records. Through periodic site audits and visits, PHS staff review completed consent forms to determine compliance with the regulation. Thus, the purpose of the consent form is twofold. First, it serves as a mechanism to ensure that a person receives information about sterilization and voluntarily consents to the procedure. Second, it facilitates compliance monitoring. The Sterilization Consent Form has been revised to reflect a new expiration date on the Required Consent Form. There are no other revisions to the form.

Likely Respondents: Interested persons who desire to send comments regarding this burden estimate or any other aspect of this collection of information that OS specifically requests comments.

TOTAL ESTIMATED ANNUALIZED BURDEN—HOURS

Type of respondent	Information collection	Number of respondents	Number of responses per respondent	Average burden per response	Total hours
Citizens Seeking Sterilization	Information Disclosure for *Sterilization Consent Form.*	100,000	1	1	100,000
Citizens Seeking Sterilization	Record-keeping for *Sterilization Consent Form.*	100,000	1	15/60	25,000
Total					125,000

Darius Taylor,

Information Collection Clearance Officer.

BILLING CODE 4150–34–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

National Institutes of Health

Center for Scientific Review Notice of Closed Meetings

Pursuant to section 10(d) of the Federal Advisory Committee Act, as amended (5 U.S.C. App.), notice is hereby given of the following meetings.

The meetings will be closed to the public in accordance with the provisions set forth in sections 552b(c)(4) and 552b(c)(6), Title 5 U.S.C., as amended. The grant applications and the discussions could disclose confidential trade secrets or commercial property such as patentable material, and personal information concerning individuals associated with the grant applications, the disclosure of which would constitute a clearly unwarranted invasion of personal privacy.

Name of Committee: Center for Scientific Review Special Emphasis Panel; Psychosocial Risk and Disease Prevention.

Date: October 5, 2015.

Time: 2:00 p.m. to 2:30 p.m.

Agenda: To review and evaluate grant applications.

Place: Embassy Suites at the Chevy Chase Pavilion, 4300 Military Road NW., Washington, DC 20015.

Contact Person: John H. Newman, Scientific Review Officer, Center for Scientific Review, National Institutes of Health, 6701 Rockledge Drive, Room 3222, MSC 7808, Bethesda, MD 20892, (301) 435–0628, *newmanjh@csr.nih.gov.*

Name of Committee: Interdisciplinary Molecular Sciences and Training Integrated Review Group; Enabling Bioanalytical and Imaging Technologies Study Section; Enabling Bioanalytical and Imaging Technologies.

Date: October 8–9, 2015.

Time: 8:00 a.m. to 8:00 p.m.

Agenda: To review and evaluate grant applications.

Place: Bethesda North Marriott Hotel & Conference Center, 5701 Marinelli Road, Bethesda, MD 20852.

Contact Person: Kenneth Ryan, Ph.D., Scientific Review Officer, Center for Scientific Review, National Institutes of Health, 6701 Rockledge Drive, Room 3218, MSC 7717, Bethesda, MD 20892, 301–435–0229, *kenneth.ryan@nih.hhs.gov.*

Name of Committee: Oncology 1—Basic Translational Integrated Review Group; Cancer Etiology Study Section.

Date: October 8–9, 2015.

Time: 8:00 a.m. to 6:00 p.m.

Agenda: To review and evaluate grant applications.

Place: Marriott Courtyard Gaithersburg Washingtonian Ctr, 204 Boardwalk Place, Gaithersburg, MD 20878.

Contact Person: Svetlana Kotliarova, Ph.D., Scientific Review Officer, Center For Scientific Review, National Institutes of Health, 6701 Rockledge Drive, Room 6214, Bethesda, MD 20892, 301–594–7945, *kotliars@mail.nih.gov.*

Name of Committee: Center for Scientific Review Special Emphasis Panel; Musculoskeletal, Oral and Skin Sciences AREA review.

Date: October 14, 2015.

Time: 9:00 a.m. to 6:00 p.m.

Submission for OMB Review; 30-Day Comment Request: Population Sciences Biospecimen Catalog (PSBC)

SUMMARY: Under the provisions of Section 3507(a)(1)(D) of the Paperwork Reduction Act of 1995, the National Cancer Institute, the National Institutes of Health, has submitted to the Office of Management and Budget (OMB) a request for review and approval of the information collection listed below. This proposed information collection was previously published in the **Federal Register** on (June 30, 2015 P.37280) and allowed 60-days for public comment. No public comments were received. The purpose of this notice is to allow an additional 30 days for public comment. The National Cancer Institute (NCI), National Institutes of Health, may not conduct or sponsor, and the respondent is not required to respond to, an information collection that has been extended, revised, or implemented on or after October 1, 1995, unless it displays a currently valid OMB control number.

Direct Comments to OMB: Written comments and/or suggestions regarding the item(s) contained in this notice, especially regarding the estimated public burden and associated response time, should be directed to the: Office of Management and Budget, Office of Regulatory Affairs, *OIRA_submission@omb.eop.gov* or by fax to 202–395–6974, Attention: NIH Desk Officer.

Comment Due Date: Comments regarding this information collection are best assured of having their full effect if received within 30 days of the date of this publication.

FOR FURTHER INFORMATION CONTACT: To obtain a copy of the data collection plans and instruments, or request more information on the proposed project, contact: Danielle Carrick, Program Director, Division of Cancer Control and Population Sciences (DCCPS), National Cancer Institute, 9609 Medical Center Dr., Room 4E224, Rockville, MD 20850 or call non-toll-free number (240) 276–6749 or Email your request, including your address to: *Danielle.Carrick@nih.gov.* Formal requests for additional plans and instruments must be requested in writing.

Proposed Collection: Population Sciences Biospecimen Catalog (PSBC) (NCI), 0925—NEW, National Cancer Institute(NCI), National Institutes of Health (NIH).

Need and Use of Information Collection: This is a request for approval of a new collection. The National Cancer Institute (NCI) Division of Cancer Control and Population Sciences (DCCPS) has previously demonstrated that approximately 60% of population based studies funded by the division use existing biospecimens from other collections, and that those studies are more cost and time efficient than studies collecting new specimens. Yet, it is difficult for researchers to identify potentially appropriate sources for biospecimens and accompanying epidemiologic and exposure data. Development of a searchable inventory of population-based biospecimen resources was a major recommendation resulting from an NCI think tank held in August 2013 ("Utilizing Existing Clinical and Population Biospecimen Resources for Discovery or Validation of

Markers for Early Cancer Detection") and would also be directly addressing four of the key recommendations that emerged in an NCI sponsored workshop titled "Trends in 21st Century Epidemiology: From Scientific Discoveries to Population Health" (CEBP, 2013, issue 22, page 508). In response to this, NCI DCCPS is developing a biospecimen inventory and online searchable catalog (or "Population Sciences Biospecimen Catalog (PSBC)"). The PSBC allows scientists in the research community and the NCI to locate specimens appropriate for their population based research projects. It is not NCI's intent to collect biospecimens; rather the collections are descriptions of the available data that can act as a resource and be shared with researchers and scientists who are interested. This submission is via data upload to the secure Web site in order to collect information to manage and improve a program and its resources for the use by all scientists.

OMB approval is requested for 3 years. There are no costs to respondents other than their time. The total estimated annualized burden hours are 80.

ESTIMATED ANNUALIZED BURDEN HOURS

Form name	Type of respondent	Number of respondents	Number of responses per respondent	Average time per response (in hours)	Total annual burden hour
Population Sciences Biospecimen Catalog Initial Request.	Private Sector	30	1	1	30
	State Government	30	1	1	30
Population Sciences Biospecimen Catalog Annual Update.	Private Sector	30	1	20/60	10
	State Government	30	1	20/60	10

Dated: September 1, 2015.

Karla Bailey,

NCI Project Clearance Liaison, National Cancer Institute, NIH.

Submission for OMB Review; 30-Day Comment Request; Characterization of Risk of HIV and HIV Outcomes in the Brazilian Sickle Cell Disease (SCD) Population and Comparison of SCD Outcomes Between HIV Sero-Positive and Negative SCD (NHLBI)

SUMMARY: Under the provisions of Section 3507(a)(1)(D) of the Paperwork Reduction Act of 1995, the National Heart, Lung, and Blood Institute (NHLBI), the National Institutes of Health (NIH) has submitted to the Office of Management and Budget (OMB) a request for review and approval of the information collection listed below. This proposed information collection was previously published in the **Federal Register** on June 8, 2015 (80 FR 32388) and allowed 60-days for public comment. No public comments were received. The purpose of this notice is to allow an additional 30 days for public comment. The National Institutes of Health may not conduct or sponsor, and the respondent is not required to respond to, an information collection that has been extended, revised, or implemented on or after October 1, 1995, unless it displays a currently valid OMB control number.

Direct Comments to OMB: Written comments and/or suggestions regarding the item(s) contained in this notice, especially regarding the estimated public burden and associated response time, should be directed to the: Office of Management and Budget, Office of Regulatory Affairs, *OIRA_submission@omb.eop.gov* or by fax to 202–395–6974, Attention: Desk Officer for NIH.

DATES: *Comments Due Date:* Comments regarding this information collection are best assured of having their full effect if received within 30 days of the date of this publication.

FOR FURTHER INFORMATION CONTACT: To obtain a copy of the data collection plans and instruments or request more information on the proposed project contact: Simone Glynn, MD, Project Officer/ICD Contact, Two Rockledge Center, Suite 9142, 6701 Rockledge Drive, Bethesda, MD 20892, or call 301–435–0065, or Email your request, including your address to: *glynnsa@nhlbi.nih.gov.* Formal requests for additional plans and instruments must be requested in writing.

Proposed Collection: Characterization of risk of HIV and HIV outcomes in the Brazilian Sickle Cell Disease (SCD) population and comparison of SCD outcomes between HIV sero-positive and negative SCD patients 0925–NEW, National Heart, Lung, and Blood Institute (NHLBI), the National Institutes of Health (NIH).

Need and Use of Information Collection: The National Heart, Lung, and Blood Institute (NHLBI) Recipient Epidemiology and Donor Evaluation Study-III (REDS–III) program conducts research focused on the safety of the blood supply, the patients who are in need of transfusions, and the epidemiology of transfusion-transmissible infections such as human immunodeficiency virus (HIV). Sickle cell disease (SCD) is a blood disorder that affects thousands of people in the United States and Brazil. Many patients with SCD need to be chronically transfused with red blood cells and the REDS–III research program has established in Brazil a cohort of patients with SCD to study transfusion outcomes and infectious diseases such as HIV in the SCD population.

Sickle cell disease predominantly affects persons with sub-Saharan Africa and other malaria-endemic regions ancestry because people who carry one sickle cell disease gene (you need 2 to have sickle cell disease) have a survival advantage for malaria. Sub-Saharan Africa, where most people with SCD in the world live, remains one of the regions most severely affected by HIV, with nearly 1 in every 20 adults living with the virus. In the United States, HIV also disproportionately affects persons with African ancestry. Despite the diseases' occurrence in similar populations and the fact that both HIV and SCD are independent predictors of outcomes such as stroke, there is a lack of data to evaluate if patients with SCD and HIV have different illnesses than patients who have SCD- or HIV-only. The proposed study will seek to understand the risk of HIV in the SCD population, describe HIV outcomes in patients with SCD and compare SCD complications between HIV-positive

and HIV-negative patients with SCD using the infrastructure established by the REDS–III SCD Cohort study.

The limited studies focused on HIV in SCD have suggested that HIV may not occur as frequently in patients with SCD as in people who do not have SCD. While it has been hypothesized that perhaps SCD pathophysiology has a unique effect on HIV infection or replication, none of the studies have adequately measured risk factors for HIV in patients with SCD. The first objective of the proposed study is to compare HIV risk factors between 150 patients with SCD (cases) randomly selected from the REDS–III SCD Cohort study and 150 individuals without SCD (controls) from a demographically similar population. An assessment that has been well validated in previous studies has been modified for the SCD population and will be used to collect data regarding HIV risk behaviors. The second objective of the proposed study will seek to enroll approximately 25 patients with SCD and HIV who consent to have detailed information regarding their diseases retrieved from their medical records. This will allow for an in-depth evaluation of how patients with both diseases fare. Additionally, patients who have SCD but not HIV will be compared to patients who have both diseases to better understand how one disease affects the other disease. Information on the HIV-negative patients with SCD has already been collected because they participated in the REDS–III SCD Cohort study. This study will provide critical information to guide the management and future research for patients with HIV and SCD in Brazil, the United States, and worldwide.

OMB approval is requested for 3 years. There are no costs to respondents other than their time. The total estimated annualized burden hours are 325.

Form name	Type of respondents	Number of respondents	Number of responses per respondent	Average burden per response (in hours)	Total annual burden hours
Objective 1, Risk Factor Informed Consents.	Adult SCD cases and controls	300	1	15/60	75
Objective 2, Risk Factor Informed Consent.	Adult previously enrolled REDS–II and III HIV SCD patients.	25	1	15/60	6
Objectives 1 and 2, Risk Factor Assessment.	Adult SCD cases and controls, and Adult previously enrolled REDS–II and III HIV SCD patients.	325	1	45/60	244

Dated: September 8, 2015.

Valery Gheen,

NHLBI Project Clearance Liaison, National Institutes of Health.

Draft Restoration Plan and Programmatic Environmental Impact Statement for Restoration Resulting From the Kalamazoo River Natural Resource Damage Assessment

AGENCY: Fish and Wildlife Service, Interior.

ACTION: Notice of availability; request for comments.

SUMMARY: The U.S. Fish and Wildlife Service (USFWS), the National Oceanic and Atmospheric Administration (NOAA), the Michigan Department of

Environmental Quality, the Michigan Department of Natural Resources, and the Michigan Attorney General, collectively acting as Trustees for natural resources, announce the availability of the *Draft Restoration Plan and Programmatic Environmental Impact Statement for Restoration Resulting from the Kalamazoo River Natural Resource Damage Assessment.* Publication of this notice begins the public comment period for this Draft Restoration Plan and Programmatic Environmental Impact Statement (Draft RP/PEIS). The purpose of the Draft RP/PEIS is to present the Trustees' proposed approach to restoration to compensate the public for losses to natural resources resulting from the release of polychlorinated biphenyls (PCBs) and to evaluate, in compliance with the National Environmental Policy Act (NEPA), the potential direct, indirect, and cumulative impacts of implementing the alternative programmatic approaches to restoration in the Kalamazoo River watershed.

DATES: Written comments must be received by October 29, 2015.

ADDRESSES: *Submitting Comments:* Written comments for the Trustees to consider should be sent to Lisa Williams, U.S. Fish and Wildlife Service, East Lansing Field Office, 2651 Coolidge Road, East Lansing, MI 48823. Comments may also be submitted electronically to *kzoorivernrda@fws.gov,* with "Kalamazoo River RP/PEIS" in the subject line. For more information, see Public Comments under **SUPPLEMENTARY INFORMATION.**

Viewing the Administrative Record: Contact Judith Alfano, at (517) 373–7402 or *alfanoj@michigan.gov;* selected documents are also available at *http://www.fws.gov/midwest/es/ec/nrda/KalamazooRiver.*

Viewing EPA's Comments on the PEIS: For how to view comments on the PEIS from the Environmental Protection Agency (EPA), or for information on EPA's role in the EIS process, see EPA's Role in the EIS Process under **SUPPLEMENTARY INFORMATION.**

FOR FURTHER INFORMATION CONTACT: Lisa Williams, USFWS, by email at *lisa_williams@fws.gov* or by phone at (517) 351–8324, or Julie Sims, NOAA Restoration Center, by email at *julie.sims@noaa.gov* or by phone at (734) 741–2385.

SUPPLEMENTARY INFORMATION: The U.S. Fish and Wildlife Service (USFWS) and the National Oceanic and Atmospheric Administration (NOAA), the Michigan Department of Environmental Quality (MDEQ), the Michigan Department of Natural Resources, and the Michigan Attorney General, collectively acting as Trustees for natural resources, have prepared this Draft Restoration Plan and Programmatic Environmental Impact Statement (Draft RP/PEIS) for restoration in the Kalamazoo River watershed pursuant to both CERCLA NRDA regulations and the National Environmental Policy Act of 1969, as amended (42 U.S.C. 4321–4347 *et seq.;* NEPA), and its implementing regulations in the Code of Federal Regulations (CFR) at 40 CFR parts 1500–1508. NEPA requires Federal agencies to conduct environmental reviews of proposed actions to consider the potential impacts on the environment.

In the Draft RP/PEIS, the Trustees describe restoration projects that could compensate for injuries to natural resources from polychlorinated biphenyls (PCBs) released at and from the Allied Paper, Inc./Portage Creek/Kalamazoo River Superfund Site (Superfund Site). These include both general types of restoration projects as well as two specific projects to restore aquatic connectivity on the Kalamazoo River by removing dams in and near Otsego, Michigan. The public is invited to provide comments to the Trustees on the Draft RP/PEIS, including the proposed restoration projects and techniques, the programmatic restoration alternatives, and the potential impacts of the alternatives on the environment.

Industrial activities in the Kalamazoo area have released PCBs into the environment. Recycling of carbonless copy paper at several area paper mills was the primary source of PCB release. Waste from the recycling of such paper conducted at Kalamazoo-area paper mills also contained PCBs, and the waste was disposed of by several methods that resulted in releases of PCBs into the environment. These PCBs have contaminated sediments, the water column, and biota in and adjacent to downstream sections of Portage Creek, the Kalamazoo River, and Lake Michigan.

Based on the risks that PCBs pose to the environment and to human health, the U.S. Environmental Protection Agency (EPA) listed the Allied Paper, Inc./Portage Creek/Kalamazoo River Superfund Site on the National Priorities List on August 30, 1990. PCBs are listed as hazardous substances under CERCLA. EPA and MDEQ currently describe the site being addressed by the Superfund remedial investigation as including: (1) Five disposal areas and six paper mill properties; (2) a 3-mile stretch of Portage Creek from Cork Street in the City of Kalamazoo to where the creek meets the Kalamazoo River; and (3) an approximately 80-mile stretch of the Kalamazoo River, from Morrow Dam to Lake Michigan, with adjacent floodplains, wetlands, and in-stream sediments.

As defined in the Stage 1 Assessment Report (MDEQ *et al.* 2005; available at *http://www.fws.gov/midwest/es/ec/nrda/KalamazooRiver*), the Trustees are using the term Kalamazoo River Environment (KRE) to represent the entire natural resource damage assessment area. The KRE encompasses the area being addressed by the Superfund remedial investigations for the site's operable units, along with any area where hazardous substances released at or from the Superfund site have come to be located, and areas where natural resources or the services they provide may have been affected by the site-related hazardous substances releases (MDEQ *et al.* 2005).

The Trustees expect to have opportunities to settle natural resource damage claims for the KRE with willing parties. The Draft RP/PEIS will provide an ecological framework, with public input, to maximize the benefits of specific restoration projects to the affected resources in the KRE that might be included in or funded by future settlements or past bankruptcy settlements. The Draft RP/PEIS will provide criteria and guidance for Trustees to use in selecting feasible restoration projects.

In compliance with 40 CFR part 1505 *et seq.,* the Trustees will include in the NRDA Administrative Record (Record) documents that the Trustees rely upon during the development of the Draft RP/PEIS. The hard copy Record is on file at MDEQ (contact Judith Alfano; see **FOR FURTHER INFORMATION CONTACT**).

CERCLA

Under the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA; 42 U.S.C. 9601 *et seq.*), parties responsible for releasing hazardous substances into the environment are liable both for the costs of responding to the release (by cleaning up, containing, or otherwise remediating the release) and for damages arising from injuries to publicly owned or managed natural resources resulting from the release. CERCLA's Natural Resource Damage Assessment (NRDA) regulations (43 CFR 11) describe the process of assessing the nature and extent of the resulting injury, destruction, or loss of natural resources and the services they provide. Carrying out of the NRDA process also includes determining the compensation required to make the public whole for such injuries, destruction, or loss. CERCLA

authorizes certain Federal and State agencies and Indian tribes to act on behalf of the public as Trustees for affected natural resources. Under CERCLA, these agencies and tribes are authorized to assess natural resource injuries and to seek compensation, referred to as damages, from responsible parties, including the costs of performing the damage assessment. The Trustees are required to use recovered damages for the following purposes only: To restore, replace, or acquire the equivalent of the injured or lost resources and services.

EPA's Role in the EIS Process

In addition to this **Federal Register** notice, EPA is publishing a notice announcing the PEIS, as required under section 309 of the Clean Air Act (42 U.S.C. 7401 *et seq.;* CAA).

The EPA is charged under the CAA to review all Federal agencies' EISs and to comment on the adequacy and the acceptability of the environmental impacts of proposed actions in the EISs. EPA also serves as the repository (EIS database) for EISs prepared by Federal agencies and provides notice of their availability in the **Federal Register**. The EIS database provides information about EISs prepared by Federal agencies, as well as EPA's comments concerning the EISs. All EISs are filed with EPA, which publishes a notice of availability on Fridays in the **Federal Register**.

For more information, see *http://www.epa.gov/compliance/nepa/eisdata.html.* You may search for EPA comments on EISs, along with EISs themselves, at *https://cdxnodengn.epa.gov/cdx-enepa-public/action/eis/search.*

Public Comments

Comments are specifically requested regarding the alternatives, proposed restoration techniques and projects, scope of analysis, and assessment of impacts. Please see the **ADDRESSES** section for how to submit information.

Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

Dated: August 24, 2015.

Charles Wooley,

Acting Regional Director, Midwest Region, U.S. Fish and Wildlife Service.

BILLING CODE 4310–55–P

DEPARTMENT OF THE INTERIOR

Bureau of Indian Affairs

[156A2100DD/AAKC001030/A0A501010.999900 253G]

Renewal of Agency Information Collection for Leases and Permits

AGENCY: Bureau of Indian Affairs, Interior.

ACTION: Notice of request for comments.

SUMMARY: In compliance with the Paperwork Reduction Act of 1995, the Bureau of Indian Affairs (BIA) is seeking comments on the renewal of Office of Management and Budget (OMB) approval for the collection of information for Leases and Permits, 25 CFR 162. The information collection is currently authorized by OMB Control Number 1076–0155. This information collection expires November 30, 2015.

DATES: Submit comments on or before November 13, 2015.

ADDRESSES: You may submit comments on the information collection to Ms. Sharlene Roundface, Office of Trust Services, Bureau of Indian Affairs, 1849 C Street NW., Mailstop 3642—MIB, Washington, DC 20240; email: *Sharlene.Roundface@bia.gov.*

FOR FURTHER INFORMATION CONTACT: Ms. Sharlene Roundface, telephone: (202) 208–5831.

SUPPLEMENTARY INFORMATION:

I. Abstract

The Bureau of Indian Affairs (BIA) is seeking renewal of the approval for information collection conducted under 25 CFR 162, Leases and Permits, for the review and approval of leases and permits on land the United States holds in trust or restricted status for individual Indians and Indian tribes. This information collection allows BIA to review applications for leases and permits, modifications, and assignments, and to determine:

(a) Whether or not a lease may be approved or granted;

(b) The value of each lease;

(c) The appropriate compensation to landowners; and

(d) Provisions for violations of trespass.

A response is required to obtain or retain a benefit.

II. Request for Comments

The BIA requests your comments on this collection concerning: (a) The necessity of this information collection for the proper performance of the functions of the agency, including whether the information will have practical utility; (b) The accuracy of the agency's estimate of the burden (hours and cost) of the collection of information, including the validity of the methodology and assumptions used; (c) Ways we could enhance the quality, utility, and clarity of the information to be collected; and (d) Ways we could minimize the burden of the collection of the information on the respondents.

Please note that an agency may not conduct or sponsor, and an individual need not respond to, a collection of information unless it has a valid OMB Control Number.

It is our policy to make all comments available to the public for review at the location listed in the **ADDRESSES** section. Before including your address, phone number, email address or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

III. Data

OMB Control Number: 1076–0155.

Title: Leases and Permits, 25 CFR 162.

Brief Description of Collection: Generally, trust and restricted land may be leased by Indian landowners with the approval of the Secretary of the Interior, except when specified by statute. Submission of this information allows BIA to review applications for obtaining, modifying and assigning leases and permits of land that the United States holds in trust or restricted status for individual Indians and Indian tribes. The information is used to determine approval of a lease, amendment, assignment, sublease, mortgage or related document. Response is required to obtain or retain a benefit.

Type of Review: Extension without change of currently approved collection.

Respondents: Individual Indians and Indian tribes seeking to lease their trust or restricted land and businesses that lease trust and restricted land.

Estimated Number of Respondents: 127,110.

Frequency of Response: One approval per lease, other collections occur fewer than once per lease, on average, upon

request for modification or assignment or upon a trespass violation.

Estimated Time per Response: Ranges from 15 minutes to 3 hours.

Estimated Total Annual Hour Burden: 108,975 hours.

Estimated Total Annual Non-Hour Dollar Cost: $1,813,000.

Elizabeth K. Appel,

Director, Office of Regulatory Affairs and Collaborative Action—Indian Affairs.

Renewal of Agency Information Collection for Class III Gaming; Tribal Revenue Allocation Plans; Gaming on Trust Lands

AGENCY: Bureau of Indian Affairs, Interior.

ACTION: Notice of request for comments.

SUMMARY: In compliance with the Paperwork Reduction Act of 1995, the Assistant Secretary—Indian Affairs is seeking comments on the renewal of Office of Management and Budget (OMB) approval for the collection of information for Class III Gaming Procedures authorized by OMB Control Number 1076–0149, Tribal Revenue Allocation Plans authorized by OMB Control Number 1076–0152, and Gaming on Trust Lands Acquired After October 17, 1988 authorized by OMB Control Number 1076–0158. These information collections expire January 31, 2016.

DATES: Submit comments on or before November 13, 2015.

ADDRESSES: You may submit comments on the information collection to Paula Hart, U.S. Department of the Interior, Office of Indian Gaming, 1849 C Street NW., Mail Stop 3657, Washington, DC 20240; email: *indiangaming@bia.gov.*

FOR FURTHER INFORMATION CONTACT: Paula Hart, (202) 219–4066.

SUPPLEMENTARY INFORMATION:

I. Abstract

The Assistant Secretary—Indian Affairs is seeking comments on the Class III Gaming Procedures, Tribal Revenue Allocation Plans, and Gaming on Trust Lands Acquired After October 17, 1988, as we prepare to renew these collections are required by the Paperwork Reduction Act of 1995. This information is necessary for the Office of Indian Gaming, to ensure that the applicable requirements for the Indian Gaming Regulatory Act (IGRA), 25 U.S.C. 2701 *et seq.,* are met with regard to Class III gaming procedures, tribal revenue allocation plans, and applications for gaming on trust lands acquired after October 17, 1988.

II. Request for Comments

The Assistant Secretary—Indian Affairs requests your comments on this collection concerning: (a) The necessity of this information collection for the proper performance of the functions of the agency, including whether the information will have practical utility; (b) The accuracy of the agency's estimate of the burden (hours and cost) of the collection of information, including the validity of the methodology and assumptions used; (c) Ways we could enhance the quality, utility, and clarity of the information to be collected; and (d) Ways we could minimize the burden of the collection of the information on the respondents.

Please note that an agency may not conduct or sponsor, and an individual need not respond to, a collection of information unless it displays a valid OMB Control Number.

It is our policy to make all comments available to the public for review at the location listed in the **ADDRESSES** section. Before including your address, phone number, email address or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

III. Data

OMB Control Number: 1076–0149.

Title: Class III Gaming Procedures, 25 CFR 291.

Brief Description of Collection: The collection of information will ensure that the provisions of IGRA and other applicable requirements are met when federally recognized tribes submit Class III procedures for review and approval by the Secretary of the Interior. Sections 291.4, 291.10, 291.12 and 291.15 of 25 CFR part 291, Class III Gaming Procedures, specify the information collection requirement. An Indian tribe must ask the Secretary to issue Class III gaming procedures. The information to be collected includes: The name of the tribe, the name of the State, tribal documents, State documents, regulatory schemes, the proposed procedures, and other documents deemed necessary.

Type of Review: Extension without change of currently approved collection.

Respondents: Federally recognized Indian tribes.

Number of Respondents: 12.

Estimated Time per Response: 320 hours.

Estimated Total Annual Hour Burden: 3,840 hours.

Estimated Total Annual Non-Hour Dollar Cost: $0.

OMB Control Number: 1076–0152.

Title: Tribal Revenue Allocation Plans, 25 CFR 290.

Brief Description of Collection: An Indian tribe must ask the Secretary to approve a tribal revenue allocation plan. In order for Indian tribes to distribute net gaming revenues in the form of per capita payments, information is needed by the BIA to ensure that tribal revenue allocation plans include (1) Assurances that certain statutory requirements are met, (2) a breakdown of the specific uses to which net gaming revenues will be allocated, (3) eligibility requirements for participation, (4) tax liability notification, and (5) the assurance of the protection and preservation of the per capita share of minors and legal incompetents. Sections 290.12, 290.17, 290.24 and 290.26 of 25 CFR part 290, Tribal Revenue Allocation Plans, specify the information collection requirement. The information to be collected includes: the name of the tribe, tribal documents, the allocation plan, and other documents deemed necessary.

Type of Review: Extension without change of currently approved collection.

Respondents: Federally recognized Indian tribes.

Number of Respondents: 20.

Estimated Time per Response: 100 hours.

Estimated Total Annual Hour Burden: 2,000 hours.

Estimated Total Annual Non-Hour Dollar Cost: $0.

OMB Control Number: 1076–0158.

Title: Gaming on Trust Lands Acquired After October 17, 1988, 25 CFR 292.

Brief Description of Collection: The collection of information will ensure that the provisions of IGRA, Federal law, and the trust obligations of the United States are met when federally recognized tribes submit an application under 25 CFR part 292. The applications covered by this OMB Control No. are those seeking a Secretarial determination that a gaming establishment on land acquired in trust after October 17, 1988 would be in the

best interest of the Indian tribe and its members, and would not be detrimental to the surrounding community.

Type of Review: Extension without change of currently approved collection.

Respondents: Federally recognized Indian tribes.

Number of Respondents: 2.

Estimated Time per Response: 1,000 hours.

Frequency of Response: Once.

Estimated Total Annual Burden: 2,000 hours.

Estimated Total Annual Non-Hour Dollar Cost: $0.

Elizabeth K. Appel,

Director, Office of Regulatory Affairs and Collaborative Action—Indian Affairs.

AGENCY: Bureau of Indian Affairs, Interior.

ACTION: Notice of submission to OMB.

SUMMARY: In compliance with the Paperwork Reduction Act of 1995, the Bureau of Indian Affairs (BIA) is submitting to the Office of Management and Budget (OMB) a request for approval for the collection of information for Indian Reservation Roads (IRR). The information collection is currently authorized by OMB Control Number 1076–0161, which expires September 30, 2015.

DATES: Interested persons are invited to submit comments on or before October 14, 2015.

ADDRESSES: You may submit comments on the information collection to the Desk Officer for the Department of the Interior at the Office of Management and Budget, by facsimile to (202) 395–5806 or you may send an email to: *OIRA_Submission@omb.eop.gov.* Please send a copy of your comments to: Mr. LeRoy Gishi, Chief, Division of Transportation, Bureau of Indian Affairs, 1849 C Street NW., MS–4513–MIB, Washington, DC 20240; facsimile: (202) 208–4696; email: *LeRoy.Gishi@bia.gov.*

FOR FURTHER INFORMATION CONTACT: Mr. LeRoy Gishi, (202) 513–7711. You may review the information collection request online at *http://www.reginfo.gov.* Follow the instructions to review Department of the Interior collections under review by OMB.

SUPPLEMENTARY INFORMATION:

I. Abstract

The Bureau of Indian Affairs is currently in the process of revising the regulations governing the Indian Reservations Roads (IRR) program. The proposed rule was published in the **Federal Register** on December 19, 2014 (79 FR 76192), which will update the Indian Reservation Roads program to the Tribal Transportation Program. The request for approval for this information collection does not include the suggestions and feedback on the proposed regulations, but instead will allow current participants to submit information required under the current regulations, pending the finalization and effective date of any revisions. In addition, there is a reduction in burden hours due to the elimination of the IRR High Priority Projects program under 23 U.S.C. 202(b)(3)(ii). All other programs identified under 25 CFR part 170 are valid. For this reason, the BIA is requesting approval for the revision to the information collection conducted under 25 CFR part 170.

This collection allows federally recognized tribal governments to participate in the Indian Reservation Roads (IRR) program as defined in 25 U.S.C. 202. The information collection determines the allocation of the IRR program funds to Indian tribes as described in 25 U.S.C. 202(b).

II. Request for Comments

On June 10, 2015, BIA published a notice announcing the renewal of this information collection and provided a 60-day comment period in the **Federal Register** (80 FR 32976). There were no comments received in response to this notice.

The BIA requests your comments on this collection concerning: (a) The necessity of this information collection for the proper performance of the functions of the agency, including whether the information will have practical utility; (b) The accuracy of the agency's estimate of the burden (hours and cost) of the collection of information, including the validity of the methodology and assumptions used; (c) Ways we could enhance the quality, utility, and clarity of the information to be collected; and (d) Ways we could minimize the burden of the collection of the information on the respondents.

Please note that an agency may not conduct or sponsor, and an individual need not respond to, a collection of information unless it displays a valid OMB Control Number.

It is our policy to make all comments available to the public for review at the location listed in the **ADDRESSES** section. Before including your address, phone number, email address or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

III. Data

OMB Control Number: 1076–0161.

Title: Indian Reservation Roads, 25 CFR part 170.

Brief Description of Collection: Some of the information such as the road inventory updates (25 CFR 170.443), the development of a long range transportation plan (25 CFR 170.411 and 170.412), the development of a tribal transportation improvement program and priority list (25 CFR 170.420 and 170.421) are mandatory for consideration of projects and for program funding form the formula. Some of the information, such as public hearing requirements, is necessary for public notification and involvement (25 CFR 170.437 and 170.439). While other information, such as data appeals (25 CFR 170.231) and requests for design exceptions (25 CFR 170.456), are voluntary.

Type of Review: Revision of currently approved collection.

Respondents: Federally recognized Indian tribal governments who have transportation needs associated with the IRR Program as described in 25 CFR part 170.

Number of Respondents: 1,369.

Frequency of Response: Annually or on an as needed basis.

Estimated Time per Response: Reports require from 30 minutes to 40 hours to complete. An average would be 16 hours.

Estimated Total Annual Hour Burden: 18,028 hours.

Estimated Total Annual Non-Hour Dollar Cost: $0.

Elizabeth K. Appel,

Director, Office of Regulatory Affairs and Collaborative Action—Indian Affairs.

[FR Doc. 2015–22992 Filed 9–11–15; 8:45 am]

DEPARTMENT OF THE INTERIOR

Bureau of Indian Affairs

[156A2100DD/AAKC001030/A0A501010.999900 253G]

Renewal of Agency Information Collection for Student Transportation Form

AGENCY: Bureau of Indian Affairs, Interior.

ACTION: Notice of request for comments.

SUMMARY: In compliance with the Paperwork Reduction Act of 1995, the Bureau of Indian Education (BIE) is seeking comments on the renewal of Office of Management and Budget (OMB) approval for the collection of information for Student Transportation Form. This information collection is currently authorized by OMB Control Number 1076–0134, which expires September 30, 2015.

DATES: Interested persons are invited to submit comments on or before October 14, 2015.

ADDRESSES: You may submit comments on the information collection to the Desk Officer for the Department of the Interior at the Office of Management and Budget, by facsimile to (202) 395–5806 or you may send an email to: *OIRA_Submission@omb.eop.gov.* Please send a copy of your comments to: Dr. Joe Herrin, Bureau of Indian Education, 1951 Constitution Avenue, MS–312–SIB, Washington, DC 20240; facsimile: (202) 208–3271; email: *Joe.Herrin@BIE.edu.*

FOR FURTHER INFORMATION CONTACT: Dr. Joe Herrin, phone: (202) 208–7658. You may review the information collection request online at *http://www.reginfo.gov.* Follow the instructions to review Department of the Interior collections under review by OMB.

SUPPLEMENTARY INFORMATION:

I. Abstract

The BIE is requesting renewal of OMB approval for the Student Transportation Form. The Student Transportation regulations in 25 CFR part 39, subpart G, contain the program eligibility and criteria that govern the allocation of transportation funds. Information collected from the schools will be used to determine the rate per mile. The information collection provides transportation mileage for Bureau-funded schools, which determines the allocation of transportation funds. This information is collected using a web-based system, Office of Indian Education Programs (OIEP) MultiWeb Intranet/WebET Intranet. Response is required to obtain a benefit.

II. Request for Comments

On June 10, 2015, the BIE published a notice announcing the renewal of this information collection and provided a 60-day comment period in the **Federal Register** (80 FR 32975). There were no comments received in response to this notice.

The BIE requests your comments on this collection concerning: (a) The necessity of this information collection for the proper performance of the functions of the agency, including whether the information will have practical utility; (b) The accuracy of the agency's estimate of the burden (hours and cost) of the collection of information, including the validity of the methodology and assumptions used; (c) Ways we could enhance the quality, utility, and clarity of the information to be collected; and (d) Ways we could minimize the burden of the collection of the information on the respondents.

Please note that an agency may not conduct or sponsor, and an individual need not respond to, a collection of information unless it displays a valid OMB Control Number.

It is our policy to make all comments available to the public for review at the location listed in the **ADDRESSES** section. Before including your address, phone number, email address or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you can ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

III. Data

OMB Control Number: 1076–0134.

Title: Student Transportation Form, 25 CFR 39.

Brief Description of Collection: This annual collection provides pertinent data concerning the school's bus transportation mileage and related long distance travel mileage to determine funding levels for school transportation. This information is collected using the web-based system, OIEP MultiWeb Intranet/WebET Intranet and the Indian School Equalization Program (ISEP) Student Transportation form.

Type of Review: Extension without change of currently approved collection.

Respondents: Contract and Grant schools; Bureau-operated schools.

Number of Respondents: 183 per year, on average.

Total Number of Responses: 183 per year, on average.

Frequency of Response: Once per year.

Estimated Time per Response: 2 hours.

Estimated Total Annual Hour Burden: 366 hours.

Estimated Total Annual Non-Hour Dollar Cost: $0.

Elizabeth K. Appel,

Director, Office of Regulatory Affairs and Collaborative Action—Indian Affairs.

DEPARTMENT OF THE INTERIOR

Bureau of Land Management

[LLWYD03000.L51100000.GN0000.LVEMK10CW580–WYW–184415]

Notice of Intent To Prepare an Environmental Impact Statement for the Proposed Lost Creek Uranium In-Situ Recovery Project Amendments, Sweetwater County, WY

AGENCY: Bureau of Land Management, Interior.

ACTION: Notice.

SUMMARY: In compliance with the National Environmental Policy Act of 1969 (NEPA), as amended, and the Federal Land Policy and Management Act of 1976, as amended, the Bureau of Land Management (BLM) Rawlins Field Office, Rawlins, Wyoming, intends to prepare an Environmental Impact Statement (EIS), and by this notice is announcing the beginning of the scoping process to solicit public comments and identify issues.

DATES: This notice initiates the public scoping process for the EIS. Comments on issues may be submitted in writing until 45 days after the date of publication in the **Federal Register**. The date(s) and location(s) of any scoping meetings will be announced at least 15 days in advance through local media, newspapers and the BLM Web site at: *http://www.blm.gov/wy/st/en/info/NEPA/documents/rfo/lostcreek.html.* In order to be included in the Draft EIS, all comments must be received prior to the close of the 45-day scoping period or 15 days after the last public meeting, whichever is later. We will provide additional opportunities for public participation upon publication of the Draft EIS.

ADDRESSES: You may submit comments related to the Lost Creek Uranium *In-Situ* Recovery Project Amendments by any of the following methods:

- *Web site: http://www.blm.gov/wy/st/en/info/NEPA/documents/rfo/lostcreek.html.*
- *Email: Lost_Crk_Mine_WY@blm.gov.*
- *Fax:* 307–328–4224.
- *Mail:* John Russell, Project Manager, BLM Rawlins Field Office, 1300 North Third Street, P.O. Box 2407, Rawlins, WY 82301–2407
- Documents pertinent to this proposal may be examined at the BLM Rawlins Field Office.

FOR FURTHER INFORMATION CONTACT: John Russell, Project Manager, telephone 307–328–4224; address Bureau of Land Management, Rawlins Field Office, 1300 N. Third Street, P.O. Box 2407, Rawlins, Wyoming 82301; email *Lost_Crk_Mine_WY@blm.gov.* Contact Mr. Russell to have your name added to our mailing list. Persons who use a telecommunications device for the deaf (TDD) may call the Federal Information Relay Service (FIRS) at 1–800–877–8339 to contact the above individual during normal business hours. The FIRS is available 24 hours a day, 7 days a week, to leave a message or question with the above individual. You will receive a reply during normal business hours.

SUPPLEMENTARY INFORMATION: The applicant, Lost Creek ISR, LLC, (LCI), a wholly owned subsidiary of Ur-Energy Inc., has requested to modify their Lost Creek Uranium *In-Situ* Recovery Project, 43 CFR 3809 Plan of Operations, approved October 5, 2012. The proposed plan amendments (Lost Creek East, KM Horizon, and secondary objectives received September 29, 2014) would expand uranium production by in-situ recovery methods and increase associated milling facilities, located in T. 25 N., R. 92 W.; and T. 25 N., R. 93 W., 6th P.M., Sweetwater County, Wyoming.

The Lost Creek East amendment would add approximately 5,750 acres to the existing Lost Creek Project area of approximately 4,254 acres for a new total project area of approximately 10,000 acres. LCI's proposed KM Horizon amendment would allow in-situ mining of uranium from the KM horizon, and increases the extent of mining in the existing HJ horizon within the existing project area, approved October 5, 2012. Development of the proposed amendments would result in approximately 650 acres of new surface disturbance including 5 new mine units, additional Class 1 deep disposal well pads, roads, pipelines, power lines, header houses, and mud pits. LCI also requested the BLM approve an increase of the overall production rate from 1.0 million pounds of uranium per year to 2.2 million pounds of uranium per year. This includes an increase of 0.2 million pounds of uranium per year from the facility well fields, plus an increase of 1 million pounds of uranium per year from the toll milling resin or slurry from other off-site facilities. The purpose of the public scoping process is to determine relevant issues that will influence the scope of the environmental analysis, including alternatives, and guide the process for developing the EIS. At present, the BLM has identified the following preliminary issues: (1) Potential impacts to range, water, recreation, wild horses, and wildlife resources (*e.g.,* Greater Sage-Grouse, Wyoming Pocket Gopher); (2) the need to identify opportunities to apply mitigation hierarchy strategies for on-site, regional, and compensatory mitigation efforts; and, (3) the need to apply landscape-level conservation and management actions that are appropriate to the size of the project in order to achieve resource objectives.

The BLM will use NEPA public participation requirements to assist the agency in satisfying the public involvement requirements under section 106 of the National Historic Preservation Act (NHPA) (16 U.S.C. 470(f)) pursuant to 36 CFR 800.2(d)(3). The information about historic and cultural resources within the area potentially affected by the proposed plan amendments will assist the BLM in identifying and evaluating impacts to such resources in the context of both NEPA and section 106 of the NHPA.

The BLM will consult with Indian tribes on a government-to-government basis in accordance with Executive Order 13175 and other policies. Tribal concerns, including impacts on Indian trust assets and potential impacts to cultural resources, will be given due consideration. Federal, State, and local agencies, along with tribes and other stakeholders that may be interested in or affected by the proposed plan amendments that the BLM is evaluating, are invited to participate in the scoping process and, if eligible, may request or be requested by the BLM to participate in the development of the environmental analysis as a cooperating agency.

The Nuclear Regulatory Commission and the State of Wyoming will be cooperating agencies for this project. Others are pending. Before including your address, phone number, email address, or other personal identifying information in your comment, you should be aware that your entire comment—including your personal identifying information—may be made publicly available at any time. While you may ask us in your comment to withhold your personal identifying information from public review, we cannot guarantee that we will be able to do so.

Authority: 40 CFR 1501.7.

Larry Claypool,

Acting, State Director.

Notice of Availability of Record of Decision for the Jarbidge Resource Management Plan Final Environmental Impact Statement

AGENCY: Bureau of Land Management, Interior.

ACTION: Notice of availability.

SUMMARY: The Bureau of Land Management (BLM) announces the availability of the Record of Decision (ROD) for the Approved Resource Management Plan (RMP) for the Jarbidge Field Office located in the Twin Falls District (Idaho and Nevada). The Idaho State Director signed the ROD on September 2, 2015, which constitutes the final decision of the BLM and makes the Approved RMP effective immediately.

ADDRESSES: Copies of the ROD/Approved RMP are available upon request from the Field Manager, Jarbidge Field Office, Bureau of Land Management, 2536 Kimberly Road, Twin Falls, Idaho 83301 and online at *http://www.blm.gov/id/st/en/prog/nepa_register/jarbidge-rmp-revision.html.* Copies of the ROD/Approved RMP are also available for public inspection at 2536 Kimberly Road, Twin Falls, Idaho 83301.

FOR FURTHER INFORMATION CONTACT: Elliot Traher, Jarbidge Field Manager, or Heidi Whitlach, Jarbidge RMP Project Manager, telephone 208–736–2350; address Jarbidge Field Office, 2536 Kimberly Road, Twin Falls, Idaho 83301; email *blm_id_jarbidgermp@blm.gov.* Persons who use a telecommunications device for the deaf (TDD) may call the Federal Information Relay Service (FIRS) at 1–800–877–8339 to contact the above individual during normal business hours. The FIRS is available 24 hours a day, 7 days a week, to leave a message or question with the above individual. You will receive a reply during normal business hours.

SUPPLEMENTARY INFORMATION: The Approved RMP was developed with public participation through a collaborative planning process in accordance with the Federal Land Policy and Management Act of 1976, as amended, and the National Environmental Policy Act of 1969, as amended. The Approved RMP addresses the management of resources and resource uses on about 1,371,000 acres of public land surface; 1,497,000 acres of Federal mineral estate; and 1,463,000 acres of livestock grazing (including 1,371,000 acres of public land surface and an additional 92,000 acres on the US Air Force Saylor Creek Training Range) in Elmore, Owyhee, and Twin Falls Counties in Idaho and Elko County in Nevada. The Approved RMP describes the landscape-level conservation and management actions needed to meet desired resource conditions and regional mitigation objectives for vegetation, wild horses, livestock grazing, recreation, energy development, and Areas of Critical Environmental Concern (ACECs).

In the Draft RMP/Environmental Impact Statement (EIS), Alternative IV–B was selected as the BLM's Preferred Alternative. As a result of public comment, internal review, and cooperating agency coordination on the Draft RMP/EIS, Alternative IV–B was adjusted to become Alternative VI (Proposed RMP) and analyzed in the Proposed RMP/Final EIS. The Proposed RMP/Final EIS was published in the**Federal Register**on August 22, 2014 (79 FR 49774).

The BLM received 8 protest letters during the 30-day protest period. The BLM Director denied all protest issues as reported in the Director's Protest Resolution Report, which can be reviewed at the following Web site:http://www.blm.gov/wo/st/en/prog/planning/planning_overview/protest_resolution/protestreports.html.

While the Approved RMP contains some conservation management measures for greater sage-grouse habitat, final decisions on how to manage habitat within the Jarbidge Field Office will be made in the Records of Decision for the Idaho/Southwest (SW) Montana Greater Sage-Grouse Plan Amendment and the Nevada/Northeast (NE) California Greater Sage-Grouse Plan Amendment. The Idaho/SW Montana and Nevada/NE California Greater Sage-grouse Plan Amendment EISs will fully analyze applicable greater sage-grouse conservation measures, consistent with BLM Instruction Memorandum No. 2012–044. The BLM expects to make a comprehensive set of decisions for managing greater sage-grouse on lands administered by the Jarbidge Field Office in the Records of Decision for the Idaho/SW Montana and Nevada/NE California Greater Sage-Grouse Plan Amendments.

During the Governor's consistency review process, the Idaho Governor's Office identified discrepancies between the Jarbidge Proposed RMP and laws, plans, policies and programs of the State of Idaho. The discrepancies mostly concerned greater sage-grouse direction and conservation actions in the Proposed RMP and Governor C.L. "Butch" Otter's "Alternative for Federal Lands for Greater Sage-grouse Management in Idaho" and the Idaho Department of Lands Greater Sage-grouse Conservation Plan for State Endowment Lands. The issues raised by the State of Idaho were responded to by letter from the BLM Idaho State Director. The Governor's Office did not appeal the State Director's decision to the BLM Director. The Nevada Governor's Office did not submit a response to the BLM during the Governor's consistency review period.

Authority: 40 CFR 1506.6.

Timothy M. Murphy,

BLM Idaho State Director.

Bureau of Ocean Energy Management

[MMAA 104000]

Notice of Availability of the Proposed Notice of Sale for Central Gulf of Mexico Planning Area Outer Continental Shelf Oil and Gas Lease Sale 241

AGENCY: Bureau of Ocean Energy Management (BOEM), Interior.

ACTION: Notice of availability of the proposed notice of sale for CPA sale 241.

SUMMARY: BOEM announces the availability of the Proposed Notice of Sale (NOS) for the proposed Central Gulf of Mexico Planning Area (CPA) Outer Continental Shelf (OCS) Oil and Gas Lease Sale 241 (CPA Sale 241). This Notice is published pursuant to 30 CFR 556.29(c) as a matter of information to the public. With regard to oil and gas leasing on the OCS, the Secretary of the Interior, pursuant to section 19 of the OCS Lands Act, provides affected States the opportunity to review the Proposed NOS. The Proposed NOS sets forth the proposed terms and conditions of the sale, including minimum bids, royalty rates, and rental rates.

DATES: Affected States may comment on the size, timing, and location of proposed CPA Sale 241 within 60 days following their receipt of the Proposed NOS. The Final NOS will be published in the **Federal Register** at least 30 days prior to the date of bid opening. Bid opening currently is scheduled for March 23, 2016.

SUPPLEMENTARY INFORMATION: The Proposed NOS for CPA Sale 241 and a Proposed NOS Package containing information essential to potential bidders may be obtained from the Public Information Unit, Gulf of Mexico Region, Bureau of Ocean Energy Management, 1201 Elmwood Park Boulevard, New Orleans, Louisiana 70123–2394. Telephone: (504) 736–2519. The Proposed NOS and Proposed NOS Package also are available on BOEM's Web site at *http://www.boem.gov/Sale-241/.*

NATIONAL AERONAUTICS AND SPACE ADMINISTRATION

[Notice: (15–075)]

Notice of Information Collection

AGENCY: National Aeronautics and Space Administration (NASA).

ACTION: Notice of information collection.

SUMMARY: The National Aeronautics and Space Administration, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995 (Pub. L. 104–13, 44 U.S.C. 3506(c)(2)(A)).

DATES: All comments should be submitted within 30 calendar days from the date of this publication.

ADDRESSES: Interested persons are invited to submit written comments regarding the proposed information collection to the Office of Information and Regulatory Affairs, Office of Management and Budget, 725 7th Street NW., Washington, DC 20543. Attention: Desk Officer for NASA.

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the information collection instrument(s) and instructions should be directed to Fran Teel, NASA PRA Officer, NASA Headquarters, 300 E Street SW., Mail Code JF000, Washington, DC 20546, (202) 358–2225 or *frances.c.teel@nasa.gov.*

SUPPLEMENTARY INFORMATION:

I. Abstract

The National Aeronautics and Space Administration (NASA) Office of Diversity and Equal Opportunity, in accordance with title VII of the Civil Rights Act of 1964, the Age Discrimination Act of 1975 and 42 U.S.C. 2000e–16; 29 CFR 1614.106 and 1614.108, is authorized to collect information on issues and allegations of a complaint of discrimination based on race, color, sex (including sexual harassment, religion, national origin, disability (physical or mental), reprisal, sexual orientation, gender identity, status as a parent or genetic information. This requirement for assurance of non-discrimination is long-standing and derives from civil rights implementing regulations. This information collection includes complaint investigations.

II. Method of Collection

Electronic Form.

III. Data

Title: NASA Complaint of Discrimination Form.

OMB Number: 2700–XXXX.

Type of review: Existing collection in use without an OMB control number.

Affected Public: Individuals.

Estimated Number of Respondents: 85.

Estimated Annual Responses: 80 per year.

Estimated Time per Response: 30 minutes.

Estimated Total Annual Burden Hours: 60 hours.

Estimated Total Annual Cost: $500.00.

IV. Request for Comments

Comments are invited on: (1) Whether the proposed collection of information is necessary for the proper performance of the functions of NASA, including whether the information collected has practical utility; (2) the accuracy of NASA's estimate of the burden (including hours and cost) of the proposed collection of information; (3) ways to enhance the quality, utility, and clarity of the information to be collected; and (4) ways to minimize the burden of the collection of information on respondents, including automated collection techniques or the use of other forms of information technology.

Frances Teel,

NASA PRA Clearance Officer.

BILLING CODE 7510–13–P

NATIONAL SCIENCE FOUNDATION

Management Fee Policy

AGENCY: National Science Foundation.

ACTION: Notice.

SUMMARY: On December 30, 2014, the National Science Foundation (NSF) published at 79 FR 78497 a notice and request for comments on NSF's revised policy on management fee. The payment of a small but appropriate management fee has been a long standing practice at NSF in limited circumstances related to the construction and operation of major facility projects. NSF has strengthened both the criteria used to establish such fees and the controls that may be necessary to ensure that uses of fees are consistent with those established criteria. These efforts resulted in the revised policy that was sent for public comment. On June 16, 2015, NSF received OMB approval under the Paperwork Reduction Act for the Large Facilities Manual (3145–0239) which included NSF's final policy on management fee under Section 4.2.2.2.

FOR FURTHER INFORMATION CONTACT: Suzanne Plimpton on (703) 292–7556 or send email to *splimpto@nsf.gov.* Individuals who use a telecommunications device for the deaf (TDD) may call the Federal Information Relay Service (FIRS) at 1–800–877–8339, which is accessible 24 hours a day, 7 days a week, 365 days a year (including federal holidays).

SUPPLEMENTARY INFORMATION: The following final Management Fee Policy can be found in NSF's Large Facilities Manual:

4.2.2.2 Management Fee

Management fee is an amount of money paid to a recipient in excess of a cooperative agreement's or cooperative support agreement's allowable costs. Generally, NSF does not permit the payment of fee (profit) to organizations under financial assistance. However, a management fee may be authorized for awards in the limited circumstances of construction or operations of a large facility as the responsible organization is likely to incur certain legitimate business expenses that may not be reimbursable under the governing cost principles. NSF provides for a

management fee in these limited circumstances, as appropriate, recognizing that the awardee would only incur such expenses as a result of its support of the NSF-funded activity.

Prior Approval of Management Fees—A management fee proposal must be submitted to NSF that provides sufficient visibility into each expense category to identify its intended purpose. Agreement on management fee amounts shall be completed and a specific dollar amount established prior to the initiation of work under an award, or any subsequent period not authorized as part of the initial award. Any amount negotiated shall be expressly set forth in the terms and conditions of the award. Awardees may draw down the management fee in proportion to the amount incurred during the performance period. Fee established for a period longer than one year shall be subject to adjustment in the event of a significant change to the budget or work scope.

The following expense categories will be used in the negotiation and award of a management fee:

- Working capital necessary to fund operations under an award—An amount for working capital may be necessary to ensure a level of retained earnings available to the organization in order to secure credit and borrowing to assure the financial health of the organization.
- Facilities capital necessary to acquire assets for performance—An amount for facilities capital may be necessary to allow the organization to acquire major assets and to address expenses that require immediate substantive financial outlays but that are only reimbursed through depreciation or amortization over a period of years.
- Other ordinary and necessary expenses for business operations that are not otherwise reimbursable under the governing cost principles—An amount for other expenses that are ordinary and necessary but not otherwise reimbursable may be necessary to provide a reasonable allowance for management initiative and investments that will directly or indirectly benefit the NSF-funded activity. Inclusion of amounts under this category warrants careful consideration of the benefits that may be obtained when providing management fee. Examples of potential appropriate needs include expenses related to contract terminations and losses, certain appropriate educational and public outreach activities, and financial incentives to obtain and retain high caliber staff.
- Prohibited Use of Management Fees—Although not an exhaustive list, the following are examples of expenses that are not appropriate uses of a management fee:
  - Alcoholic beverages
  - Tickets to concerts, sporting and other events
  - Vacation or other travel for non-business purposes
  - Social or sporting club memberships
  - Meals or social activities for non-business purposes
  - Meals or social activities for business purposes that are so extravagant as to constitute entertainment
  - Luxury or personal items
  - Lobbying as set forth at 2 CFR 200.450 and FAR 31.205–22, as appropriate to the recipient type

In addition, costs incurred under the award that are otherwise allowable under the governing cost principles must be classified as direct or indirect charges to the award and shall not be included as proposed management fee elements.

Documentation Requirements on Use of Management Fees—Even though the management fee represents an amount in excess of allowable cost and is therefore not subject to the governing cost principles, NSF, as a matter of policy, has determined that review of appropriate use of such funds is necessary. Information available on actual uses of management fee previously awarded by NSF in the preceding five-year period under any award shall be included in the proposing organization's fee proposal. As a term and condition of the award, the awardee will be required to provide information (typically annually) on the actual use(s) of the management fee. NSF will conduct reviews of this information regarding the extent to which the awardee fee proposals have proven reliable when compared with actual uses of management fee (both as to the fee amount as well as the planned uses of the fee). Unexplained failure to reasonably adhere to planned uses of fee will result in reduction of future management fee amounts under the award.

Dated: September 9, 2015.

Suzanne H. Plimpton,

Reports Clearance Officer, National Science Foundation.

BILLING CODE 7555–01–P

NUCLEAR REGULATORY COMMISSION

[Docket Nos. 50–336 and EA–13–188; NRC–2015–0217]

In the Matter of Dominion Nuclear Connecticut, Inc. (Millstone Power Station Unit 2)

AGENCY: Nuclear Regulatory Commission.

ACTION: Confirmatory order; issuance.

SUMMARY: The U.S. Nuclear Regulatory Commission (NRC) and the Dominion Nuclear Connecticut, Inc. (DNC) engaged in mediation as part of the NRC's Alternative Dispute Resolution Program which resulted in a settlement agreement as reflected in the confirmatory order relating to Millstone Unit 2.

DATES: *Effective Date:* August 26, 2015.

ADDRESSES: Please refer to Docket ID NRC–2015–0217 when contacting the NRC about the availability of information regarding this document. You may obtain publicly-available information related to this document using any of the following methods:

- *Federal Rulemaking Web site:* Go to *http://www.regulations.gov* and search for Docket ID NRC–2015–0217. Address questions about NRC dockets to Carol Gallagher; telephone: 301–415–3463; email: *Carol.Gallagher@nrc.gov.* For questions about this Order, contact the individual listed in the **FOR FURTHER INFORMATION CONTACT** section of this document.
- *NRC's Agencywide Documents Access and Management System (ADAMS):* You may obtain publicly-available documents online in the ADAMS Public Documents collection at *http://www.nrc.gov/reading-rm/adams.html.* To begin the search, select "*ADAMS Public Documents*" and then select "*Begin Web-based ADAMS Search.*" For problems with ADAMS, please contact the NRC's Public Document Room (PDR) reference staff at 1–800–397–4209, 301–415–4737, or by email to *pdr.resource@nrc.gov.* The ADAMS accession number for each document referenced (if it available in ADAMS) is provided the first time that a document is referenced.
- *NRC's PDR:* You may examine and purchase copies of public documents at the NRC's PDR, Room O1–F21, One White Flint North, 11555 Rockville Pike, Rockville, Maryland 20852.

FOR FURTHER INFORMATION CONTACT: Richard Guzman, Office of Nuclear Reactor Regulation, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001; telephone: 301–415–1030, email: *Richard.Guzman@nrc.gov.*

SUPPLEMENTARY INFORMATION: The text of the Order is attached.

Dated at Rockville, Maryland, this 3rd day of September 2015.

For the Nuclear Regulatory Commission.

Dave J. Vito,

Acting Chief, Concerns Resolution Branch, Office of Enforcement.

UNITED STATES OF AMERICA

NUCLEAR REGULATORY COMMISSION

In the Matter of Dominion Nuclear Connecticut, Inc. (Millstone Power Station Unit 2)

Docket No. 50–336
License No. DPR–65
EA–13–188

CONFIRMATORY ORDER MODIFYING LICENSE

(EFFECTIVE IMMEDIATELY)

I.

Dominion Nuclear Connecticut, Inc. (DNC or Licensee) is the holder of Facility Operating License No. DPR–65 issued by the Nuclear Regulatory Commission (NRC or Commission) pursuant to Title 10 of the *Code of Federal Regulations* (10 CFR) part 50 on September 26, 1975. The license authorizes the operation of Millstone Power Station (Millstone) Unit 2 in accordance with conditions specified therein. Millstone Power Station Unit 2 is located in the vicinity of Waterford, Connecticut.

This Confirmatory Order is the result of an agreement reached during an alternative dispute resolution (ADR) mediation process which included one meeting on July 14, 2015, and two follow up teleconferences on July 16, 2015 and July 24, 2015.

II.

On May 23, 2013, the NRC's Office of Investigations (OI) completed an investigation to determine if DNC staff at Millstone deliberately violated NRC requirements in section 50.59 of Title 10 of the *Code of Federal Regulations* (10 CFR), "Changes, Tests, and Experiments," when implementing changes to documents related to the Millstone Unit 2 chemical and volume control system (CVCS) charging pumps and spent fuel decay time limits. The investigation also evaluated whether DNC staff deliberately submitted inaccurate and incomplete information to the NRC pertaining to these changes.

Based on the evidence developed during this investigation, the NRC concluded that three apparent violations occurred, two of which were considered for escalated enforcement action. The first apparent violation (AV) involved changes made by DNC to Section 14.6.1 of the Millstone Unit 2 Updated Final Safety Analysis Report (UFSAR) that removed credit for the CVCS charging pump flow in the mitigation of the design basis accident involving the inadvertent opening of pressurizer power operated relief valves (PORVs), without obtaining prior NRC approval. The NRC found that willfulness was associated with this apparent violation. DNC does not agree that willfulness was associated with this apparent violation.

The second AV involved the failure by DNC to provide complete and accurate information to the NRC in reports and other documents pertaining to the aforementioned UFSAR change, including a failure to notify the Commission of information having significant implications for public health and safety. Willfulness was not associated with this apparent violation.

The third AV involved changes made by DNC to Chapter 9 of the Millstone Unit 2 UFSAR and Section 3/4.9.3 of the Technical Specification Bases that decreased the required amount of irradiated fuel decay time from 150 to 100 hours prior to fuel movement in the reactor vessel, without obtaining prior NRC approval. Willfulness was not associated with this apparent violation.

In a letter dated April 29, 2015, the NRC provided DNC the results of the investigation, informed DNC that escalated enforcement action was being considered for two of the three apparent violations, and offered DNC the opportunity to attend a predecisional enforcement conference or to participate in ADR in which a neutral mediator with no decision-making authority would facilitate discussions between the NRC and DNC. The neutral mediator would assist the NRC and DNC in reaching an agreement, if possible. DNC chose to participate in ADR. This Confirmatory Order is issued pursuant to the agreement reached during the ADR process.

III.

In response to the NRC's offer, DNC requested use of the NRC ADR process to resolve differences it had with the NRC. During that ADR process, a preliminary settlement agreement was reached the terms of which are set forth in Section IV below.

Based on those commitments, the NRC agreed not to take further enforcement action on the three apparent violations identified in the NRC April 29, 2015, letter.

On August 20, 2015, DNC consented to issuing this Confirmatory Order with the commitments, as described in Section IV below. DNC further agreed that this Confirmatory Order is to be effective upon issuance and that it has waived its right to a hearing.

I find that the DNC's commitments as set forth in Section IV are acceptable and necessary and conclude that with these commitments the plant's safety is reasonably assured. In view of the foregoing, I have determined that public health and safety require that DNC's commitments be confirmed by this Confirmatory Order. Based on the above and DNC's consent, this Confirmatory Order is effective upon issuance. By no later than thirty (30) days after the completion of the commitments in Section IV, DNC is required to notify the NRC in writing and summarize its actions.

IV.

Accordingly, pursuant to Sections 104b, 161b, 161i, 161o, 182 and 186 of the Atomic Energy Act of 1954, as amended, and the Commission's regulations in 10 CFR 2.202 and 10 CFR part 50, IT IS HEREBY ORDERED THAT LICENSE NO. DPR–65 IS MODIFIED AS FOLLOWS:

Compliance.

1. Within sixty (60) calendar days of the date of this Confirmatory Order, DNC will:

a. Revise, as necessary, Standing Order 14–016 dated May 11, 2014, to incorporate applicable Millstone Unit 2 Technical Specifications (TSs); limiting conditions of operations (LCOs); actions; and surveillances that reflect the safety analysis of the inadvertent opening of the PORVs prior to implementation of Amendment No. 283. This revision of the standing order will be made available for NRC review prior to implementation.

b. Complete an operability evaluation for the use of charging pumps in accordance with Standing Order 14–016, as revised by paragraph 1.a., associated with the inadvertent opening of PORVs and make the operability evaluation available to NRC for review; and

c. Evaluate the effect of three pump charging pump operation (*i.e.*, three charging pumps auto start and provide flow) with the current plant configuration. If the evaluation concludes no adverse effect, revised Standing Order 14–016 will be changed to require that three charging pumps auto start and provide flow. This evaluation will be made available for NRC review.

2. By no later than February 15, 2016, DNC will submit a license amendment request to the NRC addressing the use of charging pumps in the analysis of the inadvertent opening of PORVs. If DNC

does not submit a license amendment request by February 15, 2016, the Millstone Unit 2 design and licensing basis for the operation of charging pumps to mitigate the inadvertent opening of PORVs that was in place prior to Amendment No. 283 (dated September 9, 2004) will be reinstated by this Confirmatory Order, and DNC will take all actions necessary to conform Millstone Unit 2 to the reinstated design and licensing basis.

3. DNC's Standing Order 14–016 (Rev. 0, dated May 11, 2014), as revised in accordance with paragraph 1 above, will remain in place until the NRC makes a final determination on the license amendment request submitted under paragraph 2 above.

4. If the NRC denies the license amendment request submitted under paragraph 2 above, or the licensee withdraws the license amendment request, the Millstone Unit 2 design and licensing basis for the operation of charging pumps to mitigate the inadvertent opening of PORVs that was in place prior to implementation of Amendment No. 283 (dated September 9, 2004) will be reinstated by this Confirmatory Order, and DNC will take all actions necessary to conform Millstone Unit 2 to the reinstated design and licensing basis.

5. By no later than February 15, 2016, DNC will submit a license amendment request seeking NRC approval of the spent fuel pool heat load analysis and any associated technical specification changes. This will be treated as a high priority review by the NRC.

6. DNC's Standing Order 14–021 (Rev. 0 dated July 9, 2014) will remain in place until the NRC makes a final determination on the license amendment request submitted under paragraph 5 above.

7. If the NRC denies the license amendment request submitted under paragraph 5 above, or the licensee withdraws the license amendment request, TS 3/4.9.3.1 in the Millstone Unit 2 license will be revised by this Confirmatory Order to require 150 hours of decay time before moving irradiated fuel from the reactor to the spent fuel pool, and changes made by Licensing Basis Document Change Request 10–MP2–007 (dated June 22, 2010) to Chapter 9 of the Millstone Unit 2 UFSAR and to the TS Bases will be replaced by the prior content of those documents. DNC will take all actions necessary to conform Millstone Unit 2 to the requirements of the revised TS and UFSAR.

Assessment.

8. By no later than June 30, 2016, DNC will complete a self-assessment of its 10 CFR 50.59 program and procedures (including applicability, screening and evaluations) including a review of procedures, implementation, initial training, continuing training, and safety review committee activities. A majority of the self-assessment team will be comprised of a combination of non-Dominion industry experts and peers. The assessment will also address the Millstone Nuclear Oversight organization's responsibilities and the effectiveness of the execution of those responsibilities regarding the 10 CFR 50.59 program.

a. DNC shall make available to the NRC, upon request, the results of the assessment and any corrective actions DNC will take to address the results.

b. DNC will complete corrective actions resulting from findings of the assessment consistent with the requirements of the Millstone Corrective Action Program.

9. DNC has conducted two apparent cause evaluations to address the issues included in this Confirmatory Order.

a. The results of these evaluations will be made available to the NRC for review.

10. By no later than March 1, 2016, DNC will complete a common cause evaluation of 10 CFR 50.59 issues that have been identified after July 1, 2012, with emphasis on any underlying culture-related issues that specifically may exist in the Millstone Power Station Engineering and Licensing groups and the Facility Safety Review Committee. The team will include a member trained in cultural issues. Interviews of a sample of the staff members from the above groups will be included in the evaluation. In regard to this evaluation, DNC shall:

a. Make the results of the evaluation available to the NRC.

b. Communicate to Millstone Power Station employees the results of the evaluation within three (3) months of receiving the evaluation results.

c. Review the results of the common cause evaluation and initiate corrective actions as appropriate within 30 days of receiving evaluation results.

Extent of Condition.

11. By no later than June 30, 2016, DNC will complete a formal sampling program, using MIL Standard 105 or similar, of products (applicability determinations, screenings, and evaluations) completed using the DNC 10 CFR 50.59 programs and procedures.

a. The reviewers conducting the sampling program will be third party independent reviewers.

b. Applicability determinations, screenings, and evaluations will be sampled as separate populations.

c. For each population, the sampling time period will begin in 2002 and end as of the date of this Confirmatory Order.

d. DNC will enter any identified deficiencies into DNC's corrective action program.

e. Pursuant to Section 3.3 of the NRC Enforcement Policy, the NRC will consider exercising enforcement discretion to refrain from issuing a Notice of Violation or civil penalty for any non-willful Severity Level II, III, or IV violation identified as part of the sampling program described above, if the violation meets all of the following criteria:

(1) the violation has the same or similar cause as the apparent violations of 10 CFR 50.59 that are the subject of this Confirmatory Order;

(2) the violation is a newly-found violation that occurred prior to issuance of this Confirmatory Order;

(3) the violation does not substantially change the safety significance or the character of the regulatory concerns arising out of the apparent violations that underlie this Confirmatory Order; and

(4) the violation is corrected, by both immediate corrective action(s) and long-term comprehensive corrective action(s), within a reasonable time following identification.

f. The NRC will also consider discretion for any DNC-identified performance deficiencies that meet the criteria listed in paragraph 11.e and are categorized as a Green or White finding under the NRC's Reactor Oversight Program.

Communication.

12. By no later than thirty (30) calendar days after the issuance of this Confirmatory Order, DNC's Chief Nuclear Officer will issue a fleet-wide communication (written or recorded) to reinforce the importance of providing complete and accurate information to the NRC, including requirements for updating out-of-date information, and the potential consequences of a failure to comply with these requirements. The communication, whether written or recorded, and any associated materials or references, will be made available to the NRC.

13. By no later than December 31, 2016, DNC will provide a presentation at an industry forum to discuss the events that led to this Confirmatory Order, the lessons learned, and actions taken. The presentation and any associated material will be made available to the NRC.

Training.

14. DNC will review its plant access training and revise it as necessary to

ensure that it includes training on compliance with NRC requirements, including, but not limited to, 10 CFR 50.5 and 50.9. Any revisions will be made available to the NRC.

15. Notwithstanding that NRC and DNC disagree about whether a willful violation occurred, DNC will develop and provide focused training to Dominion corporate Engineering and Licensing personnel who perform work for Millstone and to DNC Engineering and Licensing personnel, to ensure awareness of the importance of complying with regulatory requirements, and the potential consequences of a failure to comply, including what constitutes a willful violation of NRC requirements. DNC will provide this training by April 1, 2016, and will repeat it 12 months after the initial training session. The training and any associated training materials will be made available to the NRC.

16. DNC will develop and provide focused training to Dominion corporate Engineering and Licensing personnel performing work for Millstone and to DNC Engineering and Licensing personnel, covering the requirements of 10 CFR 50.9, emphasizing the importance of providing complete and accurate information to the NRC and of informing the NRC promptly upon discovery of inaccurate information or omissions associated with pending NRC licensing actions or other information submitted to the NRC. DNC will provide this training by April 1, 2016. The training and any associated training materials will be made available to the NRC.

Other Considerations.

17. The NRC agrees not to pursue any further enforcement action relating to the notice of apparent violations (Case no. EA–13–188, Inspection Report 05000336/2015201, Office of Investigations Report No. 1–2012–008), dated April 29, 2015.

18. This Confirmatory Order will not be considered an escalated enforcement action by the NRC for future assessment of violations occurring at Millstone Power Station Unit 2.

19. In the event of the transfer of the operating license of Millstone Power Station Unit 2 to another entity, the commitments hereunder shall survive any transfer of ownership and will be binding on the new licensee.

The Director, Office of Enforcement, may, in writing, relax or rescind any of the above conditions upon demonstration by the Licensee of good cause.

V.

Any person adversely affected by this Confirmatory Order, other than DNC, may request a hearing within 30 days of issuance. Where good cause is shown, consideration will be given to extending the time to request a hearing. A request for extension of time must be made in writing to the Director, Office of Enforcement, U.S. Nuclear Regulatory Commission, Washington, DC 20555, and include a statement of good cause for the extension.

All documents filed in NRC adjudicatory proceedings, including a request for hearing, a petition for leave to intervene, any motion or other document filed in the proceeding prior to the submission of a request for hearing or petition to intervene, and documents filed by interested governmental entities participating under 10 CFR 2.315(c), must be filed in accordance with the NRC E-Filing rule (72 FR 49139, August 28, 2007). The E-Filing process requires participants to submit and serve all adjudicatory documents over the internet, or in some cases to mail copies on electronic storage media. Participants may not submit paper copies of their filings unless they seek an exemption in accordance with the procedures described below.

To comply with the procedural requirements of E-Filing, at least ten (10) days prior to the filing deadline, the participant should contact the Office of the Secretary by email at *hearing.docket@nrc.gov*, or by telephone at 301–415–1677, to (1) request a digital ID certificate, which allows the participant (or its counsel or representative) to digitally sign documents and access the E-Submittal server for any proceeding in which it is participating; and (2) advise the Secretary that the participant will be submitting a request or petition for hearing (even in instances in which the participant, or its counsel or representative, already holds an NRC-issued digital ID certificate). Based upon this information, the Secretary will establish an electronic docket for the hearing in this proceeding if the Secretary has not already established an electronic docket.

Information about applying for a digital ID certificate is available on NRC's public Web site at *http://www.nrc.gov/site-help/e-submittals/apply-certificates.html*. System requirements for accessing the E-Submittal server are detailed in NRC's "Guidance for Electronic Submission," which is available on the agency's public Web site at *http://www.nrc.gov/site-help/e-submittals.html*. Participants may attempt to use other software not listed on the Web site, but should note that the NRC's E-Filing system does not support unlisted software, and the NRC Meta System Help Desk will not be able to offer assistance in using unlisted software.

If a participant is electronically submitting a document to the NRC in accordance with the E-Filing rule, the participant must file the document using the NRC's online, Web-based submission form. Further information on the Web-based submission form is available on the NRC's public Web site at *http://www.nrc.gov/site-help/e-submittals.html*.

Once a participant has obtained a digital ID certificate and a docket has been created, the participant can then submit a request for hearing or petition for leave to intervene. Submissions should be in Portable Document Format (PDF) in accordance with NRC guidance available on the NRC public Web site at *http://www.nrc.gov/site-help/e-submittals.html*. A filing is considered complete at the time the documents are submitted through the NRC's E-Filing system. To be timely, an electronic filing must be submitted to the E-Filing system no later than 11:59 p.m. Eastern Time on the due date. Upon receipt of a transmission, the E-Filing system time-stamps the document and sends the submitter an email notice confirming receipt of the document. The E-Filing system also distributes an email notice that provides access to the document to the NRC Office of the General Counsel and any others who have advised the Office of the Secretary that they wish to participate in the proceeding, so that the filer need not serve the documents on those participants separately. Therefore, applicants and other participants (or their counsel or representative) must apply for and receive a digital ID certificate before a hearing request/petition to intervene is filed so that they can obtain access to the document via the E-Filing system.

A person filing electronically using the agency's adjudicatory E-Filing system may seek assistance by contacting the NRC Electronic Filing Help Desk through the "Contact Us" link located on the NRC Web site at *http://www.nrc.gov/site-help/e-submittals.html*, by email at *MSHD.Resource@nrc.gov*, or by a toll-free call at (866) 672–7640. The NRC Electronic Filing Help Desk is available between 8 a.m. and 8 p.m., Eastern Time, Monday through Friday, excluding government holidays.

Participants who believe that they have a good cause for not submitting documents electronically must file an exemption request, in accordance with 10 CFR 2.302(g), with their initial paper filing requesting authorization to continue to submit documents in paper format. Such filings must be submitted by: (1) first class mail addressed to the Office of the Secretary of the Commission, U.S. Nuclear Regulatory Commission, Washington, DC 20555–0001, Attention: Rulemaking and Adjudications Staff; or (2) courier, express mail, or expedited delivery service to the Office of the Secretary, Sixteenth Floor, One White Flint North, 11555 Rockville Pike, Rockville, Maryland, 20852, Attention: Rulemaking and Adjudications Staff. Participants filing a document in this manner are responsible for serving the document on all other participants. Filing is considered complete by first-class mail as of the time of deposit in the mail, or by courier, express mail, or expedited delivery service upon depositing the document with the provider of the service. A presiding officer, having granted an exemption request from using E-Filing, may require a participant or party to use E-Filing if the presiding officer subsequently determines that the reason for granting the exemption from use of E-Filing no longer exists.

Documents submitted in adjudicatory proceedings will appear in NRC's electronic hearing docket which is available to the public at *http://ehd1.nrc.gov/ehd/*, unless excluded pursuant to an order of the Commission, or the presiding officer. Participants are requested not to include personal privacy information, such as social security numbers, home addresses, or home phone numbers in their filings, unless an NRC regulation or other law requires submission of such information. With respect to copyrighted works, except for limited excerpts that serve the purpose of the adjudicatory filings and would constitute a Fair Use application, participants are requested not to include copyrighted materials in their submission.

If a person (other than DNC) requests a hearing, that person shall set forth with particularity the manner in which his interest is adversely affected by this Confirmatory Order and shall address the criteria set forth in 10 CFR 2.309(d) and (f).

If a hearing is requested by a person whose interest is adversely affected, the Commission will issue an order designating the time and place of any hearing. If a hearing is held, the issue to be considered at such hearing shall be whether this Confirmatory Order should be sustained.

In the absence of any request for hearing, or written approval of an extension of time in which to request a hearing, the provisions specified in Section IV above shall be final 30 days from the date of issuance without further order or proceedings. If an extension of time for requesting a hearing has been approved, the provisions specified in Section IV shall be final when the extension expires if a hearing request has not been received.

Dated at Rockville, Maryland, this 26th day of August 2015.

For the Nuclear Regulatory Commission.

Scott A. Morris,

Director, Division of Inspection and Regional Support, Office of Nuclear Reactor Regulation

BILLING CODE 7590–01–P

NUCLEAR REGULATORY COMMISSION

[NRC–2015–0001]

Sunshine Act Meeting Notice

DATE: September 14, 21, 28, October 5, 12, 19, 2015.

PLACE: Commissioners' Conference Room, 11555 Rockville Pike, Rockville, Maryland.

STATUS: Public and Closed.

Week of September 14, 2015

There are no meetings scheduled for the week of September 14, 2015.

Week of September 21, 2015—Tentative

Tuesday, September 22, 2015

9:30 a.m. Discussion of Management and Personnel Issues (Closed—Ex. 2 & 6).

Thursday, September 24, 2015

9:30 a.m. Strategic Programmatic Overview of the New Reactors Business Line (Public Meeting); (Contact: Donna Williams: 301–415–1322).

This meeting will be webcast live at the Web address—*http://www.nrc.gov/.*

Week of September 28, 2015—Tentative

Monday, September 28, 2015

1:30 p.m. NRC All Employees Meeting (Public Meeting), Marriott Bethesda North Hotel, 5701 Marinelli Road, Rockville, MD 20852.

Thursday, October 1, 2015

9:00 a.m. Strategic Programmatic Overview of the Decommissioning and Low-Level Waste and Spent Fuel Storage and Transportation Business Lines (Public Meeting); (Contact: Damaris Marcano: 301–415–7328).

This meeting will be webcast live at the Web address—*http://www.nrc.gov/.*

Week of October 5, 2015—Tentative

There are no meetings scheduled for the week of October 5, 2015.

Week of October 12, 2015—Tentative

There are no meetings scheduled for the week of October 12, 2015.

Week of October 19, 2015—Tentative

Monday, October 19, 2015

9:30 a.m. Briefing on Security Issues (Closed—Ex. 1).

Wednesday, October 21, 2015

9:00 a.m. Joint Meeting of the Federal Energy Regulatory Commission and the Nuclear Regulatory Commission (Public Meeting); (Contact: Tania Martinez-Navedo: 301–415–6561).

* * * * *

The schedule for Commission meetings is subject to change on short notice. For more information or to verify the status of meetings, contact Glenn Ellmers at 301–415–0442 or via email at *Glenn.Ellmers@nrc.gov.*

* * * * *

The NRC Commission Meeting Schedule can be found on the Internet at: *http://www.nrc.gov/public-involve/public-meetings/schedule.html.*

* * * * *

The NRC provides reasonable accommodation to individuals with disabilities where appropriate. If you need a reasonable accommodation to participate in these public meetings, or need this meeting notice or the transcript or other information from the public meetings in another format (*e.g.* braille, large print), please notify Kimberly Meyer, NRC Disability Program Manager, at 301–287–0727, by videophone at 240–428–3217, or by email at *Kimberly.Meyer-Chambers@nrc.gov.* Determinations on requests for reasonable accommodation will be made on a case-by-case basis.

* * * * *

Members of the public may request to receive this information electronically. If you would like to be added to the distribution, please contact the Nuclear Regulatory Commission, Office of the Secretary, Washington, DC 20555 (301–415–1969), or email *Brenda.Akstulewicz@nrc.gov* or *Patricia.Jimenez@nrc.gov.*

Dated: September 10, 2015.

Glenn Ellmers,

Policy Coordinator, Office of the Secretary.

Extension: Rule 17a–12/Form X–17A–5 Part IIB.

Notice is hereby given that pursuant to the Paperwork Reduction Act of 1995 ("PRA") (44 U.S.C. 3501 *et seq.*), the Securities and Exchange Commission ("Commission") is soliciting comments on the existing collection of information provided for in Rule 17a–12 (17 CFR 240.17a–12) and Part IIB of Form X–17A–5 (17 CFR 249.617) under the Securities Exchange Act of 1934 (15 U.S.C. 78a *et seq.*). The Commission plans to submit this existing collection of information to the Office of Management and Budget ("OMB") for extension and approval.

Rule 17a–12 is the reporting rule tailored specifically for over-the-counter ("OTC") derivatives dealers registered with the Commission, and Part IIB of Form X–17A–5, the Financial and Operational Combined Uniform Single ("FOCUS") Report, is the basic document for reporting the financial and operational condition of OTC derivatives dealers. Rule 17a–12 requires registered OTC derivatives dealers to file Part IIB of the FOCUS Report quarterly. Rule 17a–12 also requires that OTC derivatives dealers file audited financial statements annually.

There are currently four registered OTC derivatives dealers. The staff expects that one additional firm will register as an OTC derivatives dealer within the next three years. The staff estimates that the average amount of time necessary to prepare and file the quarterly reports required by the rule is eighty hours per OTC derivatives dealer [1] and that the average amount of time to prepare and file the annual audit report is 100 hours per OTC derivatives dealer per year, for a total reporting burden of 180 hours per OTC derivatives dealer annually. Thus the staff estimates that the total industry-wide reporting burden to comply with the requirements of Rule 17a–12 is 900 hours per year (180 × 5). Further, the Commission estimates that the total internal compliance cost associated with this requirement is approximately $255,000 per year.[2] The average annual reporting cost per broker-dealer for an independent public accountant to examine the financial statements is approximately $46,300 per broker-dealer. Thus, the total industry-wide annual reporting cost is approximately $231,500 ($46,300 × 5).

Written comments are invited on: (a) Whether the proposed collection of information is necessary for the proper performance of the functions of the Commission, including whether the information shall have practical utility; (b) the accuracy of the Commission's estimate of the burden of the proposed collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; and (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology. Consideration will be given to comments and suggestions submitted in writing within 60 days of this publication.

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information under the PRA unless it displays a currently valid OMB control number.

Please direct your written comments to: Pamela Dyson, Director/Chief Information Officer, Securities and Exchange Commission, c/o Remi Pavlik-Simon, 100 F Street NE., Washington, DC 20549, or send an email to: *PRA_Mailbox@sec.gov.*

[1] Based upon an average of 4 responses per year and an average of 20 hours spent preparing each response.

[2] Based on staff experience, an OTC derivatives dealer likely would have a Compliance Manager gather the necessary information and prepare and file the quarterly reports and annual audit report and supporting schedules. According to the Securities Industry and Financial Markets Association Report on Management and Professional Earnings in the Securities Industry dated October 2013, which provides base salary and bonus information for middle-management and professional positions within the securities industry, the hourly cost of a compliance manager, which the Commission staff has modified to account for an 1800-hour work year and multiplied by 5.35 to account for bonuses, firm size, employee benefits, and overhead, is approximately $283/hour. $283/hour times 900 hours = $254,700, rounded to $255,000.

Dated: September 8, 2015.

Robert W. Errett,

Deputy Secretary.

BILLING CODE 8011–01–P

SECURITIES AND EXCHANGE COMMISSION

[Release No. 34–75856; File No. SR–MIAX–2015–53]

Self-Regulatory Organizations; Miami International Securities Exchange LLC; Notice of Filing and Immediate Effectiveness of a Proposed Rule Change To Amend Its Fee Schedule

September 8, 2015.

Pursuant to the provisions of Section 19(b)(1) of the Securities Exchange Act of 1934 ("Act"),[1] and Rule 19b–4 thereunder,[2] notice is hereby given that on August 28, 2015, Miami International Securities Exchange LLC ("MIAX" or "Exchange") filed with the Securities and Exchange Commission ("Commission") a proposed rule change as described in Items I, II, and III below, which Items have been prepared by the Exchange. The Commission is publishing this notice to solicit comments on the proposed rule change from interested persons.

I. Self-Regulatory Organization's Statement of the Terms of Substance of the Proposed Rule Change

The Exchange is filing a proposal to amend the MIAX Options Fee Schedule (the "Fee Schedule").

The text of the proposed rule change is available on the Exchange's Web site at *http://www.miaxoptions.com/filter/wotitle/rule_filing,* at MIAX's principal office, and at the Commission's Public Reference Room.

II. Self-Regulatory Organization's Statement of the Purpose of, and Statutory Basis for, the Proposed Rule Change

In its filing with the Commission, the Exchange included statements concerning the purpose of and basis for the proposed rule change and discussed any comments it received on the proposed rule change. The text of these statements may be examined at the places specified in Item IV below. The Exchange has prepared summaries, set forth in sections A, B, and C below, of the most significant aspects of such statements.

[1] 15 U.S.C. 78s(b)(1).

[2] 17 CFR 240.19b–4.

A. Self-Regulatory Organization's Statement of the Purpose of, and Statutory Basis for, the Proposed Rule Change

1. Purpose

The Exchange proposes to amend its Fee Schedule to increase the transaction fee rebate for Priority Customer[3] orders submitted by Members that meet certain percentage thresholds of national customer volume in multiply-listed option classes listed on MIAX in the Priority Customer Rebate Program (the "Program").[4]

Priority Customer Rebate Program

Currently, the Exchange credits each Member the per contract amount resulting from each Priority Customer order transmitted by that Member that is executed electronically on the Exchange in all multiply-listed option classes (excluding Qualified Contingent Cross Orders,[5] mini-options,[6] Priority Customer-to-Priority Customer Orders, PRIME Auction Or Cancel Responses, PRIME Contra-side Orders, PRIME Orders for which both the Agency and Contra-side Order are Priority Customers,[7] and executions related to contracts that are routed to one or more exchanges in connection with the Options Order Protection and Locked/Crossed Market Plan referenced in MIAX Rule 1400), provided the Member meets certain tiered percentage thresholds in a month as described in the Priority Customer Rebate Program table.[8] For each Priority Customer order transmitted by that Member and executed electronically on the Exchange, MIAX will continue to credit each member at the per contract rate for option classes that are not in MIAX Select Symbols (as defined below). For each Priority Customer order transmitted by that Member and executed electronically on the Exchange in MIAX Select Symbols (as defined below), MIAX will continue to credit each Member at the separate per contract rate for MIAX Select Symbols.[9] For each Priority Customer order submitted into the PRIME Auction as a PRIME Agency Order, MIAX will continue to credit each member at the separate per contract rate for PRIME Agency Orders.[10] The volume thresholds are calculated based on the customer volume over the course of the month. Volume will be recorded for and credits will be delivered to the Member Firm that submits the order to the Exchange.

The amount of the rebate is calculated beginning with the first executed contract at the applicable threshold per contract credit with rebate payments made at the highest achieved volume tier for each contract traded in that month. For example, under the current Program, a Member that executes a number of Priority Customer contracts above 1.75% of the national customer volume in multiply-listed options during a particular calendar month currently receives a credit of $0.17 for each Priority Customer contract (other than Select Symbols) executed during that month, even though there are lower incremental percentages for lower volume tiers leading up to the 1.75% volume threshold. In addition, all contracts (other than Select Symbols) traded in a particular month in excess of 1.75% of the national volume receive a supplemental rebate of $0.03 per contract.

The current Priority Customer Rebate Program table designates the following monthly volume tiers and corresponding per contract credits:

Percentage thresholds of national customer volume in multiply-listed options classes listed on MIAX (monthly)	Per contract credit (non-select symbols)	Per contract credit in MIAX select symbols	Per contract credit for PRIME agency order
Tier 1—0.00%–0.50%	$0.00	$0.00	$0.10
Tier 2—Above 0.50%–1.00%	0.10	0.10	0.10
Tier 3—Above 1.00%–1.75%–1.75% [sic]	0.15	0.20	0.10
Tier 4—Above 1.75%	0.17	0.20	0.10

The $0.17 per contract credit described in Tier 4 is applied to each contract traded in non-Select Symbols in that month, beginning with the first contract executed in a particular month if the Tier 4 volume threshold is achieved. In addition to the $0.17 rebate, a supplemental rebate of $0.03 per contract is applied to contracts executed in excess of 1.75% of the monthly national volume in non-Select Symbols.

Proposal

The Exchange proposes to increase the per contract credit for transactions in non-Select Symbols for Tier 4. As stated above, all contracts (other than Select Symbols) traded in a particular month when the Tier 4 volume threshold of 1.75% of the national monthly customer volume is exceeded receive a credit of $0.17 per contract for qualifying Priority Customer transactions on MIAX. The Exchange

[3] The term "Priority Customer" means a person or entity that (i) is not a broker or dealer in securities, and (ii) does not place more than 390 orders in listed options per day on average during a calendar month for its own beneficial accounts(s). *See* Exchange Rule 100.

[4] *See* Securities Exchange Act Release Nos. 75631 (August 5 [sic], 2015), 80 FR 48382 (August 6 [sic], 2015) (SR–MIAX–2015–51); 74758 (April 17, 2015), 80 FR 22756 (April 23, 2015) (SR–MIAX–2015–27); 74007 (January 9 [sic], 2015), 80 FR 1537 (January 12, 2015) (SR–MIAX–2014–69); 72799 (August 8, 2014), 79 FR 47698 (August 14, 2014) (SR–MIAX–2014–40); 72355 (June 10, 2014), 79 FR 34368 (June 16, 2014) (SR–MIAX–2014–25); 71698 (March 12, 2014), 79 FR 15185 (March 18, 2014) (SR–MIAX–2014–12); 71283 (January 10, 2014), 79 FR 2914 (January 16, 2014) (SR–MIAX–2013–63); 71009 (December 6, 2013), 78 FR 75629 (December 12, 2013) (SR–MIAX–2013–56).

[5] A Qualified Contingent Cross Order is comprised of an originating order to buy or sell at least 1,000 contracts, or 10,000 mini-option contracts, that is identified as being part of a qualified contingent trade, as that term is defined in Interpretations and Policies .01 below, coupled with a contra-side order or orders totaling an equal number of contracts. A Qualified Contingent Cross Order is not valid during the opening rotation process described in Rule 503. *See* Exchange Rule 516(j).

[6] A mini-option is a series of option contracts with a 10 share deliverable on a stock, Exchange Traded Fund share, Trust Issued Receipt, or other Equity Index-Linked Security. *See* Exchange Rule 404, Interpretations and Policies .08.

[7] The MIAX Price Improvement Mechanism ("PRIME") is a process by which a Member may electronically submit for execution ("Auction") an order it represents as agent ("Agency Order") against principal interest, and/or an Agency Order against solicited interest. For a complete description of PRIME and of PRIME order types and responses, *see* Exchange Rule 515A.

[8] *See* Fee Schedule Section (1)(a)(iii).

[9] *See* Securities Exchange [sic] Release Nos. 75631 (August 5 [sic], 2015), 80 FR 48382 (August 6 [sic], 2015) (SR–MIAX–2015–51); 74291 (February 18, 2015), 80 FR 9841 (February 24, 2015) (SR–MIAX–2015–09); 74288 (February 18, 2015), 80 FR 9837 (February 24, 2015) (SR–MIAX–2015–08); 71700 (March 12, 2014), 79 FR 15188 (March 18, 2014) (SR–MIAX–2014–13); 72356 (June 10, 2014), 79 FR 34384 (June 16, 2014) (SR–MIAX–2014–26); 72567 (July 8, 2014), 79 FR 40818 (July 14, 2014) (SR–MIAX–2014–34); 73328 (October 9, 2014), 79 FR 62230 (October 16, 2014) (SR–MIAX–2014–50).

[10] *See* Securities Exchange [sic] Release No. 72943 (August 28, 2014), 79 FR 52785 (September 4, 2014) (SR–MIAX–2014–45).

proposes to increase this per contract credit for Priority Customer transactions in non-Select Symbols in Tier 4 to $0.21. Contracts executed in non-Select Symbols in excess of 1.75% of national monthly customer volume currently receive a supplemental rebate of $0.03 per contract. The Exchange proposes to eliminate this additional $0.03 rebate per contract.

The Exchange also proposes to increase the per contract credit for transactions in MIAX Select Symbols for tiers 3 and 4. Currently, the Exchange credits $0.20 per contract for qualifying Priority Customer transactions in MIAX Select Symbols in tiers 3 and 4. The Exchange proposes to increase the per contract credit for transactions in MIAX Select Symbols to $0.21 for the tier 3 and 4 volume thresholds.

Specifically, the new per contract credits will be as set forth in the following table:

Percentage thresholds of national customer volume in multiply-listed options classes listed on MIAX (monthly)	Per contract credit (non-select symbols)	Per contract credit in MIAX select symbols	Per contract credit for PRIME agency order
Tier 1—0.00%–0.50%	$0.00	$0.00	$0.10
Tier 2—Above 0.50%–1.00%	0.10	0.10	0.10
Tier 3—Above 1.00%–1.75%	0.15	0.21	0.10
Tier 4—Above 1.75%	0.21	0.21	0.10

The Exchange believes that the proposed new monthly credits should provide incentives for Members to direct greater Priority Customer trade volume to the Exchange.

MIAX Select Symbols

The proposed new monthly per contract credits will apply to MIAX Select Symbols,[11] with the per contract credit increasing for certain monthly volume thresholds. The monthly per contract rebate will increase to $0.21 for all contracts executed in Select Symbols in tiers 3 and 4.

MIAX Non-Select Symbols

Proposed new monthly per contract credits will apply to non-Select Symbols with the per contract credit increasing for certain monthly volume thresholds. The monthly per contract credit will increase to $0.21 for all contracts executed in non-Select Symbols in tier 4. The Exchange also proposes to eliminate the current additional rebate of $0.03 per contract for non-Select Symbol contracts executed in excess of the Tier 4 monthly volume of 1.75% of the national customer volume. Under the proposal, all contracts (other than Select Symbols) traded in a particular month when the Tier 4 volume threshold of 1.75% of the national monthly customer volume is exceeded will receive a credit of $0.21, and contracts executed in non-Select Symbols in excess of 1.75% of national monthly customer volume will no longer receive a supplemental rebate of $0.03 per contract. The Exchange believes that this new, increased rebate which is calculated beginning with the first executed contract at the applicable threshold per contract credit with rebate payments made at $0.21 for each contract trade or [sic] that month obviates the need for the supplemental rebate.

All other aspects of the Program will remain unchanged. The Exchange is not proposing any change to the per contract credit for PRIME Agency Orders. Consistent with the current Fee Schedule, the Exchange will continue to aggregate the contracts resulting from Priority Customer orders transmitted and executed electronically on the Exchange from affiliated Members for purposes of the thresholds above, provided there is at least 75% common ownership between the firms as reflected on each firm's Form BD, Schedule A. In the event of a MIAX System outage or other interruption of electronic trading on MIAX, the Exchange will adjust the national customer volume in multiply-listed options for the duration of the outage. A Member may request to receive its credit under the Priority Customer Rebate Program as a separate direct payment.

The purpose of the proposed rule change is to encourage Members to direct greater Priority Customer trade volume to the Exchange and to compete with other options exchanges that have a similar rebate.[12] The Exchange believes that increased Priority Customer volume will attract more liquidity to the Exchange, which benefits all market participants. Increased retail customer order flow should attract professional liquidity providers (Market Makers), which in turn should make the MIAX marketplace an attractive venue where Market Makers will submit narrow quotations with greater size, deepening and enhancing the quality of the MIAX marketplace. This should provide more trading opportunities and tighter spreads for other market participants and result in a corresponding increase in order flow from such other market participants.

The specific volume thresholds of the Program's tiers are set based upon business determinations and an analysis of current volume levels. The volume thresholds are intended to incentivize firms to increase the number of Priority Customer orders they send to the Exchange so that they can achieve the next threshold, and to encourage new participants to send Priority Customer orders as well. Increasing the number of orders sent to the Exchange will in turn provide tighter and more liquid markets, and therefore attract more business overall. Similarly, the different credit rates at the different tier levels are based on an analysis of current revenue and volume levels and are intended to provide increasing "rewards" to MIAX participants for increasing the volume of Priority Customer orders sent to, and Priority Customer contracts executed on, the Exchange. The specific amounts of the tiers and rates are set in order to encourage suppliers of Priority Customer order flow to reach for higher tiers.

The credits paid out as part of the program will be drawn from the general revenues of the Exchange.[13] The Exchange calculates volume thresholds on a monthly basis.

[11] The term "MIAX Select Symbols" means options overlying AA, AAL, AAPL, AIG, AMAT, AMD, AMZN, BA, BABA, BBRY, BIDU, BP, C, CAT, CBS, CELG, CLF, CVX, DAL, EBAY, EEM, FB, FCX, GE, GILD, GLD, GM, GOOGL, GPRO, HAL, HTZ, INTC, IWM, JCP, JNJ, JPM, KMI, KO, MO, MRK, NFLX, NOK, NQ, ORCL, PBR, PFE, PG, QCOM, QQQ, RIG, S, SPY, SUNE, T, TSLA, USO, VALE, VXX, WBA, WFC, WMB, WY, X, XHB, XLE, XLF, XLP, XOM, XOP and YHOO. *See* Fee Schedule, note 13.

[12] See, e.g., Securities Exchange Act Release No. 75702 (August 14, 2015), 80 FR 50685 (August 20, 2015) (SR–PHLX–2015–68).

[13] Despite providing credits under the Program, the Exchange represents that it will continue to have adequate resources to fund its regulatory program and fulfill its responsibilities as a self-regulatory organization while the Program is in effect.

2. Statutory Basis

The Exchange believes that its proposal to amend its fee schedule is consistent with Section 6(b) of the Act[14] in general, and furthers the objectives of Section 6(b)(4) of the Act[15] in particular, in that it is an equitable allocation of reasonable fees and other charges among Exchange members.

The Exchange believes that the proposal is equitable and not unfairly discriminatory. The Program and the proposed increase in the per contract rebate is reasonably designed because it will encourage providers of Priority Customer order flow to send that Priority Customer order flow to the Exchange in order to receive an increasing per contract credit with each volume tier achieved. The Exchange believes that the proposed increase in the per contract rate should improve market quality for all market participants. The proposed changes to the rebate program are fair and equitable and not unreasonably discriminatory because they apply equally to all Priority Customer orders. All similarly situated Priority Customer orders are subject to the same rebate schedule, and access to the Exchange is offered on terms that are not unfairly discriminatory. Furthermore, the proposed increase in credits is equitable and not unfairly discriminatory because the proposed rates and changes encourage Members to direct increased amounts of Priority Customer contracts to the Exchange. Market participants want to trade with Priority Customer order flow. To the extent Priority Customer order flow is increased by the proposal, market participants will increasingly compete for the opportunity to trade on the Exchange including sending more orders and providing narrower and larger sized quotations in the effort to trade with such Priority Customer order flow. The resulting increased volume and liquidity will benefit all Exchange participants by providing more trading opportunities and tighter spreads.

B. Self-Regulatory Organization's Statement on Burden on Competition

The Exchange does not believe that the proposed rule change will impose any burden on competition not necessary or appropriate in furtherance of the purposes of the Act. The Exchange believes that the proposed change would increase both intermarket and intramarket competition by encouraging Members to direct their Priority Customer orders to the Exchange, which should enhance the quality of quoting and increase the volume of contracts traded on MIAX. Respecting the competitive position of non-Priority Customers, the Exchange believes that this rebate program should provide additional liquidity that enhances the quality of its markets and increases the number of trading opportunities on MIAX for all participants, including non-Priority Customers, who will be able to compete for such opportunities. This should benefit all market participants and improve competition on the Exchange.

The Exchange notes that it operates in a highly competitive market in which market participants can readily favor competing venues if they deem fee levels at a particular venue to be excessive. In such an environment, the Exchange must continually adjust its fees and rebates to remain competitive with other exchanges and to attract order flow to the Exchange. The Exchange believes that the proposed rule change reflects this competitive environment because it increases rebates and thus encourages market participants to direct their customer order flow, to provide liquidity, and to attract additional transaction volume to the Exchange. Given the robust competition for volume among options markets, many of which offer the same products, enhancing the existing volume based customer rebate program to attract order flow is consistent with the goals of the Act. The Exchange believes that the proposal will enhance competition, because market participants will have another additional pricing consideration in determining where to execute orders and post liquidity if they factor the benefits of the proposed rebate program into the determination.

C. Self-Regulatory Organization's Statement on Comments on the Proposed Rule Change Received From Members, Participants, or Others

Written comments were neither solicited nor received.

III. Date of Effectiveness of the Proposed Rule Change and Timing for Commission Action

The foregoing rule change has become effective pursuant to Section 19(b)(3)(A)(ii) of the Act.[16] At any time within 60 days of the filing of the proposed rule change, the Commission summarily may temporarily suspend such rule change if it appears to the Commission that such action is necessary or appropriate in the public interest, for the protection of investors, or otherwise in furtherance of the purposes of the Act. If the Commission takes such action, the Commission shall institute proceedings to determine whether the proposed rule should be approved or disapproved.

IV. Solicitation of Comments

Interested persons are invited to submit written data, views, and arguments concerning the foregoing, including whether the proposed rule change is consistent with the Act. Comments may be submitted by any of the following methods:

Electronic Comments

- Use the Commission's Internet comment form (*http://www.sec.gov/rules/sro.shtml*); or
- Send an email to *rule-comments@sec.gov*. Please include File Number SR–MIAX–2015–53 on the subject line.

Paper Comments

- Send paper comments in triplicate to Brent J. Fields, Secretary, Securities and Exchange Commission, 100 F Street NE., Washington, DC 20549–1090.

All submissions should refer to File Number SR–MIAX–2015–53. This file number should be included on the subject line if email is used. To help the Commission process and review your comments more efficiently, please use only one method. The Commission will post all comments on the Commission's Internet Web site (*http://www.sec.gov/rules/sro.shtml*). Copies of the submission, all subsequent amendments, all written statements with respect to the proposed rule change that are filed with the Commission, and all written communications relating to the proposed rule change between the Commission and any person, other than those that may be withheld from the public in accordance with the provisions of 5 U.S.C. 552, will be available for Web site viewing and printing in the Commission's Public Reference Room, 100 F Street NE., Washington, DC 20549 on official business days between the hours of 10:00 a.m. and 3:00 p.m. Copies of such filing also will be available for inspection and copying at the principal office of the Exchange. All comments received will be posted without change; the Commission does not edit personal identifying information from submissions. You should submit only information that you wish to make available publicly. All submissions should refer to File Number SR–MIAX–2015–53, and should be submitted on or before October 5, 2015.

[14] 15 U.S.C. 78f(b).

[15] 15 U.S.C. 78f(b)(4).

[16] 15 U.S.C. 78s(b)(3)(A)(ii).

For the Commission, by the Division of Trading and Markets, pursuant to delegated authority.[17]

BILLING CODE P

DEPARTMENT OF STATE

[Public Notice 9267]

60-Day Notice of Proposed Information Collection: Application Under the Hague Convention on the Civil Aspects of International Child Abduction

ACTION: Notice of request for public comment.

SUMMARY: The Department of State is seeking Office of Management and Budget (OMB) approval for the information collection described below. In accordance with the Paperwork Reduction Act of 1995, we are requesting comments on this collection from all interested individuals and organizations. The purpose of this notice is to allow 60 days for public comment preceding submission of the collection to OMB.

DATES: The Department will accept comments from the public up to November 13, 2015.

ADDRESSES: You may submit comments by any of the following methods:

- *Web:* Persons with access to the Internet may comment on this notice by going to *www.Regulations.gov.* You can search for the document by entering Docket Number: DOS–2015–0035 in the search field. Then click the "Comment Now" button and complete the comment form.
- *Email: mailto:Shawkm@state.gov.*
- *Regular Mail:* Send written comments to: U.S. Department of State, CA/OCS/PMO, SA–17, 10th Floor, Washington, DC 20036.
- *Fax:* 202–736–9111.
- *Hand Delivery or Courier:* U.S. Department of State, CA/OCS/PMO, 600 19th St. NW., 10th Floor, Washington, DC 20036.

You must include the DS form number (if applicable), information collection title, and the OMB control number in any correspondence.

FOR FURTHER INFORMATION CONTACT: Direct requests for additional information regarding the collection listed in this notice, including requests for copies of the proposed collection instrument and supporting documents, to Kaye Shaw, Bureau of Consular Affairs, Overseas Citizens Services (CA/OCS/PMO), U.S. Department of State, SA–17, 10th Floor, Washington, DC 20036 or at *mailto:shawkm@state.gov.*

SUPPLEMENTARY INFORMATION:

- *Title of Information Collection:* Application Under the Hague Convention on the Civil Aspects of International Child Abduction.
- *OMB Control Number:* 1405–0076.
- *Type of Request:* Extension.
- *Originating Office:* CA/OCS/L.
- *Form Number:* DS–3013, 3013–s.
- *Respondents:* Person seeking return of or access to child.
- *Estimated Number of Respondents:* 565.
- *Estimated Number of Responses:* 565.
- *Average Time per Response:* 1 hour.
- *Total Estimated Burden Time:* 565 hours.
- *Frequency:* On Occasion.
- *Obligation to Respond:* Voluntary.

We are soliciting public comments to permit the Department to:

- Evaluate whether the proposed information collection is necessary for the proper functions of the Department.
- Evaluate the accuracy of our estimate of the time and cost burden for this proposed collection, including the validity of the methodology and assumptions used.
- Enhance the quality, utility, and clarity of the requests for information to be collected.
- Minimize the reporting burden on those who are to respond, including the use of automated collection techniques or other forms of information technology.

Please note that comments submitted in response to this Notice are public record. Before including any detailed personal information, you should be aware that your comments as submitted, including your personal information, will be available for public review.

Abstract of proposed collection: The Application Under the Hague Convention on the Civil Aspects of International Child Abduction (DS–3013 and DS 3013–s) is used by parents or legal guardians who are requesting the State Department's assistance in seeking the return of, or access to, a child or children alleged to have been wrongfully removed from or retained outside of the child's habitual residence and currently located in another country that is also party to the Hague Convention on the Civil Aspects of International Child Abduction (the Convention). The application requests information regarding the identities of the applicant, the child or children, and the person alleged to have wrongfully removed or retained the child or children. In addition, the application requires that the applicant provide the circumstances of the alleged wrongful removal or retention and the legal justification for the request for return or access. The State Department, as the U.S. Central Authority for the Convention, uses this information to establish, if possible, the applicants' claims under the Convention; to inform applicants about available remedies under the Convention; and to provide the information necessary to the foreign Central Authority in its efforts to locate the child or children, and to facilitate return of or access to the child or children pursuant to the Convention. 42 U.S.C. 11608 is the legal authority that permits the Department to gather this information.

Methodology: The completed form DS–3013 and DS 3013–s may be submitted to the Office of Children's Issues by mail, by fax, or electronically accessed through *www.travel.state.gov.*

[17] 17 CFR 200.30–3(a)(12).

Dated: September 1, 2015.

Michelle Bernier-Toth,

Managing Director, Bureau of Consular Affairs, Department of State.

BILLING CODE 4710–06–P

DEPARTMENT OF STATE

[Public Notice 9268]

Meeting of Advisory Committee on International Communications and Information Policy

The Department of State's Advisory Committee on International Communications and Information Policy (ACICIP) will hold a public meeting on Friday, October 2, 2015 from 2:00 p.m. to 5:00 p.m. in the Loy Henderson Auditorium of the Harry S Truman (HST) Building of the U.S. Department of State. The Truman Building is located at 2201 C Street NW., Washington, DC 20520.

The committee provides a formal channel for regular consultation and coordination on major economic, social and legal issues and problems in international communications and information policy, especially as these issues and problems involve users of information and communications services, providers of such services, technology research and development, foreign industrial and regulatory policy, the activities of international organizations with regard to communications and information, and developing country issues.

The meeting will be led by Ambassador Daniel A. Sepulveda, U.S. Coordinator for International Communications and Information Policy. The meeting's agenda will include discussions pertaining to various upcoming international telecommunications meetings and conferences, as well as efforts focused on technology and international development and the Information and Communications Technology (ICT) aspects of international disaster response.

Members of the public may submit suggestions and comments to the ACICIP. Comments concerning topics to be addressed in the agenda should be received by the ACICIP Executive Secretary (contact information below) at least ten working days prior to the date of the meeting. All comments must be submitted in written form and should not exceed one page. Resource limitations preclude acknowledging or replying to submissions. While the meeting is open to the public, admittance to the building is only by means of a pre-clearance. For placement on the pre-clearance list, please submit the following information no later than 5:00 p.m. on Tuesday, September 29, 2015. (Please note that this information is required by Diplomatic Security for each entrance into HST and must therefore be re-submitted for each ACICIP meeting):

I. State That You Are Requesting Pre-Clearance to a Meeting

II. Provide the Following Information

1. Name of meeting and its date and time
2. Visitor's full name
3. Visitor's organization/company affiliation
4. Date of Birth
5. Citizenship
6. Acceptable forms of identification for entry into the building include:
   - U.S. driver's license with photo
   - Passport
   - U.S. government agency ID
7. ID number on the form of ID that the visitor will show upon entry
8. Whether the visitor has a need for reasonable accommodation. Such requests received after September 17, 2015, might not be possible to fulfill. Send the above information to Joseph Burton by fax (202) 647–5957 or email *BurtonKJ@state.gov.*

Please note that registrations will be accepted to the capacity of the meeting room. All visitors for this meeting must use the 23rd Street entrance. The valid ID bearing the number provided with your pre-clearance request will be required for admittance. Non-U.S. government attendees must be escorted by Department of State personnel at all times when in the building. Personal data is requested pursuant to Public Law 99–399 (Omnibus Diplomatic Security and Antiterrorism Act of 1986), as amended; Public Law 107–56 (USA PATRIOT Act); and Executive Order 13356. The purpose of the collection is to validate the identity of individuals who enter Department facilities. The data will be entered into the Visitor Access Control System (VACS–D) database. Please see the Security Records System of Records Notice (State–36) at *http://www.state.gov/documents/organization/103419.pdf* for additional information.

For further information, please contact Joseph Burton, Executive Secretary of the Committee, at (202) 647–5231 or *BurtonKJ@state.gov.*

General information about ACICIP and the mission of International Communications and Information Policy is available at: *http://www.state.gov/e/eb/adcom/acicip/index.htm.*

Dated: September 4, 2015.

Joseph Burton,

ACICIP Executive Secretary, Department of State.

BILLING CODE 4710–07–P

DEPARTMENT OF STATE

[Public Notice: 9265]

U.S. Advisory Panel to the U.S. Section of the North Pacific Anadromous Fish Commission; Notice of Renewal

The Department of State has renewed the Charter of the U.S. Advisory Panel to the U.S. Section of the North Pacific Anadromous Fish Commission (NPAFC) for another two years.

The NPAFC was established by the Convention for the Conservation of Anadromous Stocks in the North Pacific Ocean, signed on February 12, 1992, by Canada, Japan, the Russian Federation, and the United States, and entered into force on February 16, 1993. The U.S. Advisory Panel will continue to work with the U.S. Section to promote the conservation of anadromous fish stocks, particularly salmon, throughout their migratory range in the North Pacific Ocean, as well as ecologically related species.

The U.S. Section of the Commission is composed of three Commissioners who are appointed by the President. Each Commissioner is appointed for a term not to exceed 4 years, but is eligible for reappointment. The Secretary of State, in consultation with the Secretary of Commerce, may designate alternate commissioners. The Advisory Panel to the U.S. Section is composed of 14 members, 11 of whom are appointed by the Secretary of State in consultation with the Secretary of Commerce. Advisory Panel members serve for a term not to exceed 4 years, and may not serve more than two consecutive terms.

The Advisory Panel will continue to follow the procedures prescribed by the Federal Advisory Committee Act (FACA). Meetings will continue to be open to the public unless a determination is made in accordance with section 10 of the Federal Advisory Committee Act and 5 U.S.C. 552b(c) that a meeting or a portion of the meeting should be closed to the public. For further information on the renewal of the Advisory Panel, please contact Michael Clark, Office of Marine Conservation in the Department of State, (202) 647–3010.

Dated: August 20, 2015.

David A. Balton,

Deputy Assistant Secretary for Oceans and Fisheries, Department of State.

DEPARTMENT OF TRANSPORTATION

Federal Aviation Administration

Sixteenth Meeting: NextGen Advisory Committee (NAC)

AGENCY: Federal Aviation Administration (FAA), U.S. Department of Transportation (DOT).

ACTION: Notice of Sixteenth NextGen Advisory committee meeting.

SUMMARY: The FAA is issuing this notice to advise the public of the sixteenth NextGen Advisory Committee meeting.

DATES: The meeting will be held October 8th from 9:00 a.m.–3:00 p.m.

ADDRESSES: The meeting will be held at FedEx Express Headquarters, 3855 Airways Boulevard, Module D, 3rd Floor, Memphis, TN 38116, Tel: (202) 330–0652.

FOR FURTHER INFORMATION CONTACT: The RTCA Secretariat, 1150 18th Street NW., Suite 910, Washington, DC 20036, or by telephone at (202) 833–9339, fax at (202) 833–9434, or Web site at *http://www.rtca.org* or Andy Cebula, NAC Secretary, RTCA, Inc., *acebula@rtca.org,* (202) 330–0652.

SUPPLEMENTARY INFORMATION: Pursuant to section 10(a)(2) of the Federal Advisory Committee Act (Pub. L. 92–463, 5 U.S.C., App.), notice is hereby given for a meeting of the NextGen Advisory Committee. The agenda will include the following:

Thursday, October 8, 2015

1. Opening of Meeting/Introduction of NAC Members—Chairman Richard Anderson, Chief Executive Officer, Delta Air Lines, Inc.
2. Official Statement of Designated Federal Official—The Honorable Mike Whitaker, FAA Deputy Administrator
3. Review and Approval of June 5, 2015 Meeting Summary
4. Chairman's Report—Chairman Anderson
5. FAA Report—Mr. Whitaker
6. NextGen Integration Working Group (NIWG) Reports & Discussion—DataComm, Multiple Runway Operations, Performance Based Navigation, Surface
7. Metrics: Measuring Effects of Implementations—Overview of Reporting Process; FAA Actions on Performance Reporting; Industry Performance Tracking–vendor presentation
8. ADS–B—Status of implementation; Spaced based deployment, oceanic surveillance, common weather picture
9. Performance Based Navigation (PBN) National Airspace System Navigation Strategy
10. NextGen Plan
11. Summary of meeting and next steps—DFO and NAC Chairman Closing Comments
12. Other business
13. Adjourn

Attendance is open to the interested public but limited to space availability. With the approval of the chairman, members of the public may present oral statements at the meeting. Persons wishing to present statements or obtain information should contact the person listed in the **FOR FURTHER INFORMATION CONTACT** section. Contact Betty Reschenberg at (901) 224–5470 or *bareschenberg@fedex.com* to register. In order for US Citizens to pre-register, please provide your first and last name (as it appears on your state Driver's License or Identification); employer's name and address; and phone number. In order to Non-US Citizens to pre-register, please provide your full name (as it appears on your passport); country of citizenship; passport and Visa numbers, type and expiration date; employer name and address; and phone number. Members of the public may present a written statement to the committee at any time.

Issued in Washington, DC, on September 10, 2015.

Latasha Robinson,

Management & Program Analyst, Next Generation, Enterprise Support Services Division, Federal Aviation Administration.

BILLING CODE 4910–13–P

DEPARTMENT OF TRANSPORTATION

Federal Motor Carrier Safety Administration

[Docket No. FMCSA–2014–0382]

Qualification of Drivers; Exemption Applications; Epilepsy and Seizure Disorders

AGENCY: Federal Motor Carrier Safety Administration (FMCSA), DOT.

ACTION: Notice of final disposition.

SUMMARY: FMCSA announces its decision to grant requests from 14 individuals for exemptions from the regulatory requirement that interstate commercial motor vehicle (CMV) drivers have "no established medical history or clinical diagnosis of epilepsy or any other condition which is likely to cause loss of consciousness or any loss of ability to control a CMV." The regulation and the associated advisory criteria published in the Code of Federal Regulations as the "Instructions for Performing and Recording Physical Examinations" have resulted in numerous drivers being prohibited from operating CMVs in interstate commerce based on the fact that they have had one or more seizures and are taking anti-seizure medication, rather than an individual analysis of their circumstances by a qualified medical examiner. The Agency concluded that granting exemptions for these CMV drivers will provide a level of safety that is equivalent to or greater than the level of safety maintained without the exemptions. FMCSA grants exemptions that will allow these 14 individuals to operate CMVs in interstate commerce for a 2-year period. The exemptions preempt State laws and regulations and may be renewed.

DATES: The exemptions are effective September 14, 2015. The exemptions expire on September 14, 2017.

FOR FURTHER INFORMATION CONTACT: Charles A. Horan, III, Director, Office of Carrier, Driver and Vehicle Safety, (202) 366–4001, or via email at *fmcsamedical@dot.gov,* or by letter to FMCSA, Department of Transportation, 1200 New Jersey Avenue SE., Room W64–224, Washington, DC 20590–0001. Office hours are 8:30 a.m. to 5 p.m., Monday through Friday, except Federal holidays.

SUPPLEMENTARY INFORMATION:

A. Electronic Access

You may see all the comments online through the Federal Document Management System (FDMS) at: *http://www.regulations.gov.*

Docket: For access to the docket to read background documents or comments, go to *www.regulations.gov* and/or Room W12–140 on the ground level of the West Building, 1200 New Jersey Avenue SE., Washington DC, between 9 a.m. and 5 p.m., Monday through Friday, except Federal holidays.

Privacy Act: In accordance with 5 U.S.C. 553(c), DOT solicits comments from the public to better inform its rulemaking process. DOT posts these comments, without edit, including any personal information the commenter provides, to *www.regulations.gov,* as described in the system of records

notice (DOT/ALL–14 FDMS), which can be reviewed at *www.dot.gov/privacy.*

B. Background

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the safety regulations for a 2-year period if it finds "such exemption would likely achieve a level of safety that is equivalent to or greater than the level that would be achieved absent such exemption." The statute also allows the Agency to renew exemptions at the end of the 2-year period.

FMCSA grants 14 individuals an exemption from the regulatory requirement in § 391.41(b)(8), to allow these individuals who take anti-seizure medication to operate CMVs in interstate commerce for a 2-year period. The Agency's decision on these exemption applications is based on an individualized assessment of each applicant's medical information, including the root cause of the respective seizure(s), the length of time elapsed since the individual's last seizure, and each individual's treatment regimen. In addition, the Agency reviewed each applicant's driving record found in the Commercial Driver's License Information System (CDLIS) [1] for commercial driver's license (CDL) holders, and interstate and intrastate inspections recorded in Motor Carrier Management Information System (MCMIS).[2] For non-CDL holders, the Agency reviewed the driving records from the State licensing agency. The Agency acknowledges the potential consequences of a driver experiencing a seizure while operating a CMV. However, the Agency believes the drivers covered by the exemptions granted here have demonstrated that they are unlikely to have a seizure and their medical condition does not pose a risk to public safety.

In reaching the decision to grant these exemption requests, the Agency considered both current medical literature and information and the 2007 recommendations of the Agency's Medical Expert Panel (MEP). The Agency previously gathered evidence for potential changes to the regulation at 49 CFR 391.41(b)(8) by conducting a comprehensive review of scientific literature that was compiled into the "*Evidence Report on Seizure Disorders and Commercial Vehicle Driving*" (*Evidence Report*) [CD–ROM HD TL230.3 .E95 2007]. The Agency then convened a panel of medical experts in the field of neurology (the MEP) on May 14–15, 2007, to review 49 CFR 391.41(b)(8) and the advisory criteria regarding individuals who have experienced a seizure, and the 2007 *Evidence Report.* The *Evidence Report* and the MEP recommendations are published on-line at *http://www.fmcsa.dot.gov/regulations/medical/reports-how-medical-conditions-impact-driving,* under Seizure Disorders, and are in the docket for this notice.

MEP Criteria for Evaluation

On October 15, 2007, the MEP issued the following recommended criteria for evaluating whether an individual with epilepsy or a seizure disorder should be allowed to operate a CMV.[3] The MEP recommendations are included in previously published dockets.

Epilepsy diagnosis. If there is an *epilepsy diagnosis,* the applicant should be seizure-free for *8 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with an epilepsy diagnosis should be performed every year.

Single unprovoked seizure. If there is a *single unprovoked seizure* (*i.e.,* there is no known trigger for the seizure), the individual should be seizure-free for *4 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with a single unprovoked seizure should be performed every 2 years.

Single provoked seizure. If there is a *single provoked seizure* (*i.e.,* there is a known reason for the seizure), the Agency should consider specific criteria that fall into the following two categories: low-risk factors for recurrence and moderate-to-high risk factors for recurrence.

- *Examples of low-risk factors for recurrence* include seizures that were caused by a medication; by non-penetrating head injury with loss of consciousness less than or equal to 30 minutes; by a brief loss of consciousness not likely to recur while driving; by metabolic derangement not likely to recur; and by alcohol or illicit drug withdrawal.
- *Examples of moderate-to-high-risk factors for recurrence* include seizures caused by non-penetrating head injury with loss of consciousness or amnesia greater than 30 minutes, or penetrating head injury; intracerebral hemorrhage associated with a stroke or trauma; infections; intracranial hemorrhage; post-operative complications from brain surgery with significant brain hemorrhage; brain tumor; or stroke.

The MEP report indicates individuals with moderate to high-risk conditions should not be certified. Drivers with a history of a single provoked seizure with low risk factors for recurrence should be recertified every year.

Medical Review Board Recommendations and Agency Decision

FMCSA presented the MEP's findings and the *Evidence Report* to the Medical Review Board (MRB) for consideration. The MRB reviewed and considered the 2007 "Seizure Disorders and Commercial Driver Safety" evidence report and the 2007 MEP recommendations. The MRB recommended maintaining the current advisory criteria, which provide that "drivers with a history of epilepsy/seizures off anti-seizure medication and seizure-free for 10 years may be qualified to drive a CMV in interstate commerce. Interstate drivers with a history of a single unprovoked seizure may be qualified to drive a CMV in interstate commerce if seizure-free and off anti-seizure medication for a 5 year period or more" [Advisory criteria to 49 CFR 391.43(f)].

The Agency acknowledges the MRB's position on the issue but believes relevant current medical evidence supports a less conservative approach. The medical advisory criteria for epilepsy and other seizure or loss of consciousness episodes was based on the 1988 "Conference on Neurological Disorders and Commercial Drivers" (NITS Accession No. PB89–158950/AS). A copy of the report can be found in the docket referenced in this notice.

The MRB's recommendation treats all drivers who have experienced a seizure the same, regardless of individual medical conditions and circumstances. In addition, the recommendation to continue prohibiting drivers who are

[1] *Commercial Driver License Information System* (CDLIS) is an information system that allows the exchange of commercial driver licensing information among all the States. CDLIS includes the databases of fifty-one licensing jurisdictions and the CDLIS Central Site, all connected by a telecommunications network.

[2] *Motor Carrier Management Information System* (MCMIS) is an information system that captures data from field offices through SAFETYNET, CAPRI, and other sources. It is a source for FMCSA inspection, crash, compliance review, safety audit, and registration data.

[3] Engel, J., Fisher, R.S., Krauss, G.L., Krumholz, A., and Quigg, M.S., "Expert Panel Recommendations: Seizure Disorders and Commercial Motor Vehicle Driver Safety," FMCSA, October 15, 2007.

taking anti-seizure medication from operating a CMV in interstate commerce does not consider a driver's actual seizure history and time since the last seizure. The Agency has decided to use the 2007 MEP recommendations as the basis for evaluating applications for an exemption from the seizure regulation on an individual, case-by-case basis.

C. Exemptions

Following individualized assessments of the exemption applications, including a review of detailed follow-up information requested from each applicant, FMCSA is granting exemptions from 49 CFR 391.41(b)(8) to 14 individuals. Under current FMCSA regulations, all of the 14 drivers receiving exemptions from 49 CFR 391.41(b)(8) would have been considered physically qualified to drive a CMV in interstate commerce except that they presently take or have recently stopped taking anti-seizure medication. For these 14 drivers, the primary obstacle to medical qualification was the FMCSA Advisory Criteria for Medical Examiners, based on the 1988 "Conference on Neurological Disorders and Commercial Drivers," stating that a driver should be off anti-seizure medication in order to drive in interstate commerce. In fact, the Advisory Criteria have little if anything to do with the actual risk of a seizure and more to do with assumptions about individuals who are taking anti-seizure medication.

In addition to evaluating the medical status of each applicant, FMCSA evaluated the crash and violation data for the 14 drivers, some of whom currently drive a CMV in intrastate commerce. The CDLIS and MCMIS were searched for crash and violation data on the 14 applicants. For non-CDL holders, the Agency reviewed the driving records from the State licensing agency.

These exemptions are contingent on the driver maintaining a stable treatment regimen and remaining seizure-free during the 2-year exemption period. The exempted drivers must submit annual reports from their treating physicians attesting to the stability of treatment and that the driver has remained seizure-free. The driver must undergo an annual medical examination by a medical examiner, as defined by 49 CFR 390.5, following the FCMSA's regulations for the physical qualifications for CMV drivers.

FMCSA published a notice of receipt of application and requested public comment during a 30-day public comment period in a **Federal Register** notice for each of the applicants. A short summary of the applicants' qualifications follows this section. For applicants who were denied an exemption, a notice was previously published.

D. Comments

Docket #FMCSA–2014–0382

On April 13, 2015, FMCSA published a notice of receipt of exemption applications and requested public comment on 19 individuals (80 FR 19730; Docket number FMCSA–2015–08392). The comment period ended on May 13, 2015. No commenters responded to this **Federal Register** notice. Of the 19 applicants, five were denied. The Agency has determined that the following 14 applicants should be granted an exemption.

Daryl Charles Anderson

Mr. Anderson is a 61 year-old class A CDL holder in Michigan. He has a history of a seizure disorder and has remained seizure free since 1989. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Anderson receiving an exemption.

Ronald J. Bennett

Mr. Bennett is a 58 year-old class B CDL holder in New York. He has a history of epilepsy and has remained seizure free since 2002. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Bennett receiving an exemption.

Don Carrol Darbyshire

Mr. Darbyshire is a 51 year-old class B CDL holder in Iowa. He has a history of epilepsy and has remained seizure free since 1993. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Darbyshire receiving an exemption.

Monte James DeRocini

Mr. DeRocini is a 53 year-old class A CDL holder in Pennsylvania. He has a history of a single seizure in 2011. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. DeRocini receiving an exemption.

Martin L. Ford

Mr. Ford is a 57 year-old class C CDL holder in Mississippi. He has a history of seizures and has remained seizure free since 2003. He takes anti-seizure medication with the dosage and frequency remaining the same since 2008. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Ford receiving an exemption.

Roger Green

Mr. Green is a 60 year-old class A CDL holder in Pennsylvania. He has a history of a seizure disorder and has remained seizure free since 1971. He takes anti-seizure medication with the dosage and frequency remaining the same since 2004. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Green receiving an exemption.

Susie B. Harvey

Ms. Harvey is a 64 year-old class B CDL holder in Virginia. She has a history of epilepsy and has remained seizure free since 1985. She takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, she would like to drive a CMV. Her physician states that he is supportive of Ms. Harvey receiving an exemption.

Timothy G. Huntley

Mr. Huntley is a 40 year-old class B CDL holder in Maine. He has a history of a seizure disorder and has remained seizure free since 2000. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Huntley receiving an exemption.

Chance Joseph O'Mary

Mr. O'Mary is a 29 year-old class A CDL holder in Alaska. He has a history of a seizure disorder and has remained seizure free since 2005. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. O'Mary receiving an exemption.

Robert D. Richter, Sr.

Mr. Richter is a 58 year-old driver in Pennsylvania. He has a history of a seizure disorder and has remained seizure free since 1976. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he

would like to drive a CMV. His physician states that he is supportive of Mr. Richter receiving an exemption.

Michael Scott Shumake

Mr. Shumake is a 37 year-old driver in Virginia. He has a history of a seizure disorder and has remained seizure free since 2000. He takes anti-seizure medication with the dosage and frequency remaining the same since 2001. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Shumake receiving an exemption.

Charles Ray Taylor

Mr. Taylor is a 49 year-old class A CDL holder in Mississippi. He has a history of a single seizure in 2009. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Taylor receiving an exemption.

Karin Hawley Wagasy

Ms. Wagasy is a 58 year-old driver in Tennessee. She has a history of a seizure disorder and has remained seizure free since 1975. She takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, she would like to drive a CMV. Her physician states that he is supportive of Ms. Wagasy receiving an exemption.

Trever A. Williams

Mr. Williams is a 44 year-old class A CDL holder in Minnesota. He has a history of a single seizure in 1983 which occurred postoperatively, after a surgical procedure to remove a foreign body from his head. He takes anti-seizure medication with the dosage and frequency remaining the same since 2006. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Williams receiving an exemption.

E. Basis for Exemption

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the epilepsy/seizure standard in 49 CFR 391.41(b)(8) if the exemption is likely to achieve an equivalent or greater level of safety than would be achieved without the exemption. Without the exemption, applicants will continue to be restricted to intrastate driving. With the exemption, applicants can drive in interstate commerce. Thus, the Agency's analysis focuses on whether an equal or greater level of safety is likely to be achieved by permitting each of these drivers to drive in interstate commerce as opposed to restricting the driver to driving in intrastate commerce.

Conclusion

The Agency is granting exemptions from the epilepsy standard, 49 CFR 391.41(b)(8), to 14 individuals based on a thorough evaluation of each driver's safety experience and medical condition. Safety analysis of information relating to these 14 applicants meets the burden of showing that granting the exemptions would achieve a level of safety that is equivalent to or greater than the level that would be achieved without the exemption. By granting the exemptions, the interstate CMV industry will gain 14 highly trained and experienced drivers. In accordance with 49 U.S.C. 31315(b)(1), each exemption will be valid for 2 years, with annual recertification required unless revoked earlier by FMCSA. The exemption will be revoked if the following occurs: (1) The person fails to comply with the terms and conditions of the exemption; (2) the exemption has resulted in a lower level of safety than was maintained prior to being granted; or (3) continuation of the exemption would not be consistent with the goals and objectives of 49 U.S.C. 31136 and 31315.

FMCSA exempts the following 14 drivers for a period of 2 years with annual medical certification required: Daryl Charles Anderson (MI); Ronald J. Bennett (NY); Don Carrol Darbyshire (IA); Monte James DeRocini (PA); Martin L. Ford (MS); Roger Green (PA); Susie B. Harvey (VA); Timothy G. Huntley (ME); Chance Joseph O'Mary (AK); Robert D. Richter, Sr. (PA); Michael Scott Shumake (VA); Charles Ray Taylor (MS); Karin Hawley Wagasy (TN); and Trever A. Williams (MN) from the prohibition of CMV operations by persons with a clinical diagnosis of epilepsy or seizures. If the exemption is still in effect at the end of the 2-year period, the person may apply to FMCSA for a renewal under procedures in effect at that time.

Issued on: September 2, 2015.

Larry W. Minor,

Associate Administrator for Policy.

DEPARTMENT OF TRANSPORTATION

Federal Motor Carrier Safety Administration

[Docket No. FMCSA–2014–0379]

Qualification of Drivers; Exemption Applications; Epilepsy and Seizure Disorders

AGENCY: Federal Motor Carrier Safety Administration (FMCSA), DOT.

ACTION: Notice of final disposition.

SUMMARY: FMCSA announces its decision to grant requests from 6 individuals for exemptions from the regulatory requirement that interstate commercial motor vehicle (CMV) drivers have "no established medical history or clinical diagnosis of epilepsy or any other condition which is likely to cause loss of consciousness or any loss of ability to control a CMV." The regulation and the associated advisory criteria published in the Code of Federal Regulations as the "Instructions for Performing and Recording Physical Examinations" have resulted in numerous drivers being prohibited from operating CMVs in interstate commerce based on the fact that they have had one or more seizures and are taking anti-seizure medication, rather than an individual analysis of their circumstances by a qualified medical examiner. The Agency concluded that granting exemptions for these CMV drivers will provide a level of safety that is equivalent to or greater than the level of safety maintained without the exemptions. FMCSA grants exemptions that will allow these 6 individuals to operate CMVs in interstate commerce for a 2-year period. The exemptions preempt State laws and regulations and may be renewed.

DATES: The exemptions are effective September 14, 2015. The exemptions expire on September 14, 2017.

FOR FURTHER INFORMATION CONTACT: Charles A. Horan, III, Director, Office of Carrier, Driver and Vehicle Safety, (202) 366–4001, or via email at *fmcsamedical@dot.gov,* or by letter to FMCSA, Department of Transportation, 1200 New Jersey Avenue SE., Room W64–224, Washington, DC 20590–0001. Office hours are 8:30 a.m. to 5 p.m., Monday through Friday, except Federal holidays.

SUPPLEMENTARY INFORMATION:

A. Electronic Access

You may see all the comments online through the Federal Document Management System (FDMS) at: *http://www.regulations.gov.*

Docket: For access to the docket to read background documents or comments, go to *www.regulations.gov* and/or Room W12–140 on the ground level of the West Building, 1200 New Jersey Avenue SE., Washington, DC, between 9 a.m. and 5 p.m., Monday through Friday, except Federal holidays.

Privacy Act: In accordance with 5 U.S.C. 553(c), DOT solicits comments from the public to better inform its rulemaking process. DOT posts these comments, without edit, including any personal information the commenter provides, to *www.regulations.gov,* as described in the system of records notice (DOT/ALL–14 FDMS), which can be reviewed at *www.dot.gov/privacy.*

B. Background

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the safety regulations for a 2-year period if it finds "such exemption would likely achieve a level of safety that is equivalent to or greater than the level that would be achieved absent such exemption." The statute also allows the Agency to renew exemptions at the end of the 2-year period.

FMCSA grants 6 individuals an exemption from the regulatory requirement in § 391.41(b)(8), to allow these individuals who take anti-seizure medication to operate CMVs in interstate commerce for a 2-year period. The Agency's decision on these exemption applications is based on an individualized assessment of each applicant's medical information, including the root cause of the respective seizure(s), the length of time elapsed since the individual's last seizure, and each individual's treatment regimen. In addition, the Agency reviewed each applicant's driving record found in the Commercial Driver's License Information System (CDLIS) [1] for commercial driver's license (CDL) holders, and interstate and intrastate inspections recorded in Motor Carrier Management Information System (MCMIS).[2] For non-CDL holders, the Agency reviewed the driving records from the State licensing agency. The Agency acknowledges the potential consequences of a driver experiencing a seizure while operating a CMV. However, the Agency believes the drivers covered by the exemptions granted here have demonstrated that they are unlikely to have a seizure and their medical condition does not pose a risk to public safety.

In reaching the decision to grant these exemption requests, the Agency considered both current medical literature and information and the 2007 recommendations of the Agency's Medical Expert Panel (MEP). The Agency previously gathered evidence for potential changes to the regulation at 49 CFR 391.41(b)(8) by conducting a comprehensive review of scientific literature that was compiled into the "*Evidence Report on Seizure Disorders and Commercial Vehicle Driving*" (*Evidence Report*) [CD–ROM HD TL230.3 .E95 2007]. The Agency then convened a panel of medical experts in the field of neurology (the MEP) on May 14–15, 2007, to review 49 CFR 391.41(b)(8) and the advisory criteria regarding individuals who have experienced a seizure, and the 2007 *Evidence Report.* The *Evidence Report* and the MEP recommendations are published on-line at *http://www.fmcsa.dot.gov/regulations/medical/reports-how-medical-conditions-impact-driving,* under Seizure Disorders, and are in the docket for this notice.

MEP Criteria for Evaluation

On October 15, 2007, the MEP issued the following recommended criteria for evaluating whether an individual with epilepsy or a seizure disorder should be allowed to operate a CMV.[3] The MEP recommendations are included in previously published dockets.

Epilepsy diagnosis. If there is an *epilepsy diagnosis,* the applicant should be seizure-free for *8 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with an epilepsy diagnosis should be performed every year.

Single unprovoked seizure. If there is a *single unprovoked seizure* (*i.e.,* there is no known trigger for the seizure), the individual should be seizure-free for *4 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with a single unprovoked seizure should be performed every 2 years.

Single provoked seizure. If there is a *single provoked seizure* (*i.e.,* there is a known reason for the seizure), the Agency should consider specific criteria that fall into the following two categories: low-risk factors for recurrence and moderate-to-high risk factors for recurrence.

- *Examples of low-risk factors for recurrence* include seizures that were caused by a medication; by non-penetrating head injury with loss of consciousness less than or equal to 30 minutes; by a brief loss of consciousness not likely to recur while driving; by metabolic derangement not likely to recur; and by alcohol or illicit drug withdrawal.
- *Examples of moderate-to-high-risk factors for recurrence* include seizures caused by non-penetrating head injury with loss of consciousness or amnesia greater than 30 minutes, or penetrating head injury; intracerebral hemorrhage associated with a stroke or trauma; infections; intracranial hemorrhage; post-operative complications from brain surgery with significant brain hemorrhage; brain tumor; or stroke. The MEP report indicates individuals with moderate to high-risk conditions should not be certified. Drivers with a history of a single provoked seizure with low risk factors for recurrence should be recertified every year.

Medical Review Board Recommendations and Agency Decision

FMCSA presented the MEP's findings and the *Evidence Report* to the Medical Review Board (MRB) for consideration. The MRB reviewed and considered the 2007 "Seizure Disorders and Commercial Driver Safety" evidence report and the 2007 MEP recommendations. The MRB recommended maintaining the current advisory criteria, which provide that "drivers with a history of epilepsy/seizures off anti-seizure medication and seizure-free for 10 years may be qualified to drive a CMV in interstate commerce. Interstate drivers with a history of a single unprovoked seizure may be qualified to drive a CMV in interstate commerce if seizure-free and off anti-seizure medication for a 5 year period or more" [Advisory criteria to 49 CFR 391.43(f)].

The Agency acknowledges the MRB's position on the issue but believes relevant current medical evidence

[1] *Commercial Driver License Information System* (CDLIS) is an information system that allows the exchange of commercial driver licensing information among all the States. CDLIS includes the databases of fifty-one licensing jurisdictions and the CDLIS Central Site, all connected by a telecommunications network.

[2] *Motor Carrier Management Information System* (MCMIS) is an information system that captures data from field offices through SAFETYNET, CAPRI, and other sources. It is a source for FMCSA inspection, crash, compliance review, safety audit, and registration data.

[3] Engel, J., Fisher, R.S., Krauss, G.L., Krumholz, A., and Quigg, M.S., "Expert Panel Recommendations: Seizure Disorders and Commercial Motor Vehicle Driver Safety," FMCSA, October 15, 2007.

supports a less conservative approach. The medical advisory criteria for epilepsy and other seizure or loss of consciousness episodes was based on the 1988 "Conference on Neurological Disorders and Commercial Drivers" (NITS Accession No. PB89–158950/AS). A copy of the report can be found in the docket referenced in this notice.

The MRB's recommendation treats all drivers who have experienced a seizure the same, regardless of individual medical conditions and circumstances. In addition, the recommendation to continue prohibiting drivers who are taking anti-seizure medication from operating a CMV in interstate commerce does not consider a driver's actual seizure history and time since the last seizure. The Agency has decided to use the 2007 MEP recommendations as the basis for evaluating applications for an exemption from the seizure regulation on an individual, case-by-case basis.

C. Exemptions

Following individualized assessments of the exemption applications, including a review of detailed follow-up information requested from each applicant, FMCSA is granting exemptions from 49 CFR 391.41(b)(8) to 6 individuals. Under current FMCSA regulations, all of the 6 drivers receiving exemptions from 49 CFR 391.41(b)(8) would have been considered physically qualified to drive a CMV in interstate commerce except that they presently take or have recently stopped taking anti-seizure medication. For these 6 drivers, the primary obstacle to medical qualification was the FMCSA Advisory Criteria for Medical Examiners, based on the 1988 "Conference on Neurological Disorders and Commercial Drivers," stating that a driver should be off anti-seizure medication in order to drive in interstate commerce. In fact, the Advisory Criteria have little if anything to do with the actual risk of a seizure and more to do with assumptions about individuals who are taking anti-seizure medication.

In addition to evaluating the medical status of each applicant, FMCSA evaluated the crash and violation data for the 6 drivers, some of whom currently drive a CMV in intrastate commerce. The CDLIS and MCMIS were searched for crash and violation data on the 6 applicants. For non-CDL holders, the Agency reviewed the driving records from the State licensing agency.

These exemptions are contingent on the driver maintaining a stable treatment regimen and remaining seizure-free during the 2-year exemption period. The exempted drivers must submit annual reports from their treating physicians attesting to the stability of treatment and that the driver has remained seizure-free. The driver must undergo an annual medical examination by a medical examiner, as defined by 49 CFR 390.5, following the FCMSA's regulations for the physical qualifications for CMV drivers.

FMCSA published a notice of receipt of application and requested public comment during a 30-day public comment period in a **Federal Register** notice for each of the applicants. A short summary of the applicants' qualifications and a discussion of the comments received follows this section. For applicants who were denied an exemption, a notice was previously published.

D. Comments

Docket #FMCSA–2014–0379

On November 24, 2014, FMCSA published a notice of receipt of exemption applications and requested public comment on 12 individuals (79 FR 69981; Docket number FMCSA–2014–27755). The comment period ended on December 24, 2014. Two commenters responded to this notice expressing support for the epilepsy standard and the duty to keep our roads safe. Of the 12 applicants, six were denied. The Agency has determined that the following six applicants should be granted an exemption.

Theodore C. Banet

Mr. Banet is a 43 year-old driver in Pennsylvania. He has a history of epilepsy and has remained seizure free since 2004. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted an exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Banet receiving an exemption.

David S. Campbell

Mr. Campbell is a 70 year-old driver in Massachusetts. He has a history of seizures and has remained seizure free since 2005. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted an exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Campbell receiving an exemption.

Lewis R. Holbrook

Mr. Holbrook is a 43 year-old driver in North Carolina. He has a history of a seizure disorder and has remained seizure free since 2004. He takes anti-seizure medication with the dosage and frequency remaining the same since 2005. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Holbrook receiving an exemption.

Dominick Rezza

Mr. Rezza is a 58 year-old class A CDL holder in Texas. He has a history of a seizure disorder and has remained seizure free since 1995. He takes anti-seizure medication with the dosage and frequency remaining the same since 1996. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Rezza receiving an exemption.

Edgar A. Snapp

Mr. Snapp is a 52 year-old class B CDL holder in Indiana. He has a history of a seizure disorder and has remained seizure free since 1988. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Snapp receiving an exemption.

Gregory W. Young

Mr. Young is a 50 year-old class A CDL holder in South Carolina. He has a history of seizure and has remained seizure free since 1983. He takes anti-seizure medication with the dosage and frequency remaining the same since 2004. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Young receiving an exemption.

E. Basis for Exemption

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the epilepsy/seizure standard in 49 CFR 391.41(b)(8) if the exemption is likely to achieve an equivalent or greater level of safety than would be achieved without the exemption. Without the exemption, applicants will continue to be restricted to intrastate driving. With the exemption, applicants can drive in interstate commerce. Thus, the Agency's analysis focuses on whether an equal or greater level of safety is likely to be achieved by permitting each of these drivers to drive in interstate commerce as opposed to restricting the driver to driving in intrastate commerce.

Conclusion

The Agency is granting exemptions from the epilepsy standard, 49 CFR 391.41(b)(8), to 6 individuals based on a thorough evaluation of each driver's safety experience, and medical condition. Safety analysis of information relating to these 6 applicants meets the burden of showing

that granting the exemptions would achieve a level of safety that is equivalent to or greater than the level that would be achieved without the exemption. By granting the exemptions, the interstate CMV industry will gain 6 highly trained and experienced drivers. In accordance with 49 U.S.C. 31315(b)(1), each exemption will be valid for 2 years, with annual recertification required unless revoked earlier by FMCSA. The exemption will be revoked if the following occurs: (1) The person fails to comply with the terms and conditions of the exemption; (2) the exemption has resulted in a lower level of safety than was maintained prior to being granted; or (3) continuation of the exemption would not be consistent with the goals and objectives of 49 U.S.C. 31136 and 31315.

FMCSA exempts the following 6 drivers for a period of 2 years with annual medical certification required: Theodore Banet (PA); David Campbell (MA); Lewis Holbrook (NC); Dominick Rezza (TX); Edgar Snapp (IN); and Gregory Young (SC) from the prohibition of CMV operations by persons with a clinical diagnosis of epilepsy or seizures. If the exemption is still in effect at the end of the 2-year period, the person may apply to FMCSA for a renewal under procedures in effect at that time.

Issued on: September 3, 2015.

Larry W. Minor,

Associate Administrator for Policy.

DEPARTMENT OF TRANSPORTATION

Federal Motor Carrier Safety Administration

[Docket No. FMCSA–2015–0116]

Qualification of Drivers; Exemption Applications; Epilepsy and Seizure Disorders

AGENCY: Federal Motor Carrier Safety Administration (FMCSA), DOT.

ACTION: Notice of final disposition.

SUMMARY: FMCSA announces its decision to grant requests from 9 individuals for exemptions from the regulatory requirement that interstate commercial motor vehicle (CMV) drivers have "no established medical history or clinical diagnosis of epilepsy or any other condition which is likely to cause loss of consciousness or any loss of ability to control a CMV." The regulation and the associated advisory criteria published in the Code of Federal Regulations as the "Instructions for Performing and Recording Physical Examinations" have resulted in numerous drivers being prohibited from operating CMVs in interstate commerce based on the fact that they have had one or more seizures and are taking anti-seizure medication, rather than an individual analysis of their circumstances by a qualified medical examiner. The Agency concluded that granting exemptions for these CMV drivers will provide a level of safety that is equivalent to or greater than the level of safety maintained without the exemptions. FMCSA grants exemptions that will allow these 9 individuals to operate CMVs in interstate commerce for a 2-year period. The exemptions preempt State laws and regulations and may be renewed.

DATES: The exemptions are effective September 14, 2015. The exemptions expire on September 14, 2017.

B. Background

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the safety regulations for a 2-year period if it finds "such exemption would likely achieve a level of safety that is equivalent to or greater than the level that would be achieved absent such exemption." The statute also allows the Agency to renew exemptions at the end of the 2-year period.

FMCSA grants 9 individuals an exemption from the regulatory requirement in § 391.41(b)(8), to allow these individuals who take anti-seizure medication to operate CMVs in interstate commerce for a 2-year period. The Agency's decision on these exemption applications is based on an individualized assessment of each applicant's medical information, including the root cause of the respective seizure(s), the length of time elapsed since the individual's last seizure, and each individual's treatment regimen. In addition, the Agency reviewed each applicant's driving record found in the Commercial Driver's License Information System (CDLIS) [1] for commercial driver's license (CDL) holders, and interstate and intrastate inspections recorded in Motor Carrier Management Information System (MCMIS).[2] For non-CDL holders, the Agency reviewed the driving records from the State licensing agency. The Agency acknowledges the potential consequences of a driver experiencing a seizure while operating a CMV. However, the Agency believes the drivers covered by the exemptions granted here have demonstrated that they are unlikely to have a seizure and their medical condition does not pose a risk to public safety.

In reaching the decision to grant these exemption requests, the Agency considered both current medical literature and information and the 2007 recommendations of the Agency's Medical Expert Panel (MEP). The Agency previously gathered evidence for potential changes to the regulation at 49 CFR 391.41(b)(8) by conducting a comprehensive review of scientific literature that was compiled into the "*Evidence Report on Seizure Disorders and Commercial Vehicle Driving*" (*Evidence Report*) [CD–ROM HD TL230.3 .E95 2007]. The Agency then convened a panel of medical experts in the field of neurology (the MEP) on May

[1] *Commercial Driver License Information System* (CDLIS) is an information system that allows the exchange of commercial driver licensing information among all the States. CDLIS includes the databases of fifty-one licensing jurisdictions and the CDLIS Central Site, all connected by a telecommunications network.

[2] *Motor Carrier Management Information System* (MCMIS) is an information system that captures data from field offices through SAFETYNET, CAPRI, and other sources. It is a source for FMCSA inspection, crash, compliance review, safety audit, and registration data.

14–15, 2007, to review 49 CFR 391.41(b)(8) and the advisory criteria regarding individuals who have experienced a seizure, and the 2007 *Evidence Report.* The *Evidence Report* and the MEP recommendations are published on-line at *http://www.fmcsa.dot.gov/regulations/medical/reports-how-medical-conditions-impact-driving,* under Seizure Disorders, and are in the docket for this notice.

MEP Criteria for Evaluation

On October 15, 2007, the MEP issued the following recommended criteria for evaluating whether an individual with epilepsy or a seizure disorder should be allowed to operate a CMV.[3] The MEP recommendations are included in previously published dockets.

Epilepsy diagnosis. If there is an *epilepsy diagnosis,* the applicant should be seizure-free for *8 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with an epilepsy diagnosis should be performed every year.

Single unprovoked seizure. If there is a *single unprovoked seizure* (*i.e.,* there is no known trigger for the seizure), the individual should be seizure-free for *4 years, on or off medication.* If the individual is taking anti-seizure medication(s), the plan for medication should be stable for *2 years.* Stable means no changes in medication, dosage, or frequency of medication administration. Recertification for drivers with a single unprovoked seizure should be performed every 2 years.

Single provoked seizure. If there is a *single provoked seizure* (*i.e.,* there is a known reason for the seizure), the Agency should consider specific criteria that fall into the following two categories: low-risk factors for recurrence and moderate-to-high risk factors for recurrence.

- *Examples of low-risk factors for recurrence* include seizures that were caused by a medication; by non-penetrating head injury with loss of consciousness less than or equal to 30 minutes; by a brief loss of consciousness not likely to recur while driving; by metabolic derangement not likely to recur; and by alcohol or illicit drug withdrawal.

- *Examples of moderate-to-high-risk factors for recurrence* include seizures caused by non-penetrating head injury with loss of consciousness or amnesia greater than 30 minutes, or penetrating head injury; intracerebral hemorrhage associated with a stroke or trauma; infections; intracranial hemorrhage; post-operative complications from brain surgery with significant brain hemorrhage; brain tumor; or stroke.

The MEP report indicates individuals with moderate to high-risk conditions should not be certified. Drivers with a history of a single provoked seizure with low risk factors for recurrence should be recertified every year.

Medical Review Board Recommendations and Agency Decision

FMCSA presented the MEP's findings and the *Evidence Report* to the Medical Review Board (MRB) for consideration. The MRB reviewed and considered the 2007 "Seizure Disorders and Commercial Driver Safety" evidence report and the 2007 MEP recommendations. The MRB recommended maintaining the current advisory criteria, which provide that "drivers with a history of epilepsy/seizures off anti-seizure medication and seizure-free for 10 years may be qualified to drive a CMV in interstate commerce. Interstate drivers with a history of a single unprovoked seizure may be qualified to drive a CMV in interstate commerce if seizure-free and off anti-seizure medication for a 5 year period or more" [Advisory criteria to 49 CFR 391.43(f)].

The Agency acknowledges the MRB's position on the issue but believes relevant current medical evidence supports a less conservative approach. The medical advisory criteria for epilepsy and other seizure or loss of consciousness episodes was based on the 1988 "Conference on Neurological Disorders and Commercial Drivers" (NITS Accession No. PB89–158950/AS). A copy of the report can be found in the docket referenced in this notice.

The MRB's recommendation treats all drivers who have experienced a seizure the same, regardless of individual medical conditions and circumstances. In addition, the recommendation to continue prohibiting drivers who are taking anti-seizure medication from operating a CMV in interstate commerce does not consider a driver's actual seizure history and time since the last seizure. The Agency has decided to use the 2007 MEP recommendations as the basis for evaluating applications for an exemption from the seizure regulation on an individual, case-by-case basis.

C. Exemptions

Following individualized assessments of the exemption applications, including a review of detailed follow-up information requested from each applicant, FMCSA is granting exemptions from 49 CFR 391.41(b)(8) to 9 individuals. Under current FMCSA regulations, all of the 9 drivers receiving exemptions from 49 CFR 391.41(b)(8) would have been considered qualified physically to drive a CMV in interstate commerce except that they presently take or have recently stopped taking anti-seizure medication. For these 9 drivers, the primary obstacle to medical qualification was the FMCSA Advisory Criteria for Medical Examiners, based on the 1988 "Conference on Neurological Disorders and Commercial Drivers," stating that a driver should be off anti-seizure medication in order to drive in interstate commerce. In fact, the Advisory Criteria have little if anything to do with the actual risk of a seizure and more to do with assumptions about individuals who are taking anti-seizure medication.

In addition to evaluating the medical status of each applicant, FMCSA evaluated the crash and violation data for the 9 drivers, some of whom currently drive a CMV in intrastate commerce. The CDLIS and MCMIS were searched for crash and violation data on the 9 applicants. For non-CDL holders, the Agency reviewed the driving records from the State licensing agency.

These exemptions are contingent on the driver maintaining a stable treatment regimen and remaining seizure-free during the 2-year exemption period. The exempted drivers must submit annual reports from their treating physicians attesting to the stability of treatment and that the driver has remained seizure-free. The driver must undergo an annual medical examination by a medical examiner, as defined by 49 CFR 390.5, following the FCMSA's regulations for the physical qualifications for CMV drivers.

FMCSA published a notice of receipt of application and requested public comment during a 30-day public comment period in a **Federal Register** notice for each of the applicants. A short summary of the applicants' qualifications and a discussion of the comments received follows this section. For applicants who were denied an exemption, a notice was previously published.

D. Comments

Docket # FMCSA–2015–0116

On July 13, 2015, FMCSA published a notice of receipt of exemption

[3] Engel, J., Fisher, R.S., Krauss, G.L., Krumholz, A., and Quigg, M.S., "Expert Panel Recommendations: Seizure Disorders and Commercial Motor Vehicle Driver Safety," FMCSA, October 15, 2007.

applications and requested public comment on 21 individuals (80 FR 40127; Docket number FMCSA–2015–17022). The comment period ended on August 12, 2015. Ten commenters responded to this notice, seven of whom specifically expressed support for applicant Daniel Dellaserra. Paula Johnson expressed support for her son Kristopher Fraser because he has been seizure free for over eight years, compliant with his treatment, and desires to advance in his career. Michael Muise, a certified medical examiner expressed support for drivers with seizure disorders driving commercially if controlled with medication similar to diabetics on insulin. The Agency has determined that the following 9 applicants should be granted an exemption.

William Howard Brown

Mr. Brown is a 58 year-old class A CDL holder in North Carolina. He has a history of epilepsy and has remained seizure free since 1999. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Brown receiving an exemption.

Daniel Dellaserra

Mr. Dellaserra is a 54 year-old class A CDL holder in California. He has a history of seizures and has remained seizure free since 1998. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Dellaserra receiving an exemption.

Thomas A. Granese

Mr. Granese is a 70 year-old class A CDL holder in Massachusetts. He has a history of seizure disorder and has remained seizure free since 2003. He takes anti-seizure medication with the dosage and frequency remaining the same since 2010. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Granese receiving an exemption.

Paul E. Granger

Mr. Granger is a 50 year-old chauffeur license holder in Michigan. He has a history of a seizure disorder and has remained seizure free since 1987. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, she would like to drive a CMV. His physician states that he is supportive of Mr. Granger receiving an exemption.

Charles Terrell Gray

Mr. Gray is a 69 year-old driver in Oklahoma. He has a history of a single unprovoked seizure and has remained seizure free since 1993. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Gray receiving an exemption.

David Allen Griggs

Mr. Griggs is a 55 year-old class A CDL holder in Minnesota. He has a history of a seizure disorder and has remained seizure free since 1987. He takes anti-seizure medication with the dosage and frequency remaining the same since April 2013. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Griggs receiving an exemption.

Dennis Edward Klamm

Mr. Klamm is a 52 year-old class C CDL holder in Minnesota. He has a history of a seizure disorder and has remained seizure free since 1987. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Klamm receiving an exemption.

Christina L. Petti

Ms. Petti is a 45 year-old class B CDL holder in New Jersey. She has a history of a seizure disorder and has remained seizure free since 1985. She takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, she would like to drive a CMV. Her physician states that he is supportive of Ms. Petti receiving an exemption.

Christopher L. Phillips

Mr. Phillips is a 46 year-old class A CDL holder in Pennsylvania. He has a history of a seizure disorder and has remained seizure free since 1989. He takes anti-seizure medication with the dosage and frequency remaining the same since that time. If granted the exemption, he would like to drive a CMV. His physician states that he is supportive of Mr. Phillips receiving an exemption.

E. Basis for Exemption

Under 49 U.S.C. 31136(e) and 31315(b), FMCSA may grant an exemption from the epilepsy/seizure standard in 49 CFR 391.41(b)(8) if the exemption is likely to achieve an equivalent or greater level of safety than would be achieved without the exemption. Without the exemption, applicants will continue to be restricted to intrastate driving. With the exemption, applicants can drive in interstate commerce. Thus, the Agency's analysis focuses on whether an equal or greater level of safety is likely to be achieved by permitting each of these drivers to drive in interstate commerce as opposed to restricting the driver to driving in intrastate commerce.

Conclusion

The Agency is granting exemptions from the epilepsy standard, 49 CFR 391.41(b)(8), to 9 individuals based on a thorough evaluation of each driver's safety experience, and medical condition. Safety analysis of information relating to these 9 applicants meets the burden of showing that granting the exemptions would achieve a level of safety that is equivalent to or greater than the level that would be achieved without the exemption. By granting the exemptions, the interstate CMV industry will gain 9 highly trained and experienced drivers. In accordance with 49 U.S.C. 31315(b)(1), each exemption will be valid for 2 years, with annual recertification required unless revoked earlier by FMCSA. The exemption will be revoked if the following occurs: (1) The person fails to comply with the terms and conditions of the exemption; (2) the exemption has resulted in a lower level of safety than was maintained prior to being granted; or (3) continuation of the exemption would not be consistent with the goals and objectives of 49 U.S.C. 31136 and 31315.

FMCSA exempts the following 9 drivers for a period of 2 years with annual medical certification required: William Howard Brown (NC); Daniel Dellaserra (CA); Thomas A. Granese (MA); Paul E. Granger (MI); Charles Terrell Gray (OK); David Allen Griggs (MN); Dennis Edward Klamm (MN); Christina L. Petti (NJ); and Christopher L. Phillips (PA) from the prohibition of CMV operations by persons with a clinical diagnosis of epilepsy or seizures. If the exemption is still in effect at the end of the 2-year period, the person may apply to FMCSA for a renewal under procedures in effect at that time.

Issued on: September 3, 2015.

Larry W. Minor,

Associate Administrator for Policy.

BILLING CODE 4910–EX–P

DEPARTMENT OF TRANSPORTATION

Surface Transportation Board

[Docket No. AB 57 (Sub-No. 62X]

Soo Line Railroad Company—Abandonment Exemption—in Hennepin County, Minn.

Soo Line Railroad Company d/b/a Canadian Pacific (Soo Line) has filed a verified notice of exemption under 49 CFR 1152 subpart F–*Exempt Abandonments* to abandon a 0.4-mile line of railroad between milepost 0.59 +/− (approximately 100 feet southeast of the bridge that crosses Interstate 94) and milepost 0.99 +/− at or near Essex Street, SE. (East side spur) in Hennepin County, Minn. (the Line). The Line traverses United States Postal Service Zip Code 55414.

Soo Line has certified that: (1) No local traffic has moved over the Line for at least two years; (2) any overhead traffic can be and has been rerouted over other lines; (3) no formal complaint filed by a user of rail service on the Line (or by a state or local government entity acting on behalf of such user) regarding cessation of service over the Line either is pending with the Surface Transportation Board (Board) or with any U.S. District Court or has been decided in favor of complainant within the two-year period; and (4) the requirements at 49 CFR 1105.7(c) (environmental report), 49 CFR 1105.11 (transmittal letter), 49 CFR 1105.12 (newspaper publication), and 49 CFR 1152.50(d)(1) (notice to governmental agencies) have been met.

As a condition to this exemption, any employee adversely affected by the abandonment shall be protected under *Oregon Short Line Railroad—Abandonment Portion Goshen Branch Between Firth & Ammon, in Bingham & Bonneville Counties, Idaho,* 360 I.C.C. 91 (1979). To address whether this condition adequately protects affected employees, a petition for partial revocation under 49 U.S.C. 10502(d) must be filed.

Provided no formal expression of intent to file an offer of financial assistance (OFA) has been received, this exemption will be effective on October 14, 2015, unless stayed pending reconsideration. Petitions to stay that do not involve environmental issues,[1] formal expressions of intent to file an OFA under 49 CFR 1152.27(c)(2),[2] and trail use/rail banking requests under 49 CFR 1152.29 must be filed by September 24, 2015. Petitions to reopen or requests for public use conditions under 49 CFR 1152.28 must be filed by October 5, 2015, with the Surface Transportation Board, 395 E Street, SW., Washington, DC 20423–0001.

A copy of any petition filed with the Board should be sent to Soo Line's representative: W. Karl Hansen, Stinson Leonard Street LLP, 150 South Fifth Street, Suite 2300, Minneapolis, Minn. 55402.

If the verified notice contains false or misleading information, the exemption is void *ab initio.*

Soo Line has filed environmental and historic reports that address the effects, if any, of the abandonment on the environment and historic resources. OEA will issue an environmental assessment (EA) by September 18, 2015. Interested persons may obtain a copy of the EA by writing to OEA (Room 1100, Surface Transportation Board, Washington, DC 20423–0001) or by calling OEA at (202) 245–0305. Assistance for the hearing impaired is available through the Federal Information Relay Service at (800) 877–8339. Comments on environmental and historic preservation matters must be filed within 15 days after the EA becomes available to the public.

Environmental, historic preservation, public use, or trail use/rail banking conditions will be imposed, where appropriate, in a subsequent decision.

Pursuant to the provisions of 49 CFR 1152.29(e)(2), Soo Line shall file a notice of consummation with the Board to signify that it has exercised the authority granted and fully abandoned the Line. If consummation has not been effected by Soo Line's filing of a notice of consummation by September 14, 2016, and there are no legal or regulatory barriers to consummation, the authority to abandon will automatically expire.

Board decisions and notices are available on our Web site at *www.stb.dot.gov.*

[1] The Board will grant a stay if an informed decision on environmental issues (whether raised by a party or by the Board's Office of Environmental Analysis (OEA) in its independent investigation) cannot be made before the exemption's effective date. *See Exemption of Out-of-Serv. Rail Lines,* 5 I.C.C. 2d 377 (1989). Any request for a stay should be filed as soon as possible so that the Board may take appropriate action before the exemption's effective date.

[2] Each OFA must be accompanied by the filing fee, which is currently set at $1,600. *See* 49 CFR 1002.2(f)(25).

Decided: September 9, 2015.

By the Board, Rachel D. Campbell, Director, Office of Proceedings.

Jeffrey Herzig,

Clearance Clerk.

BILLING CODE 4915–01–P

DEPARTMENT OF THE TREASURY

Internal Revenue Service

Proposed Collection; Comment Request for Form 4876–A

AGENCY: Internal Revenue Service (IRS), Treasury.

ACTION: Notice and request for comments.

SUMMARY: The Department of the Treasury, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995, Public Law 104–13 (44 U.S.C. 3506(c)(2)(A)). Currently, the IRS is soliciting comments concerning Form 4876–A, Election to Be Treated as an Interest Charge DISC.

DATES: Written comments should be received on or before November 13, 2015 to be assured of consideration.

ADDRESSES: Direct all written comments to Martha Brinson, Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224.

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the form and instructions should be directed to Kerry Dennis, Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224, or through the internet at *Kerry.Dennis@irs.gov.*

SUPPLEMENTARY INFORMATION:

Title: Election To Be Treated as an Interest Charge DISC.

OMB Number: 1545–0190.

Form Number: 4876–A.

Abstract: A domestic corporation and its shareholders must elect to be an interest charge domestic international sales corporation (IC–DISC). Form 4876–A is used to make the election. The IRS uses the information to determine if the corporation qualifies to be an IC–DISC.

Current Actions: There are no changes being made to the form at this time.

Type of Review: Extension of a currently approved collection.

Affected Public: Business or other for-profit organizations.

Estimated Number of Responses: 1,000.

Estimated Time per Response: 6 hrs., 22 minutes.

Estimated Total Annual Burden Hours: 6,360.

The following paragraph applies to all of the collections of information covered by this notice:

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless the collection of information displays a valid OMB control number. Books or records relating to a collection of information must be retained as long as their contents may become material in the administration of any internal revenue law. Generally, tax returns and tax return information are confidential, as required by 26 U.S.C. 6103.

Request for Comments: Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval. All comments will become a matter of public record. Comments are invited on: (a) Whether the collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; (b) the accuracy of the agency's estimate of the burden of the collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology; and (e) estimates of capital or start-up costs and costs of operation, maintenance, and purchase of services to provide information.

Approved: August 19, 2015.

Martha Brinson,

IRS Tax Analyst.

BILLING CODE 4830–01–P

DEPARTMENT OF THE TREASURY

Internal Revenue Service

Proposed Collection; Comment Request for Regulation Project

AGENCY: Internal Revenue Service (IRS), Treasury.

ACTION: Notice and request for comments.

SUMMARY: The Department of the Treasury, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995, Public Law 104–13 (44 U.S.C. 3506(c)(2)(A)). Currently, the IRS is soliciting comments concerning limitations on percentage depletion in the case of oil and gas wells.

DATES: Written comments should be received on or before November 13, 2015 to be assured of consideration.

ADDRESSES: Direct all written comments to Martha Brinson, Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224.

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the regulation should be directed to Kerry Dennis, Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224, or through the internet at *Kerry.Dennis@irs.gov.*

SUPPLEMENTARY INFORMATION:

Title: Limitations on Percentage Depletion in the Case of Oil and Gas Wells.

OMB Number: 1545–1251.

Regulation Project Number: TD 8437.

Abstract: This regulation concerns oil and gas property held by partnerships. Because the depletion allowance with respect to production from domestic oil and gas properties is computed by the partners and not by the partnership, section 1.613A–3(e)(6)(i) of the regulation requires each partner to separately keep records of the partner's share of the adjusted basis in each oil and gas property of the partnership.

Current Actions: There is no change to this existing regulation.

Type of Review: Extension of a currently approved collection.

Affected Public: Business or other for-profit organizations.

Estimated Number of Respondents: 1,500,000.

Estimated Time per Respondent: 2 minutes.

Estimated Total Annual Burden Hours: 49,950.

The following paragraph applies to all of the collections of information covered by this notice:

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless the collection of information displays a valid OMB control number. Books or records relating to a collection of information must be retained as long as their contents may become material in the administration of any internal revenue law. Generally, tax returns and tax return information are confidential, as required by 26 U.S.C. 6103.

Request for Comments: Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval. All comments will become a matter of public record. Comments are invited on: (a) Whether the collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; (b) the accuracy of the agency's estimate of the burden of the collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology; and (e) estimates of capital or start-up costs and costs of operation, maintenance, and purchase of services to provide information.

Approved: August 19, 2015.

Martha Brinson,

IRS Tax Analyst.

SUPPLEMENTARY INFORMATION:

Title: Waiver of Right to Consistent Agreement of Partnership Items and Partnership-Level Determinations as to Penalties, Additions to Tax, and Additional Amounts.

OMB Number: 1545–1969.

Form Number: 13751.

Abstract: The information requested on Form 13751 will be used to determine the eligibility for participation in the settlement initiative of taxpayers related through TEFRA partnerships to ineligible applicants. Such determinations will involve partnership items and partnership-level determinations, as well as the calculation of tax liabilities resolved under this initiative, including penalties and interest.

Current Actions: There are no changes being made to the form at this time.

Type of Review: Extension of a currently approved collection.

Affected Public: Individuals or households, Business or other for-profit organizations, not-for-profit institutions.

Estimated Number of Respondents: 100.

Estimated Time per Respondent: 1 hour.

Estimated Total Annual Burden Hours: 100.

BILLING CODE 4830–01–P

DEPARTMENT OF THE TREASURY

Internal Revenue Service

Proposed Collection; Comment Request for Notice 2009–89 (as Modified by 2012–54) and Form 8936

AGENCY: Internal Revenue Service (IRS), Treasury.

ACTION: Notice and request for comments.

SUMMARY: The Department of the Treasury, as part of its continuing effort to reduce paperwork and respondent burden, invites the general public and other Federal agencies to take this opportunity to comment on proposed and/or continuing information collections, as required by the Paperwork Reduction Act of 1995, Public Law 104–13 (44 U.S.C. 3506(c)(2)(A)). Currently, the IRS is soliciting comments concerning qualified plug-in electric vehicle credit.

DATES: Written comments should be received on or before November 13, 2015 to be assured of consideration.

ADDRESSES: Direct all written comments to Martha Brinson, Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224.

FOR FURTHER INFORMATION CONTACT: Requests for additional information or copies of the form and instructions should be directed to Kerry Dennis, at Internal Revenue Service, Room 6129, 1111 Constitution Avenue NW., Washington, DC 20224, or through the internet at *Kerry.Dennis@irs.gov* .

SUPPLEMENTARY INFORMATION:

Title: Qualified Plug-in Electric Vehicle Credit (Notice 2009–89, as modified by Notice 2012–54).

OMB Number: 1545–2137.

Form Number: 8936.

Abstract: Notice 2009–54 sets forth interim guidance, pending the issuance of regulations, relating to the qualified plug-in electric drive motor vehicle credit under section 30D of the Internal Revenue Code, as in effect for vehicles acquired after December 31, 2009. Notice 2012–54 modifies Notice 2009–89, by providing a new address to which a vehicle manufacturer (or, in the case of a foreign vehicle manufacturer, its domestic distributor) must send vehicle certifications and quarterly reports under Notice 2009–89.

Form 8936, is used for tax years beginning after 2008, to figure the credit for qualified plug-in electric drive motor vehicles placed in service during your tax year. The credit attributable to depreciable property (vehicles used for business or investment purposes) is treated as a general business credit. Any credit not attributable to depreciable property is treated as a personal credit.

Current Actions: There is no change in the paperwork burden previously approved by OMB.

Type of Review: Extension of a currently approved collection.

Affected Public: Individual, Businesses and other for-profit organizations.

Notice 2012–54

Estimated Number of Respondents: 12.

Estimated Time per Respondent: 24 hours.

Estimated Total Annual Burden Hours: 280.

Form 8936

Estimated Number of Respondents: 50,000.

Estimated Time per Respondent: 5 hours, 21 minutes.

Estimated Total Annual Burden Hours: 267,500.

The following paragraph applies to all of the collections of information covered by this notice:

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless the collection of information displays a valid OMB control number. Books or records relating to a collection of information must be retained as long as their contents may become material in the administration of any internal revenue law. Generally, tax returns and tax return information are confidential, as required by 26 U.S.C. 6103.

Request for Comments: Comments submitted in response to this notice will be summarized and/or included in the request for OMB approval. All comments will become a matter of public record. Comments are invited on: (a) Whether the collection of information is necessary for the proper performance of the functions of the agency, including whether the information shall have practical utility; (b) the accuracy of the agency's estimate of the burden of the collection of information; (c) ways to enhance the quality, utility, and clarity of the information to be collected; (d) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or other forms of information technology; and (e) estimates of capital or start-up costs and costs of operation, maintenance, and purchase of services to provide information.

Approved: August 19, 2015.

Martha Brinson,

IRS Tax Analyst.

BILLING CODE 4830–01–P

DEPARTMENT OF VETERANS AFFAIRS

Advisory Committee on Former Prisoners of War; Notice of Meeting

The Department of Veterans Affairs (VA) gives notice under the Federal Advisory Committee Act, 5 U.S.C. App. 2, that the Advisory Committee on Former Prisoners of War (FPOW) will meet on October 5–7, 2015. The first two meetings will be held on October 5–6 from 9:00 a.m. to 4:00 p.m. at the Audie Murphy VA Medical Center, 7400

Merton Minter Blvd., San Antonio, TX. The third meeting will be held on October 7 from 9:00 a.m. to 12:00 p.m. at the Courtyard Marriott, 8585 Marriott Dr., San Antonio, TX. The meetings are open to the public.

The purpose of the Committee is to advise the Secretary of VA on the administration of benefits under title 38, United States Code, for Veterans who are FPOWs. The Committee also makes recommendations on the needs of FPOW Veterans for compensation, health care, and rehabilitation.

The Committee will hear from its Chairman and will receive briefings by representatives from the Veterans Benefits Administration and the Veterans Health Administration. On October 6, at 3:30 p.m., the Committee will host an open public forum and FPOW panel to gain information from FPOWs about their experiences, issues, and recommendations for health benefits and claims processing. Participation is limited to FPOWs. On October 7, the Committee will begin drafting their 2016 recommendations and decide the location of their next meeting in the spring.

FPOWs who wish to speak at the public forum are invited to submit a 1–2 page summary of their comments at the end of the meeting for inclusion in the official meeting record. Members of the public may also submit written statements for the Committee's review to Mr. Eric Robinson, Designated Federal Officer, Advisory Committee on Former Prisoners of War, (and Program Analyst, Compensation Service), Department of Veterans Affairs, 810 Vermont Avenue NW., Washington, DC 20420 (212), or by email at *eric.robinson3@va.gov.* Any member of the public seeking additional information should contact Mr. Robinson by email or call (202) 443–6016.

Dated: September 9, 2015.

Jelessa Burney,

Federal Advisory Committee Management Officer.

BILLING CODE P

DEPARTMENT OF VETERANS AFFAIRS

[OMB Control No. 2900–0764]

Agency Information Collection (Survey of Health Care Experiences Dental Patient Satisfaction Survey) Activities Under OMB Review

AGENCY: Veterans Health Administration, Department of Veterans Affairs.

ACTION: Notice.

SUMMARY: In compliance with the Paperwork Reduction Act (PRA) of 1995 (44 U.S.C. 3501–3521), this notice announces that the Veterans Health Administration (VHA), Department of Veterans Affairs, will submit the collection of information abstracted below to the Office of Management and Budget (OMB) for review and comment. The PRA submission describes the nature of the information collection and its expected cost and burden and includes the actual data collection instrument.

DATES: Written comments and recommendations on the proposed collection of information should be received on or before October 14, 2015.

ADDRESSES: Submit written comments on the collection of information through *www.Regulations.gov,* or to Office of Information and Regulatory Affairs, Office of Management and Budget, Attn: VA Desk Officer; 725 17th St. NW., Washington, DC 20503 or sent through electronic mail to *oira_submission@omb.eop.gov.* Please refer to "OMB Control No. 2900–0764 (SURVEY OF HEALTHCARE EXPERIENCES DENTAL PATIENT SATISFACTION SURVEY) in any correspondence. During the comment period, comments may be viewed online through the FDMS.

FOR FURTHER INFORMATION CONTACT: Crystal Rennie, Enterprise Records Service (005R1B), Department of Veterans Affairs, 810 Vermont Avenue NW., Washington, DC 20420, (202) 632–7492 or email *crystal.rennie@va.gov.* Please refer to "OMB Control No. 2900–0764 (Survey of Health Care Experiences Dental Patient Satisfaction Survey) in any correspondence.

SUPPLEMENTARY INFORMATION: Under the PRA of 1995 (Public Law 104–13; 44 U.S.C. 3501–3521), Federal agencies must obtain approval from the Office of Management and Budget (OMB) for each collection of information they conduct or sponsor. This request for comment is being made pursuant to Section 3506(c)(2)(A) of the PRA.

With respect to the following collection of information, VHA invites comments on: (1) Whether the proposed collection of information is necessary for the proper performance of VHA's functions, including whether the information will have practical utility; (2) the accuracy of VHA's estimate of the burden of the proposed collection of information; (3) ways to enhance the quality, utility, and clarity of the information to be collected; and (4) ways to minimize the burden of the collection of information on respondents, including through the use of automated collection techniques or the use of other forms of information technology.

SUPPLEMENTARY INFORMATION:

Titles:

1. Survey of Health Care Experiences Dental Patient Satisfaction Survey.

2. *OMB Control Number:* 2900–0764.

Type of Review: Extension of a currently approved collection.

Abstracts:

The mission of the Veterans Health Administration (VHA) is to provide high quality medical and dental care to eligible veterans. Executive Order 12862, dated September 11, 1993, calls for the establishment and implementation of customer service standards, and for agencies to "survey customers to determine the kind and quality of services they want and their level of satisfaction with current services". At present, VA does not specifically evaluate patient satisfaction for over 400,000 veterans receiving dental services each year.

The Dental Patient satisfaction survey is comprised primarily of questions taken from two validated and extensively tested surveys. The first survey is the VA Nation-wide Customer Satisfaction Survey: Survey of Health Experience of Patients (SHEP); this has OMB approval under clearance number 2900–0712. The second survey, Dental Consumer Assessment of Healthcare Provider and Systems (DCAHPS), was developed by the Agency for Healthcare Research and Quality (AHRQ). The psychometric properties of this survey are well documented and the survey has been used extensively in measuring patient satisfaction for TRICARE dental services.

Affected Public: Individuals or households.

Estimated Annual Burden:

a. Survey of Health Care Experiences Dental Patient Satisfaction Survey, VA Form 10–10070—9,146 hours.

Estimated Average Burden per Respondent:

a. Survey of Health Care Experiences Dental Patient Satisfaction Survey, VA Form 10–10070—15 minutes.

Frequency of Response: Annually.

Estimated Annual Responses:

a. Survey of Health Care Experiences Dental Patient Satisfaction Survey, VA Form 10–10070—36,585.

By direction of the Secretary.

Kathleen M. Manwell,

Program Analyst, VA Privacy Service, Office of Privacy and Records Management, Department of Veterans Affairs.

Vol. 80 Monday,
No. 177 September 14, 2015

Part II

Securities and Exchange Commission

17 CFR Part 240
Access to Data Obtained by Security-Based Swap Data Repositories and Exemption From Indemnification Requirement; Proposed Rule

SECURITIES AND EXCHANGE COMMISSION

17 CFR Part 240

[Release No. 34–75845; File No. S7–15–15]

RIN 3235–AL74

Access to Data Obtained by Security-Based Swap Data Repositories and Exemption From Indemnification Requirement

AGENCY: Securities and Exchange Commission.

ACTION: Proposed rule.

SUMMARY: Pursuant to section 763(i) of Title VII ("Title VII") of the Dodd-Frank Wall Street Reform and Consumer Protection Act of 2010 ("Dodd-Frank Act"), the Securities and Exchange Commission ("Commission") is proposing amendments to rule 13n–4 under the Securities Exchange Act of 1934 ("Exchange Act") related to regulatory access to security-based swap data held by security-based swap data repositories. The proposed rule amendments would implement the conditional Exchange Act requirement that security-based swap data repositories make data available to certain regulators and other authorities, and would set forth a conditional exemption from the statutory indemnification requirement associated with that regulatory access provision.

DATES: Submit comments on or before October 29, 2015.

ADDRESSES: Comments may be submitted by any of the following methods:

Electronic Comments

- Use the Commission's Internet comment form (*http://www.sec.gov/rules/proposed.shtml*); or
- Send an email to *rule-comments@sec.gov*. Please include File Number S7–15–15 on the subject line; or
- Use the Federal eRulemaking Portal (*http://www.regulations.gov*). Follow the instructions for submitting comments.

Paper Comments

- Send paper comments to Secretary, Securities and Exchange Commission, 100 F Street NE., Washington, DC 20549–1090.

All submissions should refer to File Number S7–15–15. This file number should be included on the subject line if email is used. To help us process and review your comments more efficiently, please use only one method. The Commission will post all comments on the Commission's Internet Web site (*http://www.sec.gov/rules/proposed.shtml*). Comments are also available for Web site viewing and printing in the Commission's Public Reference Room, 100 F Street NE., Washington, DC 20549 on official business days between the hours of 10:00 a.m. and 3:00 p.m. All comments received will be posted without change; the Commission does not edit personal identifying information from submissions. You should submit only information that you wish to make available publicly.

Studies, memoranda, or other substantive items may be added by the Commission or staff to the comment file during this rulemaking. A notification of the inclusion in the comment file of any such materials will be made available on the SEC's Web site. To ensure direct electronic receipt of such notifications, sign up through the "Stay Connected" option at *www.sec.gov* to receive notifications by email.

FOR FURTHER INFORMATION CONTACT: Carol McGee, Assistant Director, or Joshua Kans, Senior Special Counsel, at (202) 551–5870; Division of Trading and Markets, Securities and Exchange Commission, 100 F Street NE., Washington, DC 20549–7010.

SUPPLEMENTARY INFORMATION: The Commission is proposing to add paragraphs (b)(9) and (b)(10) to Exchange Act rule 13n–4 to implement the statutory requirement that security-based swap data repositories conditionally provide data to certain regulators and other authorities. The Commission also is proposing to add paragraph (d) to rule 13n–4 to provide a conditional exemption from the associated statutory indemnification requirement.

I. Background

A. Statutory Requirements for Access to Security-Based Swap Data Repository Information

Title VII of the Dodd-Frank Act amended the Exchange Act to provide a comprehensive regulatory framework for security-based swaps, including the regulation of security-based swap data repositories.[1]

Those amendments, among other things, require that security-based swap data repositories make data available to certain regulators and other entities. In particular, the amendments conditionally require that security-based swap data repositories "on a confidential basis pursuant to section 24, upon request, and after notifying the Commission of the request, make available all data obtained by the security-based swap data repository, including individual counterparty trade and position data."[2] The repositories must make that data available to: "each appropriate prudential regulator";[3] the Financial Stability Oversight Council ("FSOC"); the Commodity Futures Trading Commission ("CFTC"); the Department of Justice; and "any other person that the Commission determines to be appropriate," including foreign financial supervisors (including foreign futures authorities), foreign central banks and foreign ministries.[4]

This access to data is conditional, however. In part, before a repository shares such data, the repository "shall receive a written agreement from each entity stating that the entity shall abide by the confidentiality requirements described in section 24 relating to the information on security-based swap transactions that is provided."[5] Moreover, before such data is shared, "each entity shall agree to indemnify the security-based swap data repository and the Commission for any expenses arising from litigation relating to the information provided under section 24."[6]

B. Prior Proposals and Comments Received

1. 2010 proposal

In 2010, the Commission proposed several rules to implement statutory provisions related to the registration process, duties and core principles applicable to security-based swap data repositories.[7] That proposal, among other things, encompassed rules that

[1] Public Law 111–203, section 761(a) (adding Exchange Act section 3(a)(75) (defining "security-based swap data repository")) and section 763(i) (adding Exchange Act section 13(n) (establishing a regulatory regime for security-based swap data repositories)).

References in this release to the terms "data repository," "trade repository," "repository" or "SDR" generally address security-based swap data repositories unless stated otherwise.

[2] Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G). The confidentiality requirements addressed by Exchange Act section 24, 15 U.S.C. 78x, are addressed below. *See* note 84, *infra*.

[3] As discussed below, the term "prudential regulator" encompasses the Board of Governors of the Federal Reserve System and certain other regulators, with regard to certain categories of regulated entities. *See* note 44, *infra*.

[4] Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G).

[5] Exchange Act section 13(n)(5)(H)(i), 15 U.S.C. 78m(n)(5)(H)(i).

[6] Exchange Act section 13(n)(5)(H)(ii), 15 U.S.C. 78m(n)(5)(H)(ii).

[7] *See* Security-Based Swap Data Repository Registration, Duties, and Core Principles, Exchange Act Release No. 63347 (Nov. 19, 2010), 75 FR 77306 (Dec. 10, 2010), *corrected at* 75 FR 79320 (Dec. 20, 2010) *and* 76 FR 2287 (Jan. 13, 2011) ("SDR Proposing Release").

incorporated the statutory language that set forth the data access provisions.[8]

In proposing those rules, the Commission recognized that "regulators may be legally prohibited or otherwise restricted from agreeing to indemnify third parties, including SDRs as well as the Commission," and that the "indemnification provision could chill requests for access to data obtained by SDRs, thereby hindering the ability of others to fulfill their regulatory mandates and responsibilities." [9] The Commission added that it expected that a repository "would not go beyond the minimum requirements of the statute so as not to preclude [recipient entities described by the statute] from obtaining the data maintained by an SDR." [10] The Commission further noted that the Commission itself had the authority to share nonpublic information with, among others, certain domestic and foreign regulatory authorities.[11]

In response, four commenters addressed the data access provisions.[12] Those commenters generally supported providing relevant authorities with access to security-based swap data maintained by repositories when the access is within the scope of those authorities' mandates, but expressed particular concerns relating to the indemnification requirement and to the scope of authorities' access to data. Two commenters concurred that relevant authorities likely would be unable to agree to indemnify data repositories or the Commission.[13] One commenter expressed the concern that the statutory requirement is vague and could result in a data repository providing access to persons without proper authority.[14] Another commenter recommended that the Commission adopt rules to help streamline the indemnification requirement for an "efficient exchange of information." [15]

2. 2013 Cross-Border Proposal

a. Proposed Exemption to Indemnification Requirement

In 2013, the Commission proposed a number of rules related to the cross-border application of the Title VII security-based swap requirements. At that time, recognizing the significance of commenter concerns and understanding that certain authorities may be unable to agree to indemnify a data repository and the Commission, the Commission preliminarily concluded that the indemnification requirement could frustrate the purposes of the statutory requirement that repositories make available data to relevant authorities. The Commission further took the view that the indemnification requirement should not be applied rigidly so as to frustrate the statutory purposes of data repositories, and hinder relevant authorities' ability to fulfill their regulatory mandates and legal responsibilities.[16]

To address these concerns, the Commission proposed an exemption to provide that a data repository "is not required" to comply with the indemnification requirement, conditioned on: (1) An entity requesting the information "to fulfill a regulatory mandate and/or legal responsibility"; (2) the request pertaining "to a person or financial product subject to the jurisdiction, supervision or oversight of the entity"; and (3) the entity having entered into a supervisory and enforcement memorandum of understanding ("MOU") or other arrangement addressing the confidentiality of the information provided and any other matter as determined by the Commission.[17] The Commission took the preliminary view that the proposed exemption was consistent with commenters' views, including one commenter's suggestion that the indemnification requirement not apply when relevant authorities carry out their responsibilities in accordance with international agreements and while maintaining the

[8] *See* SDR Proposing Release, 75 FR 77368 (paragraphs (b)(9) and (b)(10) of proposed Exchange Act rule 13n-4 incorporated relevant language of Exchange Act sections 13(n)(5)(G) and (H)).

[9] 75 FR 77318–19.

[10] 75 FR 77319.

[11] *Id.*

[12] Cleary Gottlieb comment (Sept. 20, 2011) at 31–32 (comment was provided in response to a joint SEC–CFTC roundtable regarding the cross-border application of Title VII, and can be found at *http://www.sec.gov/comments/4-636/4-636.shtml*), DTCC comment (Nov. 15, 2010) at 3, ESMA comment (Jan. 17, 2011) at 2 and Managed Funds Association comment (Jan. 24, 2011) at 3.

[13] Prior to the proposed rules, one of those commenters described the indemnification requirement as contravening the purpose of data repositories and jeopardizing market stability by diminishing regulators' ability to carry out oversight functions. *See* DTCC comment (Nov. 15, 2010) at 3. This comment and other comments that addressed data repository issues in response to a general request for comments regarding the implementation of Title VII are located on the Commission's Web site at *http://www.sec.gov/comments/df-title-vii/swap-data-repositories/swap-data-repositories.shtml.*

Subsequently, in response to the proposed rules, that commenter further: (1) Stated that the indemnification requirement should not apply where relevant authorities carry out their regulatory responsibilities in accordance with international agreements and while maintaining the confidentiality of data provided to them; (2) suggested that the Commission provide model indemnification language; and (3) urged that "any indemnity should be limited in scope to minimize the potential reduction in value of registered SDRs to the regulatory community." *See* DTCC comment (Jan. 24, 2011) at 12. These and other comments addressing the proposed implementation of the data access provisions (as well as other aspects of the Commission's 2010 proposal regarding security-based swap data repository registration, duties and core principles) are located on the Commission's Web site at *http://www.sec.gov/comments/s7-35-10/s73510.shtml.*

Another commenter stated that because indemnification would not be feasible, "it would be problematic for [the Commission and the CFTC] to require non-U.S. SDRs to register with the Commissions," and that the indemnification requirement could impede effective regulatory coordination. *See* Cleary Gottlieb comment (Sept. 20, 2011) at 31–32.

That commenter further stated that when a non-U.S. data repository registers with the Commission "but is also subject to regulatory oversight by an appropriate non-U.S. regulator," the SEC should adopt the CFTC's interpretation "that the non-U.S. regulator is not as a result subject to Dodd-Frank's notice and indemnification provisions." *See id.* The Commission since then has issued final rules and interpretations regarding the cross-border application of the registration requirement for security-based swap data repositories, which exempts certain non-U.S. data repositories subject to regulation abroad from having to comply with requirements otherwise applicable to repositories. *See* Exchange Act Release No. 74246 (Feb. 11, 2015), 80 FR 14438, 14450–51, 14516–17, 14556 (Mar. 19, 2015) ("SDR Adopting Release") (generally stating that a non-U.S. person that performs the functions of a security-based swap data repository within the United States is required to register with the Commission absent an exemption, and adopting Exchange Act rule 13n–12 to provide an exemption from data repository requirements for certain non-U.S. persons when regulators with supervisory authority over those non-U.S. persons have entered into a memorandum of understanding ("MOU") or other arrangement with the Commission regarding the confidentiality of data collected and maintained by such non-U.S. person, access by the Commission to such data, and any other matters determined by the Commission). Also, under the preliminary interpretation discussed below, the conditions to the Exchange Act data access requirements would not restrict access when a repository registered with the Commission also is registered or licensed with a foreign authority that obtains the data pursuant to foreign law. *See* part IV.A, *infra.*

[14] That commenter particularly expressed concern regarding the possibility of "unfettered access" to security-based swap information by regulators, including foreign financial supervisors, foreign central banks and foreign ministries, "beyond their regulatory authority and mandate." *See* Managed Funds Association comment (Jan. 24, 2011) at 3. That comment further recommended that the Commission take an approach similar to that taken by rules proposed by the CFTC, requiring any regulator requesting access to such data to certify the statutory authority for the request and detail the basis for the request. *See id.* at 3–4. The CFTC subsequently adopted that certification requirement as a final rule, but did not adopt the proposed requirement that the regulator also detail the basis for the request. *See* note 31, *infra*, and accompanying text.

[15] That commenter also reiterated the notion that relevant authorities must ensure the confidentiality of security-based swap data provided to them, and that the indemnification requirement "undermines the key principle of trust according to which exchange of information [among relevant authorities] should occur." *See* ESMA comment (Jan. 17, 2011) at 2.

[16] *See* Exchange Act Release No. 69490 (May 1, 2013), 78 FR 30968, 31048–49 (May 23, 2013) ("Cross-Border Proposing Release").

[17] *See id.* at 31209 (paragraph (d) of proposed Exchange Act rule 13n–4).

confidentiality of data provided to them.[18]

The Commission further stated that the exemption's proposed condition that the request be for the purpose of fulfilling a relevant authority's regulatory mandate or legal responsibility was aligned with statutory requirements to protect the security-based swap information maintained by a repository, including proprietary and highly sensitive data, from unauthorized disclosure, misappropriation or misuse.[19] The Commission also expressed the preliminary view that the proposed condition that the Commission enter into an MOU or other arrangement with a relevant authority represented an effective way to streamline the indemnification requirement for an "efficient exchange of information" to help protect the confidentiality of information and further the purposes of the Dodd-Frank Act.[20]

b. Additional guidance

In the Cross-Border Proposing Release, the Commission also addressed the application of the statutory requirement that repositories notify the Commission regarding data requests. The Commission stated its preliminarily belief that repositories could satisfy that requirement by providing the Commission with notice of an initial request by a relevant authority, and maintaining records of the initial request and all subsequent requests.[21] The Commission further expressed preliminary views regarding the process for determining which additional authorities may obtain information from data repositories pursuant to these data access provisions.[22]

c. Comments

In response to this proposal, the Commission received one comment that addressed the data access provisions, including the indemnification requirement. That commenter stated that the proposal "did not erase the need for a legislative solution to clarify the scope and applicability" of the indemnification requirement.[23] The commenter further recommended that the Commission incorporate, as part of the exemption, a "safe harbor provision from liability for information shared pursuant to global information sharing agreements."[24]

The commenter also objected to the prospect that repositories would be required to notify the Commission of an initial information request, stating that such a requirement could lead authorities to hesitate to make requests if that would trigger notice, "particularly if such request is pursuant to an investigation." The commenter instead recommended that the Commission consider the notification requirement to be satisfied if the request is made "pursuant to an established information sharing agreement."[25]

3. Final Rules Reserving Action on the Data Access Provisions

In February 2015, the Commission adopted a number of final rules governing the registration process, duties and core principles applicable to security-based swap data repositories.[26] Those final rules, however, neither addressed the statutory data access requirements applicable to data repositories, nor provided an exception to the indemnification requirement. The Commission instead stated that final resolution of the issue would benefit from further consideration and public comment.[27]

C. Treatment of These Issues in the Swaps Context

The Dodd-Frank Act also revised the Commodity Exchange Act ("CEA") to impose comparable data access requirements—including confidentiality and indemnification conditions—upon swap data repositories that are subject to CFTC jurisdiction.[28]

1. Certification of Scope of Jurisdiction

To implement those requirements, the CFTC adopted rules that in part identify the domestic[29] and foreign regulators[30] to which a swap data repository must make swap data available. The rules provide that when those regulators seek access to data maintained by a swap data repository, they must file a request with the swap data repository and certify that they are acting within the scope of their jurisdiction.[31]

2. Scope of Confidentiality and Indemnification Requirements

The CFTC implementing rules generally require domestic and foreign regulators to execute confidentiality and indemnification agreements with the swap data repository prior to receipt of any requested swap data.[32] The CFTC,

[18] *See id.* at 31049 (addressing DTCC comment from Jan. 24, 2011). The Commission also stated that the proposal was consistent with commenter suggestions that the exemption be "location agnostic" (by treating relevant domestic and foreign authorities similarly), and that the exemption was intended to help preserve the "spirit of cooperation and coordination" between regulators around the world. *See id.*

[19] *See id.* at 31049–50.

[20] *See id.* at 31050. The Commission moreover expressed the preliminary view that, in determining whether to enter into such an MOU or other arrangement, the Commission would consider, among other things, whether: (1) "The relevant authority needs security-based swap information from an SDR to fulfill its regulatory mandate or legal responsibilities; (2) the relevant authority agrees to protect the confidentiality of the security-based swap information provided to it; (3) the relevant authority agrees to provide the Commission with reciprocal assistance in securities matters within the Commission's jurisdiction; and (4) a supervisory and enforcement MOU or other arrangement would be in the public interest." *See id.* at 31049–50.

[21] *See id.* at 31046–47.

[22] *See id.* at 31047–48 (indicating that the Commission would make such determinations by order, and that the Commission would consider a variety of factors, including whether there is a supervisory and enforcement MOU between the Commission and the relevant authority, and whether the relevant authority has a legitimate need for the information).

[23] *See* DTCC cross-border comment (Aug. 21, 2013) at 6–7 (expressing concern that the indemnification provision would continue to limit data sharing across jurisdictions, leading foreign regulators to seek to establish "national" repositories that would fragment data among jurisdictions). That comment and other comments responding to the cross-border proposal are located on the Commission's Web site at: *http://www.sec.gov/comments/s7-02-13/s70213.shtml.*

[24] *See* DTCC cross-border comment at 8.

[25] *See id.* at 7.

[26] *See* SDR Adopting Release.

[27] *See id.*, 80 FR 14487–88 (further noting that repositories will have to comply with all statutory requirements, including the indemnification requirement, when the current exemptive relief from requirements applicable to repositories expires). As a result, in adopting those final rules the Commission reserved paragraphs (b)(9) and (b)(10) of Exchange Act rule 13n–4 (which as proposed would have addressed the data access obligations of registered security-based swap data repositories), and did not adopt the indemnification exemption proposed as paragraph (d) of rule 13n–4.

[28] *See* CEA sections 21(c)(7), (d), 7 U.S.C. 24a(c)(7), (d).

[29] The CFTC has defined "Appropriate Domestic Regulator" to mean: (i) The SEC; (ii) each prudential regulator "with respect to requests related to any of such regulator's statutory authorities, without limitation to the activities listed for each regulator" in the statutory definition; (iii) the Financial Stability Oversight Council; (iv) the Department of Justice; (v) any Federal Reserve Bank; (vi) the Office of Financial Research; and (vii) any other person the CFTC deems appropriate. *See* 17 CFR 49.17(b)(1).

[30] The CFTC has defined "Appropriate Foreign Regulator" to mean foreign regulators "with an existing memorandum of understanding or other similar type of information sharing arrangement" executed with the CFTC, and/or foreign regulators "without an MOU as determined on a case-by-case basis" by the CFTC. *See* 17 CFR 49.17(b)(2).

[31] *See* 17 CFR 49.17(d)(1). In this regard, the CFTC did not adopt proposed requirements to require regulators to set forth the basis for their requests in sufficient detail, and to require a swap data repository to provide access only if it is satisfied that the regulator is acting within the scope of its authority. *See* 76 FR 54538, 54553 (Sept. 1, 2011).

[32] *See* 17 CFR 49.17(d)(6), 49.18(b).

however, also recognized that it might be difficult for certain regulators to implement those confidentiality and indemnification requirements.[33] Accordingly, the CFTC provided that a domestic regulator with regulatory jurisdiction over a swap data repository registered with it pursuant to separate statutory authority may access such data without the need to enter into confidentiality or indemnification agreements if: (i) The domestic regulator executes an MOU or similar information sharing arrangement with the CFTC; and (ii) the CFTC designates the domestic regulator to receive direct electronic access.[34]

The CFTC implementing rules further provided that a foreign regulator with supervisory responsibility over a swap data repository registered with the foreign regulator pursuant to foreign law and/or regulation would not need to enter into such confidentiality or indemnification agreements.[35] In addition, the CFTC noted that the confidentiality and indemnification requirements would not apply when the CFTC itself shares information in its possession with foreign authorities.[36]

The CFTC subsequently issued an interpretative statement that the indemnification and confidentiality provisions under the CEA generally apply only to such data reported pursuant to the CEA and CFTC regulations, and that those confidentiality and indemnification provisions "should not operate to inhibit or prevent foreign regulatory authorities from accessing data in which they have an independent regulatory interest (even if that data also has been reported pursuant to the CEA and [CFTC] regulations)." [37] The CFTC further stated that a registered swap data repository would not be subject to the indemnification and confidentiality provisions under the CEA if the swap data repository is "registered, recognized or otherwise authorized in a foreign jurisdiction's regulatory regime," when the data sought to be accessed by the foreign regulatory authority has been reported to the swap data repository "pursuant to the foreign jurisdiction's regulatory regime." [38]

D. The Current Proposal

The Commission today is proposing rules related to the data access obligation applicable to security-based swap data repositories, including rules to provide a conditional exemption from the indemnification requirement. This new proposal builds upon the earlier proposals, but with certain changes.

Among other aspects, as discussed below, the proposal would provide for the statutory confidentiality agreement requirement to be satisfied via the use of MOUs or other agreements between the Commission and the entity accessing data from a security-based swap data repository. The proposal also encompasses an indemnification exemption that would be effective when the relevant conditions are met, in contrast to the earlier proposed approach of conditionally allowing a data repository to elect whether to waive the indemnification requirement.

Taken as a whole, the proposal would provide that when the conditions to the data access provisions are satisfied—including as applicable the conditions to the indemnification exemption—a repository would be required to provide security-based swap data to relevant authorities.

II. Proposed Data Access Rules

The Commission is proposing rules, to implement the data access provisions of Exchange Act sections 13(n)(5)(G) and (H),[39] that address commenter concerns and reflect the Commission's further consideration of the issues. Under the proposal:

- Security-based swap data repositories generally would be required, on a confidential basis after notifying the Commission, to make available security-based swap data, including individual counterparty trade and position data, to certain entities that are identified in the proposed rules and any other persons that are determined by the Commission to be appropriate.[40]
- The data access requirement would be subject to a confidentiality provision that conditions the data access requirement on there being an agreement between the Commission and the entity (in the form of an MOU or otherwise) that addresses the confidentiality of the information received.[41]
- In addition, as discussed below, there would be a conditional exemption to the statutory provision that conditions the data access on the recipient of the data agreeing to indemnify the repository and the Commission for expenses arising from litigation related to the information provided.[42]

A. Data Access Requirement

1. Application to Prudential Regulators and Federal Reserve Banks

The Exchange Act specifically states that a repository is conditionally obligated to make information available to, among others, "each appropriate prudential regulator." [43] The proposed rules would specifically identify, as being eligible to access data, each of the entities encompassed within the statutory "prudential regulator" definition: The Board of Governors of the Federal Reserve System ("Board"), the Office of the Comptroller of the Currency, the Federal Deposit Insurance Corporation ("FDIC"), the Farm Credit Administration, and the Federal Housing Finance Agency.[44]

---

[33] *See* 76 FR 54554.

[34] *See* 17 CFR 49.17(d)(2), 49.18(c); 76 FR 54554 (also referencing a separate statutory provision, CEA section 21(c)(4)(A), 7 U.S.C. 24a(c)(4)(A), that requires swap data repositories to provide "direct electronic access" to the CFTC and its designees).

There are differences between the Commission's proposed approach, discussed below, and the approach the CFTC has taken in adopting rules to implement the data access requirement under the CEA. In part, while the CFTC rule requires that entities accessing swap data certify that they are acting within the scope of their jurisdiction, the Commission's proposal instead anticipates considering an entity's interest in the security-based swap information when determining whether to determine that entity may access security-based swap information. *See* part II.A.3.a, *infra*. Also, the Commission's proposed exemption from the indemnification requirement is conditioned in part on an entity requesting security-based swap information in connection with a regulatory mandate, or legal responsibility or authority. *See* part III.B.1.a, *infra*.

[35] *See* 17 CFR 49.17(d)(3), 49.18(c); 76 FR 54555 n.166 (adding that the CFTC does not interpret the notification and indemnification provisions to apply "in circumstances in which an Appropriate Foreign Regulator possesses independent sovereign legal authority to obtain access to the information and data held and maintained by an SDR").

[36] *See* 76 FR 54554.

[37] *See* Swap Data Repositories: Interpretative Statement Regarding the Confidentiality and Indemnification Provisions of the Commodity Exchange Act, 77 FR 65177, 65180–81 (Oct. 25, 2012).

[38] *See id.* The CFTC added that this principle applies even if the applicable data also is reported pursuant to CFTC rules, and that foreign and domestic regulatory authorities also may receive data from the CFTC (rather than the swap data repository) without execution of a confidentiality and indemnification agreement. *See id.* at 65181.

[39] 15 U.S.C. 78m(n)(5)(G) and (H).

[40] *See* proposed Exchange Act rule 13n–4(b)(9).

[41] *See* proposed Exchange Act rule 13n–4(b)(10).

[42] *See* proposed Exchange Act rule 13n–4(b)(ii).

[43] *See* Exchange Act section 13(n)(5)(G)(i), 15 U.S.C. 78m(n)(5)(G)(i).

[44] *See* proposed Exchange Act rule 13n–4(b)(9)(i)–(v).

Exchange Act section 3(a)(74), 15 U.S.C. 78c(a)(74), defines "prudential regulator" by reference to the CEA. The CEA, in turn, defines "prudential regulator" to encompass: (a) The Board, (b) the Office of the Comptroller of the Currency, (c) the FDIC, (d) the Farm Credit Administration or (e) the Federal Housing Finance Agency—in each case with respect to swap dealers, major swap participants, security-based swap dealers or major security-based swap participants (cumulatively, "dealers" or "major participants") that fall within the regulator's authority. *See* CEA section 1a(39); 7 U.S.C. 1a(39).

Continued

Under this approach of specifically identifying each of those regulators, rather than generally referring to "appropriate prudential regulators," the ability of those regulators to access security-based swap data would not vary depending on whether entities regulated by the regulators are acting as security-based swap dealers, as major security-based swap participants, or in some other capacity.[45] For similar reasons, under this approach those regulators' access also would not vary depending on whether the regulator acts in a "prudential" capacity in connection with the information.[46]

The proposed rules also would include "any Federal Reserve Bank" among the entities conditionally eligible to access security-based swap data from repositories,[47] in accordance with the Exchange Act provision that extends data access to "any other person that the Commission determines to be appropriate."[48] Consistent with the standards the Commission expects to consider in connection with determining other entities to be authorized to access such data—including consideration of a relevant authority's interest in accessing security-based swap data based on its regulatory mandate, or legal responsibility or authority[49]—the Commission preliminarily believes that it is appropriate for the Federal Reserve Banks to be able to access such data. The Commission particularly understands that the Federal Reserve Banks occupy important oversight roles under delegated authority from the Board, including supervision of banks that are under the Board's authority, and gathering and analyzing information to inform the Federal Open Market Committee regarding financial conditions.[50] We further understand that the Federal Reserve Banks, as well as the Board, would use data from security-based swap data repositories to fulfill statutory responsibilities related to prudential supervision and financial stability.[51] The Commission accordingly believes preliminarily that the Federal Reserve Banks' access to security-based swap data held by repositories would appropriately fall within their regulatory mandate and legal responsibility or authority, and that the Federal Reserve Banks should conditionally have access to the security-based swap data.[52]

A Federal Reserve Bank's ability to access such data would be subject to conditions related to confidentiality and indemnification (as would the ability of any other entity that is identified by statute or determined by the Commission to access such data).[53]

2. FSOC, CFTC, Department of Justice and Office of Financial Research

The Exchange Act also states that FSOC, CFTC, and the Department of Justice may access security-based swap data.[54] The proposed rules accordingly would identify those entities as being conditionally authorized to access such data.[55]

The proposed rules further would make the Office of Financial Research ("OFR") conditionally eligible to access such data,[56] in accordance with the Exchange Act provision that that extends data access to "any other person

For example, the definition provides that the Board is a prudential regulator with regard to, among others, certain dealers and major participants that are: State-chartered banks and agencies, foreign banks that do not operate insured branches, or members of bank holding companies. Also, for example, the definition provides that the Office of the Comptroller of the Currency is a prudential regulator with regard to, among others, certain dealers or major participants that are national banks, federally chartered branches or agencies of foreign banks or federal saving associations.

[45] This approach particularly addresses the fact that the statutory "prudential regulator" definition noted above specifically refers to those regulators in connection with dealers and major participants that fall within their authority. In the Commission's preliminary view the application of the data access provision should not vary depending on whether an entity regulated by the regulator is acting as a dealer or major participant, or in some other capacity. Such a reading would not further the purposes of Title VII, and the Dodd-Frank Act more generally, including facilitating regulator access to security-based swap information to help address the risks associated with those instruments. Accordingly, the proposed rule does not limit those regulators' access to security-based swap information based on the capacity in which a regulated entity is acting.

[46] Those regulators' ability to access security-based swap data accordingly would not be limited to situations in which they act in the capacity of a prudential supervisor. Thus, for example, the FDIC would conditionally be authorized to access security-based swap data from a repository in connection with all of its statutory capacities, including its prudential supervisory capacity as well as other capacities such as the FDIC's resolution authority pursuant to the Federal Deposit Insurance Act and the Orderly Liquidation Authority provisions of Title II of the Dodd-Frank Act.

[47] *See* proposed Exchange Act rule 13n–4(b)(9)(i).

[48] *See* Exchange Act section 13(n)(5)(G)(v), 15 U.S.C. 78m(n)(5)(G)(v). The CFTC has identified the Federal Reserve Banks as being "appropriate domestic regulators" that may access swap data from swap data repositories. *See* note 29 *supra*.

[49] *See* part II.A.3, *infra*.

[50] Section 11(k) of the Federal Reserve Act grants the Board authority "to delegate, by published order or rule . . . any of its functions, other than those relating to rulemaking or pertaining to monetary and credit policies to . . . members or employees of the Board, or Federal Reserve banks." 12 U.S.C. 248(k). The Federal Reserve Banks carry out the Board's activities including the supervision, examination and regulation of financial institutions as directed by the Board and under its supervision. *See* the Board's Rules of Organization, sec. 3(j) FRRS 8–008 (providing that the Director of the Board's Division of Banking Supervision and Regulation "coordinates the System's supervision of banks and bank holding companies and oversees and evaluates the Reserve Banks' examination procedures"). The Board further has delegated extensive authority to the Reserve Banks with respect to numerous supervisory matters. *See* 12 CFR 265.11 (functions delegated by the Board to the Federal Reserve Banks).

[51] We understand that the Board and the Federal Reserve Banks jointly would use the data in support of the prudential supervision of institutions under the Board's jurisdiction, such as state member banks, bank holding companies, and Edge Act corporations. *See, e.g.*, section 9 of the Federal Reserve Act, 12 U.S.C. 321–338a (supervision of state member banks); the Bank Holding Company Act, 12 U.S.C. 1841–1852 (supervision of bank holding companies); the Edge Act, 12 U.S.C. 610 *et seq.* (supervision of Edge Act corporations). We also understand that the Board and the Federal Reserve Banks would use the data in support of the implementation of monetary policy, such as through market surveillance and research. *See, e.g.*, section 12A of the Federal Reserve Act, 12 U.S.C. 263 (establishing the Federal Open Market Committee); and section 2A of the Federal Reserve Act, 12 U.S.C. 225a (setting monetary policy objectives). In addition, we understand that the Board and the Federal Reserve Banks would use the data in fulfilling the Board's responsibilities with respect to assessing, monitoring and mitigating systemic risk, such as supervision of systemically important institutions. *See, e.g.*, section 113 of the Dodd-Frank Act, 12 U.S.C. 5323 (SIFIs); and section 807 of the Dodd-Frank Act, 12 U.S.C. 5466 (designated FMUs).

[52] The Federal Reserve Banks' access to this information, like the access of the entities directly identified by the statute, would be subject to conditions related to confidentiality and indemnification as discussed below, including conditions to limit an authority's access to data by linking the scope of the exemption from the indemnification requirement to information that is related to persons or activities within an entity's regulatory mandate or its legal responsibility or authority, as specified in an MOU between the Commission and the entity. *See* parts II.C and III.C, *infra*.

In proposing to permit the Federal Reserve Banks to access security-based swap information pursuant to the data access provisions, the Commission preliminarily believes that the Federal Reserve Banks' access should not be limited to information regarding security-based swap transactions entered into by banks supervised by the Board, but should be available more generally with regard to security-based swap transaction data. This is consistent with the fact that Title VII does not limit the Board's access to data in such a way. This view also reflects the breadth of the Federal Reserve Banks' responsibilities regarding prudential supervision and financial stability, as addressed above.

[53] In this regard, the Commission notes that personnel of the Board and the Reserve Banks already are subject to a number of confidentiality requirements. *See* 18 U.S.C. 1905 (imposing criminal sanctions on U.S. government personnel who disclose non-public information except as provided by law), 18 U.S.C. 641 (imposing criminal sanctions on the unauthorized transfer of records), 5 CFR 2635.703 (Office of Government Ethics regulations prohibiting unauthorized disclosure of nonpublic information); *see also* Federal Reserve Bank Code of Conduct section 3.2 (requiring Reserve Bank employees to maintain the confidentiality of nonpublic information).

[54] *See* Exchange Act sections 13(n)(5)(G)(ii)–(iv), 15 U.S.C. 78m(n)(5)(G)(ii)–(iv).

[55] *See* proposed Exchange Act rule 13n–4(b)(9)(vi)–(viii).

[56] *See* proposed Exchange Act rule 13n–4(b)(9)(ix), (x).

that the Commission determines to be appropriate."

The Commission preliminarily believes that such access by the OFR is appropriate in light of the OFR's regulatory mandate and legal responsibility and authority.[57] The OFR was established by Title I of the Dodd-Frank Act to support FSOC and FSOC's member agencies by identifying, monitoring and assessing potential threats to financial stability thorough the collection and analysis of financial data gathered from across the public and private sectors.[58] In connection with this statutory mandate to monitor and assess potential threats to financial stability, the OFR's access to security-based swap transaction data may be expected to help assist it in examining the manner in which derivatives exposures and counterparty risks flow through the financial system, and in otherwise assessing those risks. The Commission accordingly believes preliminarily that the OFR's access to security-based swap data held by repositories would appropriately fall within its regulatory mandate and legal responsibility and authority, and that the OFR should conditionally have access to the security-based swap data.[59]

As with the other entities that may access data pursuant to the data access provision, the OFR's ability to access such data would be subject to conditions related to confidentiality and indemnification.[60]

3. Future Commission Determination of Additional Entities

The proposal also would require that repositories provide data to any other person that the Commission determines to be appropriate. The Commission anticipates that entities that may seek such access would likely include foreign financial supervisors (including foreign futures authorities), foreign central banks and foreign ministries.[61] One or more self-regulatory organizations also potentially may seek such access. The proposal further would provide that the Commission will make such determinations through the issuance of Commission orders, and that such determinations may be conditional or unconditional.[62] A relevant authority would be able to request that the Commission make such a determination.

a. Determination Factors and Conditions

The Commission continues to expect that it would consider a variety of factors in connection with making such a determination, and that it may impose associated conditions in connection with the determination. The Commission expects to consider the factors discussed below, as well as any other factors the Commission determines to be relevant.[63]

In part, the Commission expects to consider whether there is an MOU or other arrangement[64] between the Commission and the relevant authority that is designed to protect the confidentiality of the security-based swap data provided to the authority.[65] The Commission also expects to consider whether information accessed by the applicable authority would be subject to robust confidentiality safeguards. The Commission believes that these factors are important given the proprietary and highly sensitive nature of the data maintained by the repository.[66]

In making a determination the Commission also may consider the relevant authority's interest in access to security-based swap data based on the relevant authority's regulatory mandate, or legal responsibility or authority. Limiting the amount of information accessed by an authority in this manner may help minimize the risk of unauthorized disclosure, misappropriation, or misuse of security-based swap data because each relevant authority will only have access to information within its regulatory mandate, or legal responsibility or authority.

---

[57] See proposed Exchange Act rule 13n–4(b)(9)(ix). We note that the CFTC has identified the OFR as being an "appropriate domestic regulator" that may access swap data from swap data repositories. *See* note 29, *supra*.

[58] *See* Dodd-Frank Act section 153(a) (identifying the purpose of the OFR as: (1) Collecting data on behalf of FSOC and providing such data to FSOC and its member agencies; (2) standardizing the types and formats of data reported and collected; (3) performing applied research and essential long-term research; (4) developing tools for risk measurement and monitoring; (5) performing other related services; (6) making the results of the activities of the Office available to financial regulatory agencies; and (7) assisting those member agencies in determining the types and formats of data authorized by the Dodd-Frank Act to be collected by the member agencies); Dodd-Frank Act section 154(c) (requiring that OFR's Research and Analysis Center, on behalf of FSOC, develop and maintain independent analytical capabilities and computing resources to: (A) Develop and maintain metrics and reporting systems for risks to U.S. financial stability; (B) monitor, investigate, and report on changes in systemwide risk levels and patterns to FSOC and Congress; (C) conduct, coordinate, and sponsor research to support and improve regulation of financial entities and markets; (D) evaluate and report on stress tests or other stability-related evaluations of financial entities overseen by FSOC member agencies; (E) maintain expertise in such areas as may be necessary to support specific requests for advice and assistance from financial regulators; (F) investigate disruptions and failures in the financial markets, report findings and make recommendations to FSOC based on those findings; (G) conduct studies and provide advice on the impact of policies related to systemic risk; and (H) promote best practices for financial risk management).

The OFR is also required to report annually to Congress its analysis of any threats to the financial stability of the United States. *See* Dodd-Frank Act section 154(d).

[59] As discussed below, the conditions to the proposed indemnification exemption would limit an entity's access to data by linking the scope of the exemption to information that related to persons or activities within an entity's regulatory mandate or legal responsibility or authority, as specified in an MOU between the Commission and the entity. *See* part III.C, *infra*.

[60] As U.S. government personnel, OFR personnel are subject to the same general confidentiality requirements that are addressed above in the context of the Board and the Federal Reserve Banks. *See* note 53, *supra*. In addition, the OFR is required to keep data collected and maintained by the OFR data center secure and protected against unauthorized disclosure. *See* Dodd-Frank Act section 154(b)(3); *see also* 12 CFR 1600.1 (ethical conduct standards applicable to OFR employees, including post-employment restrictions linked to access to confidential information); 31 CFR 0.206 (Treasury Department prohibition on employees disclosing official information without proper authority).

[61] *See* proposed Exchange Act rule 13n–4(b)(9)(x).

[62] *See id.* In those respects, the proposed rule would implement the corresponding statutory language, which provides the Commission with the authority to allow data access to "any other person that the Commission determines to be appropriate." *See* Exchange Act section 13(n)(5)(G)(v), 15 U.S.C. 78m(n)(5)(G)(v).

[63] The factors discussed below that may be expected to be relevant to a Commission's determination that a person is eligible to access security-based swap information pursuant the statutory data access provisions—including factors related to the presence of a confidentiality MOU and related to a person's regulatory mandate, or legal responsibility or authority—parallel certain of the conditions to the exemption from the indemnification requirement. *See* parts III.B, C, *infra*.

[64] The Cross-Border Proposing Release specifically referred to a "supervisory and enforcement MOU or other arrangement" in this context. *See* Cross-Border Proposing Release, 78 FR 31047. The Commission is revising its proposed guidance to refer to MOUs and other arrangements generally—rather than "supervisory and enforcement" MOUs and arrangements—to allow the parties more flexibility in arriving at such confidentiality arrangements.

[65] Such an MOU or other arrangement may also satisfy the statutory requirement that a security-based swap data repository obtain a confidentiality agreement from the authority. *See* part II.B.1, *infra* (proposed Exchange Act rule 13n–4(b)(10)(i) would permit an agreement between the Commission and a relevant authority to satisfy the statutory condition that the repository obtain a confidentiality agreement from the authority).

Moreover, this MOU or other arrangement further may satisfy the proposed indemnification exemption's condition that there be an arrangement between the Commission and an entity regarding the confidentiality of the information provided. *See* part III.C, *infra*. To the extent that a relevant authority's needs access to additional information, the relevant authority may request that the Commission consider revising its determination order, and MOU or other arrangement, as applicable.

[66] *See* Exchange Act section 13(n)(5)(H)(i).

Consistent with this factor, the Commission preliminarily expects that such determination orders typically would incorporate conditions that specify the scope of a relevant authority's access to data, and that limit this access in a manner that reflects the relevant authority's regulatory mandates or legal responsibility or authority.[67] Depending on the nature of the relevant authority's interest in the data, such conditions potentially could address factors such as the domicile of the counterparties to the security-based swap, and the domicile of the underlying reference entity.[68] Focusing access to data in this way should help address one commenter's concerns regarding "unfettered access" to such proprietary data.[69]

The Commission further anticipates taking into account any other factors that are appropriate to the determination, including whether such a determination would be in the public interest. This consideration likely would include whether the relevant authority agrees to provide the Commission and other U.S. authorities with reciprocal assistance in matters within their jurisdiction.

b. Additional Matters Related to the Determinations

The Commission contemplates taking various approaches in deciding whether to impose additional conditions in connection with its consideration of requests for determination orders. For example, the Commission may issue a determination order that is for a limited time. The Commission further may revoke a determination at any time. For example, the Commission may revoke a determination or request additional information from a relevant authority to support the continuation of the determination if for example a relevant authority fails to comply with the MOU, such as by failing to keep confidential security-based swap data provided to it by a repository. Even absent such a revocation, moreover, an authority's access to data pursuant to these provisions also would cease upon the termination of the MOU or other arrangement used to satisfy the confidentiality condition, or, as applicable, the indemnification exemption.[70]

The Commission preliminarily believes that the determination process described above represents a reasonable approach toward providing appropriate access to relevant authorities. Moreover, the Commission preliminarily believes that this process—particularly the link between access and the authority's interest in the information—appropriately builds upon existing voluntary frameworks, in accordance with one commenter's suggestion that the applicable framework incorporate other cooperative efforts with regard to access to information.[71]

The Commission expects that repositories will provide relevant authorities with access to security-based swap data in accordance with the determination orders, and the Commission generally does not expect to be involved in reviewing, signing-off on or otherwise approving relevant authorities' requests for security-based swap data from repositories that are made in accordance with a determination order. Moreover, the Commission continues preliminarily to believe that it is not necessary to prescribe by rule specific processes to govern a repository's treatment of requests for access.[72]

Finally, the Commission notes that it may elect to apply these determination factors and consider applying protections similar to those in the data access provisions of Exchange Act sections 13(n)(5)(G) and (H) when designating authorities to receive direct access under section 13(n)(5)(D). Section 13(n)(5)(D) states that a repository must provide direct electronic access to the Commission "or any designee of the Commission, including another registered entity." [73] In practice, the Commission expects that security-based swap data repositories may satisfy their obligation to make available data pursuant to sections 13(n)(5)(G) and (H) by providing electronic access to appropriate authorities. To the extent a repository were to satisfy those requirements by some method other than electronic access, however, the Commission separately may consider whether to also designate particular authorities as being eligible for electronic access to the repository pursuant to section 13(n)(5)(D). In making such assessments under section 13(n)(5)(D), the Commission preliminarily believes that it may consider factors similar to the above determination factors, including the presence of confidentiality safeguards, and the authority's interest in the information based on its regulatory mandate or legal responsibility or authority.

4. Notification Requirement

The proposal would implement the statutory notification requirement—which states that a repository must notify the Commission when an entity requests that the repository make

[67] To appropriately limit a relevant authority's access to only security-based swap data that is consistent with the MOU between the Commission and the relevant authority, a repository may, for example, need to customize permissioning parameters to reflect each relevant authority's electronic access to security-based swap data. *See generally* note 103, *infra* (discussing access criteria currently used by DTCC in connection with current voluntary disclosure practices).

[68] *See* note 105, *infra*, and accompanying text (discussing application of those factors in the context of the indemnification exemption).

[69] *See* note 14, *supra* (comment voicing concerns about "unfettered access" to security-based swap information by regulators, including foreign financial supervisors, foreign central banks and foreign ministries, beyond their regulatory authority and mandate).

As discussed below, moreover, the availability of the proposed indemnification exemption would similarly be conditioned to reflect the recipient's regulatory mandates or legal responsibility or authority. *See* part III.C, *infra*. Accordingly, based on the expectation that persons who seek access pursuant to these provisions would rely on the indemnification exemption, there would be comparable limitations to access applicable to persons directly identified by Exchange Act sections 15(n)(5)(i) through (iv) (the "prudential regulators," FSOC, CFTC and Department of Justice) or added by the proposed rules (the Federal Reserve Banks and the OFR).

[70] *See* parts II.B and III.B, C, *supra*.

[71] *See* DTCC comment (June 3, 2011) at 6–7 ("It is critical that the United States, the European Union and the other major global markets align their regulatory regimes to limit opportunities for market distorting arbitrage. The creation of a global credit default swap repository would not have occurred without the global regulatory cooperation achieved through the OTC Derivatives Regulators' Forum ('ODRF') and the OTC Derivatives Regulators Supervisors Group ('ODSG'). It is important that the global SDR framework incorporate their efforts, particularly the ODRF's guidelines on regulatory access to information stored in trade repositories for over-the-counter derivatives."); DTCC comment (Jan. 24, 2011) at 3 ("DTCC relies upon the direction provided by the OTC Derivatives Regulators' Forum ('ODRF'), whose membership includes the SEC and the Commodity Futures Trading Commission ('CFTC'). DTCC's Trade Information Warehouse (the 'Warehouse' or 'TIW') has followed the ODRF's guidance, recognizing that broad agreement among global regulators is difficult to achieve. DTCC is committed to complying with the policies adopted by the regulators and working with the Commission in this regard.").

In this regard, DTCC further has stated that it routinely provides U.S. regulators with credit default swap data related to overseas transactions entered into by non-U.S. persons on U.S. reference entities, and that it provides European regulators with data related to transactions in the U.S. by U.S. persons on European reference entities. *See* DTCC comment (Jan. 24, 2011) at 12; *see also* DTCC comment (June 3, 2011) at 7–8.

[72] *See* Cross-Border Proposing Release, 78 FR 31047–48. One commenter suggested that the Commission adopt an approach proposed by the CFTC, whereby a regulator requesting access to data first file a request for access and certify the statutory authority for the request and detail the basis for the request. *See* Managed Funds Association comment (Jan. 24, 2011) at 3–4. In contrast to that proposal, however, the final CFTC rules do not require relevant authorities to detail the basis for their requests, and do not require a swap data repository to provide access only if it is satisfied that the regulator is acting within the scope of its authority. *See* note 31, *supra*.

[73] 15 U.S.C. 78m(n)(5)(D).

available security-based swap data [74]—by requiring the repository to inform the Commission upon its receipt of the first request for data from a particular entity (which may include any request that the entity be provided ongoing online or electronic access to the data).[75] A repository must keep such notifications and any related requests confidential.[76]

The repository further would have to maintain records of all information related to the initial and all subsequent requests for data access requests from that entity, including records of all instances of online or electronic access, and records of all data provided in connection with such requests or access.[77] For these purposes, we believe that "all information related to" such requests would likely include, among other things: The identity of the requestor or person accessing the data; the date, time and substance of the request or access; and copies of all data reports or other aggregations of data provided in connection with the request or access.

In the Commission's preliminary view, the proposed notification requirement is designed to account for the way in which we believe entities are likely to access such data from repositories, by distinguishing steps that an entity takes to arrange access from subsequent electronic instructions and other means by which the recipient obtains data. By making relevant data available to the Commission in this manner, the proposed approach would place the Commission on notice that a recipient has the ability to access security-based swap data, and place the Commission in a position to examine such access as appropriate, while avoiding the inefficiencies that would accompany an approach whereby a repository must direct to the Commission information regarding each instance of access by each recipient. Moreover, the proposed approach would be consistent with the manner in which the Commission examines the records of regulated entities under the Commission's authority.

The Commission recognizes that one commenter opposed any requirement that the Commission receive notice of a recipient's initial request, on the grounds that such notice may cause other authorities to hesitate to make such requests.[78] While the Commission appreciates the commenter's concerns, the Commission preliminarily believes that it is necessary for the Commission to be informed of the initial request from a particular entity so that the Commission may assess whether the initial conditions to data access (*i.e.*, MOUs or other arrangements as needed to satisfy the confidentiality condition and the indemnification exemption) [79] have been met at the time the repository first is requested to provide the entity with information pursuant to the data access provisions, and, more generally, to facilitate the Commission's ongoing assessment of the repository's compliance with the data access provisions. The Commission also believes that commenter concerns that other regulators may be reluctant to place the Commission on notice of such initial requests are mitigated by the Commission's long history of cooperation with other authorities in supervisory and enforcement matters.[80]

5. Limitation to "Security-Based Swap Data"

Repositories that obtain security-based swap data may also obtain data regarding other types of financial instruments, such as swaps under the CFTC's jurisdiction. We do not read the data access provisions of Exchange Act sections 13(n)(5)(G) and (H)—which were added by Subtitle B of Title VII (which focused on the regulatory treatment of security-based swaps) [81] to the Exchange Act (which generally addresses the regulation of securities such as security-based swaps)—to require a repository to make available data that does not involve security-based swaps. The statutory confidentiality condition to the data access requirement further suggests that the data access provisions are intended to apply only to security-based swap data.[82] Accordingly, the proposed rules specifically address access to "security-based swap data" obtained by a security-based swap data repository.[83]

B. Confidentiality Condition

The Exchange Act provides that, prior to providing data, a repository "shall receive a written agreement from each entity stating that the entity shall abide by the confidentiality requirements described in section 24 relating to the information on security-based swap transactions that is provided." [84]

[74] *See* Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G). As discussed below, *see* part IV, *infra*, the notification requirement does not apply to circumstances in which disclosures are made outside of the requirements of Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G), particularly when a dually regulated data repository makes disclosure pursuant to foreign law, or when the Commission provides security-based swap data to an entity.

[75] *See* proposed Exchange Act rule 13n–4(e). The rule does not require the repository to proactively inform the Commission of subsequent requests.

[76] Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G), and proposed rule 13n–4(b)(9) both require that a repository must make data available "on a confidential basis." Failure by a repository to treat such notifications and requests as confidential could have adverse effects on the underlying basis for the requests. If, for example, a regulatory use of the data is improperly disclosed, such disclosure could signal a pending investigation or enforcement action, which could have detrimental effects.

[77] *See* proposed Exchange Act rule 13n–4(e).

We note that Exchange Act rule 13n–7(b)(1) requires security-based swap data repositories to maintain copies of "all documents and policies and procedures required by the Act and the rules and regulations thereunder, correspondence, memoranda, papers, books, notices, accounts and other such records as shall be made or received by it in the course of its business as such." *See also* SDR Adopting Release, 80 FR 14501 ("This rule includes all electronic documents and correspondence, such as data dictionaries, emails and instant messages, which should be furnished in their original electronic format."). Proposed Exchange Act rule 13n–4(e) identifies specific types of records that must be maintained in the specific context of access request to repositories.

[78] *See* DTCC comment (Aug. 13, 2013) ("DTCC discourages the Commission from requiring a notification requirement upon initial request as suggested by the Cross-Border Proposal. Authorities will likely be hesitant to make such request to an SDR if it triggers a notice to another authority, particularly if such request is pursuant to an investigation. DTCC proposes that the Commission consider notification to be deemed satisfied if the request is made by an entity to the SDR pursuant to an established information sharing arrangement[.]").

[79] *See* parts II.B and III.B, *infra*.

[80] The Commission also recognizes that the same commenter stated that "regulators want direct electronic access to data in SDRs where that data is needed to fulfill regulatory responsibilities" rather than access "by request, with notice to another regulatory authority." *See* DTCC comment (Jan. 24, 2011) at 11–12. Data repositories in fact can provide direct electronic access to relevant authorities under the proposed interpretation. The proposed requirement that the repository inform the Commission when the relevant authority first requests access to security-based swap data maintained by the repository, and to retain records of subsequent access, is designed to facilitate such direct access.

[81] *See* Dodd-Frank Act section 763(i) (addressing "public reporting and repositories for security-based swaps," including the addition of section 13(n), 15 U.S.C. 78m(n), to the Exchange Act to address security-based swap data repositories); *see generally* Subtitle B to Title VII of the Dodd-Frank Act, section 761 *et seq.* (addressing "Regulation of Security-Based Swap Markets").

[82] In particular, the confidentiality condition to the data access provisions specifically requires that the recipient entity abide by confidentiality requirements for "the information on security-based swap transactions that is provided," suggesting that the Exchange Act data access provisions are intended solely to address security-based swap data. *See* Exchange Act section 13(n)(5)(H)(i), 15 U.S.C. 78m(n)(5)(H)(i).

Moreover, this approach is consistent with the CFTC's comparable rules, which apply only to swap data. *See* 17 CFR 49.17(d) and 49.18 (discussing regulators' access to swap data under the CEA).

[83] *See* proposed Exchange Act rule 13n–4(b)(9).

[84] *See* Exchange Act section 13(n)(5)(H)(i), 15 U.S.C. 78m(n)(5)(H)(i).

Exchange Act section 24, 15 U.S.C. 78x, generally addresses disclosures of information by the Commission and its personnel. In relevant part it provides that the Commission may, "in its discretion and upon a showing that such

Continued

The proposed rule implementing this condition would require that, before a repository provides information pursuant to the data access provisions, "there shall be in effect an arrangement between the Commission and the entity (in the form of a memorandum of understanding or otherwise) to address the confidentiality of the security-based swap information made available to the entity." [85] The proposed rule further would provide that this arrangement would be deemed to satisfy the statutory requirement that the repository receive a written confidentiality agreement from the entity.[86]

This proposed approach to implementing the confidentiality condition, in other words, would use an arrangement between the Commission and a regulator or other recipient entity to satisfy the statutory confidentiality condition. The approach would not necessitate the use of confidentiality agreements entered into by repositories.[87]

In the Commission's preliminary view, this approach reflects an appropriate way to satisfy the interests associated with the confidentiality condition, while facilitating the statutory data access provision's goal of promoting the flow of information to authorities. The approach further would build upon the Commission's experience in negotiating MOUs with other regulators in connection with enforcement and supervision, particularly the Commission's experience in connection with the development of provisions related to maintaining the confidentiality of information.

As a result, the approach would potentially obviate the need for each individual repository to negotiate and enter into dozens of confidentiality agreements. By building upon the Commission's experience and expertise in this area, moreover, the Commission expects that this approach also would help avoid the possibility of uneven and potentially inconsistent application of confidentiality protections across data repositories and recipient entities.

In proposing this approach, the Commission also is mindful that the statutory provision specifically references the "confidentiality requirements described in section 24" of the Exchange Act. In the Commission's preliminary view this statutory language articulates a standard which requires that there be adequate confidentiality assurances. Thus, the Commission preliminarily believes that the proposed provision, under which the Commission would negotiate and enter into agreements providing such confidentiality assurances, appropriately implements the statutory reference to section 24.

C. Request for Comment

The Commission requests comment regarding all aspects of these proposed rules regarding access to security-based swap data from repositories. Among other things, commenters particularly are invited to address the proposal that the confidentiality agreement requirement would be satisfied by an MOU or other agreement between the Commission and another entity. Commenters also are invited to address: The proposed limitation of the data access requirement to security-based swap data; the proposed provisions related to access by prudential regulators, the Federal Reserve Banks and the OFR; the criteria that the Commission should consider in evaluating whether to determine to permit additional entities to access data from repositories; whether the orders that make such determinations generally should encompass conditions that limit a relevant authority's access to information to reflect its regulatory mandate or legal responsibility or authority; whether the Commission should prescribe specific processes to govern requests for such access; and whether the Commission should prescribe a process to govern a repository's treatment of requests for access.

In addition, commenters are invited to address the proposed rules implementing the notification requirement, including the proposed provisions regarding the maintenance of information related to data requests. In this regard, is there an alternative to requiring repositories to maintain copies of all data they provide in connection with the data access provisions that would still permit the Commission to assess the repository's ongoing compliance with those provisions? For example, are alternative approaches available such that the Commission should not require repositories to maintain actual copies of all reports or other aggregations of data provided pursuant to the data access provisions, such as if the repository instead implements policies and procedures sufficient to demonstrate a process for creating records that reflect the data provided, and the repository produces promptly copies of such records upon request by a representative of the Commission? [88] Would such an alternative approach reduce the burdens on repositories while still permitting the Commission to assess ongoing compliance?

Commenters further are invited to address whether the Commission should determine that other domestic authorities, such as one or more self-regulatory organizations, should be eligible to access security-based swap data pursuant to these provisions. If so, should the access of such self-regulatory organizations be limited in any particular respects?

information is needed," provide all records and other information "to such persons, both domestic and foreign, as the Commission by rule deems appropriate if the person receiving such records or information provides such assurances of confidentiality as the Commission deems appropriate." *See* Exchange Act section 24(c), 15 U.S.C. 78x(c); *see also* Exchange Act rule 24c–1(b) (providing that the Commission may, upon "such assurances of confidentiality as the Commission deems appropriate," provide non-public information to persons such as domestic and foreign governments or their political subdivisions, authorities, agencies or instrumentalities, self-regulatory organizations and foreign financial authorities).

[85] *See* proposed Exchange Act rule13n-4(b)(10).

[86] *See* Exchange Act section 13(n)(5)(H)(1). As discussed below, *see* part IV, *infra*, the confidentiality condition does not apply to circumstances in which disclosures are made outside of the requirements of Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G), particularly when a dually regulated data repository makes disclosure pursuant to foreign law, or when the Commission provides security-based swap data to an entity.

[87] In this regard, the Commission notes that the statute does not require that the security-based swap data repository "agree" with the entity, "enter into" an agreement, or otherwise be a party to the confidentiality agreement. The statute merely states that the repository "receive" such an agreement. *See* Exchange Act section 13(n)(5)(H)(i), 15 U.S.C. 78m(n)(5)(H)(i). Accordingly, we believe that, at a minimum, the statutory language is ambiguous as to whether the data repository must itself be a party to the confidentiality agreement. In light of this ambiguity, we have preliminarily determined to read the statute to permit the Commission to enter into confidentiality agreements with the entity, with the repository receiving the benefits of the agreement. Accordingly, the Commission believes that it is appropriate to view a security-based swap data repository as having received a confidentiality agreement when the entity enters into a confidentiality agreement with the Commission and that agreement runs to the benefit of the repository.

[88] For example, in adopting Exchange Act rule 17a–4(b)(13) to provide that broker-dealers must preserve certain written policies and procedures in connection with creditworthiness assessments, the Commission stated that although the rule does not require that a broker-dealer maintain a record of each such creditworthiness determination, a broker-dealer would need to be able to support each such determination, and that the broker-dealer may do so by either maintaining documentation of those determinations or by being in a position to "replicate the original credit risk determination using the same process, information, and inputs employed to make the original determination." *See* Exchange Act Release No. 71194 (Dec. 27, 2013), 79 FR 1522, 1528–29, 1550 (Jan. 8, 2014).

III. Proposed Exemption From the Indemnification Requirement

A. Proposed Exemption

The Exchange Act also conditions the data access requirement on each recipient entity agreeing "to indemnify the security-based swap data repository and the Commission for any expenses arising from litigation relating to information provided under section 24." [89]

Pursuant to the Commission's authority under Exchange Act section 36,[90] the Commission is proposing a conditional exemption from that statutory indemnification requirement. This proposed exemption would be effective whenever the applicable conditions are met, in contrast with the earlier proposal, which would have conditionally exempted regulators and other authorities from the indemnification requirement only at the election of the data repository.[91]

This proposed exemption reflects the Commission's preliminary concern that requiring authorities to agree to provide indemnification could lead to negative consequences in practice. The Commission continues to understand that certain authorities may be legally prohibited or otherwise limited from agreeing to indemnify data repositories or the Commission for expenses arising in connection with the information received from a repository.[92]

As a result, application of the indemnification requirement may chill some requests by regulators or other authorities for access to security-based swap data, which would hinder those authorities' ability to address their own regulatory mandate or legal responsibility or authority.[93] The resulting lack of access also may impair coordination among regulators with regard to the oversight of market participants that engage in security-based swap transactions across national boundaries. For example, European Union ("EU") law provides that the ability of certain non-EU regulators to access data from EU repositories is conditioned on there being an international agreement that ensures that EU authorities have "immediate and continuous access to all of the information needed for the exercise of their duties." [94] As a result, application of the indemnification requirement without an exemption being available potentially could preclude EU authorities from accessing data from U.S. security-based swap data repositories. Under such circumstances, it is possible that EU authorities may be unwilling to permit the Commission and other U.S. regulators to access security-based swap data from EU repositories. The resulting concerns associated with a lack of regulatory access to security-based swap data are particularly significant given that data access allows relevant authorities to be in a better position to, among other things, monitor risk exposures of individual counterparties to swap and security-based swap transactions, monitor concentrations of risk exposures and evaluate risks to financial stability.[95]

Such a result associated with application of the indemnification requirement further may make substituted compliance unavailable in connection with security-based swap data reporting requirements, given that under rules adopted by the Commission the availability of substituted compliance for those requirements is predicated in part on the Commission's ability to directly access data in foreign repositories.[96]

The Commission recognizes that indemnification may help support confidentiality safeguards by making a recipient liable for expenses that a repository or the Commission incurs in connection with breaches of confidentiality. Nonetheless, the

---

[89] Exchange Act section 13(n)(5)(H)(ii), 15 U.S.C. 78m(n)(5)(H)(ii). As discussed below, *see* part IV, *infra*, the statutory indemnification requirement would not always be triggered by the disclosure of security-based swap information.

In the event that the proposed exemption is unavailable, the Commission agrees with one commenter's view that "any indemnity should be limited in scope to minimize the potential reduction in value of registered SDRs to the regulatory community." *See* DTCC comment (Jan. 24, 2011) at 12. Consistent with that view, as stated in the Cross-Border Proposing Release, the Commission would not expect that an indemnification agreement would include a provision requiring a relevant authority to indemnify the repository from the repository's own wrongful or negligent acts. *See* Cross-Border Proposing Release, 78 FR 31051 n.829.

[90] 15 U.S.C. 78mm (providing the Commission with general exemptive authority . . . "to the extent that such exemption is necessary or appropriate in the public interest, and is consistent with the protection of investors").

[91] To implement this approach, the Commission proposes in relevant part that the indemnification requirement conditionally "shall not be applicable" with regard to the repository's disclosure of security-based swap information. *See* proposed Exchange Act rule 13n–4(d)(1). The earlier proposal would have conditionally provided that a registered security-based swap data repository "is not required to comply" with the indemnification requirement. *See* Cross-Border Proposing Release, 78 FR 31209 (paragraph (d) of proposed rule 13n–4).

[92] As stated in the Cross-Border Proposing Release, the Commission recognizes that certain domestic authorities, including some of those expressly identified in Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G), as a matter of law cannot provide an open-ended indemnification agreement. *See* Cross-Border Proposing Release, 78 FR 31048–49 (particularly noting that the Antideficiency Act prohibits certain U.S. federal agencies from obligating or expending federal funds in advance or in excess of an appropriation, apportionment, or certain administrative subdivisions of those funds, *e.g.*, through an unlimited or unfunded indemnification).

[93] *See* DTCC cross-border comment (Aug. 21, 2013) at 6 ("The continued presence of the Indemnification Provision (even as modified by the exemption in the Cross-Border Proposal) may pose problems for Commission-regulated, U.S.-based SDRs and their ability to share information with third-party regulatory authorities. As a result, foreign regulators may seek to establish their own 'national' repositories to ensure access to the information they need, fragmenting the data among jurisdictions. Similarly, non-U.S. trade repositories may find themselves subject to similar reciprocal impediments to sharing information with the Commission or other U.S. regulatory agencies absent a confidentiality and indemnification agreement."); *see also* DTCC comment (Nov. 15, 2010) at 3 ("DTCC remains concerned that regulators are not likely to grant SDRs indemnification in exchange for access to the information and, accordingly, regulators may actually receive less aggregated market data. Such an outcome would result in a reduction of information accessible to regulators on a timely basis both domestically and internationally, which contravenes the purpose of SDRs and jeopardizes market stability."); Cleary Gottlieb comment (Sept. 20, 2011) at 31 ("[T]he indemnification requirement could be a significant impediment to effective regulatory coordination, since non-US regulators may establish parallel requirements for U.S. regulators to access swap data reported in their jurisdictions."); ESMA comment (Jan. 17, 2011) at 2 ("We believe that ensuring confidentiality is essential for exchanging information among regulators and such indemnification agreement undermines the key principle of trust according to which exchange of information should occur.").

[94] *See* EU regulation 648/2012 ("EMIR"), art. 75(2).

[95] *See* Darrell Duffie, Ada Li, and Theo Lubke, Policy Perspectives of OTC Derivatives Market Infrastructure, Federal Reserve Bank of New York Staff Report No. 424, dated January 2010, as revised March 2010 (with data from repositories regulators can "explore the sizes and depths of the markets, as well as the nature of the products being traded. With this information, regulators are better able to identify and control risky market practices, and are better positioned to anticipate large market movements."); *see also* DTCC comment (June 3, 2011) at 5 (noting that a data repositories should be able to provide: (i) Enforcement authorities with necessary trading information; (ii) regulatory agencies with counterparty-specific information about systemic risk based on trading activity; (iii) aggregate trade information on market-wide activity and aggregate gross and net open interest for publication; and (iv) real-time reporting from [security-based swap execution facilities] and bilateral counterparties and related dissemination).

[96] *See* Regulation SBSR, rule 908(c)(2)(iii)(C), 17 CFR 242.908(c)(2)(iii)(C) (conditioning the availability of substituted compliance in part on the Commission having "direct electronic access to the security-based swap data held by a trade repository or foreign regulatory authority to which security-based swaps are reported pursuant to the rules of that foreign jurisdiction"); *see also* Exchange Act Release No. 74244 (Feb. 11, 2015), 80 FR 14564, 14661 (Mar.19, 2015) ("Regulation SBSR Adopting Release") ("granting substituted compliance without direct electronic access would not be consistent with the underlying premise of substituted compliance: That a comparable regulatory result is reached through compliance with foreign rules rather than with the corresponding U.S. rules.").

countervailing considerations noted above indicate that indemnification—of either the repository or the Commission—should not be required so long as appropriate confidentiality protections are provided in other ways.

For these reasons the Commission preliminarily believes that it is necessary and appropriate in the public interest, and consistent with the protection of investors, that the indemnification requirement be subject to an exemption that applies whenever the applicable conditions are satisfied.[97]

B. Confidentiality Arrangement Condition

The proposal in part would condition the indemnification exemption upon there being in effect one or more arrangements (in the form of an MOU or otherwise) between the Commission and the entity that addresses the confidentiality of the security-based swap information provided and other matters as determined by the Commission.[98] The Commission preliminarily believes that such an MOU or other arrangement would address similar confidentiality interests that appear to be reflected by the statutory indemnification requirement, particularly given that the disclosure of confidential information inconsistent with such arrangements can lead to the termination of the arrangement and the loss of data access. Just as an indemnification agreement may be expected to incentivize the confidential treatment of information, such a confidentiality arrangement would help strengthen the authority's incentive to maintain the confidentiality of information.

The Commission anticipates that in determining whether to enter into such an MOU or other arrangement, it would consider, among other things, whether: (a) Security-based swap information from a repository would help fulfill the relevant authority's regulatory mandate, or legal responsibility or authority; (b) the relevant authority provides such assurances of confidentiality as the Commission deems appropriate with respect to the security-based swap information provided to the authority; (c) the relevant authority is subject to statutory and/or regulatory confidentiality safeguards; (d) the relevant authority agrees to provide the Commission with reciprocal assistance in matters within the Commission's jurisdiction; and (e) an MOU or other arrangement would be in the public interest. These considerations are comparable to the criteria that the Commission anticipates considering as it determines whether an entity is eligible to access information pursuant to the data access provisions.[99] Accordingly, for regulators or other authorities whose access is subject to a determination order, the same confidentiality MOUs or other agreements that are needed to satisfy the indemnification exemption may also serve to satisfy those prerequisites to the determinations.[100]

C. Condition Regarding Regulatory Mandate or Legal Responsibility or Authority

The proposal further would condition the indemnification exemption on the requirement that the information relate to persons or activities within the recipient entity's regulatory mandate, or legal responsibility or authority.[101] This proposed condition should reduce the potential for disclosure of confidential information by limiting the quantity of information each recipient may access. This limitation on access also should help address commenter concerns regarding "unfettered access" to security-based swap data.[102] This approach of limiting the availability of data to reflect such considerations also has parallels to the approach that one commenter indicated that it follows on a voluntary basis for providing relevant authorities with access to certain credit default swap information.[103]

The proposal would implement this requirement by further conditioning the indemnification exemption by requiring that the MOU or other arrangement between the Commission and the entity accessing the data would specify the types of security-based swap information that would relate to the recipient entity's regulatory mandate, or legal responsibility or authority.[104] While the relevant factors for specifying which information is within an entity's regulatory mandate, or legal responsibility or authority for these purposes may vary depending on the relevant facts and circumstances, such factors potentially would include the location of a counterparty to the transaction and the location of the reference entity.[105] In this way, the MOU or other arrangement would help reduce uncertainty regarding how the associated condition to the indemnification exemption may apply

[97] The Commission is not incorporating a commenter's suggestion that there be "a safe harbor provision from liability for information shared pursuant to global information sharing agreements into the Indemnification Exemption for SDRs operating pursuant to information sharing arrangements, as defined in the Indemnification Exemption, or comparable to those published by the OTC Derivatives Regulators Forum ("ODRF") or CPSS–IOSCO." *See* DTCC cross-border comment (Aug. 21, 2013) at 7; *see also* DTCC comment (Jan. 24, 2011) at 3 (urging the Commission to aim for regulatory comity as reflected in ODRF and CPSS–IOSCO standards); DTCC comment (June 3, 2011) at 6–7 (urging that the global framework incorporate efforts of the ODRF and the OTC Derivatives Regulators Supervisors Group).

To the extent that the commenter suggests that there be a safe harbor from the indemnification requirement, the Commission preliminarily believes that this proposed exemption, which is more narrowly tailored than the commenter's suggestion, would sufficiently address a repository's need for certainty. The Commission further notes that a repository's statutory duty to maintain the privacy of the information received is separate and distinct from its statutorily mandated duty to provide security-based swap data to relevant authorities when specific conditions are satisfied, and that the privacy of security-based swap data provided to relevant authorities was addressed by Congress through the confidentiality agreement requirement in Exchange Act section 13(n)(5)(H), 15 U.S.C. 78m(n)(5)(H).

[98] *See* proposed Exchange Act rule 13n–4(d)(2)(ii).

[99] *See* notes 64 through 69, *supra*, and accompanying text.

[100] Those entities that are expressly identified in the statute or the implementing rules (and thus are not subject to the determination process) also would need to enter into a separate MOU or other agreement to satisfy the confidentiality agreement condition.

[101] *See* proposed Exchange Act rule 13n–4(d)(1).

[102] *See* note 14, *supra*.

[103] *See* note 71, *supra* (DTCC statement that it routinely provides U.S. regulators with data related to overseas credit default swap transactions entered into by non-U.S. persons on U.S. reference entities, and that it provides European regulators with data related to credit default swap transactions in the U.S. by U.S. persons on European reference entities).

[104] *See* proposed Exchange Act rule 13n–4(d)(2)(ii).

[105] As an example, in the event of a request for access by a foreign authority that is responsible for security-based swap market surveillance and enforcement—and subject to negotiation of such an MOU or other arrangement between the Commission and that authority—criteria indicative of data regarding a transaction being within the authority's regulatory mandate or legal responsibility or authority may include: (i) One or more of the counterparties to the transaction being domiciled or having a principal place of business in the foreign jurisdiction (including branches of entities that are domiciled or that have a principal place of business in that jurisdiction); (ii) one or more of the counterparties being a subsidiary of a person domiciled or having a principal place of business in the foreign jurisdiction; (iii) one or more of the counterparties being a fund or other collective investment vehicle with an adviser that is domiciled or that have a principal place of business in the foreign jurisdiction; (iv) one or more of the counterparties being registered with the authority as a dealer or in some other capacity; or (v) the reference entity for the security-based swap being domiciled or having a principal place of business in the foreign jurisdiction.

As another example, in the case of a foreign authority that is responsible for prudential regulation, criteria indicative of data regarding a transaction being within the entity's regulatory mandate or legal responsibility or authority may include one or more of the counterparties to the transaction being part of a consolidated organization that is supervised by the prudential authority, including all affiliates within that consolidated organization.

to particular types of information requests, and would provide direction to repositories regarding which disclosures would be covered by the indemnification exemption.[106]

D. Request for Comment

The Commission requests comment on all aspects of the proposed exemption to the statutory indemnification requirement. Commenters particularly are invited to address whether the exemption's proposed scope would adequately address the concerns associated with implementing the indemnification requirement. Among other things, commenters are invited to address whether alternative approaches or other considerations more effectively reflect the access and confidentiality interests associated with the Dodd-Frank Act? Also, should additional conditions be incorporated into the exemption?

Commenters further are invited to address whether the proposal appropriately would make use of an MOU or other arrangement to provide sufficient guidance to a repository regarding an entity's regulatory mandate, or legal responsibility or authority in connection with a request for security-based swap data. In this respect, would the proposed approach provide a repository with an adequate degree of guidance regarding which disclosures of information may or may not be subject to protection? Are there particular criteria that would be useful for incorporating into the MOU or other arrangement to help delimit which information would fall within an entity's regulatory mandate, or legal responsibility or authority?

IV. Applicability of Exchange Act Data Access and Indemnification Provisions

The Exchange Act provisions addressed above—sections 13(n)(5)(G) and (H) [107]—establish one means by which certain regulators and other authorities may access security-based swap data from repositories. It is important to recognize, however, that those provisions do not exclusively govern the means by which such regulators or other authorities might access security-based swap data.

In particular, in the circumstances discussed below, regulators and other authorities in certain circumstances may access security-based swap data via authority that is independent of the above provisions. In those circumstances, the Commission preliminarily believes that the conditions associated with those data access provisions—particularly the provisions regarding indemnification, notification and confidentiality agreements—should not govern access arising from such independent authority.

A. Data Access Authorized by Foreign Law

The Commission continues to believe preliminarily, as discussed in the Cross-Border Proposing Release, that "the Indemnification Requirement does not apply when an SDR is registered with the Commission and is also registered or licensed with a foreign authority and that authority is obtaining security-based swap information directly from the SDR pursuant to that foreign authority's regulatory regime." [108] In those circumstances, the dually registered data repository would be subject to a data access obligation that is independent of the Exchange Act data access obligation, and the notification, confidentiality and indemnification conditions to the Exchange Act data access provision would not apply.

B. Receipt of Information Directly From the Commission

The Exchange Act also provides that relevant authorities may obtain security-based swap data from the Commission, rather than directly from data repositories.[109]

First, Exchange Act section 21(a)(2) [110] states that, upon request of a foreign securities authority, the Commission may provide assistance in connection with an investigation the foreign securities authority is conducting to determine whether any person has violated, is violating or is about to violate any laws or rules relating to securities matters that the requesting authority administers or enforces.[111] That section further provides that, as part of this assistance, the Commission in its discretion may conduct an investigation to collect information and evidence pertinent to the foreign securities authority's request for assistance.[112]

In addition, the Commission may share "nonpublic information in its possession" with, among others, any "federal, state, local, or foreign government, or any political subdivision, authority, agency or instrumentality of such government . . . [or] a foreign financial regulatory authority." [113] This authority is subject to the recipient providing "such assurances of confidentiality as the Commission deems appropriate." [114]

In the Commission's view, and consistent with Commission practice for many years, these sections provide the Commission with separate, additional authority to assist domestic and foreign authorities in certain circumstances, such as, for example, by providing security-based swap data directly to the authority. At those times, the authority would receive information not from the data repository, but instead from the Commission.

C. Request for Comment

The Commission requests comment on these preliminary interpretations regarding the scope of the data access requirement and conditions set forth in Exchange Act sections 13(n)(5)(G) and (H).

V. Paperwork Reduction Act

Certain provisions of the proposed rules contain "collection of information" requirements within the meaning of the Paperwork Reduction Act of 1995 ("PRA").[115] The SEC has submitted them to the Office of Management and Budget ("OMB") for review in accordance with 44 U.S.C. 3507 and 5 CFR 1320.11. The title of the new collection of information is "Security-Based Swap Data Repository Data Access Requirements." An agency may not conduct or sponsor, and a

[106] The Commission anticipates that data repositories would be able to rely on the guidance provided by such arrangements when assessing whether particular information would be subject to the indemnification exemption, thus permitting an authority to access that information without an indemnification agreement.

[107] 15 U.S.C. 78m(n)(5)(G) and (H).

[108] *See* Cross-Border Proposing Release, 78 FR 31049 n.807.

[109] *See* Cross-Border Proposing Release, 78 FR 31045.

[110] 15 U.S.C. 78u(a)(2).

[111] Exchange Act section 3(a)(50), 15 U.S.C. 78c(a)(50), broadly defines "foreign securities authority" to include "any foreign government, or any governmental body or regulatory organization empowered by a foreign government to administer or enforce its laws as they relate to securities matters."

[112] Exchange Act section 21(a)(2), 15 U.S.C. 78u(a)(2), also states that the Commission may provide such assistance without regard to whether the facts stated in the request also would constitute a violation of U.S. law.

That section further states that when the Commission decides whether to provide such assistance to a foreign securities authority, the Commission shall consider whether the requesting authority has agreed to provide reciprocal assistance in securities matters to the United States, and whether compliance with the request would prejudice the public interest of the United States.

[113] *See* Exchange Act rule 24c–1(c) (implementing Exchange Act section 24(c), 15 U.S.C. 78x(c), which states that the Commission may, "in its discretion and upon a showing that such information is needed," provide records and other information "to such persons, both domestic and foreign, as the Commission by rule deems appropriate," subject to assurances of confidentiality).

[114] *See id.*

[115] 44 U.S.C. 3501 *et seq.*

person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. OMB has not yet assigned a control number to the new collection of information.

A. Summary of Collection of Information

The proposal would require security-based swap data repositories to make security-based swap data available to other parties, including certain government bodies. This data access obligation would be conditioned on confidentiality and indemnification requirements, and the indemnification requirement itself would be subject to a conditional exemption. The proposal further would require such repositories to create and maintain information regarding such data access.

B. Proposed Use of Information

The data access requirement and associated conditions would provide the regulators and other authorities that receive the relevant security-based swap data with tools to assist with the oversight of the security-based swap market and of dealers and other participants in the market, and to assist with the monitoring of risks associated with that market.

C. Respondents

The data access requirement will apply to every person required to be registered with the Commission as a security-based swap data repository—that is every U.S. person performing the functions of a security-based swap data repository, and to every non-U.S. person performing the functions of a security-based swap data repository within the United States absent an exemption.[116] Commission staff is aware of seven persons that have, to date, filed applications for registration with the CFTC as swap data repositories, three of which have withdrawn their applications and four of which are provisionally registered with the CFTC. It is reasonable to estimate that a similar number of persons provisionally registered with the CFTC may seek to register with the Commission as security-based swap data repositories. Therefore, the Commission estimates, for PRA purposes, that ten persons might register with the Commission as security-based swap data repositories.[117]

The conditions to data access under these proposed rules further will affect all persons that may seek access to security-based swap data pursuant to these provisions. As discussed below, these may include up to 30 domestic entities.

D. Total Annual Reporting and Recordkeeping Burden

1. Data Access Generally

The data access provisions may implicate various types of PRA burdens and costs: (i) Burdens and costs that regulators and other authorities incur in connection with negotiating MOUs or other arrangements with the Commission in connection with the data access provisions; (ii) burdens and costs that certain authorities that have not been determined by statute or Commission rule may incur in connection with requesting that the Commission grant them access to repository data;[118] (iii) burdens and costs associated with information technology systems that repositories develop in connection with providing data to regulators and other authorities; and (iv) burdens and costs associated with the requirement that repositories notify the Commission of requests for access to security-based swap data, including associated recordkeeping requirements.

a. MOUs

As discussed above, entities that access security-based swap data pursuant to these data access provisions would be required to enter into MOUs or other arrangements with the Commission to address the confidentiality condition and the indemnification exemption. In some cases, those entities also would enter into MOUs or other arrangements in connection with the Commission's determination of the entity as authorized to access such data (to the extent that the entity's access is already determined by statute or by the proposed rules). For purposes of the PRA requirements, the Commission estimates that up to 30 domestic entities potentially might enter into such MOUs or other arrangements, reflecting the nine entities specifically identified by statute or the proposed rules, and up to 21 additional domestic governmental entities or self-regulatory organizations that may seek access to such data. Based on the Commission's experience in negotiating similar MOUs that address regulatory cooperation, including confidentiality issues associated with regulatory cooperation, the Commission preliminarily believes that each regulator on average would expend 500 hours in negotiating such MOUs.[119]

b. Requests for Access

Separately, certain entities that are not identified by statute and/or the proposed rules may request that the Commission determine that they may access such security-based swap data. For those entities, in light of the relevant information that the Commission preliminarily would consider in connection with such determinations (apart from the MOU issues addressed above)—including information regarding how the entity would be expected to use the information, information regarding the entity's regulatory mandate or legal responsibility or authority, and information regarding reciprocal access—the Commission preliminarily estimates that each such entity would expend 40 hours in connection with such request. As noted above, the Commission estimates that 21 domestic entities not encompassed in the proposed rule may seek access to the data. Accordingly, to the extent that 21 domestic entities were to request access (apart from the nine entities identified by statute or the proposed rule), the Commission estimates a total burden of 840 hours for these entities to prepare and submit requests for access.

c. Systems Costs

The Commission previously addressed the PRA costs associated with the Exchange Act's data access

[116] As discussed above, *see* note 13, *supra*, the Commission has determined that a non-U.S. person that performs the functions of a security-based swap data repository within the United States is required to register with the Commission absent an exemption. The Commission also has adopted Exchange Act rule 13n–12 to provide an exemption from data repository requirements for certain non-U.S. persons.

[117] The Commission used the same estimate when adopting final rules to implement statutory provisions related to the registration process, duties and core principles applicable to security-based swap data repositories. *See* SDR Adopting Release, 80 FR 14521.

[118] These include MOUs and other arrangements in connection with: The determination of additional entities that may access security-based swap data (*see* part II.A.3, *supra*), the confidentiality condition (*see* part II.B.1, *supra*) and the indemnification exemption (*see* parts III.B.2, 3, *supra*).

[119] It may be expected that the initial MOU or other arrangement that is entered into between the Commission and another regulator may take up to 1,000 hours for that regulator to negotiate. In practice, however, subsequent MOUs and other arrangements involving other recipient entities would be expected to require significantly less time on average, by making use of using the prior MOUs as a basis for negotiation. Based on these principles, the Commission preliminarily estimates that the average amount of time that domestic and foreign recipients of data would incur in connection with negotiating these arrangements would be 500 hours.

To the extent that each of those 30 domestic entities were to seek to access data pursuant to these provisions, and each of the applicable MOUs or other arrangements were to take 500 hours on average, the total burden would amount to 15,000 hours.

requirement in 2010, when the Commission initially proposed rules to implement those data access requirements in conjunction with other rules to implement the duties applicable to security-based swap data repositories. At that time, based on discussions with market participants, the Commission estimated that a series of proposed rules to implement duties applicable to security-based swap data repositories—including the proposed data access rules as well as other rules regarding repository duties (*e.g.*, proposed rules requiring repositories to accept and maintain data received from third parties, to calculate and maintain position information, and to provide direct electronic access to the Commission and its designees)—together would result in an average one-time start-up burden per repository of 42,000 hours and $10 million in information technology costs for establishing systems compliant with all of those requirements. The Commission further estimated the average per-repository ongoing annual costs of such systems to be 25,200 hours and $6 million.[120]

The Commission incorporated those same burden estimates earlier this year, when the Commission adopted final rules to implement the duties applicable to security-based swap data repositories, apart from the data access requirement.[121]

Subject to the connectivity issues addressed below, the Commission believes that the burden estimates associated with the 2010 proposed repository rules encompassed the costs and burdens associated with the proposed data access requirements in conjunction with other system-related requirements applicable to security-based swap dealers. To comply with those other system-related requirements—including in particular requirements that repositories provide direct electronic access to the Commission and its designees—we preliminarily believe that it is reasonable to expect that repositories may use the same systems as they would also use to comply with the data access requirements at issue here, particularly given that both types of access requirements would require repositories to provide security-based swap information to particular recipients subject to certain parameters.[122] As a result, subject to per-recipient connectivity burdens addressed below, the Commission preliminarily believes that would be no additional burdens associated with information technology costs to implement the data access requirements of the proposed rule.

The Commission also recognizes, however, that once the relevant systems have been set up, repositories may be expected to incur addition incremental burdens and costs associated with setting up access to security-based swap data consistent with the recipient's regulatory mandate or legal responsibility or authority.[123] The Commission preliminarily believes that, for any particular recipient, security-based swap data repositories on average would incur a burden of 26 hours.[124] As discussed below, based on the estimate that approximately 300 relevant authorities may make requests for data from security-based swap data repositories,[125] the Commission preliminarily estimates that each repository would incur a one-time burden of 7,800 hours in connection with providing that connectivity.[126]

[120] *See* SDR Proposing Release, 75 FR 77348–49. The Commission previously estimated, for PRA purposes, that ten persons may register with the Commission as security-based swap data repositories. *See* SDR Adopting Release, 80 FR 14521, 14523. Based on the estimate of ten respondents, the Commission estimated total one-time costs of 420,000 hours and $10 million, and total annual ongoing systems costs of 252,000 and $60 million. *See* SDR Proposing Release, 75 FR 77349.

[121] *See* SDR Adopting Release, 80 FR 14523. The Commission submitted the PRA burden associated with that release to OMB for approval, and the OMB has approved that collection of information.

[122] The Commission also anticipates that repositories would use the same systems in connection with the Exchange Act data access requirements as they use in connection with the corresponding requirements under the CEA.

[123] In addressing those burdens, the Commission expects that the MOUs or other arrangements that are used to satisfy the conditions of the indemnification exemption will set forth objective criteria that delimit the scope of a recipient's ability to access security-based swap data pursuant to the indemnification exemption. The Commission further expects that repositories would use those criteria to program their data systems to reflect the scope of the recipient's access to repository data. Absent such objective and programmable criteria, repositories would be expected to incur greater burdens to assess whether an authority's request satisfies the relevant conditions, particularly with regard to whether particular information relates to persons or activities within the entity's regulatory mandate or legal responsibility or authority.

[124] This estimate is based on the view that for each recipient requesting data, a repository would incur a 25 hour burden associated with programming or otherwise inputting the relevant parameters, encompassing 20 hours of programmer analyst time and five hours of senior programmer time. The estimate also encompasses one hour of attorney time in connection with each such recipient.

[125] *See* part VI.C.3.ii, *infra*.

[126] Across an estimated ten repositories, accordingly, the Commission estimates that repositories cumulatively would incur a one-time burden of 78,000 hours in connection with providing such connectivity.

d. Providing Notification of Requests, and Associated Records Requirements

Under the proposed rules, repositories would be required to inform the Commission when they receive the first request for security-based swap data from a particular entity.[127] As discussed below, based on the estimate that approximately 300 relevant authorities may make requests for data from security-based swap data repositories, the Commission estimates that each repository would provide the Commission with actual notice approximately 300 times.[128] Moreover, based on the estimate that ten persons may register with the Commission as security-based swap data repository, the Commission estimates that repositories in the aggregate would provide the Commission with actual notice a total of 3,000 times. The Commission preliminarily estimates that each such notice would take no more than one-half hour to make on average, leading to a cumulative estimate of 1,500 hours associated with the notice requirement.

The proposed rule further requires that repositories must maintain records of all information related to the initial and all subsequent requests for data access, including records of all instances of online or electronic access, and records of all data provided in connection with such access.[129] The Commission estimates that there cumulatively may be 360,000 subsequent data requests or access per year across all security-based swap data repositories, for which repositories must maintain records as required by the proposed rule.[130] Based on its experience with recordkeeping costs associated with security-based swaps generally, the Commission preliminarily estimates that for each repository this requirement would create an initial burden of roughly 360 hours, and an annualized burden of roughly 280 hours and $40,000 in information technology costs.[131]

2. Confidentiality Condition

The Commission preliminarily does not believe that the confidentiality provision of the proposal would be

[127] *See* proposed Exchange Act rule 13n–4(e) (further requiring the repository to maintain records of the initial and all subsequent requests).

[128] *See* part VI.C.3.a.ii, *infra*.

[129] *See* proposed Exchange Act rule 13n–4(e).

[130] *See* part VI.C.3.a.ii, *infra*.

[131] Across an estimated ten repositories, accordingly, the Commission preliminarily estimates that repositories cumulatively will incur an initial burden of roughly 3,600 hours in information technology costs, and an annualized burden of roughly 2,800 hours and $400,000 in information technology costs.

associated with collections of information that would result in a reporting or recordkeeping burden for security-based swap data repositories. This is because, under the proposal, the confidentiality condition would be satisfied by an MOU or other arrangement between the Commission and the recipient entity (*i.e.*, another regulatory authority) addressing confidentiality. We preliminarily expect that in practice that the condition will be addressed by MOUs or other arrangements entered into by the Commission, and that repositories accordingly would not be involved in the drafting or negotiation of confidentiality agreements.

As discussed above, moreover, the confidentiality provision would be expected to impose burdens on authorities that seek to access data pursuant to these provisions, as a result of the need to negotiate confidentiality MOUs or other arrangements.[132]

E. Collection of Information Is Mandatory

The conditional data access requirements of Exchange Act sections 13(n)(5)(G) and (H) and the underlying rules are mandatory for all security-based swap data repositories. The confidentiality condition is mandatory for all entities that seek access to data under those requirements. Also, the conditions to the indemnification exemption are mandatory to entities that seek to rely on the exemption, which the Commission believes will be all entities that seek data pursuant to these requirements.

F. Confidentiality

The Commission will make public requests for a determination that an authority is appropriate to conditionally access security-based swap data, as well as Commission determinations issued in response to such requests. The Commission preliminarily expects that it will make publicly available the MOUs or other arrangements with the Commission used to satisfy the confidentiality and indemnification conditions.

Initial notices of requests for access provided to the Commission by repositories will be kept confidential, subject to the provisions of applicable law. To the extent that the Commission obtains subsequent requests for access that would be required to be maintained by the repositories, the Commission also will keep those records confidential, subject to the provisions of applicable law.

[132] *See* part V.D.1.a, *supra*.

G. Request for Comment

We request comment on our approach and the accuracy of the current estimates. Pursuant to 44 U.S.C. 3506(c)(2)(A), the Commission solicits comments to: (1) Evaluate whether the collection of information is necessary for the proper performance of the functions of the agency, including whether the information will have practical utility; (2) evaluate the accuracy of the Commission's estimate of burden of the collection of information; (3) determine whether there are ways to enhance the quality, utility and clarity of the information to be collected; and (4) evaluate whether there are ways to minimize the burden of the collection of information on those who are required to respond, including through the use of automated collection techniques or other forms of information technology.

In this regard, the Commission particularly requests comment regarding the systems-related costs associated with these data access requirements. Among other things, commenters are invited to address the burdens associated with establishing and programming systems to provide regulators and other authorities with connectivity to repository data systems, including whether such costs would be incremental to the systems-related costs associated with the existing rule requiring that repositories provide direct electronic access to the Commission and its designees, and whether such systems-related costs would encompass capacity-related elements linked to the total number of regulators and other authorities that access repositories pursuant to these data access provisions. Commenters also are invited to address the estimated burdens associated with the requirement that repositories maintain records in connection with the notification requirement.

The Commission further requests comment regarding the burdens associated with the negotiation of MOUs or other arrangements between the Commission and other authorities, including the average time required for those regulators to negotiate such MOUs or other arrangements, and whether those other authorities may incur costs to retain outside counsel in connection with such negotiations.

Persons submitting comments on the collection of information requirements should direct the comments to the Office of Management and Budget, Attention: Desk Officer for the Securities and Exchange Commission, Office of Information and Regulatory Affairs, Washington, DC 20503, and send a copy to Secretary, Securities and Exchange Commission, 100 F Street NE., Washington, DC 20549–1090, with reference to File No. S7–_____. Requests for materials submitted to OMB by the Commission with regard to these collections of information should be in writing, refer to File No. S7–_____, and be submitted to the Securities and Exchange Commission, Office of FOIA Services, 100 F Street NE., Washington, DC 20549–2736. OMB is required to make a decision concerning the collection of information between 30 and 60 days after publication of this release. Consequently, a comment to OMB is assured of having its full effect if OMB receives it within 30 days of publication.

VI. Economic Analysis

As discussed above, the Commission is proposing rules to implement data access requirements for relevant authorities other than the Commission that the Dodd-Frank Act imposes on security-based swap repositories, and to provide an exemption from the associated indemnification requirement. To carry out their regulatory mandate, or legal responsibility or authority, certain relevant entities other than the Commission may periodically need access to security-based swap data collected and maintained by SEC-registered security-based swap data repositories, and the proposed rules are intended to facilitate such access.

The Commission is sensitive to the economic effects of its rules, including the costs and benefits and the effects of its rules on efficiency, competition, and capital formation. Section 3(f) [133] of the Exchange Act requires the Commission, whenever it engages in rulemaking pursuant to the Exchange Act, to consider or determine whether an action is necessary or appropriate in the public interest, and to consider, in addition to the protection of investors, whether the action would promote efficiency, competition, and capital formation. In addition, section 23(a)(2) [134] of the Exchange Act requires the Commission, when promulgating rules under the Exchange Act, to consider the impact such rules would have on competition. Exchange Act section 23(a)(2) also provides that the Commission shall not adopt any rule which would impose a burden on competition that is not necessary or appropriate in furtherance of the purposes of the Exchange Act.

[133] 15 U.S.C. 78c(f).

[134] 15 U.S.C. 78w(a)(2).

A. Economic Considerations

1. Title VII Transparency Framework

The security-based swap market prior to the passage of the Dodd-Frank Act has been described as being opaque, in part because transaction-level data were not widely available to market participants or to regulators.[135] To increase the transparency of the over-the-counter derivatives market to both market participants and regulatory authorities, Title VII requires the Commission to undertake a number of rulemakings, including rules the Commission adopted earlier this year to address the registration process, duties and core principles applicable to security-based swap data repositories,[136] and to address regulatory reporting and public dissemination of security-based swap information.[137] Among other matters, those rules address market transparency by requiring security-based swap data repositories, absent an exemption, to collect and maintain accurate security-based swap transaction data, and address regulatory transparency by requiring security-based swap data repositories to provide the Commission with direct electronic access to such data.[138]

Consistent with the goal of increasing transparency to regulators, the data access provisions at issue here set forth a framework for security-based swap data repositories to provide access to security-based swap data to relevant authorities other than the Commission. The proposed rules would implement that framework for repositories to provide data access to other relevant entities in order to fulfill their regulatory mandate, or legal responsibility or authority.

2. Transparency in the Market for Security-Based Swaps

The proposed data access rules and indemnification exemption, in conjunction with the transparency-related requirements generally applicable to security-based swap data repositories, are designed to, among other things, make available to the Commission and other relevant authorities data that will provide a broad view of the security-based swap market and help monitor for pockets of risk and potential market abuses that might not otherwise be observed by those authorities.[139] Unlike most other securities transactions, security-based swaps involve ongoing financial obligations between counterparties during the life of transactions that typically span several years. Counterparties to a security-based swap rely on each other's creditworthiness and bear this credit risk and market risk until the security-based swap terminates or expires. This can lead to market instability when a large market participant, such as a security-based swap dealer, major security-based swap market participant, or central counterparty ("CCP") becomes financially distressed. The default of a large market participant could introduce the potential for sequential counterparty failure; the resulting uncertainty could reduce the willingness of market participants to extend credit, and substantially reduce liquidity and valuations for particular types of financial instruments.[140]

A broad view of the security-based swap market, including information regarding aggregate market exposures to particular reference entities (or securities), positions taken by individual entities or groups, and data elements necessary to determine the market value of the transaction, may be expected to provide the Commission and other relevant authorities with a better understanding of the actual and potential risks in the market and promote better risk monitoring efforts. The information provided by security-based swap data repositories also may be expected to help the Commission and other relevant authorities investigate market manipulation, fraud and other market abuses.

3. Global Nature of the Security-Based Swap Market

As highlighted in more detail in the Economic Baseline below, the security-based swap market is a global market. Based on market data in the Depository Trust and Clearing Corporation's Trade Information Warehouse ("DTCC–TIW"), the Commission estimates that only 12 percent of the global transaction volume that involves either a U.S.-domiciled counterparty or a U.S-domiciled reference entity (as measured by gross notional) between 2008 and 2014 was between two U.S.-domiciled counterparties, compared to 48 percent entered into between one U.S.-domiciled counterparty and a foreign-domiciled counterparty and 40 percent entered into between two foreign-domiciled counterparties.[141]

In light of the security-based swap market's global nature there is the possibility that regulatory data may be fragmented across jurisdictions, particularly because a large fraction of transaction volume includes at least one counterparty that is not a U.S. person[142] and the applicable U.S. regulatory reporting rules depend on the U.S. person status of the counterparties.[143] As discussed further below,

[135] With respect to one type of security-based swap, credit default swaps ("CDSs"), the Government Accountability Office found that "comprehensive and consistent data on the overall market have not been readily available," "authoritative information about the actual size of the [CDS] market is generally not available" and regulators currently are unable "to monitor activities across the market." Government Accountability Office, GAO–09–397T, *Systemic Risk: Regulatory Oversight and Recent Initiatives to Address Risk Posed by Credit Default Swaps*, at 2, 5, 27, (2009) *available at: http://www.gao.gov/new.items/d09397t.pdf; see also* Robert E. Litan, *The Derivatives Dealers' Club and Derivatives Market Reform: A Guide for Policy Makers, Citizens and Other Interested Parties*, Brookings Institution (Apr. 7, 2010), *http://www.brookings.edu/~/media/research/files/papers/2010/4/07%20derivatives%20litan/0407_derivatives_litan.pdf;* Michael Mackenzie, *Era of an Opaque Swaps Market Ends*, Financial Times, June 25, 2010, *available at: http://www.ft.com/intl/cms/s/0/f49f635c-8081-11df-be5a-00144feabdc0.html#axzz3HLUjYNI7.*

[136] *See* SDR Adopting Release, note 13, *supra.*

[137] *See* Regulation SBSR Adopting Release.

[138] *See* Exchange Act rule 13n–5 (requiring repositories to comply with data collection and data maintenance standards related to transaction and position data); Exchange Act rule 13n–4(b)(5) (requiring repositories to provide direct electronic access to the Commission and its designees).

[139] *See, e.g.*, Exchange Act section 13(n)(5)(D), 15 U.S.C. 78m(n)(5)(D), and rule 13n–4(b)(5) (requiring SDRs to provide direct electronic access to the Commission). *See also* 156 Cong. Rec. S5920 (daily ed. July 15, 2010) (statement of Sen. Lincoln) ("These new 'data repositories' will be required to register with the CFTC and the SEC and be subject to the statutory duties and core principles which will assist the CFTC and the SEC in their oversight and market regulation responsibilities.").

[140] *See, e.g.*, Markus K. Brunnermeier and Lasse Heje Pedersen, *Market Liquidity and Funding Liquidity*, 22 Review of Financial Studies 2201 (2009); Denis Gromb and Dimitri Vayanos, *A Model of Financial Market Liquidity Based on Intermediary Capital*, 8 Journal of the European Economic Association 456 (2010).

[141] The data the Commission receives from the DTCC–TIW does not include transactions between two non-U.S. domiciled counterparties that reference a non-U.S. entity or security. This is approximately 19 percent of global transaction volume. *See* note 152, *infra*. Therefore, factoring in these transactions, approximately 10 percent of global transaction volume involves two U.S.-domiciled counterparties, 39 percent involve one U.S.-domiciled counterparty and one foreign counterparty, and 51 percent are between two foreign-domiciled counterparties.

[142] This statement is based on staff analysis of voluntary CDS transaction data reported to the DTCC–TIW, which includes self-reported counterparty domicile. *See* note 161, *infra*. The Commission notes that the DTCC–TIW entity domicile may not be completely consistent with the Commission's definition of "U.S. person" in all cases but preliminarily believes that these two characteristics have a high correlation.

[143] *See* Regulation SBSR rule 908(a) (generally requiring regulatory reporting and public dissemination when at least one direct or indirect counterparty is a U.S. person). Note that current voluntary reporting considers the self-reported domicile of the counterparty but the recently adopted SBSR rules consider the counterparty's status as a U.S. person.

fragmentation of data can increase the difficulty in consolidating and interpreting security-based swap market data from repositories, potentially reducing the general economic benefits derived from transparency of the security-based swap market to regulators. Absent a framework for the cross-border sharing of data reported pursuant to regulatory requirements in various jurisdictions, the relevant authorities responsible for monitoring the security-based swap market may not be able to access data consistent with their regulatory mandate, or legal responsibility or authority.

4. Economic Purposes of the Rulemaking

The proposed data access requirements and indemnification exemption are designed to increase the quality and quantity of transaction and position information available to relevant authorities about the security-based swap market while helping to maintain the confidentiality of that information. The increased availability of security-based swap information may be expected to help relevant authorities act in accordance with their regulatory mandate, or legal responsibility or authority, and to respond to market developments.

Moreover, by facilitating access to security-based swap data for relevant authorities, including non-U.S. authorities designated by the Commission, the Commission anticipates an increased likelihood that the Commission itself will have commensurate access to security-based swap data stored in trade repositories located in foreign jurisdictions.[144] This may be particularly important in identifying transactions in which the Commission has a regulatory interest (*e.g.*, transactions involving a U.S. reference entity or security) but may not have been reported to a registered security-based swap data repository due to the transactions occurring outside of the U.S. between two non-U.S. persons.[145] This should assist the Commission in fulfilling its regulatory mandate and legal responsibility and authority, including by facilitating the Commission's ability to detect and investigate market manipulation, fraud and other market abuses, by providing the Commission with greater access to security-based swap information than that provided under the current voluntary reporting regime.[146]

Such data access may be especially critical during times of market turmoil, by giving the Commission and other relevant authorities information to examine risk exposures incurred by individual entities or in connection with particular reference entities. Increasing the available data about the security-based swap market should further give the Commission and other relevant authorities better insight into how regulations are affecting or may affect the market, which may allow the Commission and other regulators to better craft regulations to achieve desired goals, and therefore increase regulatory effectiveness.

B. Baseline

To assess the economic impact of the proposed data access rules and indemnification exemption, the Commission is using as a baseline the security-based swap market as it exists today, including applicable rules that have already been adopted and excluding rules that have been proposed but not yet finalized. Thus we include in the baseline the rules that the Commission adopted earlier this year to govern the registration process, duties and core principles applicable to security-based swap data repositories, and to govern regulatory reporting and public dissemination of security-based swap transactions.

Because those rules were adopted only recently, there are not yet any registered swap data repositories, and the Commission does not yet have access to regulatory reporting data. Hence, our characterization of the economic baseline, including the quantity and quality of security-based swap data available to the Commission and other relevant authorities and the extent to which data are fragmented, considers the anticipated effects of the final SDR rules and Regulation SBSR. The Commission acknowledges limitations in the degree to which it can quantitatively characterize the current state of the security-based swap market. As described in more detail below, because the available data on security-based swap transactions do not cover the entire market, the Commission has developed an understanding of market activity using a sample that includes only certain portions of the market.

1. Regulatory Transparency in the Security-Based Swap Market

There currently is no robust, widely accessible source of information about individual security-based swap transactions. In 2006, a group of major dealers expressed their commitment in support of DTCC's initiative to create a central trade industry warehouse for credit derivatives.[147] Moreover, in 2009, the leaders of the G20—whose members include the United States, 18 other countries, and the European Union—called for global improvements in the functioning, transparency, and regulatory oversight of over-the-counter ("OTC") derivatives markets and agreed, among other things, that OTC derivatives contracts should be reported to trade repositories.[148] A single repository, the DTCC–TIW, makes the data reported to it under the voluntary reporting regime available to the Commission and other relevant authorities in accordance with the agreement between DTCC–TIW and the OTC Derivatives Regulatory Forum ("ODRF"), of which the Commission is a member.[149] Although many jurisdictions have implemented rules concerning reporting of security-based swaps to trade repositories,[150] the Commission understands that many market participants continue to report voluntarily to the DTCC–TIW.

The data that the Commission receives from DTCC–TIW do not encompass CDS transactions that both: (i) Do not involve any U.S. counterparty, and (ii) are not based on a U.S. reference entity.[151] Based on a comparison of

[144] As discussed above, for example, EU law conditions the ability of non-EU authorities to access data from EU repositories on EU authorities having "immediate and continuous" access to the information they need. *See* note 94, *supra*, and accompanying text.

Also, as discussed above, the Commission anticipates considering whether or not the relevant authority requesting access agrees to provide the Commission and other U.S. authorities with reciprocal assistance in matters within their jurisdiction when making a determination as to whether the requesting authority shall be granted access to security-based swap data held in registered SDRs. *See* part II.A.3(a) *supra*.

[145] For example, it is possible to replicate the economic exposure of either a long or short position in a debt security that trades in U.S. markets by trading in U.S. treasury securities and credit default swaps that reference the debt security. Transactions between two non-U.S. persons on a U.S. reference entity supervised by the Commission or novations between two non-U.S. persons that reduce exposure to a U.S. registrant may provide information to the Commission about the market's views concerning the financial stability or creditworthiness of the registered entity.

[146] *See* part VI.B, *supra*, for a description of the data the Commission receives from DTCC–TIW under the current voluntary reporting regime.

[147] *See* Letter to Timothy Geithner, President, Federal Reserve Bank of New York, Mar. 10, 2006, available at: *http://www.newyorkfed.org/newsevents/news/markets/2006/industryletter2.pdf.*

[149] *See* note 71, *supra*.

[150] *See* Eighth Progress Report on Implementation of OTC Derivatives Market Reforms (Nov. 2014), *available at: http://www.financialstabilityboard.org/wp-content/uploads/r_141107.pdf.*

[151] The Commission notes that the identification of entity domicile in the voluntary data reported to

weekly transaction volume publicly disseminated by DTCC–TIW with data provided to the Commission under the voluntary arrangement, we estimate that the transaction data provided to the Commission covers approximately 77 percent of the global single-name credit default swap market.[152]

While DTCC–TIW generally provides detailed data on positions and transactions to regulators that are members of the ODRF, DTCC–TIW makes only summary information available to the public.[153]

2. Current Security-Based Swap Market

The Commission's analysis of the current state of the security-based swap market is based on data obtained from DTCC–TIW, particularly data regarding the activity of market participants for single-name credit-default swaps from 2008 to 2014. While other repositories also may collect data on transactions in total return swaps on equity and debt, the Commission does not currently have access to such data for those products (or for other products that are security-based swaps). Although the definition of "security-based swap" is not limited to single-name credit-default swaps, the Commission believes that the single-name credit default swap data are sufficiently representative of the security-based swap market and therefore can directly inform the analysis of the state of the current security-based swap market.[154] The Commission believes that DTCC–TIW's data for single-name credit default swaps appear reasonably comprehensive because they include data on almost all single-name credit default swap transactions and market participants trading in single-name credit default swaps.[155]

Based on this information, our analysis below indicates that the current security-based swap market: (i) Is global in scope, and (ii) is concentrated among a small number of dealing entities. Although under the voluntary reporting regime discussed above there was a single repository, as various jurisdictions have implemented mandatory reporting rules in their jurisdictions the number of trade repositories holding security-based swap data has grown.[156]

a. Security-Based Swap Market Participants

A key characteristic of security-based swap activity is that it is concentrated among a relatively small number of entities that engage in dealing activities.[157] Based on the Commission's analysis of DTCC–TIW data, there were 1,879 entities engaged directly in trading credit default swaps between November 2006 and December 2014.[158] Table 1 below highlights that of these entities, there were 17, or approximately 0.9 percent, that were ISDA-recognized dealers.[159] ISDA-recognized dealers executed the vast majority of transactions (82.6 percent) measured by the number of counterparties (each transaction has two counterparties or transaction sides). Many of these dealers are regulated by entities other than, or in addition to, the Commission. In addition, thousands of other market participants appear as counterparties to security-based swap transactions, including, but not limited to, investment companies, pension funds, private (hedge) funds, sovereign entities, and non-financial companies.

DTCC–TIW may not be consistent with the Commission's definition of "U.S. person" in all cases.

[152] In 2014, DTCC–TIW reported on its Web site new trades in single-name CDSs with gross notional of $15.4 trillion. During the same period, data provided to the Commission by DTCC–TIW, which include only transactions with a U.S. counterparty or transactions written on a U.S. reference entity or security, included new trades with gross notional equaling $12.4 trillion, or 81% of the total reported by DTCC–TIW.

[153] The DTCC–TIW publishes weekly transaction and position reports for single-name credit default swaps. In addition, ICE Clear Credit provides aggregated volumes of clearing activity, and large multilateral organizations periodically further report measures of market activity. For example, the Bank for International Settlements ("BIS") reports gross notional outstanding for single-name credit default swaps and equity forwards and swaps semiannually.

[154] According to data published by BIS, the global notional amount outstanding in equity forwards and swaps as of December 2014 was $2.50 trillion. The notional amount outstanding was approximately $9.04 trillion for single-name CDSs, approximately $6.75 trillion for multi-name index CDSs, and approximately $0.61 trillion for multi-name, non-index CDSs. *See* Bank of International Settlement, BIS Quarterly Review, Statistical Annex, Table 19 (June 2015), *available at: http://www.bis.org/publ/qtrpdf/r_qt1506.htm.* For purposes of this analysis, the Commission assumes that multi-name index CDSs are not narrow-based security index CDSs, and therefore do not fall within the definition of security-based swap. *See* Exchange Act section 3(a)(68)(A), 15 U.S.C. 78c(a)(68)(A); *see also* Further Definition of "Swap," "Security-Based Swap," and "Security-Based Swap Agreement"; Mixed Swaps; Security-Based Swap Agreement Recordkeeping, Exchange Act Release No. 67453 (July 18, 2012), 77 FR 48207 (Aug. 13, 2012). The Commission also assumes that instruments reported as equity forwards and swaps include instruments such as total return swaps on individual equities that fall with the definition of security-based swap. Based on these assumptions, single-name CDS appear to constitute roughly 80 percent of the security-based swap market. Although the BIS data reflects the global OTC derivatives market, and not only the U.S. market, the Commission is not aware of any reason to believe that these ratios differ significantly in the U.S. market.

[155] *See* ISDA, CDS Marketplace, Exposures & Activity, *available at: http://www.isdacdsmarketplace.com/exposures_and_activity* ("DTCC Deriv/SERV's Trade Information Warehouse is the only comprehensive trade repository and post-trade processing infrastructure for OTC credit derivatives in the world. Its Deriv/SERV matching and confirmation service electronically matches and confirms more than 98% of credit default swaps transactions globally.").

[156] *See,* for example, the list of trade repositories registered by ESMA, *available at: http://www.esma.europa.eu/content/List-registered-Trade-Repositories.* As of May 28, 2015, there were six repositories registered by ESMA, all of which are authorized to receive data on credit derivatives.

[157] *See* Exchange Act Release No.72472 (Jun. 25, 2014), 79 FR 47278, 47293 (Aug. 12, 2014) ("Cross-Border Definitions Adopting Release"). All data in this section cites updated data from that release and its accompanying discussion.

[158] These 1,879 transacting agents represent over 10,000 accounts representing principal risk holders. *See* Cross-Border Definitions Adopting Release, 79 FR 47293–94 (discussing the number of transacting agents and accounts of principal risk holders).

As noted above, the data provided to the Commission by the DTCC–TIW only includes transactions that either include at least one U.S.-domiciled counterparty or reference a U.S. entity or security. Therefore, any entity that is not domiciled in the U.S., never trades with a U.S.-domiciled entity and never buys or sells protection on a U.S. reference entity or security would not be included in this analysis.

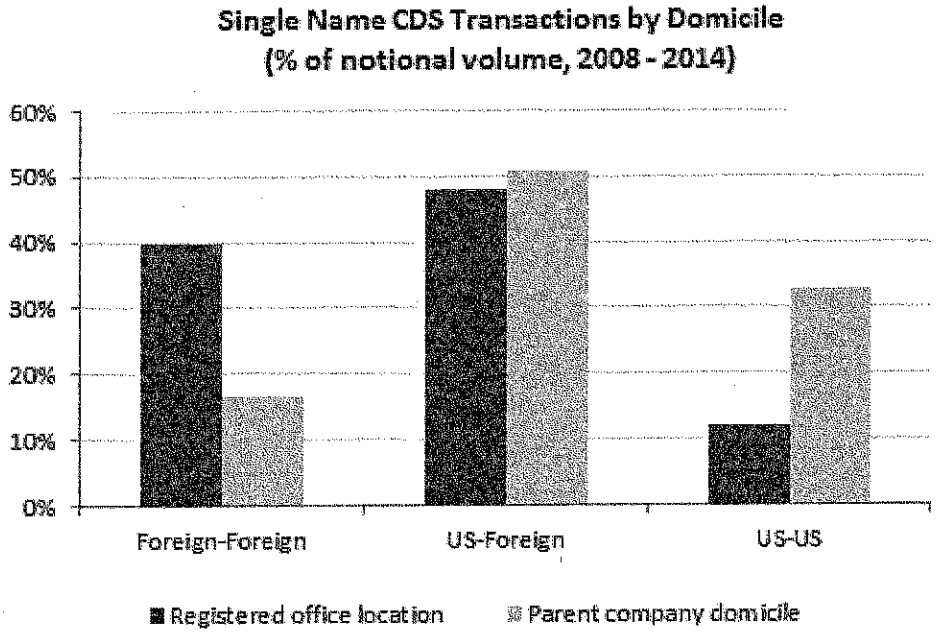
[159] For the purpose of this analysis, the ISDA-recognized dealers are those identified by ISDA as a recognized dealer in any year during the relevant period. Dealers are only included in the ISDA-recognized dealer category during the calendar year in which they are so identified. The complete list of ISDA recognized dealers is: JP Morgan Chase NA (and Bear Stearns), Morgan Stanley, Bank of America NA (and Merrill Lynch), Goldman Sachs, Deutsche Bank AG, Barclays Capital, Citigroup, UBS, Credit Suisse AG, RBS Group, BNP Paribas, HSBC Bank, Lehman Brothers, Société Générale, Credit Agricole, Wells Fargo, and Nomura. *See* ISDA, Operations Benchmarking Surveys, *available at: http://www2.isda.org/functional-areas/research/surveys/operations-benchmarking-surveys.*

TABLE 1—THE NUMBER OF TRANSACTING AGENTS IN THE SINGLE-NAME CDS MARKET BY COUNTERPARTY TYPE AND THE FRACTION OF TOTAL TRADING ACTIVITY, FROM NOVEMBER 2006 THROUGH DECEMBER 2014, REPRESENTED BY EACH COUNTERPARTY TYPE

Transacting agents	Number	Percent	Transaction share (percent)
Investment Advisers	1,419	75.5	10.9
SEC registered	*572*	*30.4*	*6.9*
Banks	260	13.8	5.0
Pension Funds	29	1.5	0.1
Insurance Companies	38	2.0	0.3
ISDA-Recognized Dealers[160]	17	0.9	82.6
Other	116	6.2	1.2
Total	1,879	100	100

Although the security-based swap market is global in nature, approximately 60 percent of the transaction volume in the 2008–2014 period included at least one U.S.-domiciled entity (see Figure 1). Moreover, 48 percent of the single-name CDS transactions reflected in DTCC–TIW data that include at least one U.S.-domiciled counterparty or a U.S. reference entity or security were between U.S.-domiciled entities and foreign-domiciled counterparties.

Figure 1: The fraction of notional volume in North American corporate single-name CDSs between (1) two U.S.-domiciled accounts, (2) one U.S.-domiciled account and one non-U.S.-domiciled account, and (3) two non-U.S.-domiciled accounts, computed from January 2008 through December 2014.



The fraction of new accounts with transaction activity that are domiciled in the U.S. fell through the 2008–2014 period. Figure 2 below is a chart of: (1) The percentage of new accounts with a domicile in the United States,[161] (2) the

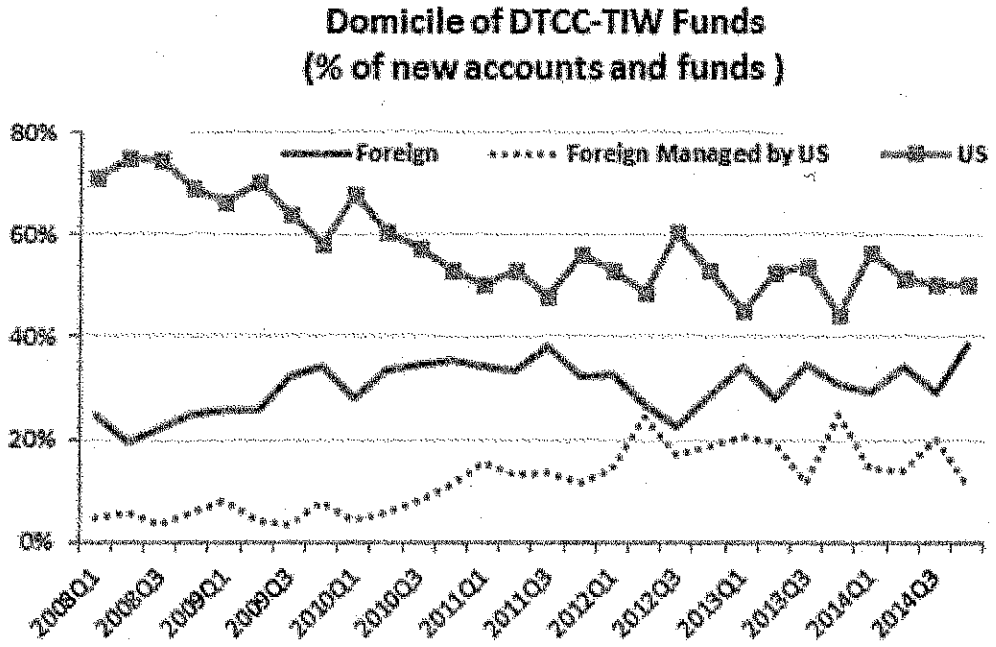
[160] For the purpose of this analysis, the ISDA-recognized dealers are those identified by ISDA as belonging to the G14 or G16 dealer group during the period: JP Morgan Chase NA (and Bear Stearns), Morgan Stanley, Bank of America NA (and Merrill Lynch), Goldman Sachs, Deutsche Bank AG, Barclays Capital, Citigroup, UBS, Credit Suisse AG, RBS Group, BNP Paribas, HSBC Bank, Lehman Brothers, Société Générale, Credit Agricole, Wells Fargo and Nomura. *See, e.g., http://www.isda.org/c_and_a/pdf/ISDA-Operations-Survey-2010.pdf.*

[161] The domicile classifications in DTCC–TIW are based on the market participants' own reporting and have not been verified by Commission staff. Prior to enactment of the Dodd-Frank Act, account holders did not formally report their domicile to DTCC–TIW because there was no systematic requirement to do so. After enactment of the Dodd-Frank Act, the DTCC–TIW has collected the registered office location of the account. This information is self-reported on a voluntary basis. It is possible that some market participants may misclassify their domicile status because the databases in DTCC–TIW do not assign a unique legal entity identifier to each separate entity. It is also possible that the domicile classifications may not correspond precisely to the definition of "U.S.

percentage of new accounts with a domicile outside the United States, and (3) the percentage of new accounts that are domiciled outside the United States but managed by a U.S. entity, foreign accounts that include new accounts of a foreign branch of a U.S. bank, and new accounts of a foreign subsidiary of a U.S. entity. Over time, a greater share of accounts entering the DTCC–TIW data either have had a foreign domicile or have had a foreign domicile while being managed by a U.S. person. The increase in foreign accounts may reflect an increase in participation by foreign accountholders, and the increase in foreign accounts managed by U.S. persons may reflect the flexibility with which market participants can restructure their market participation in response to regulatory intervention, competitive pressures and other factors. There are, however, alternative explanations for the shifts in new account domicile in Figure 2. Changes in the domicile of new accounts through time may reflect improvements in reporting by market participants to DTCC–TIW. Additionally, because the data include only accounts that are domiciled in the United States, transact with U.S.-domiciled counterparties or transact in single-name CDSs with U.S. reference entities or securities, changes in the domicile of new accounts may reflect increased transaction activity between U.S. and non-U.S. counterparties.

We note that cross-border rules related to regulatory reporting and public dissemination of security-based swap transactions depend on, among other things, the U.S. person status of the counterparties.[162] The analyses behind Figures 1 and 2 show that the security-based swap market is global, with an increasing share of the market characterized by cross-border trade.

Figure 2: The percentage of (1) new accounts with a domicile in the United States (referred to below as "US"), (2) new accounts with a domicile outside the United States (referred to below as "Foreign"), and (3) new accounts outside the United States, but managed by a U.S. entity, new accounts of a foreign branch of a U.S. bank, and new accounts of a foreign subsidiary of a U.S. entity (collectively referred to below as "Foreign Managed by US").[163] Unique, new accounts are aggregated each quarter and shares are computed on a quarterly basis, from January 2008 through December 2014.



b. Security-Based Swap Data Repositories

No security-based swap data repositories are currently registered with the Commission. The Commission is aware of one entity in the market (*i.e.*, the DTCC–TIW) that has been accepting voluntary reports of single-name and index credit default swap transactions. In 2014, DTCC–TIW received approximately 4 million records of single-name credit default swap transactions, of which approximately 868,000 were price-forming transactions.[164]

person" under the rules defined in Exchange Act rule 3a71–3(a)(4), 17 CFR 240.3a71–3(a)(4). Notwithstanding these limitations, the Commission believes that the cross-border and foreign activity demonstrates the nature of the single-name CDS market.

[162] *See* note 143, *supra*.

[163] Following publication of the Warehouse Trust Guidance on CDS data access, TIW surveyed market participants, asking for the physical address associated with each of their accounts (*i.e.*, where the account is organized as a legal entity). This is designated the registered office location by TIW. When an account does not report a registered office location, we have assumed that the settlement country reported by the investment adviser or parent entity to the fund or account is the place of domicile. This treatment assumes that the registered office location reflects the place of domicile for the fund or account.

[164] Price-forming credit default swap transactions include all new transactions, assignments, modifications to increase the notional amounts of previously executed transactions and terminations

Continued

The CFTC has provisionally registered four swap data repositories.[165] These swap data repositories are: BSDR LLC, Chicago Mercantile Exchange Inc., DTCC Data Repository LLC, and ICE Trade Vault, LLC. The Commission believes that these entities will likely register with the Commission as security-based swap data repositories and that other persons may seek to register with both the CFTC and the Commission as swap data repositories and security-based swap data repositories, respectively.[166]

Efforts to regulate the swap and security-based swap markets are underway not only in the United States, but also abroad. Consistent with the call of the G20 leaders for global improvements in the functioning, transparency and regulatory oversight of OTC derivatives markets,[167] substantial progress has been made in establishing the trade repository infrastructure to support the reporting of OTC derivatives transactions.[168] Currently, multiple trade repositories operate, or are undergoing approval processes to do so, in a number of different jurisdictions.[169] Combined with the fact that the requirements for trade reporting differ across jurisdictions, the result is that security-based swap data is fragmented across many locations, stored in a variety of formats, and subject to many different rules for authorities' access. The data in these trade repositories accordingly will need to be aggregated in various ways if authorities are to obtain a comprehensive and accurate view of the global OTC derivatives markets.

C. Economic Costs and Benefits, Including Impact on Efficiency, Competition, and Capital Formation

As discussed above, the security-based swap market to date largely has developed as an opaque OTC market with limited dissemination of transaction-level price and volume information.[170] Accordingly, the Commission envisions that registered security-based swap data repositories, by storing the security-based swap transaction and position data required to be reported to them by market participants, will become an essential part of the infrastructure of the market in part by providing the data to relevant authorities in accordance with their regulatory mandate, or legal responsibility or authority.

In proposing these rules to implement the Exchange Act data access requirement and to provide a conditional exemption from the indemnification requirement, the Commission has attempted to balance different goals. On the one hand, the Commission preliminarily believes that the proposed rules will facilitate the sharing of information held by repositories with relevant authorities, which should assist those authorities in acting in accordance with their regulatory mandate, or legal responsibility or authority. At the same time, although regulatory access raises important issues regarding the confidentiality of the information, the Commission preliminarily believes that the proposed rules should appropriately reduce the risk of breaching the confidentiality of the data by providing for a reasonable assurance that confidentiality will be maintained before access is granted.

Additionally, we note that the magnitude of the costs and benefits of the proposed rules depend in part on the type of access granted to relevant authorities. Ongoing, unrestricted direct electronic access by relevant authorities may be most beneficial in terms of facilitating efficient access to data necessary for those authorities to act in accordance with their regulatory mandate, or legal responsibility or authority, but at the cost of increasing the risk of improper disclosure of confidential information. Restricting each relevant authority's access to only that data consistent with that authority's regulatory mandate, or legal responsibility or authority reduces the quantity of data that could become subject to improper disclosure. On the other hand, restricting a relevant authority's access to data may make it more difficult for it to effectively act in accordance with its regulatory mandate or legal responsibility or authority.

The potential economic effects stemming from the proposed rules can be grouped into several categories. In this section, we first discuss the general costs and benefits of the proposed rules, including the benefits of reducing data fragmentation, data duplication and enhancing regulatory oversight, as well as the risks associated with potential breaches of data confidentiality. Next, we discuss the effects of the rules on efficiency, competition and capital formation. Finally, we discuss specific costs and benefits linked to the proposed rules.

1. General Costs and Benefits

As discussed above, the proposed rules would implement the statutory provisions that require a security-based swap data repository to disclose information to certain relevant authorities, conditional upon the authority agreeing to keep the information confidential and to indemnify the repository and the Commission for any expenses arising from litigation relating to the information provided. The proposal also would set forth a conditional exemption from the requirement that entities requesting data agree to provide indemnification. The exemption would be conditional on the requested information relating to a regulatory mandate and/or legal responsibility of the entity requesting the data, and on the entity entering into an MOU with the Commission addressing the confidentiality of the information provided and any other matters as determined by the Commission.

a. Anticipated Benefits

The proposed rules should facilitate access to security-based swap transaction and position data by entities that require such information to fulfill their regulatory mandate or legal responsibility or authority. Market participants accordingly should benefit from relevant domestic authorities other than the Commission having access to the data necessary to fulfill their responsibilities. In particular, such access could help promote stability in the security-based swap market particularly during periods of market turmoil,[171] and thus could indirectly contribute to improved stability in related financial markets, including equity and bond markets.[172]

of previously executed transactions. Transactions terminated or entered into in connection with a compression exercise, and expiration of contracts at maturity, are not considered price-forming and are therefore excluded, as are replacement trades and all bookkeeping-related trades.

[165] CFTC rule 49.3(b) provides for provisional registration of a swap data repository. 17 CFR 49.3(b).

[166] For the purpose of estimating PRA related costs, the number of swap data repositories is estimated to be as high as ten. *See* part V.C, supra.

[167] *See* note 148, *supra*, and accompanying text.

[168] *See* Eighth Progress Report on Implementation of OTC Derivatives Market Reforms (Nov. 2014), *available at: http://www.financialstabilityboard.org/wp-content/uploads/r_141107.pdf.*

[169] *Id.*

[170] *See* part VI.B.1, *supra* (addressing limited information currently available to market participants and regulators).

[171] SDR Adopting Release, 80 FR 14531 ("Enhanced transparency could produce additional market-wide benefits by promoting stability in the [security-based swap] market, particularly during periods of market turmoil, and it should indirectly contribute to improved stability in related financial markets, including equity and bond markets.").

[172] *See* Darrell Duffie, Ada Li, and Theo Lubke, *Policy Perspectives of OTC Derivatives Market Infrastructure,* Federal Reserve Bank of New York Staff Report No. 424 (Jan. 2010, as revised Mar.

Moreover, as noted in part II.A(3)(a), the Commission anticipates, when making a determination concerning a relevant authority's access to security-based swap data, considering whether the relevant authority agrees to provide the Commission and other U.S. authorities with reciprocal assistance in matters within their jurisdiction. Allowing access to security-based swap data held by registered security-based swap data repositories by non-U.S. authorities may be expected to help facilitate the Commission's own ability to access data held by repositories outside the United States.[173] Accordingly, to the extent the Commission obtains access, the proposed rules further may be expected to assist the Commission in fulfilling its regulatory responsibilities, including by detecting market manipulation, fraud and other market abuses by providing the Commission with greater access to global security-based swap information.[174]

The ability of other relevant authorities to access data held in trade repositories registered with the Commission, as well as the ability of the Commission to access data held in repositories registered with other regulators, may be especially crucial during times of market turmoil. Increased data sharing should provide the Commission and other relevant authorities more-complete information to monitor risk exposures taken by individual entities and exposures connected to particular reference entities, and should promote global stability through enhanced regulatory transparency. Security-based swap data repositories registered with the Commission are required to retain complete records of security-based swap transactions and maintain the integrity of those records.[175] Based on discussions with other regulators, the Commission believes repositories registered with other authorities are likely to have comparable requirements. As a result, rules to facilitate regulatory access to those records in line with the recipient authorities' regulatory mandate, or legal responsibility or authority are designed to help position the Commission and other authorities to: detect market manipulation, fraud and other market abuses; monitor the financial responsibility and soundness of market participants; perform market surveillance and macroprudential supervision; resolve issues and positions after an institution fails; monitor compliance with relevant regulatory requirements; and respond to market turmoil.[176]

Additionally, improving the availability of data regarding the security-based swap market should give the Commission and other relevant authorities improved insight into how regulations are affecting, or may affect, the market. This may be expected to help increase regulatory effectiveness by allowing the Commission and other regulators to better craft regulation to achieve desired goals.

In addition, the Commission believes that providing relevant foreign authorities with access to data maintained by repositories may help reduce costs to market participants by reducing the potential for duplicative security-based swap transaction reporting requirements in multiple jurisdictions.[177] The Commission anticipates that relevant foreign authorities will likely impose their own reporting requirements on market participants within their jurisdictions.[178] Given the global nature of the security-based swap market and the large number of cross-border transactions, the Commission recognizes that it is likely that such transactions may be subject to the reporting requirements of at least two jurisdictions.[179] However, the Commission preliminarily believes that if relevant authorities are able to access security-based swap data in trade repositories outside their jurisdiction, such as repositories registered with the Commission, as needed, then relevant authorities may be more inclined to permit market participants involved in such transactions to fulfill their reporting requirements by reporting the transactions to a single trade repository.[180] If market participants can report a transaction to a single trade repository rather than to separate trade repositories in each applicable

2010), note 95, *supra* ("Transparency can have a calming influence on trading patterns at the onset of a potential financial crisis, and thus act as a source of market stability to a wider range of markets, including those for equities and bonds.").

[173] *See* note 94, *supra*, and accompanying text.

[174] *See* SDR Adopting Release, 80 FR 14450 ("Requiring U.S. persons that perform the functions of an SDR to be operated in a manner consistent with the Title VII regulatory framework and subject to the Commission's oversight, among other things, helps ensure that relevant authorities are able to monitor the build-up and concentration of risk exposure in the [security-based swap] market, reduce operational risk in that market, and increase operational efficiency."); *id.* at 14529 ("In conjunction with Regulation SBSR, the SDR Rules should assist the Commission in fulfilling its regulatory mandates and legal responsibilities such as detecting market manipulation, fraud, and other market abuses by providing it with greater access to [security-based swap] information than that provided under the voluntary reporting regime."); *see also* DTCC comment (Nov. 15, 2010) at 1 ("A registered SDR should be able to provide (i) enforcement agents with necessary information on trading activity; (ii) regulatory agencies with counterparty-specific information about systemic risk based on trading activity; (iii) aggregate trade information for publication on market-wide activity; and (iv) a framework for real-time reporting from swap execution facilities and derivatives clearinghouses.").

[175] *See* SDR Adopting Release, 80 FR 14531 ("The SDR Requirements [Exchange Act section 13(n) and the rules and regulations thereunder], including requirements that SDRs register with the Commission, retain complete records of [security-based swap] transactions, maintain the integrity and confidentiality of those records, and disseminate appropriate information to the public are intended to help ensure that the data held by SDRs is reliable and that the SDRs provide information that contributes to the transparency of the [security-based swap] market while protecting the confidentiality of information provided by market participants."); *see also* Exchange Act section 13(n)(5)(C), 15 U.S.C. 78m(n)(5)(c) (requiring SDRs to maintain security-based swap data)); Exchange Act rules 13n–5(b)(3) and (4) (requiring SDRs to establish, maintain, and enforce policies and procedures reasonably designed to ensure that transaction data and positions are accurate and to maintain the transaction data and positions for specified periods of time).

[176] *See, e.g.*, SDR Proposing Release, 75 FR 77307, 77356, *corrected at* 76 FR 79320 (stating that the "data maintained by an SDR may also assist regulators in (i) preventing market manipulation, fraud, and other market abuses; (ii) performing market surveillance, prudential supervision, and macroprudential (systemic risk) supervision; and (iii) resolving issues and positions after an institution fails," and further stating that "increased transparency on where exposure to risk reside in financial markets . . . will allow regulators to monitor and act before the risks become systemically relevant. Therefore, SDRs will help achieve systemic risk monitoring."); Cross-Border Proposing Release, 78 FR 31186–31187 (discussing benefits of providing relevant foreign authorities with access to data maintained by SDRs).

[177] *Cf.* Cleary Gottlieb comment (Sept. 20, 2011) at 31 (the indemnification requirement "could be a significant impediment to effective regulatory coordination, since non-U.S. regulators may establish parallel requirements for U.S. regulators to access swap data reported in their jurisdictions.").

[178] For example, EU law requires that counterparties to derivatives contracts report the details of the contract to a trade repository, registered or recognized in accordance with EU law, no later than the working day following the conclusion, modification or termination of the contract. *See* EMIR art. 9; *see also* EC Delegated Regulation no. 148/2013 (regulatory technical standards implementing the reporting requirement).

[179] For example, as noted above, market data regarding single-name CDS transactions involving U.S.-domiciled counterparties and/or U.S.-domiciled reference entities indicates that 13 percent of such transactions involve two U.S.-domiciled counterparties, while 48 percent involve a U.S.-domiciled counterparty and a foreign-domiciled counterparty. *See* note 141, *supra*, and accompanying text.

[180] For example, EU law anticipates the possibility that market participants may be able to satisfy their EU reporting obligations by reporting to a trade repository established in a third country, so long as that repository has been recognized by the European Securities and Markets Authority. *See* EMIR art. 77; *see also* Regulation SBSR, rule 908(c) (providing that to the extent that the Commission has issued a substituted compliance order/determination, compliance with Title VII regulatory reporting and public dissemination requirements may be satisfied by compliance with the comparable rules of a foreign jurisdiction).

jurisdiction, their compliance costs may be reduced. Similarly, to the extent that security-based swap data repositories provide additional ancillary services,[181] if market participants choose to make use of such services, they would likely find such services that make use of all of their data held in a single trade repository more useful than services that are applied only to a portion of that market participant's transactions. Ancillary services applied to only a portion of a participant's transactions could result if data were divided across multiple repositories as a result of regulations requiring participants to report data to separate trade repositories in each applicable jurisdiction.

b. Anticipated Costs

The Commission believes that although there are benefits to security-based swap data repositories providing access to relevant authorities to data maintained by the repositories, such access will likely involve certain costs and potential risks. For example, the Commission expects that repositories will maintain data that are proprietary and highly sensitive[182] and that are subject to strict privacy requirements.[183] Extending access to such data to anyone, including relevant authorities, increases the risk that the confidentiality of the data maintained by repositories may not be preserved.[184] A relevant authority's inability to protect the confidentiality of data maintained by repositories could erode market participants' confidence in the integrity of the security-based swap market and increase the overall risks associated with trading.[185] As we discuss below, this may ultimately lead to reduced trading activity and liquidity in the market, hindering price discovery and impeding the capital formation process.[186]

To help mitigate these risks and potential costs to market participants, the Exchange Act and the proposed rules impose certain conditions on relevant authorities' access to data maintained by repositories.[187] In part, the Exchange Act and the proposed rules limit the authorities that may access data maintained by a security-based swap data repository to a specific list of domestic authorities and other persons, including foreign authorities, determined by the Commission to be appropriate,[188] and further require that a repository notify the Commission when the repository receives an authority's initial request for data maintained by the repository.[189] Restricting access to security-based swap data available to relevant authorities should reduce the risk of unauthorized disclosure, misappropriation or misuse of security-based swap data because each relevant authority will only have access to information within its regulatory mandate, or legal responsibility or authority.

The proposed rules further require that, before a repository shares security-based swap information with a relevant authority, there must be an arrangement (in the form of a MOU or otherwise) between the Commission and the relevant authority that addresses the confidentiality of the security-based swap information provided, and under which the relevant authority agrees to indemnify the Commission and the repository for any expenses arising from litigation relating to the information provided.[190] While the proposal also conditionally exempts the relevant authority requesting data from the indemnification requirement, it does so only if the requested information relates to a regulatory mandate or legal responsibility or authority of the entity requesting the data, and there is in effect an arrangement between the Commission and such relevant authority that addresses the confidentiality of the information provided.[191] The arrangement should further reduce the likelihood of confidential trade or position data being inadvertently made public.

Although the statutory indemnification requirement could provide a strong incentive for relevant authorities to take appropriate care in safeguarding data they might receive from a registered SDR, the Commission recognizes the significance of commenter concerns regarding the impact of requiring indemnification,[192] and understands that certain authorities may be unable to agree to indemnify a data repository and the Commission. Therefore, the Commission preliminarily believes that the indemnification requirement could frustrate the purposes of the statutory requirement that repositories make available data to relevant authorities. The Commission preliminarily believes that the proposed approach appropriately balances confidentiality concerns associated with regulatory access with the benefits accruing to security-based swap market participants from increased regulatory transparency.

2. Effects on Efficiency, Competition and Capital Formation

The rules described in this proposal are intended to facilitate access for relevant authorities to data stored in SEC-registered repositories and therefore affect such repositories, but do not directly affect security-based swap market participants. As discussed below, access by relevant authorities to security-based swap data could indirectly affect market participants through the benefits that accrue from the relevant authorities' improved ability to fulfill their regulatory mandate or legal responsibility or authority as well as the potential impact of disclosure of confidential data.

[181] According to one commenter, ancillary services "may include: asset servicing, confirmation, verification and affirmation facilities, collateral management, settlement, trade compression and netting services, valuation, pricing and reconciliation functionalities, position limits management, dispute resolution, counterparty identity verification and others." *See* MarkitSERV comment (Jan. 24, 2011) at 4 (comment in response to SDR Proposing Release).

[182] As the Commission noted in the SDR Proposing Release, such data could include information about a market participant's trades or its trading strategy; it may also include non-public personal information. SDR Proposing Release, 75 FR 77339.

[183] *See* Exchange Act section 13(n)(5)(F), 15 U.S.C. 78m(n)(5)(F) (requiring an SDR to maintain the privacy of security-based swap transaction information); Exchange Act rules 13n–4(b)(8) and 13n–9 (implementing Exchange Act section 13(n)(5)(F)).

[184] *See, e.g.*, ESMA comment (Jam. 17, 2011) at 2 (noting that relevant authorities must ensure the confidentiality of security-based swap data provided to them).

[185] For example, should it become generally known by market participants that a particular dealer had taken a large position in order to facilitate a trade by a customer and was likely to take offsetting positions to reduce its exposure, other market participants may take positions in advance of the dealer attempting to take its offsetting positions. This "front running" of the dealer's trades would likely raise its trading costs. Should the dealer believe that its market exposure may become public before it has the opportunity to hedge, the price quote offered to its customer to establish the original position would reflect the increased hedging cost.

[186] *See* SDR Proposing Release, 75 FR 77307 ("Failure to maintain privacy of [SDR data] could lead to market abuse and subsequent loss of liquidity.").

[187] Exchange Act section 13(n)(5)(G) and (H), 15 U.S.C. 78m(n)(5)(G) and (H); *see also* Exchange Act rules 13n–4(b)(9) (implementing Exchange Act sections 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G)) and (b)(10) (implementing Exchange Act section 13(n)(5)(H), 15 U.S.C. 78m(n)(5)(H)).

[188] As discussed above in part II.A.3(a), the Commission anticipates that such determinations may be conditioned, in part, by specifying the scope of a relevant authority's access to data, and may limit this access to reflect the relevant authority's regulatory mandate, or legal responsibility or authority.

[189] *See* Exchange Act section 13(n)(5)(G), 15 U.S.C. 78m(n)(5)(G); proposed Exchange Act rule 13n–4(b)(9).

[190] *See* Exchange Act section 13(n)(5)(H), 15 U.S.C. 78m(n)(5)(H); proposed Exchange Act rule 13n–4(b)(10).

[191] *See* proposed Exchange Act rule 13n–4(d).

[192] *See* note 13, *supra*.

However, because the Commission preliminarily believes that its rules will condition access to security-based swap data on the agreement of the relevant authorities to protect the confidentiality of the data, the Commission expects these rules to have little effect on the structure or operations of the security-based swap market. Therefore, the Commission preliminarily believes that effects of the proposed rules on efficiency, competition and capital formation will be small.[193] Nevertheless, there are some potential effects, particularly with respect to efficiency and capital formation, which flow from efficient collection and aggregation of security-based swap data. We describe these effects below.

In part VI.B of this release, the Commission describes the baseline used to evaluate the economic impact of the proposed rules, including the impact on efficiency, competition and capital formation. In particular, the Commission noted that the security-based swap data currently available from the DTCC–TIW is the result of a voluntary reporting system and access to that data is made consistent with guidelines published by the ODRF.

Under the voluntary reporting regime, CDS transaction data involving counterparties and reference entities from most jurisdictions is reported to a single entity, the DTCC–TIW. The DTCC–TIW, using the ODRF guidelines, then allows relevant authorities, including the Commission, to obtain data necessary to carry out their respective authorities and responsibilities with respect to OTC derivatives and the regulated entities that use derivatives.[194] As various regulators implement reporting rules within their jurisdictions, counterparties within those jurisdictions may or may not continue to report to the DTCC–TIW. As a result, the ability of the Commission and other relevant authorities to obtain the data required consistent with their regulatory mandate, or legal responsibility or authority, may require the ability to access data held in a trade repository outside of their own jurisdictions. That is, because the market is global and interconnected, effective regulatory monitoring of the security-based swap market may require regulators to have access to information on the global market, particularly during times of market turmoil. The proposed data access rule amendments and indemnification exemption should facilitate access of relevant authorities other than the Commission to security-based swap data held in repositories, and may indirectly facilitate Commission access to data held by trade repositories registered with regulators other than the Commission. To the extent that the proposed data access rules and indemnification exemption facilitate the ability of repositories to collect security-based swap information involving counterparties across multiple jurisdictions, there may be benefits in terms of efficient collection and aggregation of security-based swap data.

To the extent that the proposed data access provisions and the indemnification exemption increase the quantity of transaction and position information available to regulatory authorities about the security-based swap market, the ability of the Commission and other relevant authorities to respond in an appropriate and timely manner to market developments could enhance investor protection through improved detection, and facilitating the investigation of fraud and other market abuses. Moreover, as noted above, we do not anticipate that the proposed rules would directly affect market participants, such enhancements in investor protections may decrease the risks and indirect costs of trading and could therefore encourage greater participation in the security-based swap market for a wider range of entities seeking to engage in a broad range of hedging and trading activities.[195] While we believe that increased participation is a possible outcome of the Commission's transparency initiatives, including these proposed rules, relative to the level of participation in this market if these initiatives were not undertaken, we preliminarily believe that the benefits that flow from improved detection, facilitating the investigation of fraud and other market abuses, and more-efficient data aggregation are the more direct benefits of the rules.

In addition, the improvement in the quantity of data available to regulatory authorities, including the Commission, should improve their ability to monitor concentrations of risk exposures and evaluate risks to financial stability and could promote the overall stability in the capital markets.[196]

Aside from the effects that the proposed data access rules may have on regulatory oversight and market participation, we expect the proposed rules potentially to affect how SDRs are structured. In particular, the proposed data access rules and indemnification exemption could reduce the potential for SDRs to be established along purely jurisdictional lines, with multiple repositories established in different countries or jurisdictions. That is, effective data sharing may reduce the need for repositories to be established along jurisdictional lines, reducing the likelihood that a single security-based swap transaction must be reported to multiple swap-data repositories. As noted previously by the Commission, due to high fixed costs and increasing economies of scale, the total cost of providing trade repository services to the market for security-based swaps may be lower if the total number of repositories is not increased due to a regulatory environment that results in trade repositories being established along jurisdictional lines.[197] To the extent that the proposed rules result in fewer repositories that potentially compete across jurisdictional lines, cost savings realized by fewer repositories operating on a larger scale could result in reduced fees, with the subsequent cost to market participants to comply with reporting requirements being lower.[198]

Furthermore, multiple security-based swap data repositories with duplication of reporting requirements for cross-border transactions increase data fragmentation and data duplication, both of which increase the potential for difficulties in data aggregation. To the extent that the proposed data access rule amendments and indemnification exemption facilitate the establishment of SDRs that accept transactions from multiple jurisdictions, there may be

[193] *See* part VI.C.1b above for a discussion of the potential impact on capital formation of inadequate data confidentiality protections. The Commission preliminarily believes that the proposed approach balances the need for data confidentiality and the need for regulatory transparency.

[194] *See* note 149, *supra*.

[195] Indirect trading costs refer to costs other than direct transaction costs. Front running costs described above provide an example of indirect trading costs. In the context of investor protection, the risk of fraud represents a cost of trading in a market with few investor protections or safeguards.

[196] *See* note 95, *supra*.

[197] *See* SDR Adopting Release, 80 FR 14533 (discussion of high fixed costs and increasing economies of scale in the provision of security-based swap data repository services); *see also* SDR Adopting Release, 80 FR 14479 (discussion of rule 13n–4(c)(1)(i), which requires each SDR to ensure that any dues, fees or other charges that it imposes, and any discounts or rebates that it offers, are fair and reasonable and not unreasonably discriminatory; particularly noting that "[o]ne factor that the Commission has taken into consideration to evaluate the fairness and reasonableness of fees, particularly those of a monopolistic provider of a service, is the cost incurred to provide the service").

[198] Alternatively, fewer repositories could result in those few repositories having the ability to take advantage of the reduced level of competition to charge higher prices.

benefits in terms of efficient collection and aggregation of security-based swap data. As discussed above, to the extent that the indemnification exemption allows relevant authorities to have better access to the data necessary to form a more complete picture of the security-based swap market—including information regarding risk exposures and asset valuations—the exemption should help the Commission and other relevant authorities perform their oversight functions in a more effective manner.

However, while reducing the likelihood of having multiple SDRs established along jurisdictional lines would resolve many of the challenges involved in aggregating security-based swap data, there may be costs associated with having fewer repositories. In particular, the existence of multiple repositories may reduce operational risks, such as the risk that a catastrophic event or the failure of a repository leaves no registered repositories to which transactions can be reported, impeding the ability of the Commission and relevant authorities to obtain information about the security-based swap market.

Finally, as we noted above, a relevant authority's inability to protect the privacy of data maintained by repositories could erode market participants' confidence in the integrity of the security-based swap market. More specifically, confidentiality breaches, including the risk that trading strategies may no longer be anonymous due to a breach, may increase the overall risks associated with trading or decrease the profits realized by certain traders. Increased risks or decreased profits may reduce incentives to participate in the security-based swap markets, which may lead to reduced trading activity and liquidity in the market. Depending on the extent of confidentiality breaches, as well as the extent to which such breaches lead to market exits, disclosures of confidential information could hinder price discovery and impede the capital formation process.[199]

3. Additional Costs and Benefits of Specific Rules

Apart from the general costs and benefits associated with the structure of the Exchange Act data access provisions and proposed implementing rules, certain discrete aspects of the proposed rules and related interpretation raise additional issues related to economic costs and benefits.

a. Benefits

i. Determination of Recipient Authorities

The Commission is proposing an approach to determining whether an authority, other than those expressly identified in the Exchange Act and the implementing rules,[200] should be provided access to data maintained by SDRs. The Commission believes that this proposed approach has the benefit of appropriately limiting relevant authorities' access to data maintained by repositories to protect the confidentiality of the data.[201] The Commission expects that relevant authorities from a number of jurisdictions may seek to obtain a determination by the Commission that they may appropriately have access to repository data. Each of these jurisdictions may have a distinct approach to supervision, regulation or oversight of its financial markets or market participants and to the protection of proprietary and other confidential information. The Commission believes that the proposed factors—which among other things would consider whether an authority has an interest in access to security-based swap data based on the relevant authority's regulatory mandate or legal responsibility or authority, whether there is an MOU or other arrangement between the Commission and the relevant authority that addresses the confidentiality of the security-based swap data provided to the authority, and whether information accessed by the applicable authority would be subject to robust confidentiality safeguards[202]—appropriately condition an authority's ability to access data on the confidentiality protections the authority will afford that data. This focus further would be strengthened by the Commission's ability to revoke its determination where necessary, including, for example, if a relevant authority fails to keep such data confidential.[203] This approach should increase market participants' confidence that their confidential trade data will be protected, reducing perceived risks of transacting in security-based swaps.

The Commission also believes that its proposed approach in determining the appropriate relevant authorities would reduce the potential for fragmentation and duplication of security-based swap data among trade repositories by facilitating mutual access to the data. Narrower approaches such as allowing regulatory access to security-based swap data only to those entities specifically identified in the Exchange Act[204] may increase fragmentation and duplication, and hence increase the difficulty in consolidating and interpreting security-based swap market data from repositories, potentially reducing the general economic benefits discussed above.

Furthermore, the Commission believes that its proposed approach in conditioning access to security-based swap data held in SDRs by requiring there to be in effect an arrangement between the Commission and the authority in the form of a MOU would promote the intended benefits of access by relevant authorities to data maintained by SDRs. Under the proposed approach, rather than requiring regulatory authorities to negotiate confidentiality agreements with multiple SDRs, a single MOU between the Commission and the relevant authority can serve as the confidentiality agreement that will satisfy the requirement for a written agreement stating that the relevant authority will abide by the confidentiality requirements described in section 24 of the Exchange Act relating to the security-based swap data. The Commission routinely negotiates MOUs or other arrangements with relevant authorities to secure mutual assistance or for other purposes, and the Commission preliminarily believes that the proposed approach is generally consistent with this practice.

The Commission further preliminarily believes that negotiating a single such agreement with the Commission will be less costly for the authority requesting data than negotiating directly with each registered SDR and eliminate the need for each SDR to negotiate as many as 200 confidentiality agreements with requesting authorities. This approach would also avoid the difficulties that may be expected to accompany an approach that requires SDRs to enter into confidentiality agreements—particularly questions regarding the parameters of an adequate confidentiality agreement, and the presence of uneven and potentially inconsistent confidentiality protections across SDRs and recipient entities.

[199] *See* SDR Proposing Release, 75 FR 77307 ("Failure to maintain privacy of [SDR data] could lead to market abuse and subsequent loss of liquidity.").

[200] *See* part II.A for a discussion of specific authorities included in the implementing rules.

[201] *See* ESMA comment (Jan. 17, 2011) at 2 (noting that relevant authorities must ensure the confidentiality of security-based swap data provided to them).

[202] *See* part II.A.3.a, *supra*.

[203] *See* part II.A.4, *supra*.

[204] *See* Exchange Act section 3(a)(74), 15 U.S.C. 78c(a)(74).

ii. Notification Requirement

The Commission is proposing an approach by which SDRs may satisfy the notification requirement by notifying the Commission upon the initial request for security-based swap data by a relevant authority and maintaining records of the initial request and all subsequent requests.[205] The Commission estimates that approximately 300 relevant authorities may make requests for data from security-based swap data repositories.[206] Based on the Commission's experience in making requests for security-based swap data from trade repositories, the Commission estimates that each relevant authority will access security-based swap data held in SDRs using electronic access. Such access may be to satisfy a narrow request concerning a specific counterparty or reference entity or security, to create a summary statistic of trading activity or outstanding notional, or to satisfy a large request for detailed transaction and position data. Requests may occur as seldom as once per month if the relevant authority is downloading all data to which it has access in order to analyze it on its own systems, or may occur 100 or more times per month if multiple staff of the relevant authority are making specific electronic requests concerning particular counterparties or reference entities and associated positions or transactions. Therefore, under the Commission's proposed approach to notification requirement compliance, the Commission estimates based on staff experience that each repository would provide the Commission with actual notice as many as 300 times, and that repositories cumulatively would maintain records of as many as 360,000 subsequent data requests per year.[207] The proposed rule would be expected to permit repositories to respond to requests for data by relevant authorities more promptly and at lower cost than if notification was required for each request for data access, while helping to preserve the Commission's ability to monitor whether the repository provides data to each relevant entity consistent with the applicable conditions.

The Commission's proposed rule would also simplify relevant authorities' direct access to security-based swap data needed in connection with their regulatory mandate or legal responsibility or authority, because repositories would not be required to provide the Commission with actual notice of every request prior to providing access to the requesting relevant authority.

iii. Use of Confidentiality Agreements Between the Commission and Recipient Authorities

The proposed rules in part would condition regulatory access on there being an arrangement between the Commission and the recipient entity, in the form of an MOU or otherwise, addressing the confidentiality of the security-based swap information made available to the recipient. The proposed rules add that those arrangements shall be deemed to satisfy the statutory requirement for a written confidentiality agreement.[208]

As discussed above, the Commission preliminarily believes that this approach reflects an appropriate way to satisfy the interests associated with the confidentiality condition. The benefits associated with this approach include obviating the need for repositories to negotiate and enter into multiple confidentiality agreements, avoiding difficulties regarding the parameters of an adequate confidentiality agreement, and avoiding uneven and potentially inconsistent confidentiality protections. The proposed approach also would build upon the Commission's experience in negotiating such agreements.[209]

iv. Indemnification Exemption

The Commission also is proposing a conditional indemnification exemption, recognizing that application of the indemnification requirement could prevent some relevant domestic and foreign authorities from obtaining security-based swap information from repositories, because they cannot provide an indemnification agreement.[210] Effectively prohibiting some authorities other than the Commission from obtaining access to security-based swap data maintained by repositories potentially would greatly reduce the market transparency to regulators provided by Title VII.[211] Moreover, although relevant authorities could obtain security-based swap data from the Commission,[212] repositories are likely to have systems in place and expertise that allows them to provide such data to relevant authorities quickly, and economic incentives to minimize their own cost of providing data.

The Commission also preliminarily believes that the absence of an exemption to the indemnification requirement could increase the likelihood that foreign authorities would require duplicate reporting of cross-border transactions to repositories within the foreign jurisdiction. To the extent that relevant foreign authorities are effectively restricted in obtaining data maintained by SEC-registered repositories, the Commission's own ability to access security-based swap data may similarly be restricted.[213] More generally, the resulting restrictions on regulatory access may likely lead to duplication and fragmentation of security-based swap data among trade repositories in multiple jurisdictions, which may increase other costs that relevant authorities may incur, including, for example, the difficulty of aggregating data across multiple repositories.[214]

The Commission preliminarily believes that the proposed indemnification exemption further would be beneficial by mitigating the risks associated with permitting relevant

[205] *See* proposed Exchange Act rule 13n–4(e).

[206] *See* proposed Exchange Act rule 13n–4(b)(9)(i)–(v) for a list of prudential regulators that may request data maintained by SDRs from SDRs. The Exchange Act also states that FSOC, the CFTC, and the Department of Justice may access security-based swap data. *See* parts II.A.1, 2, *supra*. The Commission also expects that certain self-regulatory organizations and registered futures associations may request security-based swap data from repositories. Therefore, the Commission estimates that up to approximately 30 relevant authorities in the United States may seek to access security-based swap data from repositories. The Commission preliminarily believes that most requests will come from authorities in G20 countries, and estimates that each of the G20 countries will also have no more and likely fewer than 30 relevant authorities that may request data from SDRs. Certain authorities from outside the G20 also may request data. Accounting for all of those entities, the Commission estimates that there will likely be a total of no more than 300 relevant domestic and foreign authorities that may request security-based swap data from repositories.

[207] The annual estimate of 360,000 is calculated based on 300 recipient entities each making 100 requests per month cumulatively across all repositories. The estimate of 100 requests per authority is based on staff experience with similar data requests in other contexts.

[208] *See* proposed Exchange Act rule 13n–4(10)(i).

[209] *See* part II.B.1, *supra*.

[210] *See* part III.A, *supra*.

[211] *See* Proposing Release, 75 FR 77307 (describing expected benefits of SDRs, including the market transparency benefits of access by regulators); *id.* at 77356 ("The ability of the Commission and other regulators to monitor risk and detect fraudulent activity depends on having access to market data."); *see also* part VI.B.1 of this release discussing transparency in the security-based swap market.

[212] *See* part IV.B, *supra* (discussing information sharing under Exchange Act sections 21 and 24); *see also* Proposing Release, 75 FR 77319.

[213] *See* note 94, *supra*, and accompanying text.

[214] *See* Proposing Release, 75 FR 77358. The costs associated with aggregating the data of multiple repositories would likely be significantly higher under the circumstances described here, as different jurisdictions might impose different requirements regarding how data is to be reported and maintained.

authorities to obtain access to data maintained by repositories. The exemption would be available only for requests that are consistent with each requesting authority's regulatory mandate, or legal responsibility or authority. The Commission preliminarily believes that these conditions would significantly reduce the confidentiality concerns relating to relevant authorities' access to data maintained by repositories.[215] Limiting an authority's access to data to that relating to its mandate, or legal responsibility or authority would reduce the opportunity for improper disclosure of the data in part because such limits reduce the quantity of data that is subject to potential improper disclosure, and because an authority is likely to be familiar with the need to maintain the confidentiality of data that relates to its mandate or legal responsibility or authority. Further, the Commission will have an opportunity to evaluate the confidentiality protections provided by the relevant authority in the context of negotiations of an MOU or other arrangement.[216] Should the Commission believe the relevant authority has failed to comply with the confidentiality provisions of the MOU, it may terminate access by revoking a determination by the Commission that the relevant entity was appropriate, or by terminating the MOU or other arrangement used to satisfy the confidentiality condition, or, as applicable, the indemnification exemption.[217]

b. Costs

The Commission recognizes that the proposed approach to providing access to relevant authorities other than the Commission to security-based swap data held in repositories has the potential to involve certain costs and risks.

The relevant authorities requesting securities-based swap data would incur some costs in seeking a Commission order deeming the authority appropriate to receive security-based swap data. These costs would include the negotiation of an MOU to address the confidentiality of the security-based swap information it seeks to obtain and providing information to justify that the security-based swap data relates to the entity's regulatory mandate or legal responsibility or authority. As discussed above, the Commission estimates that up to 300 entities potentially might enter into such MOUs or other arrangements.[218] Based on the Commission staff's experience in negotiating MOUs that address regulatory cooperation, the Commission preliminarily estimates the cost to each relevant authority requesting data associated with negotiating such an arrangement of approximately $205,000 per entity for a total of $61,500,000.[219]

In addition, authorities that are not specified by the proposed rule may request that that the Commission determine them to be appropriate to receive access to such security-based swap data. Given the relevant information that the Commission preliminarily would consider in connection with such designations (apart from the MOU issues addressed above)—including information regarding how the authority would be expected to use the information, information regarding the authority's regulatory mandate or legal responsibility or authority, and information regarding reciprocal access—the Commission preliminarily estimates the cost associated with such a request to be approximately $15,200 per requesting entity for a total of $4,560,000.[220]

Security-based swap data repositories would incur some costs to verify that an entity requesting data entered into the requisite agreements concerning confidentiality with the Commission, and that the entity either has agreed to indemnify the Commission and the repository, or that the indemnification exemption applies. The Commission generally expects that such verification costs would be minimal because information regarding such Commission arrangements would generally be readily available.[221]

To the extent that the security-based swap data repository provides the requested data through direct electronic means, the repository may incur some cost in providing the requesting authority access to the system that provides such access and setting data permissions to allow access only to the information that relates to the authority's regulatory mandate, or legal responsibility or authority. The Commission preliminarily believes most of the costs associated with providing such access would be the fixed costs incurred in designing and building the systems to provide the direct electronic access required by the recently adopted SDR rules.[222] The Commission preliminarily believes the marginal cost of providing access to an additional relevant authority and setting the associated permissions is approximately $6,295.[223] Based on an estimated 300 entities requesting access to each of ten registered SDRs, we estimate the total cost of connecting entities to SDRs to be approximately $18,885,000.

The Commission further recognizes that the conditions in the proposed indemnification exemption would not necessarily provide repositories and the Commission with the same level of confidentiality-related protection that an indemnification agreement would provide (*i.e.*, coverage for any expenses

[215] *See, e.g.*, ESMA comment (Jan. 17, 2011) at 2 (noting that relevant authorities must ensure the confidentiality of security-based swap data provided to them).

[216] For the indemnification exemption to apply to the requests of a particular requesting authority, the authority would be required to enter into an MOU or other arrangement with the Commission, which would enable the Commission to determine, prior to operation of the indemnification exemption, that the authority has a regulatory mandate, or legal responsibility or authority to access data maintained by SDRs, that the authority agrees to protect the confidentiality of any security-based swap information provided to it and that the authority will provide reciprocal assistance in securities matters within the Commission's jurisdiction. *See* part III, *supra* (discussing the proposed indemnification exemption).

[217] *See* part II.A.3, *supra*.

[218] *See* part VI.C.3.a.ii, *supra*.

[219] These figures are based on 300 entities each requiring 500 personnel hours on average to negotiate an MOU. *See* part V.D.1.a, *supra*. The cost per entity is 400 hours × attorney at $380 per hour + 100 hours × deputy general counsel at $530 per hour = $205,000, or a total of $61,500,000. We use salary figures from SIFMA's Management & Professional Earnings in the Securities Industry 2013, modified by SEC staff to account for a 1800-hour year-week and multiplied by 5.35 to account for bonuses, firm size, employee benefits and overhead.

[220] These figures are based on roughly 300 entities (noting that certain entities designated by statute or rule would not need to prepare such requests) requiring 40 personnel hours to prepare a request for access. *See* part V.D.1.b, *supra*. The cost per entity is 40 hours × attorney at $380 per hour = $15,200, or a total of $4,560,000. We use salary figures from SIFMA's Management & Professional Earnings in the Securities Industry 2013, modified by SEC staff to account for a 1800-hour year-week and multiplied by 5.35 to account for bonuses, firm size, employee benefits and overhead.

[221] As a general matter, the Commission provides a list of MOUs and other arrangements on its public Web site, which are available at: *http://www.sec.gov/about/offices/oia/oia_cooparrangements.shtml*.

[222] *See* SDR Adopting Release, 80 FR 14523 (estimating the aggregate one-time systems costs for ten respondents to be 420,000 hours and $10 million, and estimating the aggregate ongoing systems costs as being 252,000 hours and $60 million); *see also* part IV.D.1.c, *supra*.

[223] This figure is based on the view that, for each recipient requesting data, a repository would incur an 25 hour burden associated with programming or otherwise inputting the relevant parameters, encompassing 20 hours of programmer analyst time and five hours of senior programmer time. The estimate also encompasses one hour of attorney time in connection with each such recipient. *See* part V.D.1.c, *supra*. The cost per entity is 20 hours × programmer analyst at $220 per hour + 5 hours × senior programmer at $303 per hour + 1 hour × attorney at $380 per hour = $6,295, We use salary figures from SIFMA's Management & Professional Earnings in the Securities Industry 2013, modified by SEC staff to account for a 1800-hour year-week and multiplied by 5.35 to account for bonuses, firm size, employee benefits and overhead.

arising from litigation relating to information provided to a relevant authority). The Commission preliminarily believes, however, that the conditions in the proposed indemnification exemption, related to the need for a confidentiality arrangement and requiring that the information provided relate to a regulatory mandate, or legal responsibility or authority of the recipient entity, would provide appropriate protection of the confidentiality of data maintained by SDRs, albeit one that is different from the protection provided by an indemnification agreement that addresses potential costs of litigation associated with the data provided to it by the SDR.

In addition, under the Commission's proposed notification compliance rule, SDRs would be required to notify the Commission of the initial request for data but would not have to inform the Commission of all relevant authorities' requests for data prior to a SDR fulfilling such requests. Based on the estimate that approximately 300 relevant authorities may make requests for data from security-based swap data repositories, the Commission estimates that a repository would provide the Commission with actual notice approximately 300 times.[224] Moreover, based on the estimate that ten persons may register with the Commission as SDRs,[225] this suggests that repositories in the aggregate would provide the Commission with actual notice up to a total of 3,000 times. The Commission preliminarily estimates that the total of providing such notice to be $57,000 per SDR for a total of $570,000.[226]

Pursuant to rule, SDRs would be required to maintain records of subsequent requests.[227] Not receiving actual notice of all requests may impact the Commission's ability to track such requests, but the Commission preliminarily believes that the benefits of receiving actual notice of each request would not justify the additional costs that repositories would incur in providing such notices and the potential delay in relevant authorities receiving data that they need to fulfill their regulatory mandate, or legal responsibility or authority. At the same time, providing notice of initial requests will help to preserve the Commission's ability to monitor whether the repository provides data to each relevant entity consistent with the applicable conditions. As discussed above, the Commission preliminarily estimates that the average initial paperwork burden associated with maintaining certain records related to data requests or access would be roughly 360 hours, and that the annualized burden would be roughly 280 hours and $120,000 for each repository.[228] Assuming a maximum of ten security-based swap data repositories, the estimated aggregate one-time dollar cost would be roughly $1 million,[229] and the estimated aggregate annualized dollar cost would be roughly $1.2 million.[230]

D. Alternatives

The Commission considered a number of alternative approaches to implementing the Exchange Act data access provisions, including the indemnification requirement, but, for the reasons discussed below, is not proposing them.

1. No Indemnification Exemption

The Commission considered not proposing any exemptive relief from the indemnification requirement. As discussed above, application of the indemnification requirement may prevent some relevant authorities from accessing security-based swap data directly from repositories registered with the Commission.[231] Although relevant authorities could obtain such data from the Commission,[232] that alternative would be expected to be associated with delays and higher costs, particularly during periods of market stress and particularly since repositories are likely to have expertise in providing such data to relevant authorities and economic incentives for doing so efficiently.[233]

To the extent that relevant foreign authorities are effectively restricted in obtaining data maintained by SEC-registered repositories, the Commission's own ability to access security-based swap data may similarly be restricted.[234] More generally, the resulting restrictions on regulatory access may likely lead to duplication and fragmentation of security-based swap data among trade repositories in multiple jurisdictions, which may increase other costs that relevant authorities may incur, including, for example, the difficulty of aggregating data across multiple repositories.[235]

2. Repository Option To Waive Indemnification

The Commission also considered whether to adopt the approach set forth in the Cross-Border Proposing Release, to allow the SDR the option to waive the indemnification requirement.[236] As discussed above, however, the Commission preliminarily believes that the proposed approach would more effectively address the relevant concerns associated with implementing the indemnification provision.[237] Also, requiring each repository to elect whether to waive the indemnification requirement for each requesting entity would likely impose additional costs on repositories and may result in inconsistent treatment of data requests across repositories.

3. Additional Conditions to Indemnification Requirement or Proposed Indemnification Exemption

The Commission also considered whether to prescribe additional conditions or limitations to the indemnification requirement or the proposed indemnification exemption. In part, the Commission considered one commenter's suggestion that the Commission provide model indemnification language in connection with the indemnification requirement,

[224] *See* part VI.C.3.ii, *supra*.

[225] *See* note 117, *supra*, and accompanying text

[226] These figures are based each of ten SDRs providing notice for each of 300 requesting entities. *See* part V.D.1.d, *supra*. The cost per SDR is 300 requesting entities × 0.5 hours × attorney at $380 per hour = $57,000, or a total of $570,000. We use salary figures from SIFMA's Management & Professional Earnings in the Securities Industry 2013, modified by SEC staff to account for a 1800-hour year-week and multiplied by 5.35 to account for bonuses, firm size, employee benefits and overhead.

[227] *See* part V.D.1.d, *supra*. As noted above, existing rules require SDRs to maintain copies of all documents they make or receive in their course of business, including electronic documents. *See* note 77, *supra*.

[228] *See* part V.D.1.d, *supra*.

[229] The Commission preliminarily anticipates that a repository would assign the associated responsibilities primarily to a compliance manager and a senior systems analyst. The total estimated dollar cost would be roughly $100,000 per repository, reflecting the cost of a compliance manager at $283 per hour for 300 hours, and a senior systems analyst at $260 per hour for 60 hours. Across the estimated ten repositories, this would amount to roughly $1 million.

[230] The Commission preliminarily anticipates that a repository would assign the associated responsibilities primarily to a compliance manager. The total estimated dollar cost would be roughly $120,000 per repository, reflecting $40,000 annualized information technology costs, as well as a compliance manager at $283 per hour for 280 hours. Across the estimated ten repositories, this would amount to roughly $1.2 million.

[231] *See, e.g.*, DTCC comment (Nov. 15, 2010) at 3 (discussing how the indemnification requirement would result in the reduction of information accessible to regulators on a timely basis and would greatly diminish regulators' ability to carry out oversight functions).

[232] *See* part IV.B, *supra*, discussing information sharing under Exchange Act sections 21 and 24; *see also* SDR Proposing Release, 75 FR 77319.

[233] *See* part VI.C.3.a.iv, *supra*.

[234] *See* note 94, *supra*, and accompanying text.

[235] *See* note 214, *supra*.

[236] *See* note 91, *supra*, and accompanying text.

[237] *See* part III.A, *supra*.

but concluded preliminarily that the benefits of such model language are largely mitigated by an indemnification exemption that would condition the indemnification exemption upon there being in effect one or more arrangements (in the form of an MOU or otherwise) between the Commission and the entity that addresses the confidentiality of the security-based swap information provided and other matters as determined by the Commission.[238]

4. Use of Confidentiality Arrangements Directly Between Repositories and Recipients

The Commission considered the alternative approach of permitting confidentiality agreement between SDRs and the recipient of the information to satisfy the confidentiality condition to the data access requirement. The Commission preliminarily believes, however, that the proposed approach, which would make use of confidentiality arrangements between the Commission and the recipients of the data, would avoid difficulties such as questions regarding the parameters of the confidentiality agreement, and the presence of uneven and inconsistent confidentiality protections.[239] This also would avoid the need for SDRs to potentially negotiate and enter into dozens of confidentiality agreements, instead such costs would be borne by the Commission.

6. Notice of Individual Requests for Data Access

Finally, the Commission considered requiring repositories to provide notice to the Commission of all requests for data prior to repositories fulfilling such requests, rather than the proposed approach of requiring such notice only of the first request from a particular recipient, with the repository maintaining records of all subsequent requests.[240] The Commission preliminarily believes that the benefits of receiving actual notice for each and every request would not justify the additional costs that would be imposed on repositories to provide such notice, and providing notice of subsequent requests may not be feasible if data is provided by direct electronic access.

E. Comments on the Economic Analysis

The Commission requests comment on all aspects of this economic analysis. Commenters particularly are requested to address whether there are other costs or benefits—not addressed above—that the Commission should take into account when adopting final rules. Commenters also are requested to address whether the Commission has appropriately weighed the costs and benefits of the potential alternative approaches addressed above, and whether there are other potential alternative approaches that the Commission should assess.

VII. Consideration of Impact on the Economy

For purposes of the Small Business Regulatory Enforcement Fairness Act of 1996 ("SBREFA")[241] the Commission must advise OMB whether the proposed regulation constitutes a "major" rule. Under SBREFA, a rule is considered "major" where, if adopted, it results or is likely to result in: (1) An annual effect on the economy of $100 million or more; (2) a major increase in costs or prices for consumers or individual industries; or (3) significant adverse effect on competition, investment or innovation.

The Commission requests comment on the potential impact of the proposed rules and amendments on the economy on an annual basis. Commenters are requested to provide empirical data and other factual support for their views to the extent possible.

VIII. Regulatory Flexibility Act Certification

Section 3(a) of the Regulatory Flexibility Act of 1980 ("RFA")[242] requires the Commission to undertake an initial regulatory flexibility analysis of the proposed rules on "small entities." Section 605(b) of the RFA[243] provides that this requirement shall not apply to any proposed rule or proposed rule amendment which, if adopted, would not have a significant economic impact on a substantial number of small entities. Pursuant to 5 U.S.C. 605(b), the Commission hereby certifies that the proposed rules would not, if adopted, have a significant economic impact on a substantial number of small entities. In developing these proposed rules, the Commission has considered their potential impact on small entities. For purposes of Commission rulemaking in connection with the RFA, a small entity includes: (1) When used with reference to an "issuer" or a "person," other than an investment company, an "issuer" or "person" that, on the last day of its most recent fiscal year, had total assets of $5 million or less;[244] or (2) a broker-dealer with total capital (net worth plus subordinated liabilities) of less than $500,000 on the date in the prior fiscal year as of which its audited financial statements were prepared pursuant to Rule 17a–5(d) under the Exchange Act,[245] or, if not required to file such statements, a broker-dealer with total capital (net worth plus subordinated liabilities) of less than $500,000 on the last day of the preceding fiscal year (or in the time that it has been in business, if shorter); and is not affiliated with any person (other than a natural person) that is not a small business or small organization.[246]

In initially proposing rules regarding the registration process, duties and core principles applicable to SDRs, the Commission stated that it preliminarily did not believe that any persons that would register as repositories would be considered small entities.[247] The Commission further stated that it preliminarily believed that most, if not all, SDRs would be part of large business entities with assets in excess of $5 million and total capital in excess of $500,000, and, as a result, the Commission certified that the proposed rules would not have a significant impact on a substantial number of small entities and requested comments on this certification.[248] The Commission reiterated that conclusion earlier this year in adopting final rules generally addressing repository registration, duties and core principles.[249]

The Commission continues to hold the view that any persons that would register as SDRs would not be considered small entities. Accordingly, the Commission certifies that the proposed rules—related to regulatory access to data held by SDRs and providing a conditional exemption from

[238] *See* note 98, *supra*.

[239] *See* part II.B.1, *supra*.

[240] *See* part II.A.4, *supra*.

[241] Public Law 104–121, Title II, 110 Stat. 857 (1996) (codified in various sections of 5 U.S.C., 15 U.S.C. and as a note to 5 U.S.C. 601).

[242] 5 U.S.C. 603(a).

[243] 5 U.S.C. 605(b).

[244] *See* 17 CFR 240.0–10(a).

[245] 17 CFR 240.17a–5(d).

[246] *See* 17 CFR 240.0–10(c).

For purposes of the Regulatory Flexibility Act, the definition of "small entity" also encompasses "small governmental jurisdictions," which in relevant part means governments of locales with a population of less than fifty thousand. 5 U.S.C. 601(5), (6). Although the Commission anticipates that this proposal may be expected to have an economic impact on various governmental entities that access data pursuant to Dodd-Frank's data access provisions, the Commission does not anticipate that any of those governmental entities would be small entities.

[247] *See* 75 FR 77365.

[248] *See id.* (basing the conclusions on review of public sources of financial information about the current repositories that are providing services in the OTC derivatives market).

[249] *See* SDR Adopting Release, 80 FR 14549 (noting that the Commission did not receive any comments that specifically addressed whether the applicable rules would have a significant economic impact on small entities).

the associated indemnification requirement—would not have a significant economic impact on a substantial number of small entities for purposes of the RFA. The Commission encourages written comments regarding this certification. The Commission solicits comment as to whether the proposed rules could have an effect on small entities that has not been considered. The Commission requests that commenters describe the nature of any impact on small entities and provide empirical data to support the extent of such impact.

Statutory Basis and Text of Proposed Rules

Pursuant to the Exchange Act, and particularly sections 3(b), 13(n), 23(a) and 36 thereof, 15 U.S.C. 78c(b), 78m(n), 78w(a) and 78mm, the Commission is proposing to amend rule 13n–4 by adding paragraphs (b)(9), (b)(10), (d) and (e) to that rule.

List of Subjects in 17 CFR Part 240

Confidential business information, Reporting and recordkeeping requirements, Securities.

Text of Proposed Rules

For the reasons stated in the preamble, the Commission is proposing to amend Title 17, Chapter II, of the Code of Federal Regulations as follows:

PART 240—GENERAL RULES AND REGULATIONS, SECURITIES EXCHANGE ACT OF 1934

■ 1. The authority citation for part 240 continues to read, in part, as follows:

Authority: 15 U.S.C. 77c, 77d, 77g, 77j, 77s, 77z–2, 77z–3, 77eee, 77ggg, 77nnn, 77sss, 77ttt, 78c, 78c–3, 78c–5, 78d, 78e, 78f, 78g, 78i, 78j, 78j–1, 78k, 78k–1, 78*l*, 78m, 78n, 78n–1, 78*o*, 78*o*–4, 78*o*–10, 78p, 78q, 78q–1, 78s, 78u–5, 78w, 78x, 78*ll*, 78mm, 80a–20, 80a–23, 80a–29, 80a–37, 80b–3, 80b–4, 80b–11, 7201 *et seq.*, and 8302; 7 U.S.C. 2(c)(2)(E); 12 U.S.C. 5221(e)(3); 18 U.S.C. 1350; and Pub. L. 111–203, 939A, 124 Stat. 1376 (2010), unless otherwise noted.

* * * * *

■ 2. In § 240.13n–4, amend paragraph (b)(8) by removing the word "and" at the end of the paragraph and adding paragraphs (b)(9), (b)(10), (d), and (e).

The additions read as follows:

§ 240.13n–4 Duties and core principles of security-based swap data repository.

* * * * *

(b) * * *

(9) On a confidential basis, pursuant to section 24 of the Act (15 U.S.C. 78x), upon request, and after notifying the Commission of the request in a manner consistent with paragraph (e) of this section, make available security-based swap data obtained by the security-based swap data repository, including individual counterparty trade and position data, to the following:

(i) The Board of Governors of the Federal Reserve System and any Federal Reserve Bank;

(ii) The Office of the Comptroller of the Currency;

(iii) The Federal Deposit Insurance Corporation;

(iv) The Farm Credit Administration;

(v) The Federal Housing Finance Agency;

(vi) The Financial Stability Oversight Council;

(vii) The Commodity Futures Trading Commission;

(viii) The Department of Justice;

(ix) The Office of Financial Research; and

(x) Any other person that the Commission determines to be appropriate, conditionally or unconditionally, by order, including, but not limited to—

(A) Foreign financial supervisors (including foreign futures authorities);

(B) Foreign central banks; and

(C) Foreign ministries;

(10) Before sharing information with any entity described in paragraph (b)(9) of this section, there shall be in effect an arrangement between the Commission and the entity (in the form of a memorandum of understanding or otherwise) to address the confidentiality of the security-based swap information made available to the entity; this arrangement shall be deemed to satisfy the requirement, set forth in section 13(n)(5)(H)(i) of the Act (15 U.S.C. 78m(n)(5)(H)(i)), that the security-based swap data repository receive a written agreement from the entity stating that the entity shall abide by the confidentiality requirements described in section 24 of the Act (15 U.S.C. 78x) relating to the information on security-based swap transactions that is provided; and

* * * * *

(d) *Exemption from the indemnification requirement.* The indemnification requirement set forth in section 13(n)(5)(H)(ii) of the Act (15 U.S.C. 78m(n)(5)(H)(ii)) shall not be applicable to an entity described in paragraph (b)(9) of this section with respect to disclosure of security-based swap information by the security-based swap data repository to such entity if:

(1) Such information relates to persons or activities within the entity's regulatory mandate, or legal responsibility or authority; and

(2) There is in effect one or more arrangements (in the form of memoranda of understanding or otherwise) between the Commission and such entity that:

(i) Address the confidentiality of the security-based swap information provided and any other matters as determined by the Commission; and

(ii) Specify the types of security-based swap information that would relate to persons or activities within the entity's regulatory mandate, legal responsibility or authority for purposes of paragraph (d)(1) of this section.

(e) *Notification requirement compliance.* To satisfy the notification requirement of the data access provisions of paragraph (b)(9) of this section, a security-based swap data repository shall inform the Commission upon its receipt of the first request for security-based swap data from a particular entity (which may include any request to be provided ongoing online or electronic access to the data), and the repository shall maintain records of all information related to the initial and all subsequent requests for data access from that entity, including records of all instances of online or electronic access, and records of all data provided in connection with such requests or access.

* * * * *

By the Commission.

Dated: September 4, 2015.

Brent J. Fields,

Secretary.

Title 3—

The President

Proclamation 9317 of September 9, 2015

World Suicide Prevention Day, 2015

By the President of the United States of America

A Proclamation

All people deserve the opportunity to live healthy, rewarding lives. No American should have their potential limited, have their life cut short, or be deprived of their fullest measure of happiness because they do not have the mental health support they need. On World Suicide Prevention Day, we reaffirm our belief that mental health is an essential part of overall health, and together, we renew our commitment to supporting and empowering all Americans to seek the care they need.

Suicide is often related to serious depression, substance use disorders, and other mental health conditions. That is why recognizing severe psychological distress and ensuring access to the care and services needed to diagnose and treat mental illness are crucial to our efforts to prevent suicide. Individuals can also experience emotional and mental health crises in response to a wide range of situations—from difficulties in personal relationships to the loss of a job to bullying at school. And for some of our Nation's veterans and military service members, these challenges are compounded by the invisible wounds of war. Tragically, these crises can sometimes involve thoughts of suicide—and we must do more to support those suffering.

All Americans can take part in promoting mental well-being and preventing suicide. Everyone can contribute to a culture where individuals are supported and accepted for who they are—no matter what they look like, who they love, or what challenges they face—and where it is okay to ask for help.

We can do more to recognize the signs of mental health issues early and encourage those in need to reach out for support. And we must remind our loved ones that seeking treatment is not a sign of weakness; it is a sign of strength. If you or someone you know is in need of help, the National Suicide Prevention Lifeline offers immediate assistance for all Americans at 1–800–273–TALK. Veterans, service members, and their loved ones can call this number to reach the Veterans Crisis Line, and they can also send a text message to 838255.

The Affordable Care Act extends mental health and substance use disorder benefits and parity protections to over 60 million Americans, helping men and women across our country access critical care. Protections under the health care law prohibit insurers from denying coverage because of pre-existing conditions, like a diagnosis of mental illness, and require most insurance plans to cover recommended preventive services without copays, including behavioral assessments for children and depression screenings.

In February, I was proud to sign the Clay Hunt Suicide Prevention for American Veterans Act to help fill serious gaps in serving veterans with post-traumatic stress and other illnesses. This law builds upon our ongoing efforts to end the tragedy of suicide among our troops and veterans. Last year, I announced 19 Executive actions to make it easier for service members and veterans to access the care they need when they need it, and our Government has focused additional resources on mental health services, including increasing the number of mental health providers at the Department of Veterans Affairs.

My Administration is also committed to doing all we can to empower those facing challenges and hardship. We are dedicated to combating bullying, harassment, and discrimination in our schools and communities. We are doing more to guarantee all veterans and members of our Armed Forces—as well as their families—get the help they deserve while they are serving our Nation, as they transition to civilian life, and long after they have returned home. And across the Federal Government, we are working to ensure all Americans are supported in times of crisis.

Suicide prevention is the responsibility of all people. One small act—the decision to reach out to your neighbor, offer support to a friend, or encourage a veteran in need to seek help—can make a difference. It can help energize a national conversation and a changing attitude across America. If you are hurting, know this: You are not forgotten. You are never alone. Your country is here for you, and help is available. As we pause to raise awareness of the importance of suicide prevention, let us remember all those we have lost and the loved ones they left behind. As one people, we stand with all who struggle with mental illness, and we continue our work to prevent this heartbreak in our communities.

NOW, THEREFORE, I, BARACK OBAMA, President of the United States of America, by virtue of the authority vested in me by the Constitution and the laws of the United States, do hereby proclaim September 10, 2015, as World Suicide Prevention Day. I call upon citizens, government agencies, organizations, health care providers, and research institutions to raise awareness of the mental health resources and support services available in their communities and encourage all those in need to seek the care and treatment necessary for a long and healthy life.

IN WITNESS WHEREOF, I have hereunto set my hand this ninth day of September, in the year of our Lord two thousand fifteen, and of the Independence of the United States of America the two hundred and fortieth.

LIST OF PUBLIC LAWS

Note: No public bills which have become law were received by the Office of the Federal Register for inclusion in today's **List of Public Laws.**

Last List August 11, 2015

Public Laws Electronic Notification Service (PENS)

PENS is a free electronic mail notification service of newly enacted public laws. To subscribe, go to *http://listserv.gsa.gov/archives/publaws-l.html*

Note: This service is strictly for E-mail notification of new laws. The text of laws is not available through this service. **PENS** cannot respond to specific inquiries sent to this address.

service-connected disability, the Director of the Compensation Service or his or her delegatee, upon field station submission, is authorized to approve on the basis of the criteria set forth in this paragraph (b), an extra-schedular evaluation commensurate with the actual impairment of earning capacity due exclusively to the referred disability. The governing norm in these exceptional cases is a finding by the Director of the Compensation Service or delegatee that application of the regular schedular standards is impractical because the referred disability is so exceptional or unusual due to such related factors as marked interference with employment or frequent periods of hospitalization.

Air Plan Approval; Vermont; Stage I Vapor Recovery Requirements

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The Environmental Protection Agency (EPA) is proposing to approve a State Implementation Plan (SIP) revision submitted by the State of Vermont. This revision includes regulatory amendments that clarify Stage I vapor recovery requirements at gasoline dispensing facilities (GDFs). The intended effect of this action is to approve Vermont's revised Stage I vapor recovery regulations. This action is being taken in accordance with the Clean Air Act.

DATES: Written comments must be received on or before May 20, 2016.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R01–OAR–2015–0243 at *http://www.regulations.gov,* or via email to *Arnold.Anne@epa.gov.* For comments submitted at Regulations.gov, follow the online instructions for submitting comments. Once submitted, comments cannot be edited or removed from Regulations.gov. For either manner of submission, the EPA may publish any comment received to its public docket. Do not submit electronically any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. The EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.* on the web, cloud, or other file sharing system). For additional submission methods, please contact the person identified in the **FOR FURTHER INFORMATION CONTACT** section. For the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *http://www2.epa.gov/dockets/commenting-epa-dockets.*

FOR FURTHER INFORMATION CONTACT: Ariel Garcia, Air Quality Planning Unit, U.S. Environmental Protection Agency, EPA New England Regional Office, 5 Post Office Square, Suite 100 (mail code: OEP05–2), Boston, MA 02109–3912, telephone number (617) 918–1660, fax number (617) 918–0660, email *garcia.ariel@epa.gov.*

SUPPLEMENTARY INFORMATION: In the Final Rules Section of this **Federal Register**, EPA is approving the State's SIP submittal as a direct final rule without prior proposal because the Agency views this as a noncontroversial submittal and anticipates no adverse comments. A detailed rationale for the approval is set forth in the direct final rule. If no adverse comments are received in response to this action rule, no further activity is contemplated. If EPA receives adverse comments, the direct final rule will be withdrawn and all public comments received will be addressed in a subsequent final rule based on this proposed rule. EPA will not institute a second comment period. Any parties interested in commenting on this action should do so at this time. Please note that if EPA receives adverse comment on an amendment, paragraph, or section of this rule and if that provision may be severed from the remainder of the rule, EPA may adopt as final those provisions of the rule that are not the subject of an adverse comment.

For additional information, see the direct final rule which is located in the Rules Section of this **Federal Register.**

Dated: April 1, 2016.

H. Curtis Spalding,

Regional Administrator, EPA New England.

Approval and Promulgation of Implementation Plans; Louisiana; Revisions to the New Source Review State Implementation Plan; Air Permit Procedure Revisions

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The Environmental Protection Agency (EPA) is proposing approval of portions of ten revisions to the Louisiana New Source Review (NSR) State Implementation Plan (SIP) submitted by the Louisiana Department of Environmental Quality (LDEQ). These revisions to the Louisiana SIP provide updates to the minor NSR and nonattainment new source review (NNSR) permit programs in Louisiana contained within the Chapter 5 Permit Procedures and Chapter 6 Regulations on Control of Emissions through the Use of Emission Reduction Credits (ERC) Banking rules as initially submitted on November 15, 1993, and the subsequent rule amendments for Air Permit Procedure revisions submitted through November 3, 2014. The EPA's final action will incorporate these rules into the federally approved SIP. The rules generally enhance the SIP and were evaluated in accordance with CAA guidelines for the EPA action on SIP submittals and general rulemaking authority. This proposed action is consistent with the requirements of section 110 of the CAA.

DATES: Written comments must be received on or before May 20, 2016.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–R06–OAR–2014–0821, at *http://www.regulations.gov* or via email to *kordzi.stephanie@epa.gov.* Follow the online instructions for submitting comments. Once submitted, comments cannot be edited or removed from Regulations.gov. The EPA may publish any comment received to its public docket. Do not submit electronically any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. The EPA will generally not

consider comments or comment contents located outside of the primary submission (*i.e.* on the web, cloud, or other file sharing system). For additional submission methods, please contact Stephanie Kordzi, 214–665–7520, *kordzi.stephanie@epa.gov.* For the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *http://www2.epa.gov/dockets/commenting-epa-dockets.*

Docket: The index to the docket for this action is available electronically at *www.regulations.gov* and in hard copy at the EPA Region 6, 1445 Ross Avenue, Suite 700, Dallas, Texas. While all documents in the docket are listed in the index, some information may be publicly available only at the hard copy location (*e.g.,* copyrighted material), and some may not be publicly available at either location (*e.g.,* CBI).

FOR FURTHER INFORMATION CONTACT: Stephanie Kordzi, telephone (214) 665–7520, *kordzi.stephanie@epa.gov.* To inspect the hard copy materials, please schedule an appointment with Stephanie Kordzi at 214–665–7520 or Mr. Bill Deese at 214–665–7253.

SUPPLEMENTARY INFORMATION: Throughout this document whenever "we," "us," or "our" is used, we mean the EPA.

I. Summary of State SIP Submittals for Chapter 5 and Chapter 6 Air Permit Program

The EPA is proposing approval of the SIP revisions submitted by the State of Louisiana. The proposed revisions modify Louisiana's minor NSR and NNSR Chapters 5 Permit Procedure and Chapter 6 Regulations on Control of Emissions through the Use of Emission Reduction Credits (ERC) Banking rules enacted at Louisiana Administrative Code (LAC) 33:III.501, 502, 503, 504, 511, 513.A.2., 513.A.3, 513.A.4., 513.A.5., 513.A.6., 513.B., 513.C., 515, 517, 519.A., 519.B., 521, 523, 525, 527, 529, 601, 603, 605, 607, 615, and 619. The revisions provide clarity to the rules, correct contradictory language, update permit application and fee requirements, revise the rules to conform to the latest Louisiana laws, and add to the "Insignificant Activities List".

A. November 15, 1993, Submittal

On November 15, 1993, the LDEQ submitted revisions to the SIP. This SIP submittal incorporated revisions to the Louisiana Administrative Code (LAC) during the year 1993. It includes final revised regulation enacted at LAC 33:III, sections 501, 502, 503, 504, 505, 507, 511, 513, 515, 517, 519, 521, 523, 525, 527, 529, and 533. The EPA is proposing to take action on sections 501, 502, 503, 511, 513, 515, 517, 519, 523, 525, 527, and 529. The EPA already approved section 504 (NNSR Procedures) into the SIP on October 10, 1997, 62 FR 52948. The 504 rules were then subsumed into later SIP approval revisions. The EPA returned sections 505, 507, and 533 due to their association with the Title V operating permit program requirements to the LDEQ on August 4, 2015. The EPA is not taking action and severing section 513.A.1 (which references section 531), section 519.C. (which references section 531), and section 531 regarding public notice. Those specific sections will be addressed in a separate action. The EPA is not taking action and is severing section 501.B.1.d. at this time.

B. November 10, 1994, Submittal

On November 10, 1994, the LDEQ submitted revisions to the SIP. This SIP submittal incorporated revisions to the LAC published in the Louisiana Register on November 20, 1994. It includes final revised regulations enacted at LAC 33:III, sections 501, 507, 517, 521, 527, and 533. The EPA is proposing to take action on sections 501, 517, 521, and 527. The EPA returned sections 507 and 533 due to their association with the title V operating permit program requirements to LDEQ on August 4, 2015.

C. July 25, 1997, Submittal

On July 25, 1997, the LDEQ submitted the 1996 General revisions to the SIP. This SIP submittal incorporated revisions to LAC 33:III, sections 501, 504, 509, and 517 adopted during 1996. The EPA is proposing action on section 517. The EPA already approved sections 501, 504 and 509 on November 5, 2015 (80 FR 68451). Section 504 was approved in 1997 as noted above and revisions have been subsumed into the SIP since the EPA's last action approving changes to the 504 rules on September 30, 2002 (67 FR 61260).

D. June 22, 1998, Submittal

On June 22, 1998, the LDEQ submitted the 1997 General revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the year 1997 and revisions to the LAC not previously federally approved. It includes final revised regulation at LAC 33:III, sections 501, 509, and 517. The EPA is proposing action on sections 501 and 517. The EPA already approved section 509 on November 5, 2015 (80 FR 68451).

E. June 27, 2003, Submittal

On June 27, 2003, the LDEQ submitted the 2002 General revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the year 2002. It includes final revised regulation LAC 33:III, section 501 covering the insignificant activities list. The EPA is proposing action on section 501.

F. May 5, 2006, Submittal

On May 5, 2006, the LDEQ submitted the 2005 General revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the year 2005 and revisions to the LAC not previously federally approved. It includes final revised regulation sections LAC 33:III.501, 504, 505, 507, 509, 517, and 521. The EPA is proposing action on sections 501, 517, and 521. Since the last approval of section 504 in 2002, the EPA approved changes to section 504 as well as section 509 on November 5, 2015 (80 FR 68451). The EPA returned to LDEQ sections 505 and 507.C.3. due to their association with the title V operating permit program requirements on August 4, 2015. The EPA returned to LDEQ sections 507.H.4 and 507.H.5.d. due to their association with the title V operating permit program requirements on February 2, 2016.

G. November 9, 2007, Submittal

On November 9, 2007, the LDEQ submitted the 2006 General revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the year 2006 and revisions to the LAC not previously federally approved. It includes final revised regulation sections at LAC 33:III.501, 504, 509,

513, 531, and 607. The EPA is proposing action on sections 513.A.2. and 513.A.6. The EPA already approved sections 501, 504, 509, and 607 on November 5, 2015 (80 FR 68451). The EPA is not taking action and severing section 513.A.1. (which references section 531) and section 531 regarding public notice. Those specific sections will be addressed in a separate action.

H. August 14, 2009, Submittal

On August 14, 2009, the LDEQ submitted the 2007 General revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the year 2007 and includes revisions to the LAC not previously federally approved. It includes final revised regulation sections LAC 33:III.501, 504, 505, 506, and 507 contained in Chapter 5. It also includes final revised regulation sections LAC 33:III.603, 605, 607, 613, and 615 contained in Chapter 6. The EPA is proposing action on section 501. The EPA already approved sections 504, 603, 605, 607, 613, and 615 on November 5, 2015 (80 FR 68451). The EPA already approved section 506 on April 17, 2014, (79 FR 21631). The EPA returned section 505 to LDEQ on February 2, 2016, because it addresses the Acid Rain Program Permitting Requirements, which are implemented in the title V program rather than the SIP. The EPA returned section 507 to LDEQ on February 2, 2016, because it concerns the title V program which is not part of a SIP.

I. August 29, 2013, Submittal

On August 29, 2013, the LDEQ submitted the 2008–2010 Volatile Organic Compounds Rule SIP Revision. This SIP submittal incorporated revisions to the LAC during the years 2008–2010 and includes revisions to final revised regulation section LAC 33:III.523. The EPA is proposing action on section 523.

J. November 3, 2014, Submittal

On November 3, 2014, the LDEQ submitted the 2011–2013 Permit Rule revisions to the SIP. This SIP submittal incorporated revisions to the LAC during the years 2011–2012. It includes final revised regulation sections LAC 33:III.211, 223, 317, 319, 501, 502, 503, 504, 523, 537, 601, 603, 605, 607, 615, 619, and 2132. The EPA is proposing action on sections 501, 502, 503, 504, 523, 601, 603, 605, 607, 615, and 619. The LDEQ withdrew sections 211 and 223 from SIP consideration by letter on December 2, 2015. The EPA is not acting on sections 317, 319, and 2132 because this action only addresses Chapters 5 and 6. The EPA is not taking action on section 537 (AQ286) and revised citation 501.B.2.d.i.(a) (AQ270) because the original 2008–2010 rule revision containing these sections was never submitted to the EPA. The EPA is not taking action and is severing section 501.B.1.d. at this time.

Table 1 below summarizes the changes that are in the SIP revision submittals. A summary of the EPA's evaluation of each section and the basis for our proposed approval is included in this rulemaking. The accompanying Technical Support Document (TSD) includes a detailed evaluation of the submittals and our rationale. The TSD may be accessed online at *www.regulations.gov,* Docket No. EPA–R06–OAR–2014–0821.

TABLE 1—SUMMARY OF EACH NSR SIP SUBMITTAL AFFECTED BY THIS ACTION

Title of SIP submittal	Date submitted to EPA	Date of state adoption	Regulations affected
Air Permit Procedure Revisions	11/15/1993	1993	Sections 501, 502, 503, 511, 513, 515, 517, 519.A., 519.B., 521, 523, 525, 527, and 529.
Air Permit Procedure Revisions	11/10/1994	11/20/1994	Sections 501, 517, 521, and 527.
Air Permit Procedure Revisions	7/25/1997	1996	Section 517.
Air Permit Procedure Revisions	6/22/1998	1997	Sections 501 and 517.
Air Permit Procedure Revisions	6/27/2003	2002	Section 501.
Air Permit Procedure and ERC Banking Revisions	5/5/2006	2005	Sections 501, 517, and 521.
Air Permit Procedure and ERC Banking Revisions	11/9/2007	2006	Section 513.
Air Permit Procedure Revisions	8/14/2009	2007	Section 501.
2008–2010 Volatile Organic Compounds Rule	8/29/2013	9/20/2008	Section 523.
2011–2013 Permit Rule SIP Revision	11/3/2014	2011	Sections 501, 502, 503, 504, 523, 601, 603, 605, 615, and 619.

II. Evaluation

A. Revisions to the NSR Air Permit Procedures

We evaluated the SIP submissions and are proposing approval of the Louisiana Permit Procedures Revisions and ERC Banking Provisions, as identified, beginning with the November 15, 1993, through the November 3, 2014, submissions. The Act at section 110(a)(2)(C) requires states to develop and submit to the EPA for approval into the SIP, preconstruction review programs applicable to new and modified stationary sources of air pollutants for attainment and nonattainment areas that cover both major and minor new sources and modifications, collectively referred to as the NSR SIP. The CAA NSR SIP program is composed of three separate programs: Prevention of Significant Deterioration (PSD), NNSR, and Minor NSR. PSD is established in part C of title I of the CAA and applies in areas that meet the National Ambient Air Quality Standards (NAAQS), *i.e.,* "attainment areas", as well as areas where there is insufficient information to determine if the area meets the NAAQS, *i.e.,* "unclassifiable areas." The NNSR SIP program is established in part D of title I of the CAA and applies in areas that are not in attainment of the NAAQS, *i.e.,* "nonattainment areas." The Minor NSR SIP program addresses construction or modification activities that do not emit, or have the potential to emit, beyond certain major source thresholds and thus do not qualify as "major" and applies regardless of the designation of the area in which a source is located. This particular SIP action will address the minor NSR and NNSR permitting programs.

The EPA regulations governing the criteria that states must satisfy for the EPA approval of the NSR programs as part of the SIP are contained in 40 CFR 51.160–51.166. However, the PSD rules are not being evaluated in this action and therefore 40 CFR 51.166 does not provide a basis for a decision in this proposal. In addition, there are several provisions in 40 CFR part 51 that apply generally to all SIP revisions. As stated

above, 40 CFR 51.160 establishes the enforceable procedures that all NSR programs must include. 40 CFR 51.160–51.164 require that a SIP revision demonstrate that the adopted rules will not interfere with any applicable requirement concerning attainment and reasonable further progress, or any other applicable requirement of the CAA. Based upon our evaluation of the submittals, the EPA has concluded that the submittals as ultimately revised meet the requirements of the CAA section 110(a).

Our evaluation found that May 20, 2012 and November 20, 2012 adopted revisions to the NNSR program, submitted on November 3, 2014 revised the program to address all nonattainment area pollutants and was necessary to ensure the Louisiana NNSR offset bank is able to be used in future instances where the State is designated nonattainment for other criteria pollutants. Prior to this action, the EPA proposed full approval of the major PSD and NNSR permitting program update, (80 FR 50240), specifically those NNSR requirements submitted prior to November 3, 2014. That action was finalized on November 5, 2015 (80 FR 68451).

Our evaluation of the proposed minor NSR revisions found the proposed revisions address requirements that enhance the SIP. These changes (1) define insignificant activities that will not require permitting; (2) correct contradictory language in the insignificant activities list; (3) provide edits to the Permit Procedure Rule as requested by the EPA; (4) include procedures for incorporating test results; (5) unify and streamline name and ownership changes for all media; and (6) revise references to various LDEQ divisions. All of these changes will help to ensure that the LA Minor NSR rules to meet the CAA requirements.

B. Does the proposed approval of the Louisiana minor and nonattainment NSR Air Permit procedure revisions interfere with attainment, reasonable further progress, or any other applicable requirement of the Act?

We have determined that the regulations submitted to the EPA for approval as SIP revisions meet the requirements of CAA section 110(l). The EPA's conclusion is based upon a line-by-line comparison of the proposed revisions with the federal requirements. The goal is to demonstrate that the proposed revisions will not interfere with the attainment of the NAAQS, Rate of Progress, RFP or any other applicable requirement of the CAA.

The EPA prepared a CAA section 110(l) analysis in its review of the proposed list to serve as a basis for demonstrating noninterference for the affected pollutants for any applicable requirement for attainment and reasonable further progress such as: (1) Turning a maintenance area back into a nonattainment area; (2) turning an attainment/unclassifiable area into a nonattainment area; (3) leading to a PSD increment exceedance; (4) causing the nonattainment area to have higher violations; or (5) causing a nonattainment area to have a greater number of NAAQS standard exceedances. This evaluation is contained in the individual tables for each regulatory section and is found in Section IV Conclusion of the TSD. The TSD can be found in the docket for this action. The comparison demonstrates that the changes made to the Louisiana rules reflect either the same regulatory language, or are consistent with the requirements found in the federal rules. Further, the Additional Comments to the table contained in section IV for the proposed revisions to section 501 in the TSD contain supporting technical documentation establishing in detail a CAA section 110(l) analysis regarding the tables of Insignificant Activities defined in section 501. Specifically, the Section 501.B.3, Insignificant Activities list, submitted on 5/5/2006, revised the former submittal 11/10/1994, which was then subsumed by the 6/27/2003 submittal.

Our finding is based in part on the historic trends of ambient air quality for the NAAQS pollutants, including ozone and sulfur dioxide (SO_2), since those pollutants have caused past air quality issues.[1] The EPA took into consideration the following factors when making the decision to propose approval into the SIP of the permit exemptions listed in the Insignificant Activities tables in section 501:

- Compliance with the 8-hour ozone standard has improved state-wide with ozone pollutant concentrations trending downward with an average 23% decrease in ozone since the late 1980's. This average decrease represents air monitoring values in the Louisiana cities of Baton Rouge, Lake Charles, Monroe, New Orleans, and Point Coupee Parish. 8-Hour ozone trends are listed in the table below:

LA cities	8-Hour ozone (ppb) 1986	8-Hour ozone (ppb) 2015	Reduction (%)
Baton Rouge	98	71	28
Lake Charles (Calcasieu Parish)	92	67	27
Monroe	73	61	16
New Orleans	89	70	22
Pointe Coupe Parish	85	67	21

- The Baton Rouge marginal ozone nonattainment area is currently monitoring attainment for the 2008 ozone NAAQS. The 8-Hour ozone values have dropped from 83 ppb in 2006–2008 down to 71 ppb design value for 2015 in Baton Rouge.
- Compliance with the SO_2 standard has improved significantly state-wide with SO_2 pollutant concentrations trending downward with an average 55% decrease in SO_2 since the mid 2000's. This average value represents the Louisiana air monitoring locations of Baton Rouge, Lake Charles, Chalmette, Port Allen, Shreveport, and Meraux. SO_2 trends are listed in the table below:

[1] Supporting documentation is contained in the monitoring data of ambient air quality for NAAQS criteria for cities located throughout Louisiana. See *http://www.deq.louisiana.gov/portal/DIVISIONS/Assessment/AirFieldServices/AmbientAirMonitoringProgram/AmbientAirMonitoringDataandReports.aspx.*

LA cities	SO_2 (ppb) 2007	SO_2 (ppb) 2013	Reduction (%)
Shreveport	21	12	43
Lake Charles	42	32	24
Baton Rouge	65	19	71
Meraux	32	19	41
Chalmette	331	112	66
Port Allen	143	23	84

• The EPA determined the St. Bernard 2010 SO_2 NAAQS nonattainment area was caused primarily by one large source of SO_2 emissions, the Rain CII Carbon LLC—Chalmette Coke Plant. The LDEQ is currently preparing a proposed SIP attainment demonstration, "*St. Bernard Parish SO_2 Nonattainment Area Louisiana SIP Revision,*" which was submitted to the EPA on April 1, 2015, for review. The EPA provided comments and is working with the LDEQ to ensure the SIP revision contains the appropriate emission limits to bring the area into attainment status. The St. Bernard SO_2 nonattainment area has documented SO_2 pollutant concentrations decreasing from a 331 ppm SO_2 design value in 2009 down to a 159 ppm SO_2 design value in 2014.

• Compliance with the Particulate Matter (PM_{10}) standard is maintained and is below regulatory NAAQS levels. PM_{10} emission concentrations have trended downward an average 25% statewide since the mid 2000's. The average statewide 24-hour PM_{10} concentration is 28 ug/m^3 which is 19% of the NAAQS level for PM_{10}. The average value represents the Louisiana air monitoring locations of Baton Rouge, New Orleans, Chalmette, Shreveport, and Lafayette.

• Compliance with the average statewide annual $PM_{2.5}$ standards is maintained with an average annual maximum concentration of 10.8 ug/m^3, which is below the average annual primary standard for $PM_{2.5}$ of 12 ug/m^3.

• The Baton Rouge Capitol air monitor is the only monitor collecting samples and analyzing for Carbon Monoxide (CO). The 2014 annual average CO value was 0.26 ppm and the maximum monitored value was 5.34 ppm which is below the 9 ppm standard (8 hour averaging time).

Since the list of exempted sources included in the proposed revisions have historically operated without coverage by an air permit and there are no anticipated increases in emissions or in the number of these type of sources resulting from the approval of the exempted list into the SIP, the EPA has determined the possibility of a low level of potential impacts on ambient air quality as a result of the emission sources and activities included in the proposed LAC 33:III section 501 exemptions list and this conclusion is supported by ambient air monitoring trends in the State of Louisiana.

Our determination is consistent with our assessment of the environmental insignificance of these emissions. In addition, the LDEQ has been carrying out the minor NSR air permitting program based on the codification of their permitting policy without any indication that these permit exempted sources have interfered with attainment or reasonable further progress or increased PSD increment. Therefore, the EPA proposes to approve the exemptions lists in section 501 into the Louisiana SIP.

Based on supporting air quality monitoring data documenting air quality improvements throughout the State, the EPA proposes to approve Section 501 containing the list of the exempted sources into the Louisiana SIP since it meets the requirements of CAA section 110(l) and since state agencies are provided the latitude to define the types and sizes of facilities, buildings, structures, or installations subject to review in accordance with 40 CFR 51.160(e). We believe the implementation of this rule will not interfere with any applicable requirement concerning attainment and reasonable further progress, maintaining PSD increment, or any other applicable requirement of the CAA.

III. Proposed Action

The EPA proposes approval of the identified sections of the revisions to the air permitting procedures as submitted as revisions to the Louisiana NSR SIP Permit program on November 15, 1993, November 10, 1994, July 25, 1997, June 22, 1998, June 27, 2003, May 5, 2006, November 9, 2007, August 14, 2009, August 29, 2013, and November 3, 2014, submittals. The EPA has made the determination in accordance with the CAA and the EPA regulations at 40 CFR 51.160–51.165. Therefore, under section 110 and part C of the Act, and for the reasons presented above and in our accompanying TSD, the EPA proposes approval of the revisions to the Louisiana SIP identified in Table 2 below which summarizes each regulatory citation that is affected by this action.

TABLE 2—SUMMARY OF EACH REGULATION THAT IS AFFECTED BY THIS ACTION

Section	Date submitted to EPA as SIP amendment	Affected regulation
Section 501—Scope and Applicability		
Section 501.A	11/15/1993	Sections 501.A.1. and A.2.
Section 501.B	11/15/1993	Sections 501.B.1.a., B.1.b., B.1.c., B.2., B.3., B.4., B.5., B.6., and B.7.
	11/10/1994	Sections 501.B.5.A and 501.B.5.B.
	6/22/1998	Sections 501.B.3.c. and 501.B.3.d.
	6/27/2003	Section 501.B.5.
	5/5/2006	Sections 501.B.5, 501.B.32, and 501.D.a.–d.
	11/3/2014	Sections 501.B.1.c., 501.B.1.e., 501.B.4.a.i., 501.B.5. Table 1, and 501.B.8.
Section 501.C	11/15/1993	Sections 501.C.1., C.2., C.3., C.4., C.5., C.6., C.7., C.8., and C.9.
	5/5/2006	Section 501.C.1.
	11/9/2007	Sections 501.C.11., C.12., and C.13.

IV. Incorporation by Reference

In this action, we are proposing to include in a final rule regulatory text that includes incorporation by reference. In accordance with the requirements of 1 CFR 51.5, we are proposing to incorporate by reference revisions to the Louisiana regulations as described in the Proposed Action section above. We have made, and will continue to make, these documents generally available electronically through *www.regulations.gov* and/or in hard copy at the EPA Region 6 office.

V. Statutory and Executive Order Reviews

Under the CAA, the Administrator is required to approve a SIP submission that complies with the provisions of the Act and applicable Federal regulations. 42 U.S.C. 7410(k); 40 CFR 52.02(a). Thus, in reviewing SIP submissions, the EPA's role is to approve state choices, provided that they meet the criteria of the CAA. Accordingly, this action merely proposes to approve state law as meeting Federal requirements and does not impose additional requirements beyond those imposed by state law. For that reason, this action:

- Is not a "significant regulatory action" subject to review by the Office of Management and Budget under Executive Orders 12866 (58 FR 51735, October 4, 1993) and 13563 (76 FR 3821, January 21, 2011);
- Does not impose an information collection burden under the provisions of the Paperwork Reduction Act (44 U.S.C. 3501 *et seq.*);
- Is certified as not having a significant economic impact on a substantial number of small entities

under the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.*);

- Does not contain any unfunded mandate or significantly or uniquely affect small governments, as described in the Unfunded Mandates Reform Act of 1995 (Pub. L. 104–4);
- Does not have Federalism implications as specified in Executive Order 13132 (64 FR 43255, August 10, 1999);
- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and
- Does not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

In addition, the SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the proposed rule does not have tribal implications and will not impose substantial direct costs on tribal governments or preempt tribal law as specified by Executive Order 13175 (65 FR 67249, November 9, 2000).

Proposal of Certain Federal Water Quality Standards Applicable to Maine

AGENCY: Environmental Protection Agency (EPA).

ACTION: Proposed rule.

SUMMARY: The Environmental Protection Agency (EPA) proposes federal Clean Water Act (CWA) water quality standards (WQS) that would apply to certain waters under the state of Maine's jurisdiction. EPA proposes human health criteria (HHC) to protect the sustenance fishing use in those waters in Indian lands and for waters subject to sustenance fishing rights under the Maine Implementing Act (MIA) based on a fish consumption rate that represents an unsuppressed level of fish consumption by the four federally recognized tribes. EPA proposes six additional WQS for waters in Indian lands in Maine, two WQS for all waters in Maine including waters in Indian lands, and one WQS for waters in Maine outside of Indian lands. These proposed WQS take into account the best available science, including local and regional information, as well as applicable EPA policies, guidance, and legal requirements, to protect human health and aquatic life. EPA proposes these WQS to address various disapprovals of Maine's standards that EPA issued in February, March, and June 2015, and to address the Administrator's determination that Maine's disapproved HHC are not adequate to protect the designated use of sustenance fishing for certain waters.

DATES: Comments must be received on or before June 20, 2016.

ADDRESSES: Submit your comments, identified by Docket ID No. EPA–HQ–OW–2015–0804 at *http://www.regulations.gov*. Follow the online instructions for submitting comments. Once submitted, comments cannot be edited or removed from Regulations.gov. EPA may publish any comment received to its public docket. Do not submit electronically any information you consider to be Confidential Business Information (CBI) or other information whose disclosure is restricted by statute. Multimedia submissions (audio, video, etc.) must be accompanied by a written comment. The written comment is considered the official comment and should include discussion of all points you wish to make. EPA will generally not consider comments or comment contents located outside of the primary submission (*i.e.* on the Web, cloud, or other file sharing system). For additional submission methods, the full EPA public comment policy, information about CBI or multimedia submissions, and general guidance on making effective comments, please visit *http://www.epa.gov/dockets/commenting-epa-dockets*. EPA is offering two virtual public hearings so that interested parties may also provide oral comments on this proposed rule. The first hearing will be on Tuesday, June 7, 2016 from 5:00 p.m. to 7:00 p.m. Eastern Daylight Time. The second hearing will be on Thursday, June 9, 2016 from 9:00 a.m. to 11:00 a.m. Eastern Daylight Time. For more details on the public hearings and a link to register, please visit *http://www.epa.gov/wqs-tech/proposed-rule-maine-water-quality-standards*.

FOR FURTHER INFORMATION CONTACT: Jennifer Brundage, Office of Water, Standards and Health Protection Division (4305T), Environmental Protection Agency, 1200 Pennsylvania Avenue NW., Washington, DC 20460; telephone number: (202) 566–1265; email address: *Brundage.jennifer@epa.gov*.

SUPPLEMENTARY INFORMATION: This proposed rule is organized as follows:

I. General Information
  Does this action apply to me?
II. Background
  A. Statutory and Regulatory Background
  B. EPA's Disapprovals of Portions of Maine's Water Quality Standards
  C. Scope of Waters
  D. Applicability of EPA Promulgated Water Quality Standards When Final
III. CWA 303(c)(4)(B) Determination of Necessity for Human Health Criteria That Protect Sustenance Fishing
IV. Proposed Water Quality Standards
  A. Proposed WQS for Waters in Indian Lands in Maine and for Waters Outside of Indian Lands in Maine Where the Sustenance Fishing Designated Use Established by 30 M.R.S. 6207(4) and (9) Applies
  B. Proposed WQS for Waters in Indian Lands in Maine
  C. Proposed WQS for All Waters in Maine
  D. Proposed WQS for Waters in Maine Outside of Indian Lands
V. Economic Analysis
  A. Identifying Affected Entities
  B. Method for Estimating Costs
  C. Results
VI. Statutory and Executive Order Reviews
  A. Executive Order 12866 (Regulatory Planning and Review) and Executive Order 13563 (Improving Regulation and Regulatory Review)
  B. Paperwork Reduction Act

Order 13132 (64 FR 43255, August 10, 1999);

- Is not an economically significant regulatory action based on health or safety risks subject to Executive Order 13045 (62 FR 19885, April 23, 1997);
- Is not a significant regulatory action subject to Executive Order 13211 (66 FR 28355, May 22, 2001);
- Is not subject to requirements of section 12(d) of the National Technology Transfer and Advancement Act of 1995 (15 U.S.C. 272 note) because application of those requirements would be inconsistent with the CAA; and
- Does not provide EPA with the discretionary authority to address, as appropriate, disproportionate human health or environmental effects, using practicable and legally permissible methods, under Executive Order 12898 (59 FR 7629, February 16, 1994).

In addition, the SIP is not approved to apply on any Indian reservation land or in any other area where EPA or an Indian tribe has demonstrated that a tribe has jurisdiction. In those areas of Indian country, the rule does not have tribal implications as specified by Executive Order 13175 (65 FR 67249, November 9, 2000), nor will it impose substantial direct costs on tribal governments or preempt tribal law.

The Congressional Review Act, 5 U.S.C. 801 *et seq.*, as added by the Small Business Regulatory Enforcement Fairness Act of 1996, generally provides that before a rule may take effect, the agency promulgating the rule must submit a rule report, which includes a copy of the rule, to each House of the Congress and to the Comptroller General of the United States. EPA will submit a report containing this action and other required information to the U.S. Senate, the U.S. House of Representatives, and the Comptroller General of the United States prior to publication of the rule in the **Federal Register**. A major rule cannot take effect until 60 days after it is published in the **Federal Register**. This action is not a "major rule" as defined by 5 U.S.C. 804(2).

Under section 307(b)(1) of the CAA, petitions for judicial review of this action must be filed in the United States Court of Appeals for the appropriate circuit by January 27, 2017. Filing a petition for reconsideration by the Administrator of this final rule does not affect the finality of this action for the purposes of judicial review nor does it extend the time within which a petition for judicial review may be filed, and shall not postpone the effectiveness of such rule or action. This action may not be challenged later in proceedings to enforce its requirements. *See* section 307(b)(2).

List of Subjects in 40 CFR Part 52

Environmental protection, Air pollution control, Incorporation by reference, Intergovernmental relations, Nitrogen dioxide, Ozone, Reporting and recordkeeping requirements, Volatile organic compounds.

Dated: November 7, 2016.

Heather McTeer Toney,

Regional Administrator, Region 4.

40 CFR part 52 is amended as follows:

PART 52—APPROVAL AND PROMULGATION OF IMPLEMENTATION PLANS

■ 1. The authority citation for part 52 continues to read as follows:

Authority: 42 U.S.C. 7401 *et seq.*

Subpart RR—Tennessee

■ 2. In § 52.2220, the table in paragraph (e) is amended by adding the entry "110(a)(1) and (2) Infrastructure Requirements for the 2010 1-hour SO_2 NAAQS" at the end of the table to read as follows:

§ 52.2220 Identification of plan.

* * * * *

(e) * * *

EPA-APPROVED TENNESSEE NON-REGULATORY PROVISIONS

Name of non-regulatory SIP provision	Applicable geographic or non-attainment area	State effective date	EPA approval date	Explanation
*	*	*	*	*
110 (a)(1) and (2) Infrastructure Requirements for the 2010 1-hour SO_2 NAAQS.	Tennessee	03/13/2014	11/28/16, [insert **Federal Register** citation].	With the exception of interstate transport requirements of section 110(a)(2)(D)(i)(I) and (II) (prongs 1, 2, and 4).

Revision of Certain Federal Water Quality Criteria Applicable to Washington

AGENCY: Environmental Protection Agency (EPA).

ACTION: Final rule.

SUMMARY: On September 14, 2015, the Environmental Protection Agency (EPA) proposed revisions to the federal Clean Water Act (CWA) human health criteria applicable to waters under the State of Washington's jurisdiction to ensure that the criteria are set at levels that will adequately protect Washington residents, including tribes with treaty-reserved rights, from exposure to toxic pollutants. EPA promulgated Washington's previous criteria for the protection of human health in 1992 as part of the National Toxics Rule (NTR) (amended in 1999 for Polychlorinated Biphenyls (PCBs)), using the Agency's recommended criteria values at the time. EPA derived those previously applicable criteria using a fish consumption rate (FCR) of 6.5 grams per day (g/day) based on national surveys. The best available data now demonstrate that fish consumers in Washington consume much more fish than 6.5 g/day. There are also new data and scientific information available to update the toxicity and exposure parameters used to calculate human health criteria. On August 1, 2016, the State of Washington adopted and submitted human health criteria for certain pollutants, reflecting some of these new data and information. Concurrent with this final rule, EPA is taking action under CWA 303(c) to approve in part, and disapprove in part, the human health criteria submitted by Washington. For those criteria that EPA disapproved, EPA is finalizing federal human health criteria in this final rule.

EPA is not finalizing criteria in this final rule for those state-adopted criteria that EPA approved, or for certain criteria that EPA has determined involve scientific uncertainty, as explained below.

DATES: This final rule is effective on December 28, 2016.

ADDRESSES: EPA has established a docket for this action under Docket ID No. EPA–HQ–OW–2015–0174. All documents in the docket are listed on the *http://www.regulations.gov* Web site. Although listed in the index, some information is not publicly available, *e.g.,* CBI or other information whose disclosure is restricted by statute. Certain other material, such as copyrighted material, is not placed on the Internet and will be publicly available only in hard copy form. Publicly available docket materials are available electronically through *http://www.regulations.gov.*

FOR FURTHER INFORMATION CONTACT: Erica Fleisig, Office of Water, Standards and Health Protection Division (4305T), Environmental Protection Agency, 1200 Pennsylvania Avenue NW., Washington, DC 20460; telephone number: (202) 566–1057; email address: *fleisig.erica@epa.gov.*

SUPPLEMENTARY INFORMATION: This final rule is organized as follows:

I. General Information
A. Does this action apply to me?
B. How did EPA develop this final rule?
II. Background
A. Statutory and Regulatory Background
B. EPA's CWA 303(c) Action on Washington's Human Health Criteria
C. General Recommended Approach for Deriving Human Health Criteria
III. Derivation of Human Health Criteria for Washington
A. Scope of Pollutants and Waters Covered by This Final Rule
B. Washington's Designated Uses and Tribal Reserved Fishing Rights
C. Washington-Specific Human Health Criteria Inputs
D. Final Human Health Criteria for Washington
E. Applicability of Criteria
F. Alternative Regulatory Approaches and Implementation Mechanisms
IV. Economic Analysis
A. Identifying Affected Entities
B. Method for Estimating Costs
C. Results
V. Statutory and Executive Order Reviews
A. Executive Order 12866 (Regulatory Planning and Review) and Executive Order 13563 (Improving Regulation and Regulatory Review)
B. Paperwork Reduction Act
C. Regulatory Flexibility Act
D. Unfunded Mandates Reform Act
E. Executive Order 13132 (Federalism)
F. Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments)
G. Executive Order 13045 (Protection of Children From Environmental Health and Safety Risks)
H. Executive Order 13211 (Actions That Significantly Affect Energy Supply, Distribution, or Use)
I. National Technology Transfer and Advancement Act of 1995
J. Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations)
K. Congressional Review Act (CRA)

I. General Information

A. Does this action apply to me?

Entities such as industries, stormwater management districts, or publicly owned treatment works (POTWs) that discharge pollutants to waters of the United States under the State of Washington's jurisdiction could be indirectly affected by this rulemaking, because federal water quality standards (WQS) promulgated by EPA are applicable to CWA regulatory programs, such as National Pollutant Discharge Elimination System (NPDES) permitting. Citizens concerned with water quality in Washington could also be interested in this rulemaking. Categories and entities that could potentially be affected include the following:

Category	Examples of potentially affected entities
Industry	Industries discharging pollutants to waters of the United States in Washington.
Municipalities	Publicly owned treatment works or other facilities discharging pollutants to waters of the United States in Washington.
Stormwater Management Districts	Entities responsible for managing stormwater runoff in the State of Washington.

This table is not intended to be exhaustive, but rather provides a guide for readers regarding entities that could be indirectly affected by this action. Any parties or entities who depend upon or contribute to the water quality of Washington's waters could be indirectly affected by this rule. To determine whether your facility or activities could be indirectly affected by this action, you should carefully examine this rule. If you have questions regarding the applicability of this action to a particular entity, consult the person listed in the **FOR FURTHER INFORMATION CONTACT** section.

B. How did EPA develop this final rule?

In developing this final rule, EPA carefully considered the public comments and feedback received from interested parties. EPA originally provided a 60-day public comment period after publishing the proposed rule in the **Federal Register** on September 14, 2015.[1] On October 28, 2015, in response to stakeholder requests,[2] EPA extended the public comment period for an additional 45 days.[3] In addition, EPA held two virtual public hearings on December 15th and 16th, 2015, to discuss the contents of the proposed rule and accept verbal public comments.

Over 60 organizations and individuals submitted comments on a range of issues. EPA also received over 400 letters from individuals associated with mass letter writing campaigns. Some comments addressed issues beyond the scope of the rulemaking, and thus EPA did not consider them in finalizing this rule. In each section of this preamble, EPA discusses certain public comments so that the public is aware of the Agency's position. For a full response to these and all other comments, see EPA's Response to Comments document in the official public docket.

II. Background

A. Statutory and Regulatory Background

CWA section 101(a)(2) establishes as a national goal "water quality which provides for the protection and propagation of fish, shellfish, and wildlife, and recreation in and on the water, wherever attainable." These are commonly referred to as the "fishable/swimmable" goals of the CWA. EPA

[1] See Revision of Certain Federal Water Quality Criteria Applicable to Washington: Proposed Rule, 80 FR 55063, September 14, 2015.

[2] EPA received requests from the Association of Washington Business—Washington State's Chamber of Commerce, Washington Public Ports Association (on behalf of the Association of Washington Cities and the Washington State Association of Counties), Western Wood Preservers Institute, ALCOA, American Forest and Paper Association, McFarland Cascade, Schnitzer Steel Industries, and Weyerhaeuser.

[3] See Extension of Public Comment Period for the Revision of Certain Federal Water Quality Criteria Applicable to Washington, 80 FR 65980, October 28, 2015.

interprets "fishable" uses to include, at a minimum, designated uses providing for the protection of aquatic communities and human health related to consumption of fish and shellfish.[4]

CWA section 303(c) (33 U.S.C. 1313(c)) directs states to adopt WQS for their waters subject to the CWA. CWA section 303(c)(2)(A) and EPA's implementing regulations at 40 CFR part 131 require, among other things, that a state's WQS specify appropriate designated uses of the waters, and water quality criteria that protect those uses. EPA's regulations at 40 CFR 131.11(a)(1) provide that "[s]uch criteria must be based on sound scientific rationale and must contain sufficient parameters or constituents to protect the designated use. For waters with multiple use designations, the criteria shall support the most sensitive use." In addition, 40 CFR 131.10(b) provides that "[i]n designating uses of a water body and the appropriate criteria for those uses, the state shall take into consideration the water quality standards of downstream waters and ensure that its water quality standards provide for the attainment and maintenance of the water quality standards of downstream waters."

States are required to review applicable WQS at least once every three years and, if appropriate, revise or adopt new standards (CWA section 303(c)(1)). Any new or revised WQS must be submitted to EPA for review and approval or disapproval (CWA section 303(c)(2)(A) and (c)(3)). If EPA disapproves a state's new or revised WQS, the CWA provides the state 90 days to adopt a revised WQS that meets CWA requirements, and if it fails to do so, EPA shall promptly propose and then within 90 days promulgate such standard unless EPA approves a state replacement WQS first (CWA section 303(c)(3) and (c)(4)(A)). CWA section 303(c)(4)(B) authorizes the Administrator to determine that a new or revised standard is needed to meet CWA requirements. Upon making such a determination, the CWA specifies that EPA shall promptly propose, and then within 90 days promulgate, any such new or revised standard unless prior to such promulgation, the state has adopted a revised or new WQS that EPA determines to be in accordance with the CWA.

Under CWA section 304(a), EPA periodically publishes criteria recommendations for states to consider when adopting water quality criteria for particular pollutants to protect the CWA section 101(a)(2) goal uses. In 2015, EPA updated its 304(a) recommended criteria for human health for 94 pollutants.[5] Where EPA has published recommended criteria, states should establish numeric water quality criteria based on EPA's CWA section 304(a) criteria, section 304(a) criteria modified to reflect site-specific conditions, or other scientifically defensible methods (40 CFR 131.11(b)(1)). In all cases criteria must be sufficient to protect the designated use and be based on sound scientific rationale (40 CFR 131.11(a)(1)). CWA section 303(c)(2)(B) requires states to adopt numeric criteria for all toxic pollutants listed pursuant to CWA section 307(a)(1) for which EPA has published 304(a) criteria, as necessary to support the states' designated uses.

In 1992, EPA promulgated the NTR at 40 CFR 131.36, establishing chemical-specific numeric criteria for 85 priority toxic pollutants for 14 states and territories (states), including Washington, that were not in compliance with the requirements of CWA section 303(c)(2)(B). When states covered by the NTR subsequently adopted their own criteria for toxic pollutants that EPA approved as consistent with the CWA and EPA's implementing regulations, EPA amended the NTR to remove those criteria for those states.

B. EPA's CWA 303(c) Action on Washington's Human Health Criteria

On September 14, 2015, EPA made a CWA 303(c)(4)(B) determination that new or revised WQS for the protection of human health in Washington were necessary to meet the requirements of the CWA, and proposed revised human health criteria for the state (see 80 FR 55063). At that time, Washington had not yet adopted its own criteria for the protection of human health.[6] On August 1, 2016, Washington adopted and submitted statewide human health criteria and new and revised implementation provisions. Concurrent with this final rule, EPA approved 45 and disapproved 143 of Washington's human health criteria under CWA 303(c). EPA is finalizing 144 human health criteria in this rule in accordance with CWA section 303(c)(3) and (c)(4) requirements.[7] After the effective date of this final rule, these federal criteria will be in effect for CWA purposes along with the human health criteria that Washington adopted and EPA approved.

Several commenters provided comments on the timing of EPA's rule, and the relationship between EPA's federal rulemaking and the state rulemaking process. These comments are now, for the most part, mooted by EPA's finalization of its federal rule and action on the state's submittal. For additional responses to specific comments, see EPA's Response to Comment document in the docket for this rule.

C. General Recommended Approach for Deriving Human Health Criteria

Human health criteria are designed to minimize the risk of adverse cancer and non-cancer effects occurring from lifetime exposure to pollutants through the ingestion of drinking water and consumption of fish and shellfish obtained from inland and nearshore waters (by nearshore waters, EPA refers to waters out to three miles from the coast). EPA's practice is to establish a human health 304(a) recommended criterion for both drinking water and consumption of fish and shellfish from inland and nearshore waters combined, and a separate human health criterion based only on ingestion of fish and shellfish from inland and nearshore waters. This latter criterion applies in cases where the designated uses of a waterbody include supporting fish and shellfish for human consumption but not drinking water supply sources (*e.g.*, in non-potable estuarine waters).

The criteria are based on two types of biological endpoints: (1) Carcinogenicity and (2) systemic toxicity (*i.e.*, all adverse effects other than cancer). EPA takes an integrated approach and considers both cancer and non-cancer effects when deriving human health criteria. Where sufficient data are available, EPA derives criteria using

[4] USEPA. 2000. Memorandum #WQSP–00–03, U.S. Environmental Protection Agency, Office of Water, Washington, DC *https://www.epa.gov/sites/production/files/2015-01/documents/standards-shellfish.pdf.*

[5] Final Updated Ambient Water Quality Criteria for the Protection of Human Health, (80 FR 36986, June 29, 2015). See also: USEPA. 2015. Final 2015 Updated National Recommended Human Health Criteria. U.S. Environmental Protection Agency, Office of Water, Washington, DC *https://www.epa.gov/wqc/human-health-water-quality-criteria.*

[6] Washington adopted criteria for the protection of aquatic life from toxic pollutants at WAC 173–201A–240.

[7] EPA is finalizing a different number of human health criteria (144) than it is disapproving (143) in Washington's 2016 submittal. Washington did not adopt organism-only criteria for methylmercury or water-plus-organism and organism-only criteria for bis(2-chloro-1-methylethyl) ether. These are priority pollutants listed pursuant to CWA section 307(a)(1) for which EPA has 304(a) recommended criteria, and, as such, CWA section 303(c)(2)(B) requires that states adopt numeric criteria for these pollutants, as necessary to support the states' designated uses. Therefore, EPA is including these three criteria in this final rule for Washington. This final rule, however, does not include revised water-plus-organism and organism-only criteria for arsenic, as explained below in section III.A, even though EPA is disapproving the arsenic criteria in Washington's submittal.

both carcinogenic and non-carcinogenic toxicity endpoints and recommends the lower value. Human health criteria for carcinogenic effects are calculated using the following input parameters: Cancer slope factor (CSF), cancer risk level, body weight, drinking water intake rate, fish consumption rate, and a bioaccumulation factor(s). Human health criteria for non-carcinogenic and nonlinear carcinogenic effects are calculated using a reference dose (RfD) in place of a CSF and cancer risk level, and a relative source contribution (RSC) factor, which is intended to ensure that an individual's total exposure to a given pollutant from all sources does not exceed the RfD. Each of these inputs is discussed in more detail below and in EPA's 2000 Human Health Methodology (hereafter referred to as EPA's "2000 Methodology").[8]

a. Cancer Risk Level

EPA's 304(a) national recommended human health criteria are typically based on the assumption that carcinogenicity is a "non-threshold phenomenon," which means that there are no "no-effect" levels, because even extremely small doses are assumed to cause a finite increase in the incidence of cancer. Therefore, EPA calculates 304(a) human health criteria for carcinogenic effects as pollutant concentrations corresponding to lifetime increases in the risk of developing cancer.[9] EPA calculates its 304(a) human health criteria values at a 10^{-6} (one in one million) cancer risk level and recommends cancer risk levels of 10^{-6} or 10^{-5} (one in one hundred thousand) for the general population.[10] EPA notes that states and authorized tribes can also choose a more stringent risk level, such as 10^{-7} (one in ten million), when deriving human health criteria.

If the pollutant is not considered to have the potential for causing cancer in humans (*i.e.*, systemic toxicants), EPA assumes that the pollutant has a threshold (the RfD) below which a physiological mechanism exists to avoid or overcome the adverse effects of the pollutant.

b. Cancer Slope Factor and Reference Dose

A dose-response assessment is required to understand the quantitative relationships between exposure to a pollutant and the onset of human health effects. EPA evaluates dose-response relationships derived from animal toxicity and human epidemiological studies to derive dose-response metrics. For carcinogenic toxicological effects, EPA uses an oral CSF to derive human health criteria. The oral CSF is an upper bound, approximating a 95 percent confidence limit, on the increased cancer risk from a lifetime oral exposure to a stressor. For non-carcinogenic effects, EPA uses the RfD to calculate human health criteria. A RfD is an estimate of a daily oral exposure of an individual to a substance that is likely to be without an appreciable risk of deleterious effects during a lifetime. A RfD is typically derived from a laboratory animal dosing study in which a no-observed-adverse-effect level (NOAEL), lowest-observed-adverse-effect level (LOAEL), or benchmark dose can be obtained. Uncertainty factors are applied to reflect the limitations of the data. EPA's Integrated Risk Information System (IRIS) [11] was the primary source of toxicity values (*i.e.*, RfD and CSF) for EPA's 2015 updated 304(a) human health criteria.[12] For some pollutants, however, more recent peer-reviewed and publicly available toxicological data were available from other EPA program offices (*e.g.*, Office of Pesticide Programs, Office of Water, Office of Land and Emergency Management), other national and international programs, and state programs.

c. Exposure Assumptions

EPA's latest 304(a) national human health criteria use a default drinking water intake rate of 2.4 liters per day (L/day) and default rate of 22 g/day for consumption of fish and shellfish from inland and nearshore waters, multiplied by pollutant-specific bioaccumulation factors (BAFs) to account for the amount of the pollutant in the edible portions of the ingested species. EPA's 2000 Methodology for deriving human health criteria emphasizes using, when possible, measured or estimated BAFs, which account for chemical accumulation in aquatic organisms from all potential exposure routes.[13] In the 2015 national 304(a) human health criteria update, EPA primarily used field-measured BAFs, and laboratory-measured bioconcentration factors (BCFs) with applicable food chain multipliers available from peer-reviewed, publicly available databases, to develop national BAFs for three trophic levels of fish. If this information was not available, EPA selected octanol-water partition coefficients (K_{ow} values) from peer-reviewed sources for use in calculating national BAFs.[14]

EPA's national default drinking water intake rate of 2.4 L/day represents the per capita estimate of combined direct and indirect community water ingestion at the 90th percentile for adults ages 21 and older.[15] EPA's national default FCR of 22 g/day represents the 90th percentile consumption rate of fish and shellfish from inland and nearshore waters for the U.S. adult population 21 years of age and older, based on National Health and Nutrition Examination Survey (NHANES) data from 2003 to 2010.[16] [17] EPA calculates

[8] USEPA. 2000. Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health. U.S. Environmental Protection Agency, Office of Water, Washington, DC EPA–822–B–00–004. *https://www.epa.gov/wqc/human-health-water-quality-criteria.*

[9] As noted above, EPA recommends the criterion derived for non-carcinogenic effects if it is more protective (lower) than that derived for carcinogenic effects.

[10] EPA's 2000 Methodology also states: "Criteria based on a 10^{-5} risk level are acceptable for the general population as long as states and authorized tribes ensure that the risk to more highly exposed subgroups (sport fishers or subsistence fishers) does not exceed the 10^{-4} level." Since EPA is establishing final criteria to protect a target general population of tribes with reserved subsistence fishing rights in Washington waters, the applicable EPA-recommended cancer risk levels would relate to that target general population, as opposed to the general population of Washington residents overall. See section III for additional discussion.

[15] USEPA. 2011. EPA Exposure Factors Handbook. 2011 edition (EPA 600/R–090/052F). *http://cfpub.epa.gov/ncea/risk/recordisplay.cfm?deid=236252.*

[16] USEPA. 2014. Estimated Fish Consumption Rates for the U.S. Population and Selected Subpopulations (NHANES 2003–2010). United States Environmental Protection Agency, Washington, DC EPA 820–R–14–002.

[17] EPA's national FCR is based on the total rate of consumption of fish and shellfish from inland and nearshore waters (including fish and shellfish from local, commercial, aquaculture, interstate, and international sources). This is consistent with a principle that each state does its share to protect people who consume fish and shellfish that originate from multiple jurisdictions. USEPA. January 2013. *Human Health Ambient Water Quality Criteria and Fish Consumption Rates: Frequently Asked Questions. https://www.epa.gov/wqc/human-health-ambient-water-quality-criteria-and-fish-consumption-rates-frequently-asked.*

human health criteria using a default body weight of 80 kilograms (kg), the average weight of a U.S. adult age 21 and older, based on NHANES data from 1999 to 2006.

Although EPA uses these default values to calculate national 304(a) recommended human health criteria, EPA's 2000 Methodology notes a preference for the use of local data to calculate human health criteria (*e.g.*, locally derived FCRs, drinking water intake rates and body weights, and waterbody-specific bioaccumulation rates) over national default values, where data are sufficient to do so, to better represent local conditions.[18] It is also important, where sufficient data are available, to select a FCR that reflects consumption that is not suppressed by concerns about the safety of available fish.[19] [20] Deriving human health criteria using an unsuppressed FCR furthers the restoration goals of the CWA and ensures protection of human health-related designated uses (as pollutant levels decrease, fish habitats are restored, and fish availability increases over time). See section III for additional discussion regarding use of an unsuppressed FCR to protect a subsistence or sustenance fishing use, especially where the subsistence or sustenance use is based in whole or in part on tribal treaty or other reserved fishing rights.[21]

d. Relative Source Contribution

When deriving human health criteria for non-carcinogens and nonlinear carcinogens, EPA recommends including a RSC factor to account for sources of exposure other than drinking water and fish and shellfish from inland and nearshore waters, so that the pollutant effect threshold (*i.e.*, RfD) is not apportioned to drinking water and fish consumption alone. The rationale for this approach is that for pollutants exhibiting threshold effects, the objective of the human health criteria is to ensure that an individual's total exposure from all sources does not exceed that threshold level. These other exposures include exposure to a particular pollutant from ocean fish and shellfish consumption (which is not included in EPA's default national FCR), non-fish food consumption (*e.g.*, fruits, vegetables, grains, meats, poultry), dermal exposure, and inhalation exposure. EPA's guidance includes a procedure for determining an appropriate RSC value ranging from 0.2 to 0.8 for a given pollutant.

III. Derivation of Human Health Criteria for Washington

A. Scope of Pollutants and Waters Covered by This Final Rule

In 1992, EPA did not establish human health criteria in the NTR for some priority toxic pollutants because, as stated in the preamble to the final rule at 57 FR 60848, December 22, 1992, EPA had no 304(a) recommendations for those pollutants at the time. EPA now has 304(a) recommendations for 99 priority toxic pollutants listed pursuant to CWA section 307(a)(1) (85 for which EPA established criteria in the NTR, plus 14 additional pollutants).

After consideration of all comments received on EPA's proposed rule, and EPA's CWA 303(c) action on Washington's submittal, EPA is finalizing 144 new and revised Washington-specific criteria for priority toxic pollutants in this rule. For arsenic, dioxin and thallium, EPA is not revising Washington's existing criteria from the NTR at this time, as explained below and in EPA's Response to Comments document in the docket for the final rule. For those priority pollutants for which EPA does not have 304(a) national recommended criteria, and are therefore not included in Washington's submittal or this final rule, EPA expects that Washington will continue to apply its existing narrative toxics criterion in the state's WQS at WAC 173–201A–260(2)(a).

Several commenters raised concerns about the scientific defensibility of EPA's proposed human health criteria for arsenic, and one commenter raised similar concerns about EPA's proposed criteria for 2,3,7,8–TCDD (dioxin). Additionally, after EPA proposed revised human health criteria for thallium in Washington, EPA further evaluated the scientific uncertainty around the appropriate RfD for thallium. EPA carefully considered all of these comments and information regarding these three pollutants, along with the comments that articulated it is important for Washington to have protective numeric criteria in place for priority toxic pollutants such as arsenic and dioxin. Given the scientific uncertainty regarding aspects of the science upon which the proposed human health criteria for arsenic, dioxin, and thallium were based, EPA is withdrawing its proposal of revised criteria for these three pollutants at this time and leaving the existing criteria from the NTR in effect for CWA purposes.[22] EPA did not update the 304(a) national recommended criteria for these three pollutants in 2015. As noted earlier, IRIS was the primary source of toxicity values (*i.e.*, RfD and CSF) for EPA's 2015 updated 304(a) human health criteria. For thallium, EPA's IRIS database does not currently contain an estimate of thallium's toxicity (*i.e.*, a RfD).[23] For dioxin, IRIS does not currently contain a measure of dioxin's cancer-causing ability (*i.e.*, a CSF).[24] Without such values, EPA has concluded that further analysis is necessary in order to promulgate scientifically sound revised criteria for these two pollutants. For arsenic, there is uncertainty surrounding the toxicological assessment with respect to human health effects. EPA's current plan for addressing the arsenic issues is described in the *Assessment Development Plan for the Integrated Risk Information System (IRIS) Toxicological Review of Inorganic Arsenic* (EPA/630/R–14/101, November 2015). EPA intends to reevaluate the existing federal arsenic, dioxin and thallium human health criteria for Washington by 2018, with particular consideration of any relevant toxicity and bioaccumulation information.

This rule revises the criteria that EPA promulgated for Washington in the NTR (with the exception of criteria for arsenic, dioxin, and thallium, and criteria that EPA approved in Washington's August 1, 2016 submittal), and establishes new human health criteria for 8 additional chemicals for which EPA now has 304(a) recommended criteria (and for which EPA did not approve Washington's submitted criteria): Selenium, Zinc, 1,2-Trans-Dichloroethylene, Acenaphthene, Butylbenzyl Phthalate, 2-Chloronaphthalene, 1,1,1-Trichloroethane, and 1,2,4-Trichlorobenzene. In 2001, EPA

replaced its 304(a) recommended human health criteria for total mercury with a fish tissue-based human health criterion for methylmercury.[25] Washington did not include human health criteria for mercury or methylmercury in its August 1, 2016 submittal. Therefore, with this final rule, EPA replaces the criteria for total mercury that EPA promulgated for Washington in the NTR with a methylmercury fish tissue criterion, based on EPA's 2001 304(a) recommendation but adjusted to incorporate the 175 g/day FCR that EPA used to derive revised human health criteria in Washington, as well as EPA's 2015 updated national default body weight of 80 kg.

A few commenters expressed concern that Washington would not have the data or implementation guidance to properly implement a fish tissue criterion for methylmercury, and requested that EPA leave the NTR total mercury criteria in effect in Washington. The fish tissue methylmercury criterion reflects EPA's 2000 Methodology, the best available science, and supersedes all previous 304(a) human health mercury criteria recommendations published by EPA (except for the waters of the Great Lakes System), including the 304(a) recommended criteria that served as the basis for the total mercury criteria that EPA promulgated for Washington in the NTR. EPA recommends a fish tissue water quality criterion for methylmercury for many reasons. A fish tissue water quality criterion integrates spatial and temporal complexity that occurs in aquatic systems and affects methylmercury bioaccumulation. For this pollutant, a fish tissue criterion is more closely tied to the goal of protecting human health because it is based directly on the dominant human exposure route for methylmercury in the U.S., which is consumption of fish and shellfish. The concentration of methylmercury is also generally easier to quantify in fish tissue than in water and is less variable in fish and shellfish tissue over the time periods in which WQS are typically implemented in water quality-based controls, such as NPDES permits. Finally, fish consumption advisories for mercury are also based on the amount of methylmercury in fish tissue.[26] While the purpose of a fish advisory is different from the purpose of a water quality criterion, it will be helpful to the public to have water quality criteria and fish consumption advisories for methylmercury expressed using the same terms. In response to comments regarding implementation of the methylmercury criterion, in 2010, EPA published the comprehensive *Guidance for Implementing the January 2001 Methylmercury Water Quality Criterion* (EPA 823–R–10–001), to aid states in implementing the fish tissue-based methylmercury water quality criterion. EPA is confident that Washington will be able to implement the fish tissue criterion using the information contained in that document, and EPA remains available to offer assistance in doing so. Thus there is no need or requirement to leave the NTR total mercury criteria in place in Washington.

This final rule does not change or supersede any criteria that EPA previously promulgated for other states in the NTR, nor does it change any other elements of the NTR such as EPA's original basis for promulgation. For clarity in organization, EPA is withdrawing Washington from the NTR at 40 CFR 131.36 and incorporating the Washington-specific criteria in this rule (as well as the existing NTR criteria for arsenic, dioxin and thallium) into 40 CFR 131.45 so there is a single comprehensive set of federally promulgated criteria for Washington.

This rule applies to waters under the State of Washington's jurisdiction, and not to waters within Indian country,[27] unless otherwise specified in federal law. Some waters located within Indian country already have CWA-effective human health criteria, while others do not.[28] Several tribes are working with EPA to either revise their existing CWA-effective WQS, or obtain treatment in a similar manner as a state (TAS) status in order to adopt CWA-effective WQS in the near future. EPA will continue to work closely with tribes in Washington to ensure that they adopt human health criteria that are scientifically supported and protective of designated uses, in accordance with the CWA and EPA's regulations. In addition, on September 29, 2016, EPA published an Advanced Notice of Proposed Rulemaking in the **Federal Register** that seeks input on an approach that involves EPA promulgating baseline WQS for reservations that currently have no CWA-effective WQS, including such reservations within the State of Washington.[29]

B. Washington's Designated Uses and Tribal Reserved Fishing Rights

a. EPA's Consideration of Tribal Treaty Rights

Under the Supremacy Clause of the U.S. Constitution, federal treaties have the same legal force as federal statutes.[30] As such, the provisions of federal statutes should generally be read in harmony with treaties where they both apply. In certain instances, statutes may contain provisions indicating that they *must* be read in harmony with treaties. Such is the case with the CWA, which provides that the Act "shall not be construed as . . . affecting or impairing the provisions of any treaty of the United States." [31]

In determining whether WQS satisfy the CWA and EPA's regulations, and when setting criteria for the protection of human health, it is necessary to consider other applicable laws, such as federal treaties (*e.g.,* U.S. Treaties with Indians). While treaties do not expand EPA's authority, they are binding on the federal government. As a result, EPA has an obligation to ensure that its actions do not conflict with tribal treaty rights.[32] For the foregoing reasons, and

[25] USEPA. 2001. Guidance for Implementing the January 2001 Methylmercury Water Quality Criterion. U.S. Environmental Protection Agency, Office of Water, Washington, DC EPA–823–R–01–001. *https://www.epa.gov/wqc/guidance-implementing-january-2001-methylmercury-water-quality-criterion.*

[26] While both water quality criteria and fish consumption advisories are designed ultimately to protect human health, they represent very different values and goals. Water quality criteria express or establish a desired condition and must protect the designated use, such as subsistence fishing. Fish consumption advisories start with existing levels of fish contamination resulting from impaired water quality, and provide advice to populations consuming such fish on limiting levels of consumption in order to reduce risk from contamination.

[27] See 18 U.S.C. 1151 for the definition of Indian country.

[28] Indian country waters with CWA-effective WQS include those where (a) EPA has authorized a tribe to adopt WQS under the CWA for its reservation and the tribe has adopted standards that EPA has approved, and (b) EPA has promulgated federal WQS.

[30] U.S. Const. art. IV, § 2: The "Constitution . . . of the United States . . . and all Treaties made, or which shall be made, under the Authority of the United States, shall be the supreme Law of the Land; and the Judges in every State shall be bound thereby, any Thing in the Constitution or Laws of any State to the Contrary notwithstanding."

[31] CWA Section 511, 33 U.S.C. 1371.

[32] U.S. Const. art. IV, § 2; *see United States* v. *Forty-Three Gallons of Whiskey,* 93 U.S. 188, 196 (1833) (recognizing that "the Constitution declares a treaty to be the supreme law of the land," and that "a treaty is to be regarded . . . as equivalent to an act of the legislature") and *Worcester* v. *Georgia,* 31 U.S. 515, 594 (1832) ("So long as . . . treaties exist, having been formed within the sphere of the federal powers, they must be respected and enforced by the appropriate organs of the federal government."). *See also* EPA policies on considering treaty rights: *Working Effectively With Tribal Governments: Resource Guide* at pp. 49–52, 53 (August 1998) (explaining the key principles underlying the application of Indian treaty rights, and noting that "[f]ederal, state, and local agencies need to refrain

as further explained below, it is therefore necessary and appropriate to consider tribal treaties to ensure that EPA's actions under the CWA are in harmony with such treaties. See also EPA's Response to Comment document in the docket for this rule.

b. Treaty-Reserved Subsistence Fishing Rights in Washington

The majority of waters under the jurisdiction of the State of Washington are subject to federal treaties with tribes.[33] There are eight Stevens-Palmer Treaties relevant to the State of Washington through which 24 tribes reserved for themselves identical or nearly identical fishing rights within the boundaries of present-day Washington; specifically, the treaty-reserved "right of taking fish at usual and accustomed places, in common with all citizens of the Territory." [34] The right to take fish at usual and accustomed places extends to lands formerly ceded by the tribes to the U.S. as described in the treaties, as well as to all places beyond the boundaries of the ceded territories that tribal members regularly used at treaty time.[35]

The parties to the treaties all recognized the importance of the fishing right for the tribes' subsistence, ceremonial, as well as commercial purposes.[36] In *U.S. v Washington,* the district court made detailed findings of facts regarding the reserved fishing right, including the importance of subsistence fishing to the treaty tribes:

> At the treaty negotiations, a primary concern of the tribes, whose way of life was so heavily dependent upon harvesting anadromous fish, was that they have freedom to move about to gather food, particularly salmon, . . . at their usual and accustomed fishing places. . . . Subsequent to the execution of the treaties and in reliance thereon, the members of the [treaty tribes with reserved fishing rights in Washington] have continued to fish for subsistence, sport, and commercial purposes at their usual and accustomed places. Such fishing provided and still provides an important part of their livelihood, subsistence and cultural identity. The Indian cultural identification with fishing is primarily dietary, related to the subsistence fishery, and secondarily associated with religious ceremonies and commercial fishing.[37]

Relevant case law, including Supreme Court precedents, unequivocally confirms that the treaty-reserved right to take fish includes the right to take fish for subsistence purposes.[38] Historical and current evidence of tribal members' exercise of the treaty-reserved subsistence fishing right can be found in heritage FCR reports and contemporary FCR surveys (for tables of relevant FCRs, see EPA's Response to Comment document in the docket for this rule).

As explained above, the Stevens-Palmer Treaties provide tribes the right to exercise subsistence fishing practices on waters throughout the State of Washington. EPA concludes that the purpose for which tribes reserved such fishing rights through treaties with the U.S. has important implications for water quality regulation under the CWA. Fundamentally, the tribes' ability to take fish for their subsistence purposes under the treaties would be substantially affected or impaired if it were not supported by water quality sufficient under the CWA to ensure that tribal members can safely eat the fish for their own subsistence.

Many areas where treaty-reserved fishing rights are exercised cannot be directly protected or regulated by tribal governments to ensure adequate water quality, and therefore the responsibility falls to the federal government (and the states) to ensure their protection. It is therefore appropriate and necessary for EPA (and states) to consider the tribal reserved rights within the framework of the CWA, to ensure water quality protection for treaty-reserved subsistence fishing rights. EPA's consideration of treaty-reserved fishing rights within the framework of the CWA leads to the conclusion, as described below, that the human health fishing uses for waters in Washington include subsistence fishing, as informed by the tribes' legally protected right to continue to take fish for subsistence purposes.[39]

from taking actions that are not consistent with tribal rights wherever they exist"); *Commemorating the 30th Anniversary of the EPA's Indian Policy,* Memorandum from Gina McCarthy to All EPA Employees, p. 1 (December 1, 2014) (reiterating that "EPA must ensure that its actions do not conflict with tribal treaty rights" and stating that "EPA programs should be implemented to enhance the protection of tribal treaty rights and treaty-covered resources when we have the discretion to do so"); *EPA Policy for the Administration of Environmental Programs on Indian Reservations* (November 8, 1984) (known as "EPA 1984 Indian Policy").

[33] *See http://wdfw.wa.gov/hunting/tribal/treaty_history.html.*

[34] *See e.g.* Treaty with the Yakima art. 3, June 9, 1855, 12 Stat. 951. In *United States* v. *Winans,* 198 U.S. 371 (1905), the Supreme Court adopted a "reservation of rights" approach in interpreting the Stevens Treaty with the Yakima Nation: "the treaty was not a grant of rights to the Indians, but a grant of rights from them—a reservation of those not granted." *Id.* at 381. In contrast, "off reservation fishing by other citizens and residents of the state is not a right but merely a privilege which may be granted, limited or withdrawn by the state as the interests of the state or the exercise of treaty fishing rights may require." *U.S. v Washington,* 384 F. Supp. 312, 332 (W.D. Wash. 1974) *aff'd* 520 F.2d 676 (9th Cir. 1975), *cert. denied* 423 U.S. 1086 (1976).

[35] *See Seufert Bros. Co.* v. *U.S.,* 249 U.S. 194, 199 (1919). In *U.S. v Washington,* the court stated, citing *Seufert Bros. Co.,* "every fishing location where members of a tribe customarily fished from time to time at and before treaty times, however distant from the then usual habitat of the tribe, and whether or not other tribes then also fished in the same waters, is a usual and accustomed ground or station at which the treaty tribe reserved, and its members presently have, the right to take fish." 384 F. Supp. at 332.

[36] For a thorough discussion on the treaty negotiation and execution and meaning of the reserved fishing right, *see e.g., U.S. v Washington,* 384 F. Supp. at 348–359 (containing finding of facts regarding, *inter alia,* treaty status, pre-treaty role of fishing among northwest Indians, treaty background, negotiation and execution of the treaties, and post-treaty Indian fishing); *see also id.* at 340 ("The right to fish for all species available in the waters from which, for so many ages, their ancestors derived most of their subsistence is the single most highly cherished interest and concern of the present members of plaintiff tribes, with rare exceptions even among tribal members who personally do not fish or derive therefrom any substantial amount of their subsistence."); *id.* at 343 ("The evidence shows beyond doubt that at treaty time the opportunity to take fish for personal subsistence and religious ceremonies was the single matter of utmost concern to all treaty tribes and their members."); and *U.S.* v. *Washington,* No. 13–35474, 2016 U.S. App. LEXIS 11709, at *29 (9th Cir. June 27, 2016) ("The Indians reasonably understood Governor Stevens to promise not only that they would have access to their usual and accustomed fishing places, but also that there would be fish sufficient to sustain them.").

[37] *U.S.* v *Washington,* 384 F. Supp. at 355–358 (internal citations to exhibits omitted).

[38] *See e.g., Washington* v. *Washington State Commercial Passenger Fishing Vessel Ass'n,* 443 U.S. 658, 678–679 (1979) (Because the Indians had always exercised the right to meet their subsistence and commercial needs by taking fish from treaty area waters, they would be unlikely to perceive a "reservation" of that right as merely the chance, shared with millions of other citizens, occasionally to dip their nets into the territorial waters. Moreover, the phrasing of the clause quite clearly avoids placing each individual Indian on an equal footing with each individual citizen of the State."); *U.S.* v. *Washington,* 2016 U.S. App. LEXIS 11709 at *28 (Observing that to the Tribes, the Stevens Treaties' "principal purpose was to secure a means of supporting themselves once the Treaties took effect," and to that end, "[s]almon were a central concern.").

[39] While EPA's action is based on harmonizing the requirements of the CWA with the terms of the treaty-reserved subsistence fishing right, the action also is consistent with federal Indian law principles addressing subsidiary treaty rights. A written legal opinion from the Solicitor of the U.S. Department of Interior (DOI) to EPA analyzed whether tribal reserved fishing rights include subsidiary rights to sufficient water quality. Letter from Hilary C. Tompkins, Solicitor, DOI, to Avi Garbow, General Counsel, EPA, regarding Maine's WQS and Tribal Fishing Rights of Maine Tribes (January 30, 2015). Although DOI's legal opinion primarily involved an analysis of fishing rights of tribes in Maine in connection with EPA's February 2, 2015 decision to disapprove WQS applied to waters of Indian Lands in Maine, its discussion of tribal fishing rights and water quality has relevance to tribes with reserved fishing rights in Washington. DOI's legal opinion identified several court decisions, including Supreme Court decisions interpreting the reserved fishing right in the Stevens Treaties, which have held that fishing rights for tribes encompass subsidiary rights that are necessary to render those rights meaningful. In *Washington* v. *Wash. State Commercial Passenger Fishing Vessel Ass'n,* the United States Supreme Court held that tribes with

Continued

c. Use(s) of the Water(s) in Question

Consistent with EPA's September 14, 2015 proposed rule for Washington, in order to effectuate and harmonize treaty-reserved fishing rights with the CWA, EPA has determined that such rights must be appropriately considered when determining which criteria are sufficient to adequately protect Washington's designated uses. Looking at the treaty-reserved subsistence fishing right within the CWA water quality framework, the first step is to examine the use of the water(s) in question. The CWA generally assigns to a state the responsibility of determining the designated uses of its waters (subject to certain restrictions at 40 CFR 131.10),[40] and in Washington the state's designated uses include fish and shellfish harvesting.[41] As explained above, through treaties, tribes reserved specific fishing rights in Washington's waters, including the right to take fish from such waters for their subsistence. In order to effectuate these rights in harmony with the CWA, EPA has interpreted the state's EPA-approved designated fish and shellfish harvesting use to include or encompass a subsistence fishing component based on, and consistent with, the rights reserved to the tribes through the treaties. As discussed in more detail below, EPA construes the CWA to require that, when establishing WQS for these waters, the tribal members must be considered the target general population for the purposes of setting risk levels to protect the subsistence fishing use.

d. Target General Population for Deriving Criteria Protective of the Use(s)

Developing criteria to protect the fish and shellfish harvesting use, which includes subsistence fishing as informed by reserved fishing rights, necessarily involves identifying tribal members with reserved fishing rights as the target population for protection. EPA's conclusion to identify tribes as the target population is based on EPA's CWA implementing regulations requiring criteria to support the most sensitive use (*i.e.*, subsistence fishing) and EPA's 2000 Methodology recommendation that priority be given to identifying and protecting highly exposed populations. Further, in order to derive water quality criteria sufficient under the CWA to ensure that the tribes' treaty-reserved right to take fish for subsistence purposes is not substantially affected or impaired, it is reasonable and appropriate to identify tribes as the target *general* population for protection, rather than a subpopulation, and apply the 2000 Methodology's recommendations on exposure for the general population to the tribal target population.

Per EPA's regulations at 40 CFR 131.11(a)(1), water quality criteria must contain sufficient parameters or constituents to protect the designated use, and for waters with multiple uses, the criteria must support the most sensitive use. In the case of Washington's human health-related uses, the most sensitive use is fish and shellfish harvesting, which, as explained above, EPA has interpreted to include or encompass a subsistence fishing component based on, and consistent with, the rights reserved to the tribes through the treaties. Developing water quality criteria to protect the subsistence fishing component of the fish or shellfish harvesting use necessarily involves identifying the population exercising that use.

EPA's decision to identify tribes as the target population is further supported by EPA guidance for developing water quality criteria to protect human health. As explained in EPA's 2000 Methodology, the choice of the particular population to protect is an important decision to make when setting human health criteria.[42] EPA recommends that states provide adequate protection from adverse health effects to the general population, as well as to highly exposed populations, such as recreational and subsistence fishers, two distinct groups with FCRs that may be greater than the general population.[43] In fact, EPA's 2000 Methodology recommends considering how to protect both susceptible and highly exposed populations when setting criteria:

> EPA recommends that priority be given to identifying and adequately protecting the most highly exposed population. Thus, if the State or Tribe determines that a highly exposed population is at greater risk and would not be adequately protected by criteria based on the general population, and by the national 304(a) criteria in particular, EPA recommends that the State or Tribe adopt more stringent criteria using alternative exposure assumptions.[44]

Therefore, consistent with the guidance, EPA identifies the tribal population as the target population for protection and the subsistence fishing use must be the focus of the risk assessment supporting water quality criteria to adequately protect that use. Deriving criteria protective of the tribal target population necessarily involves determining the appropriate inputs for calculating protective criteria for tribal subsistence fishers, such as the FCR and cancer risk level.

EPA's approach in the 2000 Methodology, and its approach used for deriving national 304(a) recommended criteria, is for human health water quality criteria to provide a high level of protection for the general population (for example, FCRs designed to represent "the general population of fish consumers," or a cancer risk level that "reflects an appropriate risk for the general population"), while recognizing that more highly exposed "subpopulations" may face greater levels of risk.[45] The 2000 Methodology does not, however, speak to or envision the unique situation of setting WQS that cover areas where tribes have treaty-reserved rights to practice subsistence

reserved fishing rights are entitled to something more tangible than "merely the chance . . . occasionally to dip their nets into the territorial seas." 443 U.S. 658, 679 (1979). Consistent with this reasoning, courts have held that treaty-reserved fishing rights entail the right to access fishing grounds and the right to water quantity sufficient to support fish habitat. *See e.g., United States* v. *Winans,* 198 U.S. 371, 384 (1905) (tribe must be allowed to cross private property to access traditional fishing ground); *Seufert Bros. Co.* v. *United States,* 249 U.S. 194 (1919) (tribe entitled to cross over and temporarily use any sites which they were accustomed to using at treaty time, including sites outside their ceded territories); *United States* v. *Adair,* 723 F .2d 1394, 1409–10 (9th Cir. 1983) (holding that the tribe's fishing right implicitly reserved sufficient waters to "secure to the Tribe a continuation of its traditional . . . fishing lifestyle"; *Colville Confederated Tribes* v. *Walton,* 647 F.2d 42, 47–48 (9th Cir. 1981) (implying reservation of water to preserve tribe's replacement fishing grounds). Consistent with these precedents, in June 2016 the U.S. Court of Appeals for the Ninth Circuit affirmed the district court's finding that barrier culverts constructed by the State of Washington obstructing fish passage were in violation of tribal fishing rights set forth in the Stevens Treaties, noting that "the Tribes' right of access to their usual and accustomed fishing places would be worthless without harvestable fish." *United States* v. *Washington,* 2016 U.S. App. LEXIS 11709 at *31. The court also acknowledged that the fishing clause of the Stevens Treaties could give rise to other environmental obligations, but that those would need to be addressed on a case-by-case basis depending on the precise nature of the action. *Id.* at *18–19. Consistent with this body of case law, DOI's legal opinion concludes that "fundamental, longstanding tenets of federal Indian law support the interpretation of tribal fishing rights to include the right to sufficient water quality to effectuate the fishing right." fishing.[46] Nevertheless, it is possible to apply the general principles outlined in the 2000 Methodology to this situation, as informed by the treaties.

In light of the presence of the treaty-reserved fishing rights in Washington, interpreted by the U.S. Supreme Court to encompass, among other things, subsistence fishing, and EPA's interpretation of Washington's fish and shellfish harvesting use to include subsistence fishing, it is reasonable and appropriate to require that tribes with such rights be considered as the target general population for deriving criteria protective of the use rather than a sensitive subpopulation within the overall population of Washington. Treating tribes as the target general population will help derive water quality criteria sufficient under the CWA to ensure that the tribes' treaty-reserved right to take fish for subsistence purposes is not substantially affected or impaired. Therefore, the 2000 Methodology's recommendations on exposure for the target general population can be applied accordingly. EPA's conclusion to treat tribes as the target general population, as opposed to a subpopulation, is further supported by relevant case law interpreting the treaty-reserved fishing rights applicable in Washington; specifically the phrase "in common with all citizens of the territory."

Treating tribes as the target population instead of a sensitive subpopulation also impacts another important input parameter used to derive human health criteria, the cancer risk level. For carcinogenic pollutants, EPA's 2000 Methodology recommends that states protect the general population to a level of incremental cancer risk no greater than one in one hundred thousand to one in one million (1×10^{-5} to 10^{-6}). For over 20 years, Washington has used 10^{-6} as the level of risk that must be used to establish human health criteria for carcinogenic pollutants. EPA's 2000 Methodology indicates that if there are highly exposed groups or subpopulations within that target general population, such as subsistence consumers, WQS should protect those consumers to a level of incremental risk no greater than one in ten thousand (1×10^{-4}).[47] However, where treaty-reserved tribal fishing rights apply to particular waters, it would be unreasonable to expose the communities exercising those rights to levels of risk above what would be reasonable for the general population of the state. See section III.C.b for more information on cancer risk level.

e. Water Quality Criteria Sufficient To Protect the Use(s)

The data used to determine the FCR are critical to deriving criteria that will protect the subsistence fishing portion of the fish and shellfish harvesting designated use. EPA provides a recommended national default FCR for the general population but strongly recommends the use of local or regional data, where available, over default values.[48] Further, as EPA explained in its January 2013 *Human Health Ambient Water Quality Criteria and Fish Consumption Rates: Frequently Asked Questions,* it is important to avoid selecting a FCR that reflects consumption that is suppressed due to concerns about the safety of available fish. Under certain circumstances, it may also be relevant to look at the availability of fish when considering suppression effects on current FCRs.[49] EPA maintains that it is important, as a CWA goal, to avoid the suppression effect that may occur when criteria are derived using a FCR for a given target population that reflects an artificially diminished level of fish consumption from an appropriate baseline level of consumption for that population.[50] To use a FCR that is suppressed would not result in criteria that actually protect a fishing use because it would merely reinforce the existing suppressed use, or worse, set in motion a "downward spiral" [51] of further reduction/suppression of fish consumption due to concerns about the safety of available fish or depleted fisheries. The CWA is meant not merely to maintain the status quo, but to *restore* and maintain the chemical, physical, and biological integrity of the Nation's waters. Therefore, deriving criteria using an unsuppressed FCR furthers the restoration goals of the CWA and ensures protection of human health-related designated uses (as pollutant levels decrease, fish habitats are restored, and fish availability increases over time).

CWA section 303(c)(2)(A) requires that water quality criteria be "based upon" applicable designated uses, and that such uses and criteria "shall be such as to protect the public health or welfare, enhance the quality of water and serve the purposes of this [Act]." The "purposes of this [Act]" are in section 101, and include, among other things, "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters" and "water quality which provides for the protection and propagation of fish, shellfish, and wildlife and provides for recreation in and on the water." EPA's implementing water quality regulations at 40 CFR 131.11 require water quality criteria to be based on sound scientific rationale and sufficient to protect the designated use, regardless of whether that use is currently being met. A subsistence fishing designated use, by definition, represents a level of fish consumption that is adequate to provide subsistence, regardless of whether such consumption is occurring today. It is entirely consistent with the CWA and regulations for EPA to determine that to protect the designated use, it is necessary and appropriate to derive the human health criteria using a fish consumption rate that reflects a subsistence level of consumption that is not artificially suppressed as a result of concerns about pollution or fish contamination where such data are available.

Any fish consumption rate used in setting criteria to protect a subsistence fishing use must allow for the consumption of fish from local waters at levels that could sustain and be protective of members of the target population practicing a subsistence lifestyle. Water quality criteria derived

[46] In response to comments on EPA's 1998 draft Human Health Methodology revisions, the Agency responded: "As stated in the 1998 draft Methodology revisions, 'risk levels and criteria need to be protective of tribal rights under federal law (*e.g.*, fishing, hunting, or gathering rights) that are related to water quality.' We believe the best way to ensure that Tribal treaty and other rights under Federal law are met, consistent with the Federal trust responsibility, is to address these issues at the time EPA reviews water quality standards submissions." (See 65 FR 66444, 66457 November 3, 2000).

[47] 2000 Methodology, 2–6.

[48] EPA's 2000 Methodology, 4–24—4–25 ("EPA's first preference is that States and authorized Tribes use the results from fish intake surveys of local watersheds within the State or Tribal jurisdiction to establish fish intake rates that are representative of the defined populations being addressed for the particular waterbody.")

[49] As noted by the National Environmental Justice Advisory Council in the 2002 publication *Fish Consumption and Environmental Justice,* "a suppression effect may arise when fish upon which humans rely are no longer available in historical quantities (and kinds), such that humans are unable to catch and consume as much fish as they had or would. Such depleted fisheries may result from a variety of affronts, including an aquatic environment that is contaminated, altered (due, among other things, to the presence of dams), overdrawn, and/or overfished. Were the fish not depleted, these people would consume fish at more robust baseline levels. . . . In the Pacific Northwest, for example, compromised aquatic ecosystems mean that fish are no longer available for tribal members to take, as they are entitled to do in exercise of their treaty rights."). National Environmental Justice Advisory Council, *Fish Consumption and Environmental Justice,* p.44, 46 (2002) *available at https://www.epa.gov/sites/production/files/2015-02/documents/fish-consump-report_1102.pdf.*

[50] *See id.* at 43.

[51] *See id.* at 47.

using a FCR below a level that would be adequate to sustain members of the target population exercising a subsistence use, such as tribal members who have a history of subsistence fishing in Washington, would not be protective of that use. In this context, use of an unsuppressed rate, where data to determine that rate are available, would ensure that the resulting criteria are protective of the subsistence use.

The importance of relying on an unsuppressed FCR, where data are available, is especially evident where the subsistence use is based in whole or in part on tribal treaty and other reserved subsistence fishing rights. This is because if human health criteria are set at a level that assumes only suppressed fish consumption, the waters will only be protected to support that level of suppressed fish consumption and thus never fully support—and potentially even may directly impair—the tribes' legal right to take fish for subsistence purposes. Accordingly, where adequate data are available to clearly demonstrate what the current unsuppressed FCR is for the relevant target population, the selected FCR must reflect that value. In the absence of such data, states, tribes, and EPA could consider upper percentile FCRs of local contemporary fish consumption surveys (such as the 95th or 99th percentile), heritage FCR data for the target population, and/or FCRs that provide for a subsistence fishing lifestyle. Consultation with tribes is important to ensure that all data and information relevant to this issue are considered.

Although treaties do not cover all waters in Washington, they cover the vast majority of the state's waters. Additionally, where treaty and non-treaty reserved rights apply on waters downstream of waters without reserved fishing rights, upstream WQS must provide for the attainment and maintenance of downstream WQS in accordance with EPA's regulations at 40 CFR 131.10(b). Based on a GIS analysis included in the docket for this final rulemaking, EPA concluded that greater than 90 percent of waters in Washington are covered by treaty rights and/or are upstream of waters with such rights or waters in Oregon (see section III.C.a). For any remaining waters in Washington, where reserved rights do not apply and that are not upstream of waters with such rights or waters in Oregon, it would be administratively burdensome to develop separate criteria to apply to such a small subset of waters, and would be difficult to implement separate criteria with a patchwork of protection among these areas when administering the WQS, NPDES permitting, and other programs. Therefore, EPA applies these final criteria to all waters under Washington's jurisdiction.

Many commenters supported EPA's decisions to derive criteria protective of the tribal population exercising their treaty-reserved fishing rights in Washington as the target general population, and to apply the resulting criteria to all waters under Washington's jurisdiction. Many other commenters did not support these decisions, and argued that EPA did not have a scientific or legal basis to interpret Washington's designated uses to encompass subsistence fishing and to treat the tribal population with treaty-reserved fishing rights as the target general population for protection under such use. For additional responses to these comments, see EPA's Response to Comment document in the docket for this rule.

C. Washington-Specific Human Health Criteria Inputs

a. Fish Consumption Rate

In Washington there are 24 tribes with treaty-reserved fishing rights, rights that encompass the right to fish for subsistence purposes, and several local and regional FCR surveys and heritage tribal consumption reports with widely varying estimates of tribal FCRs in Washington (for tables of relevant FCRs, see EPA's Response to Comment document in the docket for this rule). Available heritage FCRs range from 401 to 995 g/day, and contemporary survey FCRs range from 63 to 214 g/day (mean FCRs) and from 113 to 489 g/day (90th percentile FCRs). The discrepancy between contemporary and heritage FCRs suggests that current FCRs for certain tribal consumers in Washington may be suppressed.[52] [53] It is currently unclear how a contemporary fish consumption survey might quantitatively account for suppression, resulting in estimates of current FCRs that are unsuppressed to the maximum degree practicable. There is no local survey of contemporary fish consumption in Washington adjusted specifically to account for suppression, and no survey is a clear representation of current unsuppressed consumption for all tribes in Washington. Consistent with the principles outlined above, EPA considered the available, scientifically sound fish consumption data for Washington tribes and consulted with tribal governments to select a FCR for this final rulemaking.

The Washington tribes have generally agreed that 175 g/day is acceptable for deriving protective criteria at this time, when accompanied by other protective input parameters to calculate the criteria. However, EPA recognizes that some tribes have raised concerns as to whether a FCR of 175 g/day reasonably reflects current unsuppressed consumption rates of tribes within the State of Washington, based on the best currently available information. A FCR of 175 g/day approximates the 95th percentile consumption rate of surveyed tribal members from the CRITFC study[54] and includes anadromous fish, which is reasonable given that these marine species reside in Washington's nearshore (*i.e.*, within three miles of the coast) waters, especially Puget Sound, and accumulate pollutants discharged to these waters during a significant portion of their lives. The CRITFC survey also includes four tribes (three of which have treaty-reserved rights in Washington, the most of any one contemporary FCR survey in Washington) along the Columbia River in Washington, Idaho, and Oregon. Given this, and also considering the variability in heritage and contemporary FCRs and the uncertainty regarding suppression effects on current FCRs, the CRITFC survey provides scientifically sound estimates of fish consumption for the purpose of deriving a Washington statewide FCR for the tribal target general population.

Additionally, Oregon, much of which is downstream from Washington (or cross-stream in the Columbia River where it forms the border between the two states), used a FCR of 175 g/day to derive statewide human health criteria, which EPA approved in 2011. Use of this FCR to derive Washington's criteria will thus help ensure the attainment and maintenance of downstream WQS in Oregon.

Many commenters supported EPA's selected FCR, as well as the Agency's position that it is important to consider suppression effects on the FCR in general, and necessary and appropriate to do so where subsistence fishing is a reserved right and encompassed by the designated use of the waters. Some

[52] The number of fish advisories and closures due to contamination also suggest that contemporary FCRs may be suppressed due to concerns about pollution. *See* Washington Department of Health, Fish Consumption Advisories, available at *http://www.doh.wa.gov/CommunityandEnvironment/Food/Fish/Advisories.*

[53] Heritage rates refer to the rates of fish intake consistent with traditional tribal practices, prior to contact with European settlers.

[54] *Fish Consumption Survey of the Umatilla, Nez Perce, Yakama, and Warm Springs Tribes of the Columbia River Basin* (Columbia River Inter-Tribal Fish Commission (CRITFC), 1994).

commenters expressed concern that 175 g/day was not high enough to reflect current or historical consumption rates of all tribes in Washington. Many other commenters expressed the opposite concern, that 175 g/day was unreasonably high in order to protect Washington residents, and argued that treaty-reserved rights do not confer the right to eat fish at unsuppressed levels. Some of those commenters also argued that the CWA does not mention suppression. For detailed responses to these comments, see EPA's Response to Comment document in the docket for this rule.

b. Cancer Risk Level

EPA derives final human health criteria for carcinogens in Washington using a cancer risk level of one in one million (10^{-6}), based on Washington's longstanding use of that cancer risk level, EPA guidance, tribal reserved fishing rights, and downstream protection requirements.

To derive final human health criteria for each state in the NTR, EPA selected a cancer risk level based on each state's policy or practice regarding what risk level should be used when regulating carcinogens in surface waters. In its official comments on EPA's proposed NTR in 1992, Washington asked EPA to promulgate human health criteria using a cancer risk level of 10^{-6}, stating, "The State of Washington supports adoption of a risk level of one in one million for carcinogens. If EPA decides to promulgate a risk level below one in one million, the rule should specifically address the issue of multiple contaminants so as to better control overall site risks." (57 FR 60848, December 22, 1992). Accordingly, in the NTR, EPA used a cancer risk level of 10^{-6} (one in one million) to derive human health criteria for Washington. Subsequently, Washington adopted and EPA approved a provision in the state's WQS that reads: "Risk-based criteria for carcinogenic substances shall be selected such that the upper-bound excess cancer risk is less than or equal to one in a million" (WAC 173–201A–240(6)). In Washington's August 1, 2016 submittal, the cancer risk level is identified in the new text and reformatted toxics criteria table at WAC 173–201A–240.

Subsequent to promulgating the NTR, EPA issued its 2000 Methodology, which states that when promulgating water quality criteria for states and tribes, EPA intends to use the 10^{-6} cancer risk level, which reflects an appropriate risk for the general population.[55] In this action, as described above, tribes with treaty-reserved rights in Washington are the target general population for the purpose of deriving revised criteria to protect the subsistence fishing uses of Washington's waters. Because those tribes are the general population in this case, EPA's selection of a 10^{-6} cancer risk level for the tribal target general population is consistent with current EPA guidance, specifically the 2000 Methodology.

In addition, use of a cancer risk rate of 10^{-6} ensures that the resulting human health criteria for carcinogens protect the subsistence fishing component of the designated use. Due to uncertainty regarding suppression effects (see sections II.C, III.B, and III.C.a, and EPA's Response to Comment document in the docket for this rule), using a cancer risk level of 10^{-6} along with a FCR of 175 g/day ensures that tribal members with treaty-reserved fishing rights will be protected at an acceptable risk level for the target general population. Throughout tribal consultation, the tribes generally supported 175 g/day as an acceptable FCR for purposes of revising Washington's human health criteria at this time, when accompanied by other protective input parameters (*e.g.*, a cancer risk level of 10^{-6}), to account for the uncertainty around an appropriate FCR value reflective of tribal subsistence fishing.

Finally, as discussed in section III.C.a, many of Washington's rivers are in the Columbia River Basin, upstream of Oregon's portion of the Columbia River. Oregon's criteria are based on a FCR of 175 g/day and a cancer risk level of 10^{-6}. EPA's decision to derive human health criteria for Washington using a cancer risk level of 10^{-6} along with a FCR of 175 g/day helps ensure that Washington's criteria will ensure the attainment and maintenance of Oregon's downstream WQS as required by 40 CFR 131.10(b).

Many commenters supported EPA's selection of a 10^{-6} cancer risk level, and EPA's rationale for doing so. Many other commenters disagreed and argued that deriving human health criteria for Washington using a 10^{-5} cancer risk level is appropriate and consistent with EPA guidance and past practice. Many of these commenters stated that tribal treaties did not confer rights to a particular level of risk. Additionally, some commenters supported EPA's consideration of downstream WQS in Oregon when establishing the criteria upstream, while others expressed concern that EPA was suggesting that Washington's upstream criteria must be identical to Oregon's downstream criteria and in doing so, acting inconsistently with its 2014 Frequently Asked Questions document on downstream protection.[56] For detailed responses to these comments, see EPA's Response to Comment document in the docket for this rule.

c. Relative Source Contribution

EPA recommends using a RSC for non-carcinogens and nonlinear carcinogens to account for sources of exposure other than drinking water and consumption of inland and nearshore fish and shellfish (see section II.C.d). In 2015, after evaluating information on chemical uses, properties, occurrences, releases to the environment and regulatory restrictions, EPA developed chemical-specific RSCs for non-carcinogens and nonlinear carcinogens ranging from 0.2 (20 percent) to 0.8 (80 percent) following the Exposure Decision Tree approach described in EPA's 2000 Methodology.[57] [58] EPA proposed to use these same RSCs to derive human health criteria for Washington, and where EPA did not update the nationally recommended criteria for certain pollutants in 2015, EPA proposed to use a RSC of 0.2 to derive human health criteria for those pollutants in Washington to ensure protectiveness.

Several commenters supported EPA's use of RSCs to account for other sources of pollutant exposure. Several others disagreed, arguing that water quality criteria under the CWA cannot control or consider sources of exposure other than from drinking water and eating fish and shellfish, so human health criteria should not account for these sources. Many of the commenters, in addition to criticizing the concept of RSCs as overly-conservative, argued that EPA was double-counting exposure to anadromous fish (which EPA considers marine in the national dataset) by both including them in the FCR and using the pollutant-specific RSCs that EPA pairs with an inland and nearshore-only

[55] EPA's 2000 Methodology, pages 2–6.

[58] Final Updated Ambient Water Quality Criteria for the Protection of Human Health, (80 FR 36986, June 29, 2015). See also: USEPA. 2015. Final 2015 Updated National Recommended Human Health Criteria. U.S. Environmental Protection Agency, Office of Water, Washington, DC *https://www.epa.gov/wqc/human-health-water-quality-criteria.*

FCR in its 304(a) national recommended human health criteria. Commenters argued that this is inconsistent with EPA's guidance, which recommends that states adjust the RSC to reflect a greater proportion of the RfD being attributed to water, fish and shellfish intake in instances where the FCR includes freshwater, estuarine and all marine fish consumption.[59] For detailed responses to the comments, see EPA's Response to Comment document in the docket for this rule.

Additionally, after further evaluation of the proposed revised human health criteria for antimony, EPA determined that the existing 304(a) national recommended criteria for antimony (last updated in 2002) use a pollutant-specific RSC of 0.4. EPA intended to apply a 0.2 RSC as a protective approach only where pollutant-specific RSCs were not already developed, which is not the case for antimony.[60]

While the selected FCR of 175 g/day does not include all marine fish (*e.g.*, it does not include consumption of species such as swordfish, tuna, etc.), EPA acknowledges that the criteria as proposed may have double-counted potential exposure to some pollutants in certain marine fish that are anadromous (*e.g.*, salmon). Therefore, EPA reviewed the RSCs in the proposed rule in light of EPA's guidance, which includes both the Exposure Decision Tree and associated discussion in EPA's 2000 Methodology, as well as EPA's recommendation to adjust the RSC when the FCR includes freshwater, estuarine, and all marine fish consumption. Arguably, EPA's guidance does not consider this exact scenario where the selected FCR includes some, but not all, species that EPA classifies as marine in the national NHANES dataset (and excludes some species that EPA classifies as nearshore in the national NHANES dataset, *i.e.*, shellfish).

One way to adjust the RSC values to account for inclusion of marine fish in the FCR is to examine the ratio of the national data characterizing all fish consumption rates versus inland and nearshore-only fish consumption rates derived from the NHANES dataset, and apply this ratio to the proportion of the RfD reserved for inland and nearshore fish consumption in the RSC. This approach assumes that the pollutant concentrations in anadromous fish are the same as the pollutant concentrations in inland and nearshore fish, which is the same assumption inherent in including multiple fish categories in the FCR for criteria calculation. This approach further assumes that the ratio of all fish to inland and nearshore fish from NHANES data approximates the ratio of inland, nearshore, and anadromous fish to just inland and nearshore fish from CRITFC data. At the 90th percentile rate of consumption, the national adult consumption rate from NHANES data for all fish is 53 g/day and 22 g/day for inland and nearshore-only fish, or a ratio of 2.4. Applying this to a RSC of 0.2 yields 0.48, or 0.5 rounding to a single decimal place. Because the selected FCR includes some but not all marine species, EPA decided to use this approach to adjust the RSC values. However, EPA only adjusted RSC values to 0.5 for criteria calculations previously using a RSC between 0.2 and 0.5.

There are important considerations in assigning a RSC, such as the total number of potential exposure routes from sources other than fish consumption, which compels caution in using this approach in all cases. As such, EPA decided to retain RSC values of 0.5 and above, recognizing the compelling need to account for the other potential exposure sources, including marine fish not accounted for in the FCR of 175 g/day, consistent with the logic and procedures used in establishing the national 304(a) criteria recommendations. The Exposure Decision Tree in EPA's 2000 Methodology only recommends using a RSC above 0.5 when there are no significant known or potential uses/sources other than the source of concern (Box 7, Figure 4–1 in EPA's 2000 Methodology) or there are sufficient data available on each source to characterize the exposure to those sources (Box 8C, Figure 4–1). Neither of these conditions are met for most of the pollutants in the final rule for Washington. EPA is not adjusting the RSCs for pollutants that already have national recommended RSCs greater than or equal to 0.5 (2-Chloronaphthalene (0.8), Endrin (0.8), gamma-BHC/Lindane (0.5), and methylmercury (2.7×10^{-5} subtracted from the RfD, which equates to a RSC of approximately 0.73). See Table 1, column B2 for a list of EPA's final RSCs by pollutant.

d. Body Weight

EPA calculates final human health criteria for Washington using a body weight of 80 kg, which represents the average weight of a U.S. adult and is consistent with EPA's 2015 updated national default body weight (see section II.C.c).[61] Local tribal survey data relevant to Washington are also consistent with EPA's national adult body weight of 80 kg.[62] Most commenters were silent on EPA's proposal to use a body weight of 80 kg to calculate human health criteria for Washington. A few commenters were concerned that 80 kg would not ensure adequate protection of women and children, and may not be representative of all residents in Washington based on limited local or regional data on body weight specific to Washington residents. EPA understands these concerns, but decided that the survey on which EPA's national default of 80 kg is based provides the most comprehensive dataset to establish a body weight value for deriving statewide human health criteria for Washington, and is consistent with the local tribal survey data mentioned above. The data cited by commenters do not provide sufficient evidence to come up with an alternative statewide body weight input parameter since the studies cited are limited in scope and pertain to specific subpopulations. For detailed responses to the comments, see EPA's Response to Comment document in the docket for this rule.

e. Drinking Water Intake

EPA calculates final human health criteria for Washington using a drinking water intake rate of 2.4 L/day, consistent with EPA's 2015 updated national default drinking water intake rate (see section II.C.c).[63] Most commenters were

silent on or agreed with EPA's proposal to use a drinking water intake rate of 2.4 L/day to calculate human health criteria for Washington. However, two commenters stated this input was unnecessary in human health criteria derivation. Since at least the 1980s, EPA has included the drinking water exposure pathway in the development of human health criteria in order to protect water bodies with a drinking water designated use. EPA also provides the option of using organism-only human health criteria for water bodies where there is no drinking water use. One commenter stated that 2.4 L/day was an underestimate, and expressed concern that this value is not protective of tribal members who consume more water. EPA determined that it is appropriate to use its 2015 final national default drinking water intake rate, since it was adjusted pursuant to public comments after EPA issued the draft national default rate of 3 L/day in 2014. EPA acknowledges the concerns about members of the target general population who may consume larger amounts of water, but EPA does not have data (and did not receive any during the public comment period) with which to calculate a Washington-specific drinking water intake rate. For detailed responses to the comments, see EPA's Response to Comment document in the docket for this rule.

f. Pollutant-Specific Reference Doses and Cancer Slope Factors

As part of EPA's 2015 updates to its 304(a) recommended human health criteria, EPA conducted a systematic search of eight peer-reviewed, publicly available sources to obtain the most current toxicity values for each pollutant (RfDs for non-carcinogenic effects and CSFs for carcinogenic effects).[64] EPA calculates final human health criteria for Washington using the same toxicity values that EPA used in its 2015 304(a) criteria updates, to ensure that the resulting criteria are based on a sound scientific rationale. Where EPA did not update criteria for certain pollutants in 2015 and those pollutants are included in this final rule, EPA uses the toxicity values that the Agency used the last time it updated its 304(a) criteria for those pollutants as the best available scientific information. See Table 1, columns B1 and B3 for a list of EPA's final toxicity factors by pollutant.

In general, commenters were supportive of EPA using the latest and most scientifically defensible toxicity values to derive human health criteria for Washington. Some commenters expressed concern that where EPA did not update its 304(a) national recommended human health criteria for particular pollutants in 2015, the toxicity values from the existing 304(a) criteria for those pollutants were no longer valid. In particular, those commenters expressed concern about the CSFs for arsenic and PCBs, and the RfD for methylmercury, and argued that EPA should not revise Washington's criteria for those pollutants until toxicity factors are updated in the future. Unlike the situation with the toxicity factors for arsenic, dioxin and thallium (see section III.A), there is not sufficient scientific uncertainty surrounding the CSF for PCBs or the RfD for methylmercury to warrant delaying revision to Washington's human health criteria for these pollutants. For detailed responses to the comments, see EPA's Response to Comment document in the docket for this rule.

g. Pollutant-Specific Bioaccumulation Factors

For the 2015 national 304(a) human health criteria update, EPA estimated chemical-specific BAFs using a framework for deriving national BAFs described in EPA's 2000 Methodology.[65] Because the surveyed population upon which the 175 g/day FCR is based consumed almost exclusively trophic level four fish (*i.e.*, predator fish species), EPA uses the trophic level four BAF from the 2015 304(a) human health criteria updates in conjunction with the 175 g/day FCR, in order to derive protective criteria.[66] Where in 2015, EPA estimated BAFs from laboratory-measured BCFs and therefore derived a single pollutant-specific BAF for all trophic levels, EPA uses those single BAFs from the 2015 304(a) human health criteria updates. Where EPA's existing 304(a) recommended human health criteria for certain pollutants still incorporate a BCF, and those pollutants are included in this final rule, EPA uses those BCFs as the best available scientific information. See Table 1, columns B4 and B5 for a list of EPA's final bioaccumulation factors by pollutant.

Many commenters supported EPA's choice to use the latest and most scientifically defensible BAFs to derive human health criteria for Washington, and to use BCFs only when BAFs were not available for a given pollutant. Other commenters asserted that BCFs are no less scientifically defensible than BAFs, and that EPA did not provide sufficient information regarding how it developed BAFs in 2015 for commenters to fully evaluate EPA's proposed approach.

EPA's 2000 Methodology recommends use of BAFs that account for uptake of a contaminant from all sources by fish and shellfish, rather than BCFs that only account for uptake from the water column. EPA's 2015 national recommended BAFs are based on peer-reviewed, publicly available data and were developed consistent with EPA's 2000 Methodology and its supporting documents. EPA provided the basis for its 2015 BAFs in individual pollutant-specific criteria documents. The final human health criteria for Washington are consistent with EPA's 2000 Methodology, which makes clear that BAFs are a more scientifically defensible representation of bioaccumulation than BCFs. For detailed responses to the comments, see EPA's Response to Comment document in the docket for this rule.

D. Final Human Health Criteria for Washington

EPA finalizes 144 human health criteria for 74 different pollutants (72 organism-only criteria and 72 water-plus-organism criteria) to protect the applicable designated uses of Washington's waters (see Table 1). The water-plus-organism criteria in column C1 and the methylmercury criterion in column C2 of Table 1 are the applicable criteria for any waters that include the Domestic Water (domestic water supply) use defined in Washington's WQS (WAC 173–201A–600). The organism-only criteria in column C2 of Table 1 apply to waters that do not include the Domestic Water (domestic water supply) use and that Washington defines at WAC 173–201A–600 and 173–201A–610 as the following: Fresh waters—Harvesting (fish harvesting), and Recreational Uses; Marine waters—Shellfish Harvesting (shellfish—clam, oyster, and mussel—harvesting), Harvesting (salmonid and other fish

[a] This criterion refers to the inorganic form of arsenic only.
[b] This criterion is expressed as the fish tissue concentration of methylmercury (mg methylmercury/kg fish). See *Water Quality Criterion for the Protection of Human Health: Methylmercury* (EPA–823–R–01–001, January 3, 2001) for how this value is calculated using the criterion equation in EPA's 2000 Human Health Methodology rearranged to solve for a protective concentration in fish tissue rather than in water.
[c] This criterion applies to total PCBs (*e.g.*, the sum of all congener or isomer or homolog or Aroclor analyses).
* Bis(2-Chloro-1-Methylethyl) Ether was previously listed as Bis(2-Chloroisopropyl) Ether.
** These criteria were promulgated for Washington in the National Toxics Rule at 40 CFR 131.36, and are moved into 40 CFR 131.45 to have one comprehensive human health criteria rule for Washington.

E. Applicability of Criteria

These new and revised human health criteria apply for CWA purposes in addition to any existing criteria already applicable to Washington's waters, including the state's narrative toxics criteria statement at WAC 173–201A–260(2)(a), and those human health criteria that Washington submitted on August 1, 2016, and EPA approved concurrent with this final rule.

EPA replicates in 40 CFR 131.45 the same general rules of applicability for human health criteria as in 40 CFR 131.36(c), with one exception. For waters suitable for the establishment of low flow return frequencies (*i.e.*, streams and rivers), this final rule provides that Washington must not use a low flow value below which numeric standards can be exceeded that is less stringent than the harmonic mean flow (a long-term mean flow value calculated by dividing the number of daily flows analyzed by the sum of the reciprocals of those daily flows), so that the criteria are implemented to be protective of the applicable designated use. Per the *Revisions to the Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health* (65 FR 66444, November 3, 2000), EPA now recommends harmonic mean flow be used to implement human health criteria for both carcinogens and non-carcinogens.[67] EPA received one comment on this provision, asking for clarification on whether this is consistent with Washington's current permitting approach of using the 30Q5 flow for non-carcinogens.[68] In response, Washington's use of low flow statistics more stringent than the harmonic mean flow is consistent with EPA's final rule.

Under the CWA, Congress gave states primary responsibility for developing and adopting WQS for their navigable waters (CWA section 303(a)-(c)). Although EPA revises and establishes new human health criteria for Washington in this final rule, Washington continues to have the option to adopt and submit to EPA human health criteria for the pollutants in this final rule, consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131.

In its September 14, 2015 proposed rule, EPA proposed that if Washington adopted and submitted human health criteria, and EPA approved those criteria before finalizing its federal rule, EPA would not proceed with finalizing those criteria and Washington's approved criteria would be solely applicable for CWA purposes. EPA did not receive any comments opposing this provision, thus EPA is proceeding with such an approach. In this final rule, EPA is withdrawing Washington from the NTR at 40 CFR 131.36, and, with the exception of criteria for which EPA has approved Washington's criteria, EPA is incorporating the Washington-specific criteria in this rule (as well as the existing NTR criteria for arsenic, dioxin

[67] See also USEPA. 2014. Water Quality Standards Handbook—Chapter 5: General Policies. U.S. Environmental Protection Agency. Office of Water. Washington, DC EPA–820–B–14–004. *https://www.epa.gov/wqs-tech/water-quality-standards-handbook.*

[68] The 30Q5 flow is the lowest 30-day average flow event expected to occur once every five years, on average (determined hydrologically).

and thallium) into 40 CFR 131.45 so there is a single comprehensive set of federally promulgated criteria for Washington. Therefore, the CWA-effective numeric human health criteria in Washington consist of the federally promulgated criteria at 40 CFR 131.45 and those criteria that EPA approved at WAC 173–201A–240 in Washington's August 1, 2016 submittal.

Additionally, in its September 14, 2015 proposed rule, EPA proposed that if Washington adopted and submitted human health criteria after EPA finalized its rule, once EPA approved Washington's WQS, the pollutant-specific or site-specific EPA-approved criteria in Washington's WQS would become the solely effective criteria for CWA purposes and EPA's promulgated criteria for those pollutants or for that site would no longer apply. A few commenters supported this provision, where Washington's criteria for specific pollutants or sites become the only CWA-effective criteria upon EPA's approval, without any delay caused by EPA's withdrawal of the corresponding federal criteria. A few other commenters did not support this provision, and asked that EPA either delete the provision, or make clear that criteria adopted by the state would have to be at least as stringent as the federal criteria for EPA to approve and make the state criteria effective for CWA purposes. Upon further consideration of comments received on its proposed rule, EPA decided not to finalize this provision. Pursuant to 40 CFR 131.21(c), EPA's federally promulgated WQS are and will be applicable for purposes of the CWA until EPA withdraws those federally promulgated WQS. EPA would undertake such a rulemaking to withdraw the federal criteria if and when Washington adopts and EPA approves corresponding criteria that meet the requirements of section 303(c) of the CWA and EPA's implementing regulations at 40 CFR part 131.

F. Alternative Regulatory Approaches and Implementation Mechanisms

Washington has considerable discretion to implement these revised and new federal human health criteria through various water quality control programs including the NPDES program, which limits discharges to waters except in compliance with a NPDES permit. EPA's regulations at 40 CFR 131.14 authorize states and authorized tribes to adopt WQS variances to provide time to achieve the applicable WQS. 40 CFR part 131 defines WQS variances at 131.3(o) as time-limited designated uses and supporting criteria for a specific pollutant(s) or water quality parameter(s) that reflect the highest attainable conditions during the term of the WQS variances. WQS variances adopted in accordance with 40 CFR part 131 allow states and authorized tribes to address water quality challenges in a transparent and predictable way. Variances help states and authorized tribes focus on making incremental progress in improving water quality, rather than pursuing a downgrade of the underlying water quality goals through a designated use change, when the designated use is not attainable throughout the term of the variance due to one of the factors listed in 40 CFR 131.14. EPA's regulations at 40 CFR 122.47 provide the requirements when states and authorized tribes wish to include permit compliance schedules in their NPDES permits if dischargers need additional time to meet their water quality-based limits based on the applicable WQS. EPA's updated regulations at 40 CFR 131.15 require any state or authorized tribe wishing to use permit compliance schedules to also include provisions authorizing the use of permit compliance schedules after appropriate public involvement to ensure that a decision to allow permit compliance schedules derives from and complies with the applicable WQS. (80 FR 51022, August 21, 2015).

40 CFR 131.10 specifies how states and authorized tribes establish, modify or remove designated uses for their waters. 40 CFR 131.11 specifies the requirements for establishing criteria to protect designated uses, including criteria modified to reflect site-specific conditions. In the context of this rulemaking, a site-specific criterion (SSC) is an alternative value to the federal human health criteria that could be applied on a watershed, area-wide, or waterbody-specific basis that meets the regulatory test of protecting the designated use, being scientifically defensible, and ensuring the protection and maintenance of downstream WQS. A SSC may be more or less stringent than the otherwise applicable federal criterion. A SSC may be appropriate when further scientific data and analyses can bring added precision to express the concentration of a particular pollutant that protects the human health-related designated use in a particular waterbody.

A few commenters supported EPA's acknowledgement of the flexibilities that Washington has available when implementing the final criteria in this rule, while others commented that these tools allow Washington to delay or avoid implementing the criteria. EPA did not propose to change, nor does this final rule change, any of the flexibilities already afforded to Washington by EPA's regulations to modify or remove designated uses, adopt variances, issue compliance schedules, or establish site-specific criteria. These implementation tools are important for making incremental progress and allowing the time for adaptive management when designated uses and associated criteria are difficult to attain. Washington may continue to use any of these regulatory flexibilities when implementing the final federal human health criteria.

a. Designating Uses

EPA's final human health criteria apply to waters that Washington has designated for the following: Fresh waters—Harvesting (fish harvesting), Domestic Water (domestic water supply), and Recreational Uses; Marine waters—Shellfish Harvesting (shellfish—clam, oyster, and mussel—harvesting), Harvesting (salmonid and other fish harvesting, and crustacean and other shellfish—crabs, shrimp, scallops, etc.—harvesting), and Recreational Uses (see WAC 173–201A–600 and WAC 173–201A–610). If Washington removes the Domestic Water use but retains any of the other above designated uses for any particular waterbody affected by this final rule, and EPA finds that removal to be consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131, then the federal organism-only criteria will apply in place of the federal water-plus-organism criteria. If Washington removes designated uses such that none of the above uses apply to any particular waterbody affected by this final rule and adopts the highest attainable use, as defined by 40 CFR 131.3(m), consistent with 40 CFR 131.10(g), and EPA finds that removal to be consistent with CWA section 303(c) and EPA's implementing regulations at 40 CFR part 131, then the federal human health criteria will no longer apply to that waterbody. Instead, any criteria associated with the newly designated highest attainable use would apply to that waterbody.

b. Variances and Compliance Schedules

EPA's final human health criteria apply to use designations that Washington has already established. Concurrent with this final rule, EPA approved revisions to Washington's variance and compliance schedule authorizing provisions. Washington may use its EPA-approved variance procedures (see WAC 173–201A–420) to establish time-limited designated uses and criteria to apply for the purposes specified in 40 CFR 131.14 as it pertains

to federal criteria when adopting such variances. Washington has sufficient authority to use variances when implementing the human health criteria as long as such variances are adopted consistent with 40 CFR 131.14, and submitted to EPA for review under CWA section 303(c). Similarly, Washington may use its EPA-approved regulation authorizing the use of permit compliance schedules (see WAC 173–201A–510(4)), consistent with 40 CFR 131.15, to grant compliance schedules, as appropriate, for WQBELs based on the federal criteria. These state regulations are not affected by this final rule.

c. Site-Specific Criteria

As discussed in section III.E, if Washington adopts and EPA approves site-specific criteria that fully meet the requirements of section 303(c) of the CWA and EPA's implementing regulations at 40 CFR part 131, EPA will undertake a rulemaking to withdraw the corresponding federal criteria.

IV. Economic Analysis

Under the CWA, water quality criteria are set on the basis of the latest scientific knowledge. EPA is not required under the CWA nor obligated under Executive Orders 12866 and 13563 to conduct an economic analysis of the criteria. Costs cannot be considered in establishing water quality criteria as part of WQS. Nonetheless, EPA conducted a cost analysis for the criteria in this final rule for the purpose of transparency and presents this information reflecting the potential economic effects of the rule.

These WQS may serve as a basis for development of NPDES permit limits. Washington has NPDES permitting authority, and retains considerable discretion in implementing standards. EPA evaluated the potential costs to NPDES dischargers associated with state implementation of EPA's final criteria. This analysis is documented in *Final Economic Analysis for the Revision of Certain Federal Water Quality Criteria Applicable to Washington,* which can be found in the record for this rulemaking.

Any NPDES-permitted facility that discharges pollutants for which the revised human health criteria are more stringent than the applicable aquatic life criteria (or for which human health criteria are the only applicable criteria) could potentially incur compliance costs. The types of affected facilities could include industrial facilities and POTWs discharging wastewater to surface waters (*i.e.,* point sources). EPA did not attribute compliance with water quality-based effluent limitations (WQBELs) reflective of existing federal human health criteria applicable to Washington (hereafter referred to as "baseline criteria") to the final rule. Once in compliance with WQBELs reflective of baseline criteria, EPA expects that dischargers will continue to use the same types of controls to come into compliance with the revised criteria; EPA did not fully evaluate the potential for costs to nonpoint sources,[69] such as agricultural runoff, that could be incurred under a TMDL for this analysis, but did analyze the administrative costs to the state of preparing TMDLs for potentially incrementally impaired waters. Actual costs of implementation of TMDLs is beyond the scope of this analysis.

A. Identifying Affected Entities

EPA identified 406 point source facilities that could ultimately be affected by this final rule. Of these potentially affected facilities, 73 are major dischargers and 333 are minor dischargers. EPA did not include general permit facilities in its analysis because data for such facilities are limited, and flows are usually negligible. Of the potentially affected facilities, EPA evaluated a sample of 17 major facilities. Minor facilities are unlikely to incur costs as a result of implementation of the rule, because minor facilities are typically those that do not discharge toxics in toxic amounts and discharge less than 1 million gallons per day (mgd). Although lower human health criteria could potentially change this categorization, EPA did not have effluent data on toxic pollutants to evaluate minor facilities for this analysis. Table 2 summarizes these potentially affected facilities by type and category.

TABLE 2—POTENTIALLY AFFECTED FACILITIES

Category	Minor	Major	All
Municipal	184	48	232
Industrial	149	25	174
Total	333	73	406

B. Method for Estimating Costs

EPA evaluated the two major municipal facilities with design flows greater than 100 mgd and a large industrial refinery, to attempt to capture the facilities with the potential for the largest costs. For the remaining major facilities, EPA evaluated a random sample of facilities to represent discharger type and category. For all sample facilities, EPA evaluated existing baseline permit conditions, reasonable potential to exceed human health criteria based on the final rule, and potential to exceed projected effluent limitations based on the last three years of effluent monitoring data (if available). In instances of exceedances of projected effluent limitations under the final criteria, EPA determined the likely compliance scenarios and costs. Only compliance actions and costs that would be needed above the baseline level of controls are attributable to the final rule.

EPA assumed that dischargers will pursue the least cost means of compliance with WQBELs. Incremental compliance actions attributable to the final rule may include pollution prevention, end-of-pipe treatment, and alternative compliance mechanisms (*e.g.,* variances). EPA annualized one-

[69] The CWA does not regulate nonpoint sources. However, EPA recognizes that the state may require controls for nonpoint sources as part of potential incremental TMDLs. It is difficult to model and evaluate the potential cost impacts of this final rule to nonpoint sources because they are intermittent, variable, and occur under hydrologic or climatic conditions associated with precipitation events. Also, data on instream and discharge levels of the pollutants of concern after dischargers have implemented controls to meet current WQS, total maximum daily loads (TMDLs) for impaired waters, or other water quality improvement plans, are not available. Therefore, trying to determine which sources would not achieve WQS based on the revised human health criteria after complying with existing regulations and policies may not be possible. In addition, legacy contamination (*e.g.,* in sediment) may be a source of ongoing loading. Atmospheric deposition may also contribute loadings of the pollutants of concern (*e.g.,* mercury). EPA did not estimate sediment remediation costs, or air pollution controls costs, for this analysis because EPA did not have data on the contribution of these sources, and because control costs for deposition may be covered by Clean Air Act rules.

time costs (capital costs and variance costs) over 20 years using a 3 percent discount rate to obtain total annual costs per facility. For the random sample, EPA extrapolated the annualized costs based on the sampling weight for each sample facility. To obtain an estimate of total costs to point sources, EPA added the results for the certainty sample to the extrapolated random sample costs.

C. Results

Based on the results for 17 sample facilities across 8 industrial and municipal categories,[70] EPA estimated a total annual compliance cost of approximately $126,000 to $150,000 for all major dischargers in the state (using a 3 percent discount rate). Only five facilities are estimated to incur pollution prevention program costs, while two facilities are expected to also incur costs of obtaining a variance. Most of the facilities would not bear any cost. The low end of the range reflects the assumption that the compliance actions (*e.g.,* pollution prevention) will result in compliance with projected effluent limits, whereas the high scenario reflects projected effluent limits not being met, and thus includes the estimated administrative cost of also obtaining a variance. All compliance costs are for industrial facilities, and are attributable to the human health criterion for methylmercury.

If the revised criteria result in an incremental increase in impaired waters, resulting in the need for TMDL development, there could also be some costs to nonpoint sources of pollution. Using available ambient monitoring data, EPA compared pollutant concentrations to the baseline and final criteria, identifying waterbodies that may be incrementally impaired (*i.e.,* impaired under the final criteria but not under the baseline). For the parameters and stations for which EPA had sufficient monitoring data available to evaluate, there were 50 impairments under the baseline criteria and 124 under the final criteria, for a total of 74 potential incremental impairments (or a 148 percent increase relative to the baseline; including for methylmercury, PCBs, and DDT). This increase indicates the potential for nonpoint sources to bear some compliance costs, although data are not available to estimate the magnitude of these costs. The control of nonpoint sources such as in the context of a TMDL could result in different requirements, and thus different costs, for point sources.

If the net increase in potential impairments is any indication of the potential increase in the number of TMDLs, then the total administrative costs for TMDL development could be in the range of $2.7 million to $3.0 million based on national average single-cause single-waterbody TMDL development costs from U.S. EPA (2001; updated to 2014 dollars). However, these costs may be reduced if Ecology develops multi-cause or multi-waterbody TMDLs. If these costs are spread over 8 to 15 years, at a discount rate of 3 percent, the annualized costs of developing TMDLs are $229,000 to $422,000.

Combining the potential facility compliance costs and TMDL administrative costs results in total annual costs of $355,000 to $572,000, at a 3 percent discount rate.

V. Statutory and Executive Order Reviews

A. Executive Order 12866 (Regulatory Planning and Review) and Executive Order 13563 (Improving Regulation and Regulatory Review)

It has been determined that this final rule is not a "significant regulatory action" under the terms of Executive Order 12866 (58 FR 51735, October 4, 1993) and is, therefore, not subject to review under Executive Orders 12866 and 13563 (76 FR 3821, January 21, 2011). The final rule does not establish any requirements directly applicable to regulated entities or other sources of toxic pollutants. However, these WQS may serve as a basis for development of NPDES permit limits. Washington has NPDES permitting authority, and retains considerable discretion in implementing standards. In the spirit of Executive Order 12866, EPA evaluated the potential costs to NPDES dischargers associated with state implementation of EPA's final criteria. This analysis, *Final Economic Analysis for the Revision of Certain Federal Water Quality Criteria Applicable to Washington,* is summarized in section IV of the preamble and is available in the docket.

B. Paperwork Reduction Act

This action does not impose any direct new information collection burden under the provisions of the Paperwork Reduction Act, 44 U.S.C. 3501 *et seq.* Actions to implement these WQS could entail additional paperwork burden. Burden is defined at 5 CFR 1320.3(b). This action does not include any information collection, reporting, or record-keeping requirements.

C. Regulatory Flexibility Act

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. This action will not impose any requirements on small entities. EPA has the authority to promulgate WQS in any case where the Administrator determines that a new or revised standard is necessary to meet the requirements of the CWA. EPA-promulgated standards are implemented through various water quality control programs including the NPDES program, which limits discharges to navigable waters except in compliance with an NPDES permit. The CWA requires that all NPDES permits include any limits on discharges that are necessary to meet applicable WQS. Thus, under the CWA, EPA's promulgation of WQS establishes standards that the state implements through the NPDES permit process. The state has discretion in developing discharge limits, as needed to meet the standards. As a result of this action, the State of Washington will need to ensure that permits it issues include any limitations on discharges necessary to comply with the standards established in the final rule. In doing so, the state will have a number of choices associated with permit writing. While Washington's implementation of the rule may ultimately result in new or revised permit conditions for some dischargers, including small entities, EPA's action, by itself, does not impose any of these requirements on small entities; that is, these requirements are not self-implementing.

D. Unfunded Mandates Reform Act

This action contains no federal mandates under the provisions of Title II of the Unfunded Mandates Reform Act of 1995 (UMRA), 2 U.S.C. 1531–1538 for state, local, or tribal governments or the private sector. As these water quality criteria are not self-implementing, EPA's action imposes no enforceable duty on any state, local or tribal governments or the private sector. Therefore, this action is not subject to the requirements of sections 202 or 205 of UMRA.

This action is also not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that could significantly or uniquely affect small governments.

E. Executive Order 13132 (Federalism)

This action does not have federalism implications. It will not have substantial direct effects on the states, on the relationship between the national

[70] Seven industrial categories (mining, food and kindred products, paper and allied products, chemicals and allied products, petroleum refining and related industries, primary metal industries, and transportation and public utilities (except POTWs)) and municipal POTWs.

government and the states, or on the distribution of power and responsibilities among the various levels of government. This rule does not alter Washington's considerable discretion in implementing these WQS, nor will it preclude Washington from adopting WQS in the future that EPA concludes meet the requirements of the CWA, which will eliminate the need for federal standards. Thus, Executive Order 13132 does not apply to this action.

F. Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments)

This action has tribal implications. However, it will neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. In the State of Washington, there are 29 federally recognized Indian tribes. To date, nine of these Indian tribes have been approved for TAS for CWA sections 303 and 401.[71] Of these nine tribes, seven have EPA-approved WQS in their respective jurisdictions.[72] This rule could affect federally recognized Indian tribes in Washington because the numeric criteria for Washington will apply to waters adjacent to (or upstream or downstream of) the tribal waters, where many of those tribes have treaty rights to take fish for their subsistence. Additionally, there are ten federally recognized Indian tribes in the Columbia River Basin located in the states of Oregon and Idaho that this rule could impact because their waters could affect or be affected by the water quality of Washington's downstream or upstream waters.

EPA consulted with federally recognized tribal officials under EPA's Policy on Consultation and Coordination with Indian Tribes early in the process of developing this rule to permit them to have meaningful and timely input into its development. In February and March 2015, EPA held tribes-only technical staff and leadership consultation sessions to hear their views and answer questions of all interested tribes on the proposed rule. Representatives from approximately 23 tribes and four tribal consortia participated in two leadership meetings held in March 2015. EPA and tribes have also met regularly since November 2012 to discuss Washington's human health criteria at both the tribal leadership level and technical staff level. The tribes have repeatedly asked EPA to promulgate federal human health criteria for Washington if the state did not do so in a timely and protective manner. At these meetings, the tribes consistently emphasized that the human health criteria should be derived using at least a minimum FCR value of 175 g/day, a cancer risk level of 10^{-6}, and the latest scientific information from EPA's 304(a) recommended criteria. EPA considered the input received during consultation with tribes when developing this final rule (see section III for additional discussion of how EPA considered tribal input).

In subsequent coordination with tribes, EPA received a letter on August 5, 2016, from the Northwest Indian Fisheries Commission disagreeing with EPA's potential adjustments to the RSC from the proposed rule issued on September 14, 2015 to the final rule as a result of public comments. The tribes expressed concern that less stringent human health criteria as a result of the RSC adjustment would result in lower protection of designated uses and limit the ability to exercise tribal treaty rights, especially in light of a FCR that underestimates tribal consumption. EPA considered this information carefully before finalizing this rule, but for the reasons stated above, decided to adjust the RSC to account for inclusion of some marine fish in the FCR. This results in protective criteria that account for other routes of exposure in addition to drinking water and fish and shellfish from inland and nearshore waters and is consistent with EPA's guidance.

G. Executive Order 13045 (Protection of Children From Environmental Health and Safety Risks)

This rule is not subject to Executive Order 13045, because it is not economically significant as defined in Executive Order 12866, and because the environmental health or safety risks addressed by this action do not present a disproportionate risk to children.

H. Executive Order 13211 (Actions That Significantly Affect Energy Supply, Distribution, or Use)

This action is not a "significant energy action" because it is not likely to have a significant adverse effect on the supply, distribution, or use of energy.

I. National Technology Transfer and Advancement Act of 1995

This final rulemaking does not involve technical standards.

J. Executive Order 12898 (Federal Actions To Address Environmental Justice in Minority Populations and Low-Income Populations)

This action will not have disproportionately high and adverse human health or environmental effects on minority or low-income populations. Conversely, this action identifies and ameliorates disproportionately high and adverse human health effects on minority populations and low-income populations in Washington. EPA developed the human health criteria included in this final rule specifically to protect Washington's designated uses, using the most current science, including local and regional information on fish consumption. Applying these criteria to waters in the State of Washington will afford a greater level of protection to both human health and the environment.

K. Congressional Review Act (CRA)

This action is subject to the CRA, and EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is not a "major rule" as defined by 5 U.S.C. 804(2).

List of Subjects in 40 CFR Part 131

Environmental protection, Indians-lands, Intergovernmental relations, Reporting and recordkeeping requirements, Water pollution control.

Dated: November 15, 2016.

Gina McCarthy,

Administrator.

For the reasons set forth in the preamble, EPA amends 40 CFR part 131 as follows:

PART 131—WATER QUALITY STANDARDS

■ 1. The authority citation for part 131 continues to read as follows:

Authority: 33 U.S.C. 1251 *et seq.*

Subpart D—Federally Promulgated Water Quality Standards

§ 131.36 [Amended]

■ 2. In § 131.36, remove paragraph (d)(14).

■ 3. Add § 131.45 to read as follows:

§ 131.45 Revision of certain Federal water quality criteria applicable to Washington.

(a) *Scope.* This section promulgates human health criteria for priority toxic

[71] *http://water.epa.gov/scitech/swguidance/standards/wqslibrary/approvtable.cfm.*

[72] *http://yosemite.epa.gov/r10/water.nsf/34090d07b77d50bd88256b79006529e8/dd2a4df00fd7ae1a88256e0500680e86!OpenDocument.* Note that this number does not include the Confederated Tribes of the Colville Reservation, which has federally promulgated WQS from 1989. EPA is currently reviewing the Colville Tribe's application for TAS.

pollutants in surface waters in Washington.

(b) *Criteria for priority toxic pollutants in Washington.* The applicable human health criteria are shown in Table 1.

[a] This criterion refers to the inorganic form of arsenic only.
[b] This criterion is expressed as the fish tissue concentration of methylmercury (mg methylmercury/kg fish). See *Water Quality Criterion for the Protection of Human Health: Methylmercury* (EPA–823–R–01–001, January 3, 2001) for how this value is calculated using the criterion equation in EPA's 2000 Human Health Methodology rearranged to solve for a protective concentration in fish tissue rather than in water.
[c] This criterion applies to total PCBs (*e.g.*, the sum of all congener or isomer or homolog or Aroclor analyses).
* Bis(2-Chloro-1-Methylethyl) Ether was previously listed as Bis(2-Chloroisopropyl) Ether.
** These criteria were promulgated for Washington in the National Toxics Rule at 40 CFR 131.36, and are moved into 40 CFR 131.45 to have one comprehensive human health criteria rule for Washington.

(c) *Applicability.* (1) The criteria in paragraph (b) of this section apply to waters with Washington's designated uses cited in paragraph (d) of this section and apply concurrently with other applicable water quality criteria.

(2) The criteria established in this section are subject to Washington's general rules of applicability in the same way and to the same extent as are other federally promulgated and state-adopted numeric criteria when applied to the same use classifications in paragraph (d) of this section.

(i) For all waters with mixing zone regulations or implementation procedures, the criteria apply at the appropriate locations within or at the boundary of the mixing zones; otherwise the criteria apply throughout the waterbody including at the end of any discharge pipe, conveyance or other discharge point within the waterbody.

(ii) The state must not use a low flow value below which numeric non-carcinogen and carcinogen human health criteria can be exceeded that is less stringent than the harmonic mean flow for waters suitable for the establishment of low flow return frequencies (*i.e.*, streams and rivers). Harmonic mean flow is a long-term mean flow value calculated by dividing the number of daily flows analyzed by the sum of the reciprocals of those daily flows.

(iii) If the state does not have such a low flow value for numeric criteria, then none will apply and the criteria in paragraph (b) of this section herein apply at all flows.

(d) *Applicable use designations.* (1) All waters in Washington assigned to the following use classifications are subject to the criteria identified in paragraph (d)(2) of this section:

(i) Fresh waters—

(A) Miscellaneous uses: Harvesting (Fish harvesting);

(B) Recreational uses;

(C) Water supply uses: Domestic water (Domestic water supply);

(ii) Marine waters—

(A) Miscellaneous uses: Harvesting (Salmonid and other fish harvesting, and crustacean and other shellfish (crabs, shrimp, scallops, etc.) harvesting);

(B) Recreational uses;

(C) Shellfish harvesting: Shellfish harvest (Shellfish (clam, oyster, and mussel) harvesting)

Note to paragraph (d)(1): The source of these uses is Washington Administrative Code 173–201A–600 for Fresh waters and 173–201A–610 for Marine waters.

(2) For Washington waters that include the use classification of Domestic Water, the criteria in column C1 and the methylmercury criterion in column C2 of Table 1 in paragraph (b) of this section apply. For Washington waters that include any of the following use classifications but do not include the use classification of Domestic Water, the criteria in column C2 of Table 1 in paragraph (b) of this section apply: Harvesting (fresh and marine waters), Recreational Uses (fresh and marine waters), and Shellfish Harvesting.

NOTICE

The policies and procedures set forth in this document are intended solely to describe EPA methods for developing or revising ambient water quality criteria to protect human health, pursuant to Section 304(a) of the Clean Water Act, and to serve as guidance to States and authorized Tribes for developing their own water quality criteria. This guidance does not substitute for the Clean Water Act or EPA's regulations; nor is it a regulation itself. Thus, it does not impose legally-binding requirements on EPA, States, Tribes or the regulated community, and may not apply to a particular situation based upon the circumstances.

This document has been reviewed in accordance with U.S. Environmental Protection Agency policy and approved for publication. Mention of trade names or commercial products does not constitute endorsement or recommendation for use.

FOREWORD

This document presents EPA's recommended Methodology for developing ambient water quality criteria as required under Section 304(a) of the Clean Water Act (CWA). The Methodology is guidance for scientific human health assessments used by EPA to develop, publish, and from time to time revise, recommended criteria for water quality accurately reflecting the latest scientific knowledge. The recommended criteria serve States and Tribes' needs in their development of water quality standards under Section 303(c) of the CWA.

The term "water quality criteria" is used in two sections of the Clean Water Act, Section 304(a)(1) and Section 303(c)(2). The term has a different program impact in each section. In Section 304, the term represents a scientific assessment of ecological and human health effects that EPA recommends to States and authorized Tribes for establishing water quality standards that ultimately provide a basis for controlling discharges or releases of pollutants. Ambient water quality criteria associated with specific stream uses when adopted as State or Tribal water quality standards under Section 303 define the maximum levels of a pollutant necessary to protect designated uses in ambient waters. The water quality criteria adopted in the State or Tribal water quality standards could have the same numerical limits as the criteria developed under Section 304. However, in many situations States and authorized Tribes may want to adjust water quality criteria developed under Section 304 to reflect local environmental conditions and human exposure patterns before incorporation into water quality standards. When adopting their water quality criteria, States and authorized Tribes have four options: (1) adopt EPA's 304(a) recommendations; (2) adopt 304(a) criteria modified to reflect site-specific conditions; (3) develop criteria based on other scientifically defensible methods; or (4) establish narrative criteria where numeric criteria cannot be determined.

EPA will use this Methodology to develop new ambient water quality criteria and to revise existing recommended water quality criteria. It also provides States and authorized Tribes the necessary guidance to adjust water quality criteria developed under Section 304 to reflect local conditions or to develop their own water quality criteria using scientifically defensible methods consistent with this Methodology. EPA encourages States and authorized Tribes to use this Methodology to develop or revise water quality criteria to appropriately reflect local conditions. EPA believes that ambient water quality criteria inherently require several risk management decisions that are, in many cases, better made at the State, Tribal, or regional level. Additional guidance to assist States and authorized Tribes in the modification of criteria based on the Methodology will accompany this document in the form of three companion Technical Support Documents on Risk Assessment, Exposure Assessment, and Bioaccumulation Assessment.

3. RISK ASSESSMENT 3-1

3.1 Cancer Effects 3-1
3.1.1 Background on EPA Cancer Risk Assessment Guidelines 3-1
3.1.2 EPA's Proposed Guidelines for Carcinogen Risk Assessment and the Subsequent July, 1999 Draft Revised Cancer Guidelines 3-2
3.1.3 Methodology for Deriving AWQC by the 1999 Draft Revised Cancer Guidelines 3-4
3.1.3.1 Weight-of-Evidence Narrative 3-5
3.1.3.2 Mode of Action-General Considerations and Framework for Analysis 3-6
3.1.3.3 Dose Estimation 3-7
A. Determining the Human Equivalent Dose 3-7
B. Dose-Response Analysis 3-7
3.1.3.4 Characterizing Dose-Response Relationships in the Range of Observation and at Low Environmentally Relevant Doses 3-8
A. Extrapolation to Low, Environmentally Relevant Doses 3-9
B. Biologically-Based Modeling Approaches 3-9
C. Default Linear Extrapolation Approach 3-10
D. Default Nonlinear Approach 3-11
E. Both Linear and Nonlinear Approaches 3-13
3.1.3.5 AWQC Calculation 3-13
A. Linear Approach 3-13
B. Nonlinear Approach 3-14
3.1.3.6 Risk Characterization 3-14
3.1.3.7 Use of Toxicity Equivalence Factors (TEF) and Relative Potency Estimates 3-15
3.1.4 References for Cancer Section 3-16
3.2 Noncancer Effects 3-17
3.2.1 1980 AWQC National Guidelines for Noncancer Effects 3-17
3.2.2 Noncancer Risk Assessment Developments Since 1980 3-18
3.2.3 Issues and Recommendations Concerning the Derivation of AWQC for Noncarcinogens 3-20
3.2.3.1 Using the Current NOAEL/UF-Based RfD Approach or Adopting More Quantitative Approaches for Noncancer Risk Assessment 3-20
A. The Benchmark Dose 3-22
B. Categorical Regression 3-24
C. Summary 3-25
3.2.3.2 Presenting the RfD as a Single Point or as a Range for Deriving AWQC 3-25
3.2.3.3 Guidelines to be Adopted for Derivation of Noncancer Health Effects Values 3-27
3.2.3.4 Treatment of Uncertainty Factors/Severity of Effects During the RfD Derivation and Verification Process 3-27
3.2.3.5 Use of Less-Than-90-Day Studies to Derive RfDs 3-27

3.2.3.6 Use of Reproductive/Developmental, Immunotoxicity, and Neurotoxicity Data as the Basis for Deriving RfDs 3-28
3.2.3.7 Applicability of Toxicokinetic Data in Risk Assessment 3-28
3.2.3.8 Consideration of Linearity (or Lack of a Threshold) for Noncarcinogenic Chemicals 3-29
3.2.3.9 Minimum Data Guidance 3-29
3.2.4 References for Noncancer Effects 3-30

4. EXPOSURE 4-1

4.1. Exposure Policy Issues 4-1
4.1.1 Sources of Exposure Associated with Ambient Water 4-2
4.1.1.1 Appropriateness of Including the Drinking Water Pathway in AWQC 4-2
4.1.1.2 Setting Separate AWQC for Drinking Water and Fish Consumption 4-2
4.1.1.3 Incidental Ingestion from Ambient Surface Waters 4-3
4.2. Consideration of Non-Water Sources of Exposure When Setting AWQC 4-3
4.2.1 Policy Background 4-3
4.2.2 The Exposure Decision Tree Approach 4-5
4.2.2.1 Problem Formulation 4-9
4.2.2.2 Data Adequacy 4-10
4.2.2.3 Regulatory Actions 4-13
4.2.2.4 Apportionment Decisions 4-13
4.2.3 Additional Points of Clarification on the Exposure Decision Tree Approach for Setting AWQC 4-15
4.2.4 Quantification of Exposure 4-16
4.2.5 Inclusion of Inhalation and Dermal Exposures 4-16
4.3 Exposure Factors Used in the AWQC Computation 4-17
4.3.1 Human Body Weight Values for Dose Calculations 4-18
4.3.1.1 Rate Protective of Human Health from Chronic Exposure 4-19
4.3.1.2 Rates Protective of Developmental Human Health Effects 4-20
4.3.2 Drinking Water Intake Rates 4-21
4.3.2.1 Rate Protective of Human Health from Chronic Exposure 4-23
4.3.2.2 Rates Protective of Developmental Human Health Effects 4-24
4.3.2.3 Rates Based on Combining Drinking Water Intake and Body Weight 4-24
4.3.3 Fish Intake Rates 4-25
4.3.3.1 Rates Protective of Human Health from Chronic Exposure 4-25
4.3.3.2 Rates Protective of Developmental Human Health Effects 4-29
4.3.3.3 Rates Based on Combining Fish Intake and Body Weight 4-30

1. INTRODUCTION

1.1 WATER QUALITY CRITERIA AND STANDARDS

Pursuant to Section 304(a)(1) of the Clean Water Act (CWA), the U.S. Environmental Protection Agency (EPA) is required to publish, and from time to time thereafter revise, criteria for water quality accurately reflecting the latest scientific knowledge on the kind and extent of all identifiable effects on human health which may be expected from the presence of pollutants in any body of water.

Historically, the ambient water quality criteria (AWQC or 304(a) criteria) provided two essential types of information: (1) discussions of available scientific data on the effects of the pollutants on public health and welfare, aquatic life, and recreation; and (2) quantitative concentrations or qualitative assessments of the levels of pollutants in water which, if not exceeded, will generally ensure adequate water quality for a specified water use. Water quality criteria developed under Section 304(a) are based solely on data and scientific judgments on the relationship between pollutant concentrations and environmental and human health effects. The 304(a) criteria do not reflect consideration of economic impacts or the technological feasibility of meeting the criteria in ambient water. These 304(a) criteria may be used as guidance by States and authorized Tribes to establish water quality standards, which ultimately provide a basis for controlling discharges or releases of pollutants into ambient waters.

In 1980, AWQC were derived for 64 pollutants using guidelines developed by the Agency for calculating the impact of waterborne pollutants on aquatic organisms and on human health. Those guidelines consisted of systematic procedures for assessing valid and appropriate data concerning a pollutant's acute and chronic adverse effects on aquatic organisms, nonhuman mammals, and humans.

1.2 PURPOSE OF THIS DOCUMENT

The *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (2000)* (hereafter the "2000 Human Health Methodology") addresses the development of AWQC to protect human health. The Agency intends to use the 2000 Human Health Methodology both to develop new AWQC for additional pollutants and to revise existing AWQC. Within the next several years, EPA intends to focus on deriving AWQC for chemicals of high priority (including, but not limited to, mercury, arsenic, PCBs, and dioxin). Furthermore, EPA anticipates that 304(a) criteria development in the future will be for bioaccumulative chemicals and pollutants considered highest priority by the Agency. The 2000 Human Health Methodology is also intended to provide States and authorized Tribes flexibility in establishing water quality standards by providing scientifically valid options for developing their own water quality criteria that consider local conditions. States and authorized Tribes are strongly encouraged to use this Methodology to derive their own AWQC. However, the 2000 Human Health Methodology also defines the default factors EPA intends to use in evaluating and determining consistency of State water quality standards with the requirements of the CWA. The Agency intends to use these default factors to calculate national water quality criteria under

Section 304(a) of the Act. EPA will also use this Methodology as guidance when promulgating water quality standards for a State or Tribe under Section 303(c) of the CWA.

This Methodology does not substitute for the CWA or EPA's regulations; nor is it a regulation itself. Thus, the 2000 Human Health Methodology cannot impose legally-binding requirements on EPA, States, Tribes or the regulated community, and may not apply to a particular situation based upon the circumstances. EPA and State/Tribal decision-makers retain the discretion to use different, scientifically defensible, methodologies to develop human health criteria on a case-by-case basis that differ from this Methodology where appropriate. EPA may change the Methodology in the future through intermittent refinements as advances in science or changes in Agency policy occur.

The 2000 Human Health Methodology incorporates scientific advancements made over the past two decades. The use of this Methodology is an important component of the Agency's efforts to improve the quality of the Nation's waters. EPA believes the Methodology will enhance the overall scientific basis of water quality criteria. Further, the Methodology should help States and Tribes address their unique water quality issues and risk management decisions, and afford them greater flexibility in developing their water quality programs.

There are three companion Technical Support Document (TSD) volumes for the 2000 Human Health Methodology: a Risk Assessment TSD; an Exposure Assessment TSD; and a Bioaccumulation TSD. These documents are intended to further support States and Tribes in developing AWQC to reflect local conditions. The Risk Assessment TSD (USEPA, 2000) is being published concurrently with this Methodology. Publication of the Exposure Assessment and Bioaccumulation TSDs are anticipated in 2001.

1.3 HISTORY OF THE AMBIENT WATER QUALITY CRITERIA (AWQC) METHODOLOGY

In 1980, EPA published AWQC for 64 pollutants/pollutant classes identified in Section 307(a) of the CWA and provided a methodology for deriving the criteria (USEPA, 1980). These 1980 AWQC National Guidelines (or the "1980 Methodology") for developing AWQC for the protection of human health addressed three types of endpoints: noncancer, cancer, and organoleptic (taste and odor) effects. Criteria for protection against noncancer and cancer effects were estimated by using risk assessment-based procedures, including extrapolation from animal toxicity or human epidemiological studies. Basic human exposure assumptions were applied to the criterion equation.

The risk assessment-based procedures used to derive the AWQC to protect human health were specific to whether the endpoint was cancer or noncancer. When using cancer as the critical risk assessment endpoint (which had been assumed not to have a threshold), the AWQC were presented as a range of concentrations associated with specified incremental lifetime risk

levels[1]. When using noncancer effects as the critical endpoint, the AWQC reflected an assessment of a "no-effect" level, since noncancer effects were assumed to have a threshold. The key features of each procedure are described briefly in the following paragraphs.

Cancer effects. If human or animal studies on a contaminant indicated that it induced a statistically significant carcinogenic response, the 1980 AWQC National Guidelines treated the contaminant as a carcinogen and derived a low-dose cancer potency factor from available animal data using the linearized multistage model (LMS). The LMS, which uses a linear, nonthreshold assumption for low-dose risk, was used by the Agency as a science policy choice in protecting public health, and represented a plausible upper limit for low-dose risk. The cancer potency factor, which expresses incremental, lifetime risk as a function of the rate of intake of the contaminant, was then combined with exposure assumptions to express that risk in terms of an ambient water concentration. In the 1980 AWQC National Guidelines, the Agency presented a range of contaminant concentrations corresponding to incremental cancer risks of 10^{-7} to 10^{-5} (that is, a risk of one additional case of cancer in a population of ten million to one additional cancer case in a population of one hundred thousand, respectively).

Noncancer effects. If the pollutant was not considered to have the potential for causing cancer in humans (later defined as a known, probable, or possible human carcinogen by the 1986 *Guidelines for Carcinogen Risk Assessment,* USEPA, 1986d), the 1980 AWQC National Guidelines treated the contaminant as a noncarcinogen; a criterion was derived using a threshold concentration for noncancer adverse effects. The criteria derived from noncancer data were based on the Acceptable Daily Intake (ADI) (now termed the reference dose [RfD]). ADI values were generally derived using a no-observed-adverse-effect level (NOAEL) from animal studies, although human data were used whenever available. The ADI was calculated by dividing the NOAEL by an uncertainty factor to account for uncertainties inherent in extrapolating limited toxicological data to humans. In accordance with the National Research Council recommendations of 1977 (NRC, 1977), safety factors (SFs) (later redefined as uncertainty factors) of 10, 100, or 1,000 were used, depending on the quality of the data.

Organoleptic effects. Organoleptic characteristics were also used in developing criteria for some contaminants to control undesirable taste and/or odor imparted by them to ambient water. In some cases, a water quality criterion based on organoleptic effects would be more stringent than a criterion based on toxicologic endpoints. The 1980 AWQC National Guidelines emphasized that criteria derived for organoleptic endpoints are not based on toxicological information, have no direct relationship to adverse human health effects and, therefore, do not necessarily represent approximations of acceptable risk levels for humans.

[1]Throughout this document, the term "risk level" regarding a cancer assessment using linear approach refers to an upper-bound estimate of excess lifetime cancer risk.

1.4 RELATIONSHIP OF WATER QUALITY STANDARDS TO AWQC

Under Section 303(c) of the CWA, States have the primary responsibility for establishing water quality standards, defined under the Act as designated beneficial uses of a water segment and the water quality criteria necessary to support those uses. Additionally, Native American Tribes authorized to administer the water quality standards program under 40 CFR 131.8 establish water quality standards for waters within their jurisdictions. This statutory framework allows States and authorized Tribes to work with local communities to adopt appropriate designated uses and to adopt criteria to protect those designated uses. Section 303(c) provides for EPA review of water quality standards and for promulgation of a superseding Federal rule in cases where State or Tribal standards are not consistent with the applicable requirements of the CWA and the implementing Federal regulations, or where the Agency determines Federal standards are necessary to meet the requirements of the Act. Section 303(c)(2)(B) specifically requires States and authorized Tribes to adopt water quality criteria for toxics for which EPA has published criteria under Section 304(a) and for which the discharge or presence could reasonably be expected to interfere with the designated use adopted by the State or Tribe. In adopting such criteria, States and authorized Tribes must establish numerical values based on one of the following: (1) 304(a) criteria; (2) 304(a) criteria modified to reflect site-specific conditions; or, (3) other scientifically defensible methods. In addition, States and authorized Tribes can establish narrative criteria where numeric criteria cannot be determined.

It must be recognized that the Act uses the term "criteria" in two different ways. In Section 303(c), the term is part of the definition of a water quality standard. Specifically, a water quality standard is composed of designated uses and the criteria necessary to protect those uses. Thus, States and authorized Tribes are required to adopt regulations which contain legally enforceable criteria. However, in Section 304(a) the term criteria is used to describe the scientific information that EPA develops to be used as guidance by States, authorized Tribes and EPA when establishing water quality standards pursuant to 303(c). Thus, two distinct purposes are served by the 304(a) criteria. The first is as guidance to the States and authorized Tribes in the development and adoption of water quality criteria which will protect designated uses, and the second is as the basis for promulgation of a superseding Federal rule when such action is necessary.

1.5 NEED FOR THE AWQC METHODOLOGY REVISIONS

Since 1980, EPA risk assessment practices have evolved significantly in all of the major Methodology areas: that is, cancer and noncancer risk assessments, exposure assessments, and bioaccumulation. When the 1980 Methodology was developed, EPA had not yet developed formal cancer or noncancer risk assessment guidelines. Since then, EPA has published several risk assessment guidelines. In cancer risk assessment, there have been advances in the use of mode of action (MOA) information to support both the identification of potential human carcinogens and the selection of procedures to characterize risk at low, environmentally relevant exposure levels. EPA published *Proposed Guidelines for Carcinogen Risk Assessment* (USEPA, 1996a, hereafter the "1996 proposed cancer guidelines"). These guidelines presented revised procedures to quantify cancer risk at low doses, replacing the current default use of the LMS model. Following review by the Agency's Science Advisory Board (SAB), EPA published the

revised *Guidelines for Carcinogen Risk Assessment–Review Draft* in July 1999 (USEPA, 1999a, hereafter the "1999 draft revised cancer guidelines"). In noncancer risk assessment, the Agency is moving toward the use of the benchmark dose (BMD) and other dose-response approaches in place of the traditional NOAEL approach to estimate an RfD or Reference Concentration (RfC). *Guidelines for Mutagenicity Risk Assessment* were published in 1986 (USEPA, 1986b). In 1991, the Agency published *Guidelines for Developmental Toxicity Risk Assessment* (USEPA, 1991), and it issued *Guidelines for Reproductive Toxicity Risk Assessment* in 1996 (USEPA, 1996b). In 1998, EPA published final *Guidelines for Neurotoxicity Risk Assessment* (USEPA, 1998), and in 1999 it issued the draft *Guidance for Conducting Health Risk Assessment of Chemical Mixtures* (USEPA, 1999b).

In 1986, the Agency made available to the public the Integrated Risk Information System (IRIS). IRIS is a database that contains risk information on the cancer and noncancer effects of chemicals. The IRIS assessments are peer reviewed and represent EPA consensus positions across the Agency's program and regional offices.

New studies have addressed water consumption and fish tissue consumption. These studies provide a more current and comprehensive description of national, regional, and special-population consumption patterns that EPA has reflected in the 2000 Human Health Methodology. In addition, more formalized procedures are now available to account for human exposure from multiple sources when setting health goals such as AWQC that address only one exposure source. In 1986, the Agency published the *Total Exposure Assessment Methodology (TEAM) Study: Summary and Analysis, Volume I, Final Report* (USEPA, 1986c), which presents a process for conducting comprehensive evaluation of human exposures. In 1992, EPA published the revised *Guidelines for Exposure Assessment* (USEPA, 1992), which describe general concepts of exposure assessment, including definitions and associated units, and provide guidance on planning and conducting an exposure assessment. The *Exposure Factors Handbook* was updated in 1997 (USEPA, 1997a). Also in 1997, EPA developed *Guiding Principles for Monte Carlo Analysis* (USEPA, 1997b) and published its *Policy for Use of Probabilistic Analysis in Risk Assessment* (see http://www.epa.gov/ncea/mcpolicy.htm). The Monte Carlo guidance can be applied to exposure assessments and risk assessments. The Agency has recently developed the Relative Source Contribution (RSC) Policy for assessing total human exposure to a contaminant and apportioning the RfD among the media of concern, published for the first time in this Methodology.

The Agency has moved toward the use of a bioaccumulation factor (BAF) to reflect the uptake of a contaminant from all sources (e.g., ingestion, sediment) by fish and shellfish, rather than just from the water column as reflected by the use of a bioconcentration factor (BCF) in the 1980 Methodology. The Agency has also developed detailed procedures and guidelines for estimating BAF values.

Another reason for the 2000 Human Health Methodology is the need to bridge the gap between the differences in the risk assessment and risk management approaches used by EPA's Office of Water for the derivation of AWQC under the authority of the CWA and Maximum Contaminant Level Goals (MCLGs) under the Safe Drinking Water Act (SDWA). Three notable differences are the treatment of chemicals designated as Group C, possible human carcinogens

under the 1996 proposed cancer guidelines, the consideration of non-water sources of exposure when setting an AWQC or MCLG for a noncarcinogen, and cancer risk ranges. Those three differences are described in the three subsections below, respectively.

1.5.1 Group C Chemicals

Chemicals were typically classified as Group C–i.e., possible human carcinogens–under the existing (1986) EPA cancer classification scheme for any of the following reasons:

1) Carcinogenicity has been documented in only one test species and/or only one cancer bioassay and the results do not meet the requirements of "sufficient evidence."

2) Tumor response is of marginal statistical significance due to inadequate design or reporting.

3) Benign, but not malignant, tumors occur with an agent showing no response in a variety of short-term tests for mutagenicity.

4) There are responses of marginal statistical significance in a tissue known to have a high or variable background rate.

The 1986 *Guidelines for Carcinogen Risk Assessment* (hereafter the "1986 cancer guidelines") specifically recognized the need for flexibility with respect to quantifying the risk of Group C, possible human carcinogens. The 1986 cancer guidelines noted that agents judged to be in Group C, possible human carcinogens, may generally be regarded as suitable for quantitative risk assessment, but that case-by-case judgments may be made in this regard.

The EPA Office of Water has historically treated Group C chemicals differently under the CWA and the SDWA. It is important to note that the 1980 AWQC National Guidelines for setting AWQC under the CWA predated EPA's carcinogen classification system, which was proposed in 1984 (USEPA, 1984) and finalized in 1986 (USEPA, 1986a). The 1980 AWQC National Guidelines did not explicitly differentiate among agents with respect to the weight of evidence for characterizing them as likely to be carcinogenic to humans. For all pollutants judged as having adequate data for quantifying carcinogenic risk–including those now classified as Group C–AWQC were derived based on data on cancer incidence. In the1980 AWQC National Guidelines, EPA emphasized that the AWQC for carcinogens should state that the recommended concentration for maximum protection of human health is zero. At the same time, the criteria published for specific carcinogens presented water concentrations for these pollutants corresponding to individual lifetime excess cancer risk levels in the range of 10^{-7} to 10^{-5}.

In the development of national primary drinking water regulations under the SDWA, EPA is required to promulgate a health-based MCLG for each contaminant. The Agency policy has been to set the MCLG at zero for chemicals with strong evidence of carcinogenicity associated with exposure from water. For chemicals with limited evidence of carcinogenicity, including many Group C agents, the MCLG was usually obtained using an RfD based on the

pollutant's noncancer effects with the application of an additional uncertainty factor of 1 to 10 to account for carcinogenic potential of the chemical. If valid noncancer data for a Group C agent were not available to establish an RfD but adequate data are available to quantify the cancer risk, then the MCLG was based upon a nominal lifetime excess cancer risk in the range of 10^{-6} to10^{-5} (ranging from one case in a population of one million to one case in a population of one hundred thousand). Even in those cases where the RfD approach has been used for the derivation of the MCLG for a Group C agent, the drinking water concentrations associated with excess cancer risks in the range of 10^{-6} to 10^{-5} were also provided for comparison.

It should also be noted that EPA's pesticides program has applied both of the previously described methods for addressing Group C chemicals in actions taken under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) and finds both methods applicable on a case-by-case basis. Unlike the drinking water program, however, the pesticides program does not add an extra uncertainty factor to account for potential carcinogenicity when using the RfD approach.

In the 1999 draft revised cancer guidelines, there are no more alphanumeric categories. Instead, there will be longer narratives for hazard characterization that will use consistent descriptive terms when assessing cancer risk.

1.5.2 Consideration of Non-water Sources of Exposure

The 1980 AWQC National Guidelines recommended that contributions from non-water sources, namely air and non-fish dietary intake, be subtracted from the Acceptable Daily Intake (ADI), thus reducing the amount of the ADI "available" for water-related sources of intake. In practice, however, when calculating human health criteria, these other exposures were generally not considered because reliable data on these exposure pathways were not available. Consequently, the AWQC were usually derived such that drinking water and fish ingestion accounted for the entire ADI (now called RfD).

In the drinking water program, a similar "subtraction" method was used in the derivation of MCLGs proposed and promulgated in drinking water regulations through the mid-1980s. More recently, the drinking water program has used a "percentage" method in the derivation of MCLGs for noncarcinogens. In this approach, the percentage of total exposure typically accounted for by drinking water, referred to as the relative source contribution (RSC), is applied to the RfD to determine the maximum amount of the RfD "apportioned" to drinking water reflected by the MCLG value. In using this percentage procedure, the drinking water program also applies a ceiling level of 80 percent of the RfD and a floor level of 20 percent of the RfD. That is, the MCLG cannot account for more than 80 percent of the RfD, nor less than 20 percent of the RfD.

The drinking water program usually takes a conservative approach to public health by applying an RSC factor of 20 percent to the RfD when adequate exposure data do not exist, assuming that the major portion (80 percent) of the total exposure comes from other sources, such as diet.

In the 2000 Human Health Methodology, guidance for the routine consideration of non-water sources of exposure [both ingestion exposures (e.g., food) and exposures other than the oral route (e.g., inhalation)] is presented. The approach is called the Exposure Decision Tree. Relative source contribution estimates will be made by EPA using this approach, which allows for use of either the subtraction or percentage methods, depending on chemical-specific circumstances, within the 20 to 80 percent range described above.

1.5.3 Cancer Risk Ranges

In addition to the different risk assessment approaches discussed above for deriving AWQC and MCLGs for Group C agents, there have been different risk management approaches by the drinking water and surface water programs on lifetime excess risk values when setting health-based criteria for carcinogens. The surface water program has derived AWQC for carcinogens that generally corresponded to lifetime excess cancer risk levels of 10^{-7} to 10^{-5}. The drinking water program has set MCLGs for Group C agents based on a slightly less stringent risk range of 10^{-6} to 10^{-5}, while MCLGs for chemicals with strong evidence of carcinogenicity (that is, classified as Group A, known, or B probable, human carcinogen) are set at zero. The drinking water program is now following the principles of the 1999 draft revised cancer guidelines to determine the type of low-dose extrapolation based on mode of action.

It is also important to note that under the drinking water program, for those substances having an MCLG of zero, enforceable Maximum Contaminant Levels (MCLs) have generally been promulgated to correspond with cancer risk levels ranging from 10^{-6} to 10^{-4}. Unlike AWQC and MCLGs which are strictly health-based criteria, MCLs are developed with consideration given to the costs and technological feasibility of reducing contaminant levels in water to meet those standards.

With the 2000 Human Health Methodology, EPA will publish its national 304(a) water quality criteria at a 10^{-6} risk level, which EPA considers appropriate for the general population. EPA is increasing the degree of consistency between the drinking water and ambient water programs, given the somewhat different requirements of the CWA and SDWA.

1.6 OVERVIEW OF THE AWQC METHODOLOGY REVISIONS

The following equations for deriving AWQC include toxicological and exposure assessment parameters which are derived from scientific analysis, science policy, and risk management decisions. For example, values for parameters such as a field-measured BAF or a point of departure from an animal study [in the form of a lowest-observed-adverse-effect level (LOAEL)/no-observed -adverse-effect level (NOAEL)/lower 95 percent confidence limit on a dose associated with a 10 percent extra risk (LED_{10})] are empirically measured using scientific methods. By contrast, the decision to use animal effects as surrogates for human effects involves judgment on the part of the EPA (and similarly, by other agencies) as to the best practice to follow when human data are lacking. Such a decision is, therefore, a matter of science policy. The choice of default fish consumption rates for protection of a certain percentage (i.e., the 90th percentile) of the general population is clearly a risk management decision. In many cases, the Agency has selected parameter values using its best judgment regarding the overall protection afforded by the resulting AWQC when all parameters are combined. For a longer discussion of the differences between science, science policy, and risk management, please refer to Section 2 of this document. Section 2 also provides further details with regard to risk characterization for this Methodology, with emphasis placed on explaining the uncertainties in the overall risk assessment.

The generalized equations for deriving AWQC based on noncancer effects are:

Noncancer Effects[2]

$$AWQC = RfD \cdot RSC \cdot \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \cdot BAF_i)} \right) \qquad \text{(Equation 1-1)}$$

Cancer Effects: Nonlinear Low-Dose Extrapolation

$$AWQC = \frac{POD}{UF} \cdot RSC \cdot \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \cdot BAF_i)} \right) \qquad \text{(Equation 1-2)}$$

[2] Although appearing in this equation as a factor to be multiplied, the RSC can also be an amount subtracted. Refer to the explanation key below the equations.

Cancer Effects: Linear Low-Dose Extrapolation

$$AWQC = RSD \cdot \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \cdot BAF_i)} \right) \qquad \text{(Equation 1-3)}$$

where:

AWQC	=	Ambient Water Quality Criterion (mg/L)
RfD	=	Reference dose for noncancer effects (mg/kg-day)
POD	=	Point of departure for carcinogens based on a nonlinear low-dose extrapolation (mg/kg-day), usually a LOAEL, NOAEL, or LED_{10}
UF	=	Uncertainty Factor for carcinogens based on a nonlinear low-dose extrapolation (unitless)
RSD	=	Risk-specific dose for carcinogens based on a linear low-dose extrapolation (mg/kg-day) (dose associated with a target risk, such as 10^{-6})
RSC	=	Relative source contribution factor to account for non-water sources of exposure. (Not used for linear carcinogens.) May be either a percentage (multiplied) or amount subtracted, depending on whether multiple criteria are relevant to the chemical.
BW	=	Human body weight (default = 70 kg for adults)
DI	=	Drinking water intake (default = 2 L/day for adults)
FI_i	=	Fish intake at trophic level (TL) I (I = 2, 3, and 4) (defaults for total intake = 0.0175 kg/day for general adult population and sport anglers, and 0.1424 kg/day for subsistence fishers). Trophic level breakouts for the general adult population and sport anglers are: TL2 = 0.0038 kg/day; TL3 = 0.0080 kg/day; and TL4 = 0.0057 kg/day.
BAF_i	=	Bioaccumulation factor at trophic level I (I=2, 3 and 4), lipid normalized (L/kg)

For highly bioaccumulative chemicals where ingestion from water might be considered negligible, EPA is currently evaluating the feasibility of developing and implementing AWQCs that are expressed in terms of concentrations in tissues of aquatic organisms. Such tissue residue criteria might be used as an alternative to AWQCs which are expressed as concentrations in water, particularly in situations where AWQCs are at or below the practical limits for quantifying a chemical in water. Even though tissue residue criteria would not require the use of a BAF in their derivation, implementing such criteria would still require a mechanism for relating chemical loads and concentrations in water and sediment to concentrations in tissues of appropriate fish and shellfish (e.g., a BAF or bioaccumulation model). At this time, no revisions are planned to the Methodology to provide specific guidance on developing fish tissue-based water quality criteria. However, guidance may be provided in the future either as a separate document or integrated in a specific 304(a) water quality criteria document for a chemical that warrants such an approach.

AWQC for the protection of human health are designed to minimize the risk of adverse effects occurring to humans from chronic (lifetime) exposure to substances through the ingestion of drinking water and consumption of fish obtained from surface waters. The Agency is not recommending the development of additional water quality criteria similar to the "drinking water health advisories" that focus on acute or short-term effects; these are not seen as routinely having a meaningful role in the water quality criteria and standards program. However, as discussed below, there may be some instances where the consideration of acute or short-term toxicity and exposure in the derivation of AWQC is warranted.

Although the AWQC are based on chronic health effects data (both cancer and noncancer effects), the criteria are intended to also be protective against adverse effects that may reasonably be expected to occur as a result of elevated acute or short-term exposures. That is, through the use of conservative assumptions with respect to both toxicity and exposure parameters, the resulting AWQC should provide adequate protection not only for the general population over a lifetime of exposure, but also for special subpopulations who, because of high water- or fish-intake rates, or because of biological sensitivities, have an increased risk of receiving a dose that would elicit adverse effects. The Agency recognizes that there may be some cases where the AWQC based on chronic toxicity may not provide adequate protection for a subpopulation at special risk from shorter-term exposures. The Agency encourages States, Tribes, and others employing the 2000 Human Health Methodology to give consideration to such circumstances in deriving criteria to ensure that adequate protection is afforded to all identifiable subpopulations. (See Section 4.3, Factors Used in the AWQC Computation, for additional discussion of these subpopulations.)

The EPA is in the process of revising its cancer guidelines, including its descriptions of human carcinogenic potential. Once final guidelines are published, they will be the basis for assessment under this methodology. In the meanwhile, the 1986 guidelines are used and extended with principles discussed in EPA's 1999 *Guidelines for Carcinogen Risk Assessment - Review Draft* (hereafter "1999 draft revised cancer guidelines"). These principles arise from new science about cancer discovered in the last 15 years and from EPA policy of recent years supporting full characterization of hazard and risk both for the general population and potentially sensitive groups such as children. These principles are incorporated in recent and ongoing assessments such as the reassessment of dioxin, consistent with the 1986 guidelines. Until final guidelines are published, information is presented to describe risk under both the old guidelines and draft revisions. Dose-response assessment under the 1986 guidelines employs a linearized multistage model to extrapolate tumor dose-response observed in animal or human studies down to zero dose, zero extra risk. The dose-response assessment under EPA's 1999 draft revised cancer guidelines is a two-step process. In the first step, the response data are modeled in the range of empirical observation. Modeling in the observed range is done with biologically based or appropriate curve-fitting modeling. In the second step, extrapolation below the range of observation is accomplished by biologically based modeling if there are sufficient data or by a default procedure (linear, nonlinear, or both). A point of departure (POD) for extrapolation is estimated from modeling observed data. The lower 95 percent confidence limit on a dose associated with 10 percent extra risk (LED_{10}) is the standard POD for low-dose extrapolation. The linear default procedure is a straight line extrapolation to the origin (i.e., zero dose, zero extra risk) from the POD, which is the LED_{10} identified in the observable response

range. The result of this procedure is generally comparable (within 2-fold) to that of using a linearized multistage model under existing, 1986 guidelines. The linear low-dose extrapolation applies to agents that are best characterized by the assumption of linearity (e.g., direct DNA reactive mutagens) for their MOA. A linear approach would also be applied when inadequate or no information is available to explain the carcinogenic MOA; this is a science policy choice in the interest of public health. If it is determined that the MOA understanding fully supports a nonlinear extrapolation, the AWQC is derived using the nonlinear default which is based on a margin of exposure (MOE) analysis using the LED_{10} as the POD and applying uncertainty factors (UFs) to arrive at an acceptable MOE. There may be situations where it is appropriate to apply both the linear and nonlinear default procedures (e.g., for an agent that is both DNA reactive and active as a promoter at higher doses).

For substances that are carcinogenic, particularly those for which the MOA suggests nonlinearity at low doses, the Agency recommends that an integrated approach be taken in looking at cancer and noncancer effects. If one effect does not predominate, AWQC values should be determined for both carcinogenic and noncarcinogenic endpoints. The lower of the resulting values should be used for the AWQC.

When deriving AWQC for noncarcinogens and carcinogens based on a nonlinear low-dose extrapolation, a factor is included to account for other non-water exposure sources [both ingestion exposures (e.g., food) and exposures other than the oral route (e.g., inhalation)] so that the entire RfD, or POD/UF, is not apportioned to drinking water and fish consumption alone. Guidance is provided in the 2000 Human Health Methodology for determining the factor (i.e., the RSC) to be used for a particular chemical. The Agency is recommending the use of an Exposure Decision Tree procedure to support the determination of the appropriate RSC value for a given water contaminant. In the absence of data, the Agency intends to use 20 percent of the RfD (or POD/UF) as the default RSC in calculating 304(a) criteria or promulgating State or Tribal water quality standards under Section 303(c).

With AWQC derived for carcinogens based on a linear low-dose extrapolation, the Agency will publish recommended criteria values at a 10^{-6} risk level. States and authorized Tribes can always choose a more stringent risk level, such as 10^{-7}. EPA also believes that criteria based on a 10^{-5} risk level are acceptable for the general population as long as States and authorized Tribes ensure that the risk to more highly exposed subgroups (sportfishers or subsistence fishers) does not exceed the 10^{-4} level. Clarification on this risk management decision is provided in Section 2 of this document.

The default fish consumption value for the general adult population in the 2000 Human Health Methodology is 17.5 grams/day, which represents an estimate of the 90^{th} percentile consumption rate for the U.S. adult population based on the U.S. Department of Agriculture's (USDA's) Continuing Survey of Food Intake by Individuals (CSFII) 1994-96 data (USDA, 1998). EPA will use this default intake rate with future national 304(a) criteria derivations or revisions. This default value is chosen to be protective of the majority of the general population. However, States and authorized Tribes are urged to use a fish intake level derived from local data on fish consumption in place of this default value when deriving AWQC, ensuring that the fish intake level chosen is protective of highly exposed individuals in the population. EPA has

provided default values for States and authorized Tribes that do not have adequate information on local or regional consumption patterns, based on numerous studies that EPA has reviewed on sport anglers and subsistence fishers. EPA's defaults for these population groups are estimates of their average consumption. EPA recommends a default of 17.5 grams/day for sport anglers as an approximation of their average consumption and 142.4 grams/day for subsistence fishers, which falls within the range of averages for this group. Consumption rates for women of childbearing age and children younger than 14 are also provided to maximize protection in those cases where these subpopulations may be at greatest risk.

In the 2000 Human Health Methodology, criteria are derived using a BAF rather than a BCF. To derive the BAF, States and authorized Tribes may use EPA's Methodology or any method consistent with this Methodology. EPA's highest preference in developing BAFs are BAFs based on field-measured data from local/regional fish.

2. CLARIFICATIONS ON THE METHODOLOGY, RISK CHARACTERIZATION, AND OTHER ISSUES FOR DEVELOPING CRITERIA

2.1 IDENTIFYING THE POPULATION SUBGROUP THAT THE AWQC SHOULD PROTECT

Water quality criteria are derived to establish ambient concentrations of pollutants which, if not exceeded, will protect the general population from adverse health impacts from those pollutants due to consumption of aquatic organisms and water, including incidental water consumption related to recreational activities. For each pollutant, chronic criteria are derived to reflect long-term consumption of food and water. An important decision to make when setting AWQC is the choice of the particular population to protect. For instance, criteria could be set to protect those individuals who have average or "typical" exposures, or the criteria could be set so that they offer greater protection to those individuals who are more highly exposed. EPA has selected default parameter values that are representative of several defined populations: adults in the general population; sport (recreational) fishers; subsistence fishers; women of childbearing age (defined as ages 15-44); and children (up to the age of 14). In deciding on default parameter values, EPA is aware that multiple parameters are used in combination when calculating AWQC (e.g., intake rates and body weight). EPA describes the estimated population percentiles that are represented by each of the default exposure parameter values in Section 4.

EPA's national 304(a) criteria are usually derived to protect the majority of the general population from chronic adverse health effects. EPA has used a combination of median values, mean values, and percentile estimates for the parameter value defaults to calculate its national 304(a) criteria. EPA believes that its assumptions afford an overall level of protection targeted at the high end of the general population (i.e., the target population or the criteria-basis population). EPA also believes that this is reasonably conservative and appropriate to meet the goals of the CWA and the 304(a) criteria program. EPA considers that its target protection goal is satisfied if the population as a whole will be adequately protected by the human health criteria when the criteria are met in ambient water. However, associating the derived criteria with a specific population percentile is far more difficult, and such a quantitative descriptor typically requires detailed distributional exposure and dose information. EPA's *Guidelines For Exposure Assessment* (USEPA, 1992) describes the extreme difficulty in making accurate estimates of exposures and indicates that uncertainties at the more extreme ends of the distribution increase greatly. On quantifying population exposures/risks, the guidelines specifically state:

> *In practice, it is difficult even to establish an accurate mean health effect risk for a population. This is due to many complications, including uncertainties in using animal data for human dose-response relationships, nonlinearities in the dose-response curve, projecting incidence data from one group to another dissimilar group, etc. Although it has been common practice to estimate the number of cases of disease, especially cancer, for populations exposed to chemicals, it should be understood that these estimates are not meant to be accurate estimates of real (or actuarial) cases of disease. The estimate's value lies in framing*

hypothetical risk in an understandable way rather than in any literal interpretation of the term "cases."

Although it is not possible to subject the estimates to such a rigorous analysis (say, for example, to determine what criterion value provides protection of exactly the 90th percentile of the population), EPA believes that the combination of parameter value assumptions achieves its target goal, without being inordinately conservative. The standard assumptions made for the national 304(a) criteria are as follows. The assumed body weight value used is an arithmetic mean, as are the RSC intake estimates of other exposures (e.g., non-fish dietary), when data are available. The BAF component data (e.g., for lipid values, for particulate and dissolved organic carbon) are based on median (i.e., 50th percentile) values. The drinking water intake values are approximately 90th percentile estimates and fish intake values are 90th percentile estimates. EPA believes the use of these values will result in 304(a) criteria that are protective of a majority of the population; this is EPA's goal.

However, EPA also strongly believes that States and authorized Tribes should have the flexibility to develop criteria, on a site-specific basis, that provide additional protection appropriate for highly exposed populations. EPA is aware that exposure patterns in general, and fish consumption in particular, vary substantially. EPA understands that highly exposed populations may be widely distributed geographically throughout a given State or Tribal area. EPA recommends that priority be given to identifying and adequately protecting the most highly exposed population. Thus, if the State or Tribe determines that a highly exposed population is at greater risk and would not be adequately protected by criteria based on the general population, and by the national 304(a) criteria in particular, EPA recommends that the State or Tribe adopt more stringent criteria using alternative exposure assumptions.

EPA has provided recommended default intake rates for various population groups for State and Tribal consideration. EPA does not intend for these alternative default values to be prescriptive. EPA strongly emphasizes its preference that States and Tribes use local or regional data over EPA's defaults, if they so choose, as being more representative of their population groups of concern.

In the course of updating the 2000 Human Health Methodology, EPA received some questions regarding the population groups for which the criteria would be developed. EPA does not intend to derive multiple 304(a) criteria for all subpopulation groups for every chemical. As stated above, criteria that address chronic adverse health effects are most applicable to the CWA Section 304(a) criteria program and the chemicals evaluated for this program. If EPA determined that pregnant women/fetuses or young children were the target population (or criteria basis population) of a chemical's RfD or POD/UF, then the 304(a) criteria would be developed using exposure parameters for that subgroup. This would only be relevant for acute or subchronic toxicity situations. This does not conflict with the fact that chronic health effects potentially reflect a person's exposure during both childhood and adult years.

For RfD-based and POD/UF-based chemicals, EPA's policy is that, in general, the RfD (or POD/UF) should not be exceeded and the exposure assumptions used should reflect the population of concern. It is recommended that when a State or authorized Tribe sets a

waterbody-specific AWQC, they consider the populations most exposed via water and fish. EPA's policy on cancer risk management goals is discussed in Section 2.4.

Health Risks to Children

In recognition that children have a special vulnerability to many toxic substances, EPA's Administrator directed the Agency in 1995 to explicitly and consistently take into account environmental health risks to infants and children in all risk assessments, risk characterizations, and public health standards set for the United States. In April 1997, President Clinton signed Executive Order 13045 on the protection of children from environmental health risks, which assigned a high priority to addressing risks to children. In May 1997, EPA established the Office of Children's Health Protection to ensure the implementation of the President's Executive Order. EPA has increased efforts to ensure its guidance and regulations take into account risks to children. Circumstances where risks to children should be considered in the context of the 2000 Human Health Methodology are discussed in the Section 3.2, Noncancer Effects (in terms of developmental and reproductive toxicity) and in Section 4, Exposure (for appropriate exposure intake parameters).

Details on risk characterization and the guiding principles stated above are included in EPA's March 21, 1995 policy statement and the discussion of risk characterization (USEPA, 1995) and the 1999 *Guidelines for Carcinogen Risk Assessment. Review Draft* (USEPA, 1999a) and the *Reproductive and Toxicity Risk Assessment Guidelines* of 1996 (USEPA, 1996b).

2.2 SCIENCE, SCIENCE POLICY, AND RISK MANAGEMENT

An important part of risk characterization, as described later in Section 2.7, is to make risk assessments transparent. This means that conclusions drawn from the science are identified separately from policy judgments and risk management decisions, and that the use of default values or methods, as well as the use of assumptions in risk assessments, are clearly articulated. In this Methodology, EPA has attempted to separate scientific analysis from science policy and risk management decisions for clarity. This should allow States and Tribes (who are also prospective users of this Methodology) to understand the elements of the Methodology accurately and clearly, and to easily separate out the scientific decisions from the science policy and risk management decisions. This is important so that when questions are asked regarding the scientific merit, validity, or apparent stringency or leniency of AWQC, the implementer of the criteria can clearly explain what judgments were made to develop the criterion in question and to what degree these judgments were based on science, science policy, or risk management. To some extent this process will also be displayed in future AWQC documents.

When EPA speaks of science or scientific analysis, it is referring to the extraction of data from toxicological or exposure studies and surveys with a minimum of judgment being used to make inferences from the available evidence. For example, if EPA is describing a POD from an animal study (e.g., a LOAEL), this is usually determined as a lowest dose that produces an observable adverse effect. This would constitute a scientific determination. Judgments applying science policy, however, may enter this determination. For example, several scientists may differ in their opinion of what is adverse, and this in turn can influence the selection of a LOAEL

in a given study. The use of an animal study to predict effects in a human in the absence of human data is an inherent science policy decision. The selection of specific UFs when developing an RfD is another example of science policy. In any risk assessment, a number of decision points occur where risk to humans can only be inferred from the available evidence. Both scientific judgments and policy choices may be involved in selecting from among several possible inferences when conducting a risk assessment.

Risk management is the process of selecting the most appropriate guidance or regulatory actions by integrating the results of risk assessment with engineering data and with social, economic, and political concerns to reach a decision. In this Methodology, the choice of a default fish consumption rate which is protective of 90 percent of the general population is a risk management decision. The choice of an acceptable cancer risk by a State or Tribe is a risk management decision.

Many of the components in the 2000 Human Health Methodology are an amalgam of science, science policy, and/or risk management. For example, most of the default values chosen by EPA are based on examination of scientific data and application of either science policy or risk management. This includes the default assumption of 2 liters a day of drinking water; the assumption of 70 kilograms for an adult body weight; the use of default percent lipid and particulate organic carbon/dissolved organic carbon (POC/DOC) for developing national BAFs; the default fish consumption rates for the general population and sport and subsistence anglers; and the choice of a default cancer risk level. Some decisions are more grounded in science and science policy (such as the choice of default BAFs) and others are more obviously risk management decisions (such as the determination of default fish consumption rates and cancer risk levels). Throughout the 2000 Human Health Methodology, EPA has identified the kind of decision necessary to develop defaults and what the basis for the decision was. More details on the concepts of science analysis, science policy, risk management, and how they are introduced into risk assessments are included in *Risk Assessment in the Federal Government: Managing the Process* (NRC, 1983).

2.3 SETTING CRITERIA TO PROTECT AGAINST MULTIPLE EXPOSURES FROM MULTIPLE CHEMICALS (CUMULATIVE RISK)

EPA is very much aware of the complex issues and implications of cumulative risk and has endeavored to begin developing an overall approach at the Agency-wide level. Assuming that multiple exposures to multiple chemicals are additive is scientifically sound if they exhibit the same toxic endpoints and modes of action. There are numerous publications relevant to cumulative risk that can assist States and Tribes in understanding the complex issues associated with cumulative risk. These include the following:

- Durkin, P.R., R.C. Hertzberg, W. Stiteler, and M. Mumtaz. 1995. The identification and testing of interaction patterns. *Toxicol. Letters* 79:251-264.

- USEPA. 1989b. *Interim Procedures for Estimating Risks Associated with Exposures to Mixtures of Chlorinated Dibenzo-p-Dioxins and -Dibenzofurans (CDDs and CDFs) and 1989 Update*. Risk Assessment Forum. Washington, DC. EPA/625/3-89/016. March.

The Agency's program offices are also engaged in on-going discussions of the great complexities, methodological challenges, data adequacy needs and other information gaps, as well as the science policy and risk management decisions that will need to be made, as they pursue developing a sound strategy and, eventually, specific guidance for addressing cumulative

risks. As a matter of internal policy, EPA is committed to refining the Methodology as advances in relevant aspects of the science improve, as part of the water quality criteria program.

2.4 CANCER RISK RANGE

For deriving 304(a) criteria or promulgating water quality criteria for States and Tribes under Section 303(c) based on the 2000 Human Health Methodology, EPA intends to use the 10^{-6} risk level, which the Agency believes reflects an appropriate risk for the general population. EPA's program office guidance and regulatory actions have evolved in recent years to target a 10^{-6} risk level as an appropriate risk for the general population. EPA has recently reviewed the policies and regulatory language of other Agency mandates (e.g., the Clean Air Act Amendments of 1990, the Food Quality Protection Act) and believes the target of a 10^{-6} risk level is consistent with Agency-wide practice.

EPA believes that both 10^{-6} and 10^{-5} may be acceptable for the general population and that highly exposed populations should not exceed a 10^{-4} risk level. States or Tribes that have adopted standards based on criteria at the 10^{-5} risk level can continue to do so, if the highly exposed groups would at least be protected at the 10^{-4} risk level. However, EPA is not automatically assuming that 10^{-5} will protect "the highest consumers" at the 10^{-4} risk level. Nor is EPA advocating that States and Tribes automatically set criteria based on assumptions for highly exposed population groups at the 10^{-4} risk level. The Agency is simply endeavoring to add that a specific determination should be made to ensure that highly exposed groups do not exceed a 10^{-4} risk level. EPA understands that fish consumption rates vary considerably, especially among subsistence populations, and it is such great variation among these population groups that may make either 10^{-6} or 10^{-5} protective of those groups at a 10^{-4} risk level. Therefore, depending on the consumption patterns in a given State or Tribal jurisdiction, a 10^{-6} or 10^{-5} risk level could be appropriate. In cases where fish consumption among highly exposed population groups is of a magnitude that a 10^{-4} risk level would be exceeded, a more protective risk level should be chosen. Such determinations should be made by the State or Tribal authorities and are subject to EPA's review and approval or disapproval under Section 303(c) of the CWA.

Adoption of a 10^{-6} or 10^{-5} risk level, both of which States and authorized Tribes have chosen in adopting water quality standards to date, represents a generally acceptable risk management decision, and EPA intends to continue providing this flexibility to States and Tribes. EPA believes that such State or Tribal decisions are consistent with Section 303(c) if the State or authorized Tribe has identified the most highly exposed subpopulation, has demonstrated that the chosen risk level is adequately protective of the most highly exposed subpopulation, and has completed all necessary public participation. States and authorized Tribes also have flexibility in how they demonstrate this protectiveness and obtain such information. A State or authorized Tribe may use existing information as well as collect new information in making this determination. In addition, if a State or authorized Tribe does not believe that the 10^{-6} risk level adequately protects the exposed subpopulations, water quality criteria based on a more stringent risk level may be adopted. This discretion includes combining the 10^{-6} risk level with fish consumption rates for highly exposed population groups.

It is important to understand that criteria for carcinogens are based on chosen risk levels that inherently reflect, in part, the exposure parameters used to derive those values. Therefore, changing the exposure parameters also changes the risk. Specifically, the incremental cancer risk levels are *relative*, meaning that any given criterion associated with a particular cancer risk level is also associated with specific exposure parameter assumptions (e.g., intake rates, body weights). When these exposure parameter values change, so does the relative risk. For a criterion derived on the basis of a cancer risk level of 10^{-6}, individuals consuming up to 10 times the assumed fish intake rate would not exceed a 10^{-5} risk level. Similarly, individuals consuming up to 100 times the assumed rate would not exceed a 10^{-4} risk level. Thus, for a criterion based on EPA's default fish intake rate (17.5 gm/day) and a risk level of 10^{-6}, those consuming a pound per day (i.e., 454 grams/day) would potentially experience between a 10^{-5} and a 10^{-4} risk level (closer to a 10^{-5} risk level). (Note: Fish consumers of up to 1,750 gm/day would not exceed the 10^{-4} risk level.) If a criterion were based on high-end intake rates and the relative risk of 10^{-6}, then an average fish consumer would be protected at a cancer risk level of approximately 10^{-8}. The point is that the risks for different population groups are not the same.

2.5 MICROBIOLOGICAL AMBIENT WATER QUALITY CRITERIA

Guidance for deriving microbiological AWQC is not a part of this Methodology. In 1986, EPA published *Ambient Water Quality Criteria for Bacteria - 1986* (USEPA, 1986a), which updated and revised bacteriological criteria previously published in 1976 in *Quality Criteria for Water* (USEPA, 1976). The inclusion of guidance for deriving microbiological AWQC was considered in the 1992 national workshop that initiated the effort to revise the 1980 Methodology and was recommended by the SAB in 1993. Since that time, however, efforts separate from these Methodology revisions have addressed microbiological AWQC concerns. The purpose of this section is to briefly describe EPA's current recommendations and activities.

EPA's *Ambient Water Quality Criteria for Bacteria - 1986* recommends the use of *Escherichia coli* and enterococci rather than fecal coliforms (USEPA, 1986a). EPA's criteria recommendations are:

- Fresh water: *E. coli* not to exceed 126/100 ml or enterococci not to exceed 33/100 ml; and

- Marine water: enterococci not to exceed 35/100 ml.

These criteria should be calculated as the geometric mean based on five equally spaced samples taken over a 30-day period.

In addition, EPA recommends that States adopt a single sample maximum, based on the expected frequency of use. No sample taken should exceed this value. EPA specifies appropriate single sample maximum values in the 1986 criteria document.

<u>Current Activities and Plans for Future Work</u>

EPA has identified development of microbial water quality criteria as part of its strategy to control waterborne microbial disease, by controlling pathogens in waterbodies and by protecting designated uses, such as recreation and public water supplies. The program fosters an integrated approach to protect both ground-water and surface water sources. EPA plans to conduct additional monitoring for *Cryptosporidium parvum* and *E. coli*, and determine action plans in accordance with the results of this monitoring.

EPA recommends no change at this time in the stringency of its bacterial criteria for recreational waters; existing criteria and methodologies from 1986 will still apply. The recommended methods for *E. coli* and enterococci have been improved. As outlined in the *Action Plan for Beaches and Recreational Waters* (Beach Action Plan, see below), the Agency plans to conduct national studies on improving indicators together with epidemiology studies for new criteria development (USEPA, 1999b). The Agency is also planning to establish improved temporal and spatial monitoring protocols.

In the Beach Action Plan, EPA identifies a multi-year strategy for monitoring recreational water quality and communicating public health risks associated with potentially pathogen-contaminated recreational rivers, lakes, and ocean beaches. It articulates the Agency's rationale and goals in addressing specific problems and integrates all associated program, policy, and research needs and directions. The Beach Action Plan also provides information on timing, products and lead organization for each activity. These include activities and products in the areas of program development, risk communication, water quality indicator research, modeling and monitoring research, and exposure and health effects research.

Recently, EPA approved new 24-hour *E. coli* and enterococcus tests for recreational waters that may be used as an alternative to the 48-hour test (USEPA, 1997). EPA anticipates proposing these methods for inclusion in the 40 CRF 136 in the Fall of 2000. EPA has also published a video with accompanying manual on the original and newer methods for enterococci and *E. coli* (USEPA, 2000).

As part of the Beach Action Plan, EPA made the following recommendations for further Agency study:

- Future criteria development should consider the risk of diseases other than gastroenteritis. EPA intends to consider and evaluate such water-related exposure routes as inhalation and dermal absorption when addressing microbial health effects. The nature and significance of other than the classical waterborne pathogens are to some degree tied to the particular type of waste sources.

- A new set of indicator organisms may need to be developed for tropical water if it is proven that the current fecal indicators can maintain viable cell populations in the soil and water for significant periods of time in uniform tropical conditions. Some potential alternative indicators to be fully explored are coliphage, other bacteriophage, and *Clostridium perfringens*.

- Because animal sources of pathogens of concern for human infection such as *Giardia lamblia*, *Cryptosporidium parvum*, and *Escherichia coli* 0157:H7 may be waterborne or washed into water and thus become a potential source for infection, they should not be ignored in risk assessment. A likely approach would be phylogenetic differentiation; that is, indicators that are specific to, or can discriminate among, animal sources.

- EPA intends to develop additional data on secondary infection routes and infection rates from prospective epidemiology studies and outbreaks from various types of exposure (e.g., shellfish consumption, drinking water, recreational exposure).

- EPA needs to improve sampling strategies for recreational water monitoring including consideration of rainfall and pollution events to trigger sampling.

2.6 RISK CHARACTERIZATION CONSIDERATIONS

On March 21, 1995, EPA's Administrator issued the *EPA Risk Characterization Policy and Guidance* (USEPA, 1995). This policy and guidance is intended to ensure that characterization information from each stage of a risk assessment is used in forming conclusions about risk and that this information is communicated from risk assessors to risk managers, and from EPA to the public. The policy also provides the basis for greater clarity, transparency, reasonableness, and consistency in risk assessments across EPA programs. The fundamental principles which form the basis for a risk characterization are as follows:

- Risk assessments should be transparent, in that the conclusions drawn from the science are identified separately from policy judgments, and the use of default values or methods and the use of assumptions in the risk assessment are clearly articulated.

- Risk characterizations should include a summary of the key issues and conclusions of each of the other components of the risk assessments, as well as describe the likelihood of harm. The summary should include a description of the overall strengths and limitations (including uncertainties) of the assessment and conclusions.

- Risk characterizations should be consistent in general format, but recognize the unique characteristics of each specific situation.

- Risk characterizations should include, at least in a qualitative sense, a discussion of how a specific risk and its context compares with similar risks. This may be accomplished by comparisons with other pollutants or situations on which the Agency has decided to act, or other situations with which the public may be familiar. The discussion should highlight the limitations of such comparisons.

- Risk characterization is a key component of risk communication, which is an interactive process involving exchange of information and expert opinion among individuals, groups, and institutions.

Additional guiding principles include:

- The risk characterization integrates the information from the hazard identification, dose-response, and exposure assessments, using a combination of qualitative information, quantitative information, and information regarding uncertainties.

- The risk characterization includes a discussion of uncertainty and variability in the risk assessment.

- Well-balanced risk characterizations present conclusions and information regarding the strengths and limitations of the assessment for other risk assessors, EPA decision-makers, and the public.

In developing the methodology presented here, EPA has closely followed the risk characterization guiding principles listed above. As States and Tribes adopt criteria using the 2000 Human Health Methodology, they are strongly encouraged to follow EPA's risk characterization guidance. There are a number of areas within the Methodology and criteria development process where risk characterization principles apply:

- Integration of cancer and noncancer assessments with exposure assessments, including bioaccumulation potential determinations, in essence, weighing the strengths and weaknesses of the risk assessment as a whole when developing a criterion.

- Selecting a fish consumption rate, either locally derived or the national default value, within the context of a target population (e.g., sensitive subpopulations) as compared to the general population.

- Presenting cancer and/or noncancer risk assessment options.

- Describing the uncertainty and variability in the hazard identification, the dose-response, and the exposure assessment.

2.7 DISCUSSION OF UNCERTAINTY

2.7.1 Observed Range of Toxicity Versus Range of Environmental Exposure

When characterizing a risk assessment, an important distinction to make is between the observed range of adverse effects (from an epidemiology or animal study) and the environmentally observed range of exposure (or anticipated human exposure) to the contaminant. In many cases, EPA intends to apply default factors to account for uncertainties or incomplete knowledge in developing RfDs or cancer risk assessments using nonlinear low-dose extrapolation to provide a margin of protection. In reality, the actual effect level and the environmental exposure levels may be separated by several orders of magnitude. The difference between the dose causing some observed response and the anticipated human exposure should be described by risk assessors and managers, especially when comparing criteria to environmental levels of a contaminant.

2.7.2 Continuum of Preferred Data/Use of Defaults

In both toxicological and exposure assessments, EPA has defined a continuum of preferred data for toxicological assessments ranging from a highest preference for chronic human data (e.g., studies that examine a long-term exposure of humans to a chemical, usually from occupational and/or residential exposure) and actual field data for many of the exposure parameter values (e.g., locally derived fish consumption rates, waterbody-specific bioaccumulation rates), to default values which are at the lower end of the preference continuum. EPA has supplied default values for all of the risk assessment parameters in the 2000 Human Health Methodology; however, it is important to note that when default values are used, the uncertainty in the final risk assessment may be higher, and the final resulting criterion may not be as applicable to local conditions, than is a risk assessment derived from human/field data. Using defaults assumes generalized conditions and may not capture the actual variability in the population (e.g., sensitive subpopulations/high-end consumers). If defaults are chosen as the basis for criteria, these inherent uncertainties should be communicated to the risk manager and the public. While this continuum is an expression of preference on the part of EPA, it does not imply in any way that any of the choices are unacceptable or scientifically indefensible.

2.7.3 Significant Figures

The number of significant figures in a numeric value is the number of certain digits plus one estimated digit. Digits should not be confused with decimal places. For example, 15.1, 0.0151, and 0.0150 all have 3 significant figures. Decimal places may have been used to maintain the correct number of significant figures, but in themselves they do not indicate significant figures (Brinker, 1984). Since the number of significant figures must include only one estimated digit, the sources of input parameters (e.g., fish consumption and water consumption rates) should be checked to determine the number of significant figures associated with data they provide. However, the original measured values may not be available to determine the number of significant figures in the input parameters. In these situations, EPA recommends utilizing the data as presented.

When developing criteria, EPA recommends rounding the number of significant figures at the end of the criterion calculation to the same number of significant figures in the least precise parameter. This is a generally accepted practice which can be found described in greater detail in APHA (1992) and Brinker (1984). The general rule is that for multiplication or division, the resulting value should not possess any more significant figures than is associated with the factor in the calculation with the least precision. When numbers are added or subtracted, the number that has the fewest decimal places, not necessarily the fewest significant figures, puts the limit on the number of places that justifiably may be carried in the sum or difference. Rounding off a number is the process of dropping one or more digits so that the value contains only those digits that are significant or necessary in subsequent computations (Brinker, 1984). The following rounding procedures are recommended: (1) if the digit 6, 7, 8, or 9 is dropped, increase the preceding digit by one unit; (2) if the digit 0, 1, 2, 3, or 4 is dropped, do not alter the preceding digit; and (3) if the digit 5 is dropped, round off the preceding digit to the nearest even number (e.g., 2.25 becomes 2.2 and 2.35 becomes 2.4) (APHA, 1992; Brinker, 1984).

EPA recommends that calculations of water quality criteria be performed without rounding of intermediate step values. The resulting criterion may be rounded to a manageable number of decimal places. However, in no case should the number of digits presented exceed the number of significant figures implied in the data and calculations performed on them. The term "intermediate step values" refers to values of the parameters in Equations 1-1 through 1-3. The final step is considered the resulting AWQC. Although AWQC are, in turn, used for purposes of establishing water quality-based effluent limits (WQBELs) in National Pollutant Discharge Elimination System (NPDES) permits, calculating total maximum daily loads (TMDLs), and applicable or relevant and appropriate requirements (ARARs) for Superfund, they are considered the final step of this Methodology and, for the purpose of this discussion, where the rounding should occur.

The determination of appropriate significant figures inevitably involves some judgment given that some of the equation parameters are adopted default exposure values. Specifically, the default drinking water intake rate of 2 L/day is a value adopted to represent a majority of the population over the course of a lifetime. Although supported by drinking water consumption survey data, this value was adopted as a policy decision and, as such, does not have to be considered in determining the parameter with the least precision. That is, the resulting AWQC need not always be reduced to one significant digit. Similarly, the 70-kg adult body weight has been adopted Agency-wide and represents a default policy decision.

The following example with a simplified AWQC equation illustrates the rule described above. The example is for hexachlorobutadiene (HCBD), which EPA used to demonstrate the 1998 draft Methodology revisions (USEPA, 1998b). The parameters that were calculated (i.e., not policy adopted values) include values with significant figures of two (the POD and RSC), three (the UF), and four (the FI and BAF). Based on the 2000 Human Health Methodology, the final criterion should be rounded to two significant figures. The bold numbers in parentheses indicate the number of significant figures and those with asterisks also indicate Agency adopted policy values.

$$AWQC = \frac{POD}{UF} \cdot RSC \cdot \left(\frac{BW}{DI + (FI \cdot BAF)} \right) \qquad \text{(Equation 2-1)}$$

Example [Refer to draft HCBD document for details on the POD/UF, RSC and BAF data (EPA 822-R-98-004). Also note that the fish intake rate in this example is the revised value.]:

$$AWQC = \left(\frac{0.054\mathbf{(2)}}{300\mathbf{(3)}} - 1.2 \times 10^{-4}\mathbf{(2)} \right) \times \left(\frac{70\mathbf{(2^*)}}{2\mathbf{(1^*)} + (0.01750\mathbf{(4)} \times 3{,}180\mathbf{(4)})} \right)$$

AWQC = 7.3×10^{-5} mg/L (0.073 µg/L, rounded from 7.285×10^{-2} µg/L)
* represents Agency adopted policy value

A number of the values used in the equation may result in intermediate step values that have more than four figures past the decimal place and may be carried throughout the calculation. However, carrying more than four figures past the decimal place (equivalent to the most precise parameter) is unnecessary as it has no effect on the resulting criterion value.

2.8 OTHER CONSIDERATIONS

2.8.1 Minimum Data Considerations

For many of the preceding technical areas, considerations have been presented for data quality in developing toxicological and exposure assessments. For greater detail and discussion of minimum data recommendations, the reader is referred to the specific sections in the Methodology on cancer and noncancer risk assessments (and especially to the referenced EPA risk assessment guidelines documents), exposure assessment, and bioaccumulation assessment, in addition to the TSD volumes for each.

2.8.2 Site-Specific Criterion Calculation

The 2000 Human Health Methodology allows for site-specific modifications by States and Tribes to reflect local environmental conditions and human exposure patterns. "Local" may refer to any appropriate geographic area where common aquatic environmental or exposure patterns exist. Thus "local" may signify Statewide, regional, a river reach, or an entire river.

Such site-specific criteria may be developed as long as the site-specific data, either toxicological or exposure-related, is justifiable. For example, when using a site-specific fish consumption rate, a State should use a value that represents at least the central tendency of the population surveyed (either sport or subsistence, or both). If a site-specific fish consumption rate for sport anglers or subsistence anglers is lower than an EPA default value, it may be used in calculating AWQC. However, to justify such a level (either higher or lower than EPA defaults), the State should assemble appropriate survey data to arrive at a defensible site-specific fish consumption rate.

Such data must also be submitted to EPA for its review when approving or disapproving State or Tribal water quality standards under Section 303(c). The same conditions apply to site-specific calculations of BAF, percent fish lipid, or the RSC. In the case of deviations from toxicological values (i.e., IRIS values: verified noncancer and cancer assessments), EPA strongly recommends that the data upon which the deviation is based be presented to and approved by the Agency before a criterion is developed.

Additional guidance on site-specific modifications to the 2000 Human Health Methodology is provided in each of the three TSD volumes.

2.8.3 Organoleptic Criteria

Organoleptic criteria define concentrations of chemicals or materials which impart undesirable taste and/or odor to water. Organoleptic effects, while significant from an aesthetic standpoint, are not a significant health concern. In developing and utilizing such criteria, two factors must be appreciated: (1) the limitations of most organoleptic data; and (2) the human health significance of organoleptic properties. In the past, EPA has developed organoleptic criteria if organoleptic data were available for a specific contaminant. The 1980 AWQC National Guidelines made a clear distinction that organoleptic criteria and toxicity-based criteria are derived from completely different endpoints, and that organoleptic criteria have no demonstrated relationship to potential adverse human health effects because there is no toxicological basis. EPA acknowledges that if organoleptic effects (i.e., objectionable taste and odor) cause people to reject the water and its designated uses, then the public is effectively deprived of the natural resource. It is also possible that intense organoleptic characteristics could result in depressed fluid intake which, in turn, might lead to an indirect human health effect via decreased fluid consumption. Although EPA has developed organoleptic criteria in the past and may potentially do so in the future, this will not be a significant part of the water quality criteria program. EPA encourages the development of organoleptic criteria when States and Tribes believe they are needed. However, EPA cautions States and Tribes that the quality of organoleptic data is often significantly less than that of toxicologic data used in establishing health-based criteria. Therefore, a comprehensive evaluation of available organoleptic data should be made, and the selection of the most appropriate database for the criterion should be based on sound scientific judgment.

In 1980, EPA provided recommended criteria summary language when both types of data are available. The following format was used and is repeated here:

> *For comparison purposes, two approaches were used to derive criterion levels for ____. Based on available toxicity data, for the protection of public health the derived level is ____. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water the estimated level is ____. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have no demonstrated relationship to potential adverse human health effects.*

Similarly, the 1980 Methodology recommended that in those instances where a level to limit toxicity cannot be derived, the following statement should be provided:

> *Sufficient data are not available for ____ to derive a level which would protect against the potential toxicity of this compound.*

2.8.4 Criteria for Chemical Classes

The 2000 Human Health Methodology also allows for the development of a criterion for classes of chemicals, as long as a justification is provided through the analysis of mechanistic data, toxicokinetic data, structure-activity relationship data, and limited acute and chronic toxicity data. When potency differences between members of a class is great (such as in the case

of chlorinated dioxins and furans), toxicity equivalency factors (TEFs) may be more appropriately developed than one class criterion.

A chemical class is defined as any group of chemical compounds which are similar in chemical structure and biological activity, and which frequently occur together in the environment usually because they are generated by the same commercial process. In criterion development, isomers should be regarded as part of a chemical class rather than as a single compound. A class criterion, therefore, is an estimate of risk/safety which applies to more than one member of a class. It involves the use of available data on one or more chemicals of a class to derive criteria for other compounds of the same class in the event that there are insufficient data available to derive compound-specific criteria. The health-based criterion may apply to the water concentration of each member of the class, or may apply to the sum of the water concentrations of the compounds within the class. Because relatively minor structural changes within the class of compounds can have pronounced effects on their biological activities, reliance on class criteria should be minimized depending on the data available.

The following guidance should also be followed when considering the development of a class criterion.

- A detailed review of the chemical and physical properties of the chemicals within the group should be made. A close relationship within the class with respect to chemical activity would suggest a similar potential to reach common biological sites within tissues. Likewise, similar lipid solubilities would suggest the possibility of comparable absorption and distribution.

- Qualitative and quantitative toxicological data for chemicals within the group should be examined. Adequate toxicological data on a number of compounds within a group provides a more reasonable basis for extrapolation to other chemicals of the same class than minimal data on one chemical or a few chemicals within the group.

- Similarities in the nature of the toxicological response to chemicals in the class provides additional support for the prediction that the response to other members of the class may be similar. In contrast, where the biological response has been shown to differ markedly on a qualitative and quantitative basis for chemicals within a class, the extrapolation of a criterion to other members is not appropriate.

- Additional support for the validity of extrapolation of a criterion to other members of a class could be provided by evidence of similar metabolic and toxicokinetic data for some members of the class.

Additional guidance is described in the *Technical Support Document on Health Risk Assessment of Chemical Mixtures* (USEPA, 1990).

2.9.5 Criteria for Essential Elements

Developing criteria for essential elements, particularly metals, must be a balancing act between toxicity and the requirement for good health. The AWQC must consider essentiality and cannot be established at levels that would result in deficiency of the element in the human population. The difference between the recommended daily allowance (RDA) and the daily doses causing a specified risk level for carcinogens or the RfDs for noncarcinogens defines the spread of daily doses within which the criterion may be derived. Because errors are inherent in defining both essential and adverse-effect levels, the criterion is derived from a dose level near the center of such dose ranges.

The process for developing criteria for essential elements should be similar to that used for any other chemical with minor modifications. The RfD represents concern for one end of the exposure spectrum (toxicity), whereas the RDA represents the other end (minimum essentiality). While the RDA and RfD values might occasionally appear to be similar in magnitude to one another, it does not imply incompatibility of the two methodological approaches, nor does it imply inaccuracy or error in either calculation.

3. RISK ASSESSMENT

This section describes the methods used to estimate ambient water quality criteria (AWQC) for the protection of human health for carcinogenic chemicals (Section 3.1) and for noncarcinogenic chemicals (Section 3.2).

3.1 CANCER EFFECTS

3.1.1 Background on EPA Cancer Risk Assessment Guidelines

The current EPA *Guidelines for Carcinogen Risk Assessment* were published in 1986 (USEPA, 1986a, hereafter the "1986 cancer guidelines"). The 1986 cancer guidelines categorize chemicals into alpha-numerical Groups: A, known human carcinogen (sufficient evidence from epidemiological studies or other human studies); B, probable human carcinogen (sufficient evidence in animals and limited or inadequate evidence in humans); C, possible human carcinogen (limited evidence of carcinogenicity in animals in the absence of human data); D, not classifiable (inadequate or no animal evidence of carcinogenicity); and E, evidence of noncarcinogenicity for humans (no evidence of carcinogenicity in at least two adequate animal tests in different species or in both adequate epidemiological and animal studies). Within Group B there are two subgroups, Groups B1 and B2. Group B1 is reserved for agents for which there is limited evidence of carcinogenicity from epidemiological studies. Group B2 is generally for agents for which there is sufficient evidence from animal studies and for which there is inadequate evidence or no data from epidemiological studies (USEPA, 1986). The system was similar to that used by the International Agency for Research on Cancer (IARC).

The 1986 cancer guidelines include guidance on what constitutes sufficient, limited, or inadequate evidence. In epidemiological studies, sufficient evidence indicates a causal relationship between the agent and human cancer; limited evidence indicates that a causal relationship is credible, but that alternative explanations, such as chance, bias, or confounding, could not adequately be excluded; inadequate evidence indicates either lack of pertinent data, or a causal interpretation is not credible. In general, although a single study may be indicative of a cause-effect relationship, confidence in inferring a causal association is increased when several independent studies are concordant in showing the association. In animal studies, sufficient evidence includes an increased incidence of malignant tumors or combined malignant and benign tumors:

- In multiple species or strains;
- In multiple experiments (e.g., with different routes of administration or using different dose levels);
- To an unusual degree in a single experiment with regard to high incidence, unusual site or type of tumor, or early age at onset;
- Additional data on dose-response, short-term tests, or structural activity relationships.

In the 1986 cancer guidelines, hazard identification and the weight-of-evidence process focus on tumor findings. The weight-of-evidence approach for making judgments about cancer hazard analyzes human and animal tumor data separately, then combines them to make the overall conclusion about potential human carcinogenicity. The next step of the hazard analysis is an evaluation of supporting evidence (e.g., mutagenicity, cell transformation) to determine whether the overall weight-of-evidence conclusion should be modified.

For cancer risk quantification, the 1986 cancer guidelines recommend the use of linearized multistage model (LMS) as the only default approach. The 1986 cancer guidelines also mention that a low-dose extrapolation model other than the LMS might be considered more appropriate based on biological grounds. However, no guidance is given in choosing other approaches. The 1986 cancer guidelines recommended the use of body weight raised to the 2/3 power ($BW^{2/3}$) as a dose scaling factor between species.

3.1.2 EPA's Proposed Guidelines for Carcinogen Risk Assessment and the Subsequent July, 1999 Draft Revised Cancer Guidelines

In 1996, EPA published *Proposed Guidelines for Carcinogen Risk Assessment* (USEPA, 1996a, hereafter the "1996 proposed cancer guidelines"). After the publication of the 1996 proposed cancer guidelines and a February, 1997 and January, 1999 Science Advisory Board (SAB) review, a revision was made in July, 1999 *Guidelines for Carcinogen Risk Assessment - Review Draft* (hereafter the "1999 draft revised cancer guidelines"; USEPA, 1999a), and an SAB meeting was convened to review this revised document. When final guidelines are published, they will replace the 1986 cancer guidelines. These revisions are designed to ensure that the Agency's cancer risk assessment methods reflect the most current scientific information and advances in risk assessment methodology.

In the meanwhile, the 1986 guidelines are used and extended with principles discussed in the 1999 draft revised cancer guidelines. These principles arise from scientific discoveries concerning cancer made in the last 15 years and from EPA policy of recent years supporting full characterization of hazard and risk both for the general population and potentially sensitive groups such as children. These principles are incorporated in recent and ongoing assessments such as the reassessment of dioxin, consistent with the 1986 guidelines. Until final guidelines are published, information is presented to describe risk under both the 1986 guidelines and 1999 draft revisions.

The 1999 draft revised cancer guidelines call for the full use of all relevant information to convey the circumstances or conditions under which a particular hazard is expressed (e.g., route, duration, pattern, or magnitude of exposure). They emphasize understanding the mode of action (MOA) whereby the agent induces tumors. The MOA underlies the hazard assessment and provides the rationale for dose-response assessments.

The key principles in the 1999 draft revised cancer guidelines include:

a) Hazard assessment is based on the analysis of all biological information rather than just tumor findings.

b) An agent's MOA in causing tumors is emphasized to reduce the uncertainty in describing the likelihood of harm and in determining the dose-response approach(es).

c) The 1999 draft revised cancer guidelines emphasize the conditions under which the hazard may be expressed (e.g., route, pattern, duration and magnitude of exposure). Further, the guidelines call for a *hazard characterization* to integrate the data analysis of all relevant studies into a weight-of-evidence conclusion of hazard and to develop a working conclusion regarding the agent's mode of action in leading to tumor development.

d) A weight-of-evidence narrative with accompanying descriptors (listed in Section 3.1.3.1 below) would replace the current alphanumeric classification system. The narrative summarizes the key evidence for carcinogenicity, describes the agent's MOA, characterizes the conditions of hazard expression, including route of exposure, describes any disproportionate effects on subgroups of the human population (e.g., children), and recommends appropriate dose-response approach(es). Significant strengths, weaknesses, and uncertainties of contributing evidence are also highlighted.

e) Biologically based extrapolation models are the preferred approach for quantifying risk. These models integrate data and conclusions about events in the carcinogenic process throughout the dose-response range from high to low doses. It is anticipated, however, that the necessary data for the parameters used in such models will not be available for most chemicals. The 1999 draft revised cancer guidelines allow for alternative quantitative methods, including several default approaches.

f) Dose-response assessment is a two-step process. In the first step, response data are modeled in the observable range of data and a determination is made of the point of departure (POD) from the observed range to extrapolate to low doses. The second step is extrapolation from the POD to estimate dose-response at lower doses. In addition to modeling tumor data, the 1999 draft revised cancer guidelines call for the use and modeling of other kinds of responses if they are considered to be more informed measures of carcinogenic risk. Nominally, these responses reflect key events in the carcinogenic process integral to the MOA of the agent.

g) Three default approaches are provided–linear, nonlinear, or both when adequate data are unavailable to generate a biologically based model. As the first step for all approaches, curve fitting in the observed range is used to determine a POD. A standard POD is the effective dose corresponding to the lower 95 percent limit on

a dose associated with 10 percent extra risk (LED_{10}).[3] *Linear*: The linear default is a straight line extrapolation from the response at LED_{10} to the origin (zero dose, zero extra risk). *Nonlinear*: The nonlinear default begins with the identified POD and provides a margin of exposure (MOE) analysis rather than estimating the probability of effects at low doses. The MOE analysis is used to determine the appropriate margin between the POD and the exposure level of interest, in this Methodology, the AWQC. The key objective of the MOE analysis is to describe for the risk manager how rapidly responses may decline with dose. Other factors are also considered in the MOE analysis (i.e., nature of the response, slope of the dose-response curve, human sensitivity compared with experimental animals, nature and extent of human variability in sensitivity and human exposure). *Linear and nonlinear*: Section 3.1.3.4E describes the situations when both linear and nonlinear defaults are used.

h) The approach used to calculate an oral human equivalent dose when assessments are based on animal bioassays has been refined and includes a change in the default assumption for interspecies dose scaling. The 1999 draft revised cancer guidelines use body weight raised to the 3/4 power.

EPA health risk assessment practices for both cancer and noncancer endpoints are beginning to come together with recent proposals to emphasize MOA understanding in risk assessment and to model response data in the observable range to derive PODs for data sets and benchmark doses (BMDs) for individual studies. The modeling of observed response data to identify PODs in a standard way will help to harmonize cancer and noncancer dose-response approaches and permit comparisons of cancer and noncancer risk estimates.

3.1.3 Methodology for Deriving AWQC[4] by the 1999 Draft Revised Cancer Guidelines

Following the publication of the *Draft Water Quality Criteria Methodology: Human Health* (USEPA, 1998a) and the accompanying TSD (USEPA, 1998b), EPA received comments from the public. EPA also held an external peer review of the draft Methodology. Both the peer reviewers and the public recommended that EPA incorporate the new approaches into the AWQC Methodology.

Until new guidelines are published, the 1986 cancer guidelines will be used along with principles of the 1999 draft revised cancer guidelines. The 1986 guidelines are the basis for IRIS risk numbers which were used to derive the current AWQC. Each new assessment applying the principles of the 1999 draft revised cancer guidelines will be subject to peer review before being used as the basis of AWQC.

---

[3] Use of the LED_{10} as the point of departure is recommended with this Methodology, as it is with the 1999 draft revised cancer guidelines.

[4] Additional information regarding the revised method for assessing carcinogens may be found in the *Methodology for Deriving Ambient Water Quality Criteria for the Protection of Human Health (2000). Technical Support Document, Volume 1: Risk Assessment* (USEPA, 2000).

The remainder of Section 3 illustrates the methodology for deriving numerical AWQC for carcinogens applying the 1999 draft revised cancer guidelines (USEPA, 1999a). This discussion of the revised methodology for carcinogens focuses primarily on the quantitative aspects of deriving numerical AWQC values. It is important to note that the cancer risk assessment process outlined in the 1999 draft revised cancer guidelines is not limited to the quantitative aspects. A numerical AWQC value derived for a carcinogen is to be based on appropriate hazard characterization and accompanied by risk characterization information.

This section contains a discussion of the weight-of-evidence narrative, that describes all information relevant to a cancer risk evaluation, followed by a discussion of the quantitative aspects of deriving numerical AWQC values for carcinogens. It is assumed that data from an appropriately conducted animal bioassay or human epidemiological study provide the underlying basis for deriving the AWQC value. The discussion focuses on the following: (1) the weight-of-evidence narrative; (2) general considerations and framework for analysis of the MOA; (3) dose estimation; (4) characterizing dose-response relationships in the range of observation and at low, environmentally relevant doses; (5) calculating the AWQC value; (6) risk characterization; and (7) use of Toxicity Equivalent Factors (TEF) and Relative Potency Estimates. The first three topics encompass the quantitative aspects of deriving AWQC for carcinogens.

3.1.3.1 Weight-of-Evidence Narrative[5]

The 1999 draft revised cancer guidelines include a weight-of-evidence narrative that is based on an overall judgment of biological and chemical/physical considerations. Hazard assessment information accompanying an AWQC value for a carcinogen in the form of a weight-of-evidence narrative is described in the footnote. Of particular importance is that the weight-of-evidence narrative explicitly provides adequate support based on human studies, animal bioassays, and other key evidence for the conclusion whether the substance is or is likely to be carcinogenic to humans from exposures through drinking water and/or fish ingestion. The Agency emphasizes the importance of providing an explicit discussion of the MOA for the substance in the weight-of-evidence narrative if data are available, including a discussion that relates the MOA to the quantitative procedures used in the derivation of the AWQC.

3.1.3.2 Mode of Action - General Considerations and Framework for Analysis

[5] The weight-of-evidence narrative is intended for the risk manager, and thus explains in nontechnical language the key data and conclusions, as well as the conditions for hazard expression. Conclusions about potential human carcinogenicity are presented by route of exposure. Contained within this narrative are simple likelihood descriptors that essentially distinguish whether there is enough evidence to make a projection about human hazard (i.e., Carcinogenic to humans; Likely to be carcinogenic to humans; Suggestive evidence of carcinogenicity but not sufficient to assess human carcinogenic potential; Data are inadequate for an assessment of human carcinogenic potential; and Not likely to be carcinogenic to humans). Because one encounters a variety of data sets on agents, these descriptors are not meant to stand alone; rather, the context of the weight-of-evidence narrative is intended to provide a transparent explanation of the biological evidence and how the conclusions were derived. Moreover, these descriptors should not be viewed as classification categories (like the alphameric system), which often obscure key scientific differences among chemicals. The new weight-of-evidence narrative also presents conclusions about how the agent induces tumors and the relevance of the mode of action to humans, and recommends a dose-response approach based on the MOA understanding (USEPA, 1996a, 1999a).

An MOA is composed of key events and processes starting with the interaction of an agent with a cell, through operational and anatomical changes, resulting in cancer formation. "Mode" of action is contrasted with "mechanism" of action, which implies a more detailed, molecular description of events than is meant by MOA.

Mode of action analysis is based on physical, chemical, and biological information that helps to explain key events[6] in an agent's influence on development of tumors. Inputs to MOA analysis include tumor data in humans, animals, and among structural analogues as well as the other key data.

There are many examples of possible modes of carcinogenic action, such as mutagenicity, mitogenesis, inhibition of cell death, cytotoxicity with reparative cell proliferation, and immune suppression. All pertinent studies are reviewed in analyzing an MOA, and an overall weighing of evidence is performed, laying out the strengths, weaknesses, and uncertainties of the case as well as potential alternative positions and rationales. Identifying data gaps and research needs is also part of the assessment.

Mode of action conclusions are used to address the question of human relevance of animal tumor responses, to address differences in anticipated response among humans such as between children and adults or men and women, and as the basis of decisions about the anticipated shape of the dose-response relationship.

In reaching conclusions, the question of "general acceptance" of an MOA will be tested as part of the independent peer review that EPA obtains for its assessment and conclusions.

Framework for Evaluating a Postulated Carcinogenic Mode(s) of Action

The framework is intended to be an analytic tool for judging whether available data support a mode of carcinogenic action postulated for an agent and includes nine elements:

1. Summary description of postulated MOA
2. Identification of key events
3. Strength, consistency, specificity of association

3.1.3.3 Dose Estimation

[6]A "key event" is an empirically observable, precursor step that is itself a necessary element of the mode of action, or is a marker for such an element.

A. Determining the Human Equivalent Dose by the Oral Route

An important objective in the dose-response assessment is to use a measure of internal or delivered dose at the target site where possible. This is particularly important in those cases where the carcinogenic response information is being extrapolated to humans from animal studies. Generally, by the oral exposure route, the measure of a dose provided in the underlying human studies or animal bioassays is the applied dose, typically given in terms of unit mass per unit body weight per unit time, (e.g., mg/kg-day). When animal bioassay data are used, it is necessary to make adjustments to the applied dose values to account for differences in toxicokinetics between animals and humans that affect the relationship between applied dose and delivered dose at the target organ.

In the estimation of a human equivalent dose, the 1999 draft revised cancer guidelines recommend that when adequate data are available, the doses used in animal studies can be adjusted to equivalent human doses using toxicokinetic information on the particular agent. However, in most cases, there are insufficient data available to compare dose between species. In these cases, the estimate of a human equivalent dose is based on science policy default assumptions. To derive an equivalent human oral dose from animal data, the default procedure in the 1999 draft revised cancer guidelines is to scale daily applied oral doses experienced for a lifetime in proportion to body weight raised to the 3/4 power ($BW^{3/4}$). The adjustment factor is used because metabolic rates, as well as most rates of physiological processes that determine the disposition of dose, scale this way. Thus, the rationale for this factor rests on the empirical observation that rates of physiological processes consistently tend to maintain proportionality with body weight raised to 3/4 power (USEPA, 1992a, 1999a).

The use of $BW^{3/4}$ is a departure from the scaling factor of $BW^{2/3}$ that was based on surface area adjustment and was included in the 1980 AWQC National Guidelines as well as the 1986 cancer guidelines.

B. Dose-Response Analysis

If data on the agent are sufficient to support the parameters of a biologically based model and the purpose of the assessment is such as to justify investing resources supporting its use, this is the preferred approach for both the observed tumor and related response data and for extrapolation below the range of observed data in either animal or human studies.

3.1.3.4 Characterizing Dose-Response Relationships in the Range of Observation and at Low Environmentally Relevant Doses

The first quantitative component in the derivation of AWQC for carcinogens is the dose-response assessment in the range of observation. For most agents, in the absence of adequate data to generate a biologically based model, dose-response relationships in the observed range can be addressed through curve-fitting procedures for response data. It should be noted that the 1999 draft revised cancer guidelines call for modeling of not only tumor data in the observable range, but also other responses thought to be important events preceding tumor development (e.g., DNA adducts, cellular proliferation, receptor binding, hormonal changes). The modeling of

these data is intended to better inform the dose-response assessment by providing insights into the relationships of exposure (or dose) below the observable range for tumor response. These non-tumor response data can only play a role in the dose-response assessment if the agent's carcinogenic mode of action is reasonably understood, as well as the role of that precursor event.

The 1999 draft revised cancer guidelines recommend calculating the lower 95 percent confidence limit on a dose associated with an estimated 10 percent increased tumor or relevant non-tumor response (LED_{10}) for quantitative modeling of dose-response relationships in the observed range. The estimate of the LED_{10} is used as the POD for low-dose extrapolations discussed below. This standard point of departure (LED_{10}) is adopted as a matter of science policy to remain as consistent and comparable from case to case as possible. It is also a convenient comparison point for noncancer endpoints. The rationale supporting use of the LED_{10} is that a 10 percent response is at or just below the limit of sensitivity for discerning a statistically significant tumor response in most long-term rodent studies and is within the observed range for other toxicity studies. Use of lower limit takes experimental variability and sample size into account. The ED_{10} (central estimate) is also presented as a reference for comparison uses, especially for use in relative hazard/potency ranking among agents for priority setting.

For some data sets, a choice of the POD other than the LED_{10} may be appropriate. The objective is to determine the lowest reliable part of the dose-response curve for the beginning of the second step of the dose-response assessment—determine the extrapolation range. Therefore, if the observed response is below the LED_{10}, then a lower point may be a better choice (e.g., LED_5). Human studies more often support a lower POD than animal studies because of greater sample size.

The POD may be a NOAEL when a margin of exposure analysis is the nonlinear dose-response approach. The kinds of data available and the circumstances of the assessment both contribute to deciding to use a NOAEL or LOAEL which is not as rigorous or as ideal as curve fitting, but can be appropriate. If several data sets for key events and tumor response are available for an agent, and they are a mixture of continuous and incidence data, the most practicable way to assess them together is often through a NOAEL/LOAEL approach.

When an LED value estimated from animal data is used as the POD, it is adjusted to the human equivalent dose using an interspecies dose adjustment or a toxicokinetic analysis as described in Section 3.1.3.3.

Analysis of human studies in the observed range is designed on a case-by-case basis depending on the type of study and how dose and response are measured in the study.

A. Extrapolation to Low, Environmentally Relevant Doses

In most cases, the derivation of an AWQC will require an evaluation of carcinogenic risk at environmental exposure levels substantially lower than those used in the underlying study. Various approaches are used to extrapolate risk outside the range of observed experimental data. In the 1999 draft revised cancer guidelines, the choice of extrapolation method is largely

dependent on the mode of action. It should be noted that the term "mode of action" (MOA) is deliberately chosen in the 1999 draft revised cancer guidelines in lieu of the term "mechanism" to indicate using knowledge that is sufficient to draw a reasonable working conclusion without having to know the processes in detail as the term mechanism might imply. The 1999 draft revised cancer guidelines favor the choice of a biologically based model, if the parameters of such models can be calculated from data sources independent of tumor data. It is anticipated that the necessary data for such parameters will not be available for most chemicals. Thus, the 1999 draft revised cancer guidelines allow for several default extrapolation approaches (low-dose linear, nonlinear, or both).

B. Biologically Based Modeling Approaches

If a biologically based approach has been used to characterize the dose-response relationships in the observed range, and the confidence in the model is high, it may be used to extrapolate the dose-response relationship to environmentally relevant doses. For the purposes of deriving AWQC, the environmentally relevant dose would be the risk-specific dose (RSD) associated with incremental lifetime cancer risks in the 10^{-6} to 10^{-4} range for carcinogens for which a linear extrapolation approach is applied.[7] The use of the RSD and the POD/UF to compute the AWQC is presented in Section 3.1.3.5, below. Although biologically-based approaches are appropriate both for characterizing observed dose-response relationships and extrapolating to environmentally relevant doses, it is not expected that adequate data will be available to support the use of such approaches for most substances. In the absence of such data, the default linear approach, the nonlinear (MOE) approach, or both linear and nonlinear approaches will be used.

[7] For discussion of the cancer risk range, see Section 2.4.

C. Default Linear Extrapolation Approach

The default linear approach replaces the LMS approach that has served as the default for EPA cancer risk assessments. Any of the following conclusions leads to selection of a linear dose-response assessment approach:

- There is an absence of sufficient tumor MOA information.
- The chemical has direct DNA mutagenic reactivity or other indications of DNA effects that are consistent with linearity.
- Human exposure or body burden is high and near doses associated with key events in the carcinogenic process (e.g., 2,3,7,8-tetrachlorodibenzo-p-dioxin).
- Mode of action analysis does not support direct DNA effects, but the dose-response relationship is expected to be linear (e.g., certain receptor-mediated effects).

The procedures for implementing the default linear approach begin with the estimation of a POD as described above. The point of departure, LED_{10}, reflects the interspecies conversion to the human equivalent dose and the other adjustments for less-than-lifetime experimental duration. In most cases, the extrapolation for estimating response rates at low, environmentally relevant exposures is accomplished by drawing a straight line between the POD and the origin (i.e., zero dose, zero extra risk). This is mathematically represented as:

$$y = mx + b \qquad \text{(Equation 3-1)}$$
$$b = 0$$

where:

y	=	Response or incidence
m	=	Slope of the line (cancer potency factor) = $\Delta y/\Delta x$
x	=	Dose
b	=	Slope intercept

The slope of the line, "m" (the estimated cancer potency factor at low doses), is computed as:

$$m = \frac{0.10}{LED_{10}} \qquad \text{(Equation 3-2)}$$

The RSD is then calculated for a specific incremental targeted lifetime cancer risk (in the range of 10^{-6} to 10^{-4}) as:

$$RSD = \frac{\text{Target Incremental Cancer Risk}}{m} \qquad \text{(Equation 3-3)}$$

where:

RSD	=	Risk-specific dose (mg/kg-day)
Target Incremental Cancer Risk[8]	=	Value in the range of 10^{-6} to10^{-4}
m	=	Cancer potency factor $(mg/kg\text{-}day)^{-1}$

The use of the RSD to compute the AWQC is described in Section 3.1.3.5 below.

D. Default Nonlinear Approach

As discussed in the 1999 draft revised cancer guidelines, any of the following conclusions leads to a selection of a nonlinear (MOE) approach to dose-response assessment:

- A tumor MOA supporting nonlinearity applies (e.g., some cytotoxic and hormonal agents such as disruptors of hormonal homeostasis), and the chemical does not demonstrate mutagenic effects consistent with linearity.

- An MOA supporting nonlinearity has been demonstrated, and the chemical has some indication of mutagenic activity, but it is judged not to play a significant role in tumor causation.

Thus, a default assumption of nonlinearity is appropriate when there is no evidence for linearity and sufficient evidence to support an assumption of nonlinearity. The MOA may lead to a dose-response relationship that is nonlinear, with response falling much more quickly than linearly with dose, or being most influenced by individual differences in sensitivity. Alternatively, the MOA may theoretically have a threshold (e.g., the carcinogenicity may be a secondary effect of toxicity or of an induced physiological change that is itself a threshold phenomenon).

The nonlinear approach may be used, for instance, in the case of a bladder tumor inducer, where the chemical is not mutagenic and causes only stone formation in male rat bladders at high doses. This dynamic leads to tumor formation only at the high doses. Stone and subsequent tumor formation are not expected to occur at doses lower than those that induce the physiological changes that lead to stone formation. (More detail on this chemical is provided in the cancer section of the Risk Assessment TSD; USEPA, 2000). EPA does not generally try to distinguish between modes of action that might imply a “true threshold” from others with a

[8]In 1980, the target lifetime cancer risk range was set at 10-7 to 10-5. However, both the expert panel for the AWQC workshop (USEPA, 1993) and the peer review workshop experts (USEPA,1999c) recommended that EPA change the risk range to 10-6 to 10-4, to be consistent with SDWA program decisions. See Section 2.4 for more details.

nonlinear dose-response relationship, because there is usually not sufficient information to distinguish between those possibilities empirically.

The nonlinear MOE approach in the 1986 proposed cancer guidelines compares an observed response rate such as the LED_{10}, NOAEL, or LOAEL with actual or nominal environmental exposures of interest by computing the ratio between the two. In the context of deriving AWQC, the environmentally relevant exposures are nominal targets rather than actual exposures.

If the evidence for an agent indicates nonlinearity (e.g., when carcinogenicity is secondary to another toxicity for which there is a threshold), the MOE analysis for the toxicity is similar to what is done for a noncancer endpoint, and an RfD or RfC for that toxicity may also be estimated and considered in the cancer assessment. However, a threshold of carcinogenic response is not necessarily assumed. It should be noted that for cancer assessment, the MOE analysis begins from a POD that is adjusted for toxicokinetic differences between species to give a human equivalent dose.

To support the use of the MOE approach, risk assessment information provides evaluation of the current understanding of the phenomena that may be occurring as dose (exposure) decreases substantially below the observed data. This gives information about the risk reduction that is expected to accompany a lowering of exposure. The various factors that influence the selection of the UF in an MOE approach are also discussed below.

There are two main steps in the MOE approach. The first step is the selection of a POD. The POD may be the LED_{10} for tumor incidence or a precursor, or in some cases, it may also be appropriate to use a NOAEL or LOAEL value. When animal data are used, the POD is a human equivalent dose or concentration arrived at by interspecies dose adjustment (as discussed in Section 3.1.3.3) or toxicokinetic analysis.

The second step in using MOE analysis to establish AWQC is the selection of an appropriate margin or UF to apply to the POD. This is supported by analyses in the MOE discussion in the risk assessment. The following issues should be considered when establishing the overall UF for the derivation of AWQC using the MOE approach (others may be found appropriate in specific cases):

- The nature of the response used for the dose-response assessment, for instance, whether it is a precursor effect or a tumor response. The latter may support a greater MOE.

- The slope of the observed dose-response relationship at the POD and its uncertainties and implications for risk reduction associated with exposure reduction. (A steeper slope implies a greater reduction in risk as exposure decreases. This may support a smaller MOE).

- Human sensitivity compared with that of experimental animals.

- Nature and extent of human variability and sensitivity.

- Human exposure. The MOE evaluation also takes into account the magnitude, frequency, and duration of exposure. If the population exposed in a particular scenario is wholly or largely composed of a subpopulation of special concern (e.g., children) for whom evidence indicates a special sensitivity to the agent's MOA, an adequate MOE would be larger than for general population exposure.

E. Both Linear and Nonlinear Approaches

Any of the following conclusions leads to selection of both a linear and nonlinear approach to dose-response assessment. Relative support for each dose-response method and advice on the use of that information needs to be documented for the AWQC. In some cases, evidence for one MOA is stronger than for the other, allowing emphasis to be placed on that dose-response approach. In other cases, both modes of action are equally possible, and both dose-response approaches should be emphasized.

- Modes of action for a single tumor type support both linear and nonlinear dose response in different parts of the dose-response curve (e.g., 4,4' methylene chloride).

- A tumor mode of action supports different approaches at high and low doses; e.g., at high dose, nonlinearity, but, at low dose, linearity (e.g., formaldehyde).

- The agent is not DNA-reactive and all plausible modes of action are consistent with nonlinearity, but not fully established.

- Modes of action for different tumor types support differing approaches, e.g., nonlinear for one tumor type and linear for another due to lack of MOA information (e.g., trichloroethylene).

3.1.3.5 <u>AWQC Calculation</u>

A. Linear Approach

The following equation is used for the calculation of the AWQC for carcinogens where an RSD is obtained from the linear approach:

$$AWQC = RSD \cdot \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \cdot BAF_i)} \right) \qquad \text{(Equation 3-4)}$$

AWQC	=	Ambient water quality criterion (mg/L)
RSD	=	Risk-specific dose (mg/kg-day)
BW	=	Human body weight (kg)
DI	=	Drinking water intake (L/day)

FI_i	=	Fish intake at trophic level I (I = 2, 3, and 4) (kg/day)
BAF_i	=	Bioaccumulation factor for trophic level I (I = 2, 3, and 4), lipid normalized (L/kg)

B. Nonlinear Approach

In those cases where the nonlinear, MOE approach is used, a similar equation is used to calculate the AWQC [9]

$$AWQC = \frac{POD}{UF} \cdot RSC \cdot \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \cdot BAF_i)} \right) \qquad \text{(Equation 3-5)}$$

where variables are defined as for Equation 3-4 and:

POD	=	Point of departure (mg/kg-day)
UF	=	Uncertainty factor (unitless)
RSC	=	Relative source contribution (percentage or subtraction)

Differences between the AWQC values obtained using the linear and nonlinear approaches should be noted. First, the AWQC value obtained using the default linear approach corresponds to a specific estimated incremental lifetime cancer risk level in the range of 10^{-4} to 10^{-6}. In contrast, the AWQC obtained using the nonlinear approach does not describe a specific cancer risk. The AWQC calculations shown above are appropriate for waterbodies that are used as sources of drinking water.

The actual AWQC chosen for the protection of human health is based on a review of all relevant information, including cancer and noncancer data. The AWQC may, or may not, utilize the value obtained from the cancer analysis in the final AWQC value. The endpoint selected for the AWQC will be based on consideration of the weight of evidence and a complete analysis of all toxicity endpoints.

3.1.3.6 Risk Characterization

Risk assessment is an integrative process that is documented in a risk characterization summary. Risk characterization is the final step of the risk assessment process in which all preceding analyses (i.e., hazard, dose-response, and exposure assessments) are tied together to convey the overall conclusions about potential human risk. This component of the risk assessment process characterizes the data in nontechnical terms, explaining the extent and weight of evidence, major points of interpretation and rationale, and strengths and weaknesses of

[9] Although appearing in this equation as a factor to be multiplied, the RSC can also be an amount subtracted.

the evidence, and discussing alternative approaches, conclusions, uncertainties, and variability that deserve serious consideration.

Risk characterization information accompanies the numerical AWQC value and addresses the major strengths and weaknesses of the assessment arising from the availability of data and the current limits of understanding the process of cancer causation. Key issues relating to the confidence in the hazard assessment and the dose-response analysis (including the low-dose extrapolation procedure used) are discussed. Whenever more than one interpretation of the weight of evidence for carcinogenicity or the dose-response characterization can be supported, and when choosing among them is difficult, the alternative views are provided along with the rationale for the interpretation chosen in the derivation of the AWQC value. Where possible, quantitative uncertainty analyses of the data are provided; at a minimum, a qualitative discussion of the important uncertainties is presented.

3.1.3.7 Use of Toxicity Equivalence Factors and Relative Potency Estimates

The 1999 draft revised cancer guidelines state:

> *A toxicity equivalence factor (TEF) procedure is one used to derive quantitative dose-response estimates for agents that are members of a category or class of agents. TEFs are based on shared characteristics that can be used to order the class members by carcinogenic potency when cancer bioassay data are inadequate for this purpose. The ordering is by reference to the characteristics and potency of a well-studied member or members of the class. Other class members are indexed to the reference agent(s) by one or more shared characteristics to generate their TEFs.*

In addition, the 1999 draft revised cancer guidelines state that TEFs are generated and used for the limited purpose of assessment of agents or mixtures of agents in environmental media when better data are not available. When better data become available for an agent, the TEF should be replaced or revised. To date, adequate data to support use of TEFs have been found only for dibenzofurans (dioxins) and coplanar polychlorinated biphenyls (PCBs) (USEPA, 1989, 1999b).

The uncertainties associated with TEFs must be described when this approach is used. This is a default approach to be used when tumor data are not available for individual components in a mixture. Relative potency factors (RPFs) can be similarly derived and used for agents with carcinogenicity or other supporting data. The RPF is conceptually similar to TEFs, but does not have the same level of data to support it and thus has a less rigorous definition compared with the TEF. TEFs and RPFs are used only when there is no better alternative. When they are used, assumptions and uncertainties associated with them are discussed. As of today, there are only three classes of compounds for which relative potency approaches have been examined by EPA: dibenzofurans (dioxins), polychlorinated biphenyls (PCBs), and polycyclic aromatic hydrocarbons (PAHs). There are limitations to the use of TEF and RFP approaches, and caution should be exercised when using them. More guidance can be found in the draft document for conducting health risk assessment of chemical mixtures, published by the EPA Risk Assessment Forum (USEPA,1999b).

3.2 NONCANCER EFFECTS

3.2.1 1980 AWQC National Guidelines for Noncancer Effects

In the 1980 AWQC National Guidelines, the Agency evaluated noncancer human health effects from exposure to chemical contaminants using Acceptable Daily Intake (ADI) levels. ADIs were calculated by dividing NOAELs by safety factors (SFs) to obtain estimates of doses of chemicals that would not be expected to cause adverse effects over a lifetime of exposure. In accordance with the National Research Council report of 1977 (NRC, 1977), EPA used SFs of 10, 100, or 1,000, depending on the quality and quantity of the overall database. In general, a factor of 10 was suggested when good-quality data identifying a NOAEL from human studies were available. A factor of 100 was suggested if no human data were available, but the database contained valid chronic animal data. For chemicals with no human data and scant animal data, a factor of 1,000 was recommended. Intermediate SFs could also be used for databases that fell between these categories.

AWQC were calculated using the ADI levels together with standard exposure assumptions about the rates of human ingestion of water and fish, and also accounting for intake from other sources (see Equation 1-1 in the Introduction). Surface water concentrations at or below the calculated criteria concentrations would be expected to result in human exposure levels at or below the ADI. Inherent in these calculations is the assumption that, generally, adverse effects from noncarcinogens exhibit a threshold.

3.2.2 Noncancer Risk Assessment Developments Since 1980

Since 1980, the risk assessment of noncarcinogenic chemicals has changed. To remove the value judgments implied by the words “acceptable” and “safety,” the ADI and SF terms have been replaced with the terms RfD and UF/modifying factor (MF), respectively.

For the risk assessment of general systemic toxicity, the Agency currently uses the guidelines contained in the IRIS background document entitled *Reference Dose (RfD): Description and Use in Health Risk Assessments* (hereafter the “IRIS background document”. That document defines an RfD as “an estimate (with uncertainty spanning approximately an order of magnitude) of a daily exposure to the human population (including sensitive subgroups) that is likely to be without appreciable risk of deleterious effects over a lifetime” (USEPA,

1993a). The most common approach for deriving the RfD does not involve dose-response modeling. Instead, an RfD for a given chemical is usually derived by first identifying the NOAEL for the most sensitive known toxicity endpoint, that is, the toxic effect that occurs at the lowest dose. This effect is called the critical effect. Factors such as the study protocol, the species of experimental animal, the nature of the toxicity endpoint assessed and its relevance to human effects, the route of exposure, and exposure duration are critically evaluated in order to select the most appropriate NOAEL from among all available studies in the chemical's database. If no appropriate NOAEL can be identified from any study, then the LOAEL for the critical effect endpoint is used and an uncertainly factor for LOAEL-to-NOAEL extrapolation is applied. Using this approach, the RfD is equal to the NOAEL (or LOAEL) divided by the product of UFs and, occasionally, an MF:

$$\text{RfD (mg/kg/day)} = \frac{\text{NOAEL (or LOAEL)}}{\text{UF} \cdot \text{MF}} \qquad \text{(Equation 3-6)}$$

The definitions and guidance for use of the UFs and the MFs are provided in the IRIS background document and are repeated in Table 3-1.

The IRIS background document on the RfD (USEPA, 1993a) provides guidance for critically assessing noncarcinogenic effects of chemicals and for deriving the RfD. Another reference on this topic is Dourson (1994). Furthermore, the Agency has also published separate guidelines for assessing specific toxic endpoints, such as developmental toxicity (USEPA, 1991a), reproductive toxicity (USEPA, 1996a), and neurotoxicity risk assessment (USEPA, 1995). These endpoint-specific guidelines will be used for their respective areas in the hazard assessment step and will complement the overall toxicological assessment. It should be noted, however, that an RfD, derived using the most sensitive known endpoint, is considered protective against all noncarcinogenic effects.

TABLE 3-1. UNCERTAINTY FACTORS AND THE MODIFYING FACTOR

Uncertainty Factor	Definition
UF_H	Use a 1, 3, or 10-fold factor when extrapolating from valid data in studies using long-term exposure to average healthy humans. This factor is intended to account for the variation in sensitivity (intraspecies variation) among the members of the human population.
UF_A	Use an additional factor of 1, 3, or 10 when extrapolating from valid results of long-term studies on experimental animals when results of studies of human exposure are not available or are inadequate. This factor is intended to account for the uncertainty involved in extrapolating from animal data to humans (interspecies variation).
UF_S	Use an additional factor of 1, 3, or 10 when extrapolating from less-than-chronic results on experimental animals when there are no useful long-term human data. This factor is intended to account for the uncertainty involved in extrapolating from less-than-chronic NOAELs to chronic NOAELs.
UF_L	Use an additional factor of 1, 3, or 10 when deriving an RfD from a LOAEL, instead of a NOAEL. This factor is intended to account for the uncertainty involved in extrapolating from LOAELs to NOAELs.
UF_D	Use an additional 3- or 10-fold factor when deriving an RfD from an "incomplete" database. This factor is meant to account for the inability of any single type of study to consider all toxic endpoints. The intermediate factor of 3 (approximately ½ $\log_{10}$ unit, i.e., the square root of 10) is often used when there is a single data gap exclusive of chronic data. It is often designated as UF_D.

Modifying Factor

Use professional judgment to determine the MF, which is an additional uncertainty factor that is greater than zero and less than or equal to 10. The magnitude of the MF depends upon the professional assessment of scientific uncertainties of the study and database not explicitly treated above (e.g., the number of species tested). The default value for the MF is 1.

Note: With each UF or MF assignment, it is recognized that professional scientific judgment must be used. The total product of the uncertainty factors and modifying factor should not exceed 3,000.

Similar to the procedure used in the 1980 AWQC National Guidelines, the revised method of deriving AWQC for noncarcinogens uses the RfD together with various assumptions concerning intake of the contaminant from both water and non-water sources of exposure. The objective of an AWQC for noncarcinogens is to ensure that human exposure to a substance related to its presence in surface water, combined with exposure from other sources, does not exceed the RfD. The algorithm for deriving AWQC for noncarcinogens using the RfD is presented as Equation 1-1 in the Introduction.

3.2.3 Issues and Recommendations Concerning the Derivation of AWQC for Noncarcinogens

During a review of the 1980 AWQC National Guidelines (USEPA, 1993b), the Agency identified several issues that must be resolved in order to develop a final revised methodology for deriving AWQC based on noncancer effects. These issues, as discussed below, mainly concern the derivation of the RfD as the basis for such an AWQC. Foremost among these issues is whether the Agency should revise the present method or adopt entirely new procedures that use quantitative dose-response modeling for the derivation of the RfD. Other issues include the following:

- Presenting the RfD as a single point value or as a range to reflect the inherent imprecision of the RfD;
- Selecting specific guidance documents for derivation of noncancer health effect levels;
- Considering severity of effect in the development of the RfD;
- Using less-than-90-day studies as the basis for RfDs;
- Integrating reproductive/developmental, immunotoxicity, and neurotoxicity data into the RfD calculation;
- Applying toxicokinetic data in risk assessments; and
- Considering the possibility that some noncarcinogenic effects do not exhibit a threshold.

3.2.3.1 Using the Current NOAEL/UF-Based RfD Approach or Adopting More Quantitative Approaches for Noncancer Risk Assessment

The current NOAEL/UF-based RfD methodology, or its predecessor ADI/SF methodology, have been used since 1980. This approach assumes that there is a threshold exposure below which adverse noncancer health effects are not expected to occur. Exposures above this threshold are believed to pose some risk to exposed individuals; however, the current approach does not address the nature and magnitude of the risk above the threshold level (i.e., the shape of the dose-response curve above the threshold). The NOAEL/UF-based RfD approach is intended primarily to ensure that the RfD value derived from the available data falls below the population effects threshold. However, the NOAEL/UF-based RfD procedure has

limitations. In particular, this method requires that one of the actual experimental doses used by the researchers in the critical study be selected as the NOAEL or LOAEL value. The determination that a dose is a NOAEL or LOAEL will depend on the biological endpoints used and the statistical significance of the data. Statistical significance will depend on the number and spacing of dose groups and the numbers of animals used in each dose group. Studies using a small number of animals can limit the ability to distinguish statistically significant differences among measurable responses seen in dose groups and control groups. Furthermore, the determination of the NOAEL or LOAEL also depends on the dose spacing of the study. Doses are often widely spaced, typically differing by factors of three to ten. A study can identify a NOAEL and a LOAEL from among the doses studied, but the "true" effects threshold cannot be determined from those results. The study size and dose spacing limitations also limit the ability to characterize the nature of the expected response to exposures between the observed NOAEL and LOAEL values.

The limitations of the NOAEL/UF approach have prompted development of alternative approaches that incorporate more quantitative dose-response information. The traditional NOAEL approach for noncancer risk assessment has often been a source of controversy and has been criticized in several ways. For example, experiments involving fewer animals tend to produce higher NOAELs and, as a consequence, may produce higher RfDs. Larger sample sizes, on the other hand, should provide greater experimental sensitivity and lower NOAELs. The focus of the NOAEL approach is only on the dose that is the NOAEL, and the NOAEL must be one of the experimental doses. It also ignores the shape of the dose-response curve. Thus, the slope of the dose-response plays little role in determining acceptable exposures for human beings. Therefore, in addition to the NOAEL/UF-based RfD approach described above, EPA will accept other approaches that incorporate more quantitative dose-response information in appropriate situations for the evaluation of noncancer effects and the derivation of RfDs. However, the Agency wishes to emphasize that it still believes the NOAEL/UF RfD methodology is valid and can continue to be used to develop RfDs.

Two alternative approaches that may have relevance in assisting in the derivation of the RfD for a chemical are the BMD and the categorical regression approaches. These alternative approaches may overcome some of the inherent limitations in the NOAEL/UF approach. For example, the BMD analyses for developmental effects show that NOAELs from studies correlate well with a 5 percent response level (Allen et al., 1994). The BMD and the categorical regression approaches usually have greater data requirements than the RfD approach. Thus, it is unlikely that any one approach will apply to every circumstance; in some cases, different approaches may be needed to accommodate the varying databases for the range of chemicals for which water quality criteria must be developed. Acceptable approaches will satisfy the following criteria: (1) meet the appropriate risk assessment goal; (2) adequately describe the toxicity database and its quality; (3) characterize the endpoints properly; (4) provide a measure of the quality of the "fit" of the model when a model is used for dose-response analysis; and (5) describe the key assumptions and uncertainties.

A. The Benchmark Dose

The BMD is defined as the dose estimated to produce a predetermined level of change in response (the Benchmark Response level, or BMR) relative to control. The BMDL is defined as the statistical lower confidence limit on the BMD. In the derivation of an RfD, the BMDL is used as the dose to which uncertainty factors are applied instead of the NOAEL. The BMD approach first models a dose-response curve for the critical effect(s) using available experimental data. Several mathematical algorithms can be used to model the dose-response curve, such as polynomial or Weibull functions. To define a BMD from the modeled curve for quantal data, the assessor first selects the BMR. The choice of the BMR is critical. For quantal endpoints, a particular level of response is chosen (e.g., 1 percent, 5 percent, or 10 percent). For continuous endpoints, the BMR is the degree of change from controls and is based on what is considered a biologically significant change. The BMD is derived from the BMR dose by applying the desired confidence limit calculation. The RfD is obtained by dividing the BMD by one or more uncertainty factors, similar to the NOAEL approach. Because the BMD is used like the NOAEL to obtain the RfD, the BMR should be selected at or near the low end of the range of increased risks that can be detected in a study of typical size. Generally, this falls in the range between the ED_{01} and the ED_{10}.

The Agency will accept use of a BMD approach to derive RfDs for those agents for which there is an adequate database. There are a number of technical decisions associated with the application of the BMD technique. These include the following:

- The definition of an adverse response;
- Selection of response data to model;
- The form of the data used (continuous versus quantal);
- The choice of the measures of increased risk (extra risk versus additional risk);
- The choice of mathematical model (including use of nonstandard models for unusual data sets);
- The selection of the BMR;
- Methods for calculating the confidence interval;
- Selection of the appropriate BMD as the basis for the RfD (when multiple endpoints are modeled from a single study, when multiple models are applied to a single response, and when multiple BMDs are calculated from different studies); and
- The use of uncertainty factors with the BMD approach.

These topics are discussed in detail in Crump et al. (1995) and in the Risk Assessment TSD Volume (USEPA, 2000). The use of the BMD approach has been discussed in general terms by several authors (Gaylor, 1983; Crump, 1984; Dourson et al., 1985; Kimmel and Gaylor, 1988; Brown and Erdreich, 1989; Kimmel, 1990). The International Life Sciences Institute

(ILSI) also held a major workshop on the BMD in September 1993; the workshop proceedings are summarized in ILSI (1993) and in Barnes et al. (1995). For further information on these technical issues, the reader is referred to the publications referenced above.

The BMD approach addresses several of the quantitative or statistical criticisms of the NOAEL approach. These are discussed at greater length in Crump et al. (1995) and are summarized here. First, the BMD approach uses all the dose-response information in the selected study rather than just a single data point, such as the NOAEL or LOAEL. By using response data from all of the dose groups to model a dose-response curve, the BMD approach allows for consideration of the steepness of the slope of the curve when estimating the ED_{10}. The use of the full data set also makes the BMD approach less sensitive to small changes in data than the NOAEL approach, which relies on the statistical comparison of individual dose groups. The BMD approach also allows consistency in the consideration of the level of effect (e.g., a 10 percent response rate) across endpoints.

The BMD approach accounts more appropriately for the size of each dose group than the NOAEL approach. Laboratory tests with fewer animals per dose group tend to yield higher NOAELs, and thus higher RfDs, because statistically significant differences in response rates are harder to detect. Therefore, in the NOAEL approach, dose groups with fewer animals lead to a higher (less conservative) RfD. In contrast, with the BMD approach, smaller dose groups will tend to have the effect of extending the confidence interval around the ED_{10}; therefore, the lower confidence limit on the ED_{10} (the BMD) will be lower. With the BMD approach, greater uncertainty (smaller test groups) leads to a lower (more conservative) RfD.

There are some issues to be resolved before the BMD approach is used routinely. These were identified in a 1996 Peer Consultation Workshop (USEPA, 1996b). Methods for routine use of the BMD are currently under development by EPA. Several RfCs and RfDs based on the BMD approach are included in EPA's IRIS database. These include reference values for methylmercury based on delayed postnatal development in humans; carbon disulfide based on neurotoxicity; 1,1,1,2-tetrafluoroethane based on testicular effects in rats; and antimony trioxide based on chronic pulmonary interstitial inflammation in female rats.

Various mathematical approaches have been proposed for modeling developmental toxicity data (e.g., Crump, 1984; Kimmel and Gaylor, 1988; Rai and Van Ryzin, 1985; Faustman et al., 1989), which could be used to calculate a BMD. Similar methods can be used to model other types of toxicity data, such as neurotoxicity data (Gaylor and Slikker, 1990, 1992; Glowa and MacPhail, 1995). The choice of the mathematical model may not be critical, as long as estimation is within the observed dose range. Since the model fits a mathematical equation to the observed data, the assumptions in a particular model regarding the existence or absence of a threshold for the effect may not be pertinent (USEPA, 1997). Thus, any model that suitably fits the empirical data is likely to provide a reasonable estimate of a BMD. However, research has shown that flexible models that are nonsymmetric (e.g., the Weibull) are superior to symmetric models (e.g., the probit) in estimating the BMD because the data points at the higher doses have less influence on the shape of the curve than at low doses. In addition, models should incorporate fundamental biological factors where such factors are known (e.g., intralitter correlation for developmental toxicity data) in order to account for as much variability in the

data as possible. The Agency is currently using the BMD approach in risk assessments where the data support its use. Draft guidelines for application of the BMD approach also are being developed by the Agency.

Use of BMD methods involves fitting mathematical models to dose-response data obtained primarily from toxicology studies. When considering available models to use for a BMD analysis, it is important to select the model that fits the data the best and is the most biologically appropriate. EPA has developed software following several years of research and development, expert peer review, public comment, subsequent revision, and quality assurance testing. The software (BMDS, Version 1.2) can be downloaded from http://www.epa.gov/ncea/bmds.htm. BMDS facilitates these operations by providing simple data-management tools, a comprehensive help manual, an online help system, and an easy-to-use interface to run multiple models on the same dose-response data.

As part of this software package, EPA has included sixteen (16) different models that are appropriate for the analysis of dichotomous (quantal) data (Gamma, Logistic, Log-Logistic, Multistage, Probit, Log-Probit, Quantal-Linear, Quantal-Quadratic, Weibull), continuous data (Linear, Polynomial, Power, Hill), and nested developmental toxicology data (NLogistic, NCTR, Rai & Van Ryzin). Results from all models include a reiteration of the model formula and model run options chosen by the user, goodness-of-fit information, the BMD, and the estimate of the lower-bound confidence limit on the benchmark dose (BMDL). Model results are presented in textual and graphical output files which can be printed or saved and incorporated into other documents.

B. Categorical Regression

Categorical regression is an emerging technique that may have relevance for the derivation of RfDs or for estimating risk above the RfD (Dourson et al., 1997; Guth et al., 1997). The categorical regression approach, like the BMD approach, can be used to estimate a dose that corresponds to a given probability of adverse effects. This dose would then be divided by UFs to establish an RfD. However, unlike the BMD approach, the Categorical regression approach can incorporate information on different health endpoints in a single dose-response analysis. For those health effects for which studies exist, responses to the substance in question are grouped into severity categories; for example (1) no effect, (2) no adverse effect, (3) mild-to-moderate adverse effect, and (4) frank effect. These categories correspond to the dose categories currently used in setting the RfD, namely, the no-observed-effect level (NOEL), NOAEL, LOAEL, and frank-effect level (FEL), respectively. Logistic transformation or other applicable mathematical operations are used to model the probability of experiencing effects in a certain category as a function of dose (Harrell, 1986; Hertzberg, 1989). The "acceptability" of the fit of the model to the data can be judged using several statistical measures, including the χ^2 statistic, correlation coefficients, and the statistical significance of its model parameter estimates.

The resulting mathematical equation can be used to find a dose (or the lower confidence bound on the dose) at which the probability of experiencing adverse effects does not exceed a selected level, e.g., 10 percent. This dose (like the NOAEL or BMD) would then be divided by

relevant UFs to calculate an RfD. For more detail on how to employ the categorical regression approach, see the discussion in the Risk Assessment TSD (USEPA, 2000).

As with the BMD approach, the categorical regression approach has the advantage of using more of the available dose-response data to account for response variability as well as accounting for uncertainty due to sample size through the use of confidence intervals. Additional advantages of categorical regression include the combining of data sets prior to modeling, thus allowing the calculation of the slope of a dose-response curve for multiple adverse effects rather than only one effect at a time. Another advantage is the ability to estimate risks for different levels of severity from exposures above the RfD.

On the other hand, as with BMD, opinions differ over the amount and adequacy of data necessary to implement the method. The categorical regression approach also requires judgments regarding combining data sets, judging goodness-of-fit, and assigning severity to a particular effect. Furthermore, this approach is still in the developmental stage. It is not recommended for routine use, but may be used when data are available and justify the extensive analyses required.

C. Summary

Whether a NOAEL/UF-based methodology, a BMD, a categorical regression model, or other approach is used to develop the RfD, the dose-response-evaluation step of a risk assessment process should include additional discussion about the nature of the toxicity data and its applicability to human exposure and toxicity. The discussion should present the range of doses that are effective in producing toxicity for a given agent; the route, timing, and duration of exposure; species specificity of effects; and any toxicokinetic or other considerations relevant to extrapolation from the toxicity data to human-health-based AWQC. This information should always accompany the characterization of the adequacy of the data.

3.2.3.2 Presenting the RfD as a Single Point or as a Range for Deriving AWQC

Although the RfD has traditionally been presented and used as a single point, its definition contains the phrase ". . . an estimate (with uncertainty spanning perhaps an order of magnitude) . . ." (USEPA, 1993a). Underlying this concept is the reasoning that the selection of the critical effect and the total uncertainty factor used in the derivation of the RfD is based on the "best" scientific judgment, and that competent scientists examining the same database could derive RfDs which varied within an order of magnitude.

In one instance, IRIS presented the RfD as a point value within an accompanying range. EPA derived a single number as the RfD for arsenic (0.3 μg/kg-day), but added that "strong scientific arguments can be made for various values within a factor of 2 or 3 of the currently recommended RfD value, i.e., 0.1 to 0.8 μg/kg/day" (USEPA, 1993c). EPA noted that regulatory managers should be aware of the flexibility afforded them through this action.

There are situations in which the risk manager can select an alternative value to use in place of the RfD in the AWQC calculations. The domain from which this alternative value can

be selected is restricted to a defined range around the point estimate. As explained further below, the Agency is recommending that sometimes the use of a value other than the calculated RfD point estimate is appropriate in characterizing risk. The selection of an alternative value within an appropriate range must be determined for each individual situation, since several factors affect the selection of the alternative value. Observing similar effects in several animal species, including humans, can increase confidence in the selection of the critical effect and thereby narrow the range of uncertainty. There are other factors that can affect the precision. These include the slope of the dose-response curve, seriousness of the observed effect, dose spacing, and possibly the route for the experimental doses. Dose spacing and the number of animals in the study groups used in the experiment can also affect the confidence in the RfD.

To derive the AWQC, the calculated point estimate of the RfD is the default. Based on consideration of the available data, the use of another number within the range defined by the product of the UF(s) (and MF, if used) could be justified in some specific situations. This means that there are risk considerations which indicate that some value in the range other than the point estimate may be more appropriate, based on human health or environmental fate considerations. For example, the bioavailability of the contaminant in fish tissues is one factor to consider. If bioavailability from fish tissues is much lower than that from water and the RfD was derived from a study in which the contaminant exposure was from drinking water, the alternative to the calculated RfD could be selected from the high end of the range and justified using the quantitative difference in bioavailability.

Most inorganic contaminants, particularly divalent cations, have bioavailability values of 20 percent or less from a food matrix, but are much more available (about 80 percent or higher) from drinking water. Accordingly, the external dose necessary to produce a toxic internal dose would likely be higher for a study where the exposure occurred through the diet rather than the drinking water. As a result, the RfD from a dietary study would likely be higher than that for the drinking water study if equivalent external doses had been used. Conversely, in cases where the NOAEL that was the basis for the RfD came from a dietary study, the alternative value could be slightly lower than the calculated RfD.

Because the uncertainty around the dose-response relationship increases as extrapolation below the observed data increases, the use of an alternative point within the range may be more appropriate in characterizing the risk than the use of the calculated RfD, especially in situations when the uncertainty is high. Therefore, as a matter of policy, the 2000 Human Health Methodology permits the selection of a single point within a range about the calculated RfD to be used as the basis of the AWQC if an adequate justification of the alternative point is provided. More complete discussion of this option, including limitations on the span of the range, is provided in the Risk Assessment TSD (USEPA, 2000).

3.2.3.3 Guidelines to be Adopted for Derivation of Noncancer Health Effects Values

The Agency currently is using the IRIS background document as the general basis for the risk assessment of noncarcinogenic effects of chemicals (USEPA, 1993a). EPA recommends continued use of this document for this purpose. However, it should be noted that the process for evaluating chemicals for inclusion in IRIS is undergoing revision (USEPA, 1996c). The

revised assessments for many chemicals are now available on IRIS and can be consulted as examples of the RfD development process and required supporting documentation.

3.2.3.4 Treatment of Uncertainty Factors/Severity of Effects During the RfD Derivation and Verification Process

During the RfD derivation and toxicology review process, EPA considers the uncertainty in extrapolating between animal species and within individuals of a species, as well as specific uncertainties associated with the completeness of the database. The Agency's RfD Work Group has always considered the severity of the observed effects induced by the chemical under review when choosing the value of the UF with a LOAEL. For example, during the derivation and verification of the RfD for zinc (USEPA, 1992), an uncertainty factor less than the standard factor of 10 (UF of 3) was assigned to the relatively mild decrease in erythrocyte superoxide dismutase activity in human subjects. EPA recommends that the severity of the critical effect be assessed when deriving an RfD and that risk managers be made aware of the severity of the effect and the weight placed on this attribute of the effect when the RfD was derived.

3.2.3.5 Use of Less-Than-90-Day Studies to Derive RfDs

Generally, less-than-90-day experimental studies are not used to derive an RfD. This is based on the rationale that studies lasting for less than 90 days may be too short to detect various toxic effects. However, EPA, has in certain circumstances, derived an RfD based on a less-than-90-day study. For example, the RfD for nonradioactive effects of uranium is based on a 30-day rabbit study (USEPA, 1989). The short-term exposure period was used, because it was adequate for determining doses that cause chronic toxicity. In other cases, it may be appropriate to use a less-than-90-day study because the critical effect is expressed in less than 90 days. For example, the RfD for nitrate was derived and verified using studies that were less than 3-months in duration (USEPA, 1991b). For nitrate, the critical effect of methemoglobinemia in infants occurs in less than 90 days. When it can be demonstrated from other data in the toxicological database that the critical adverse effect is expressed within the study period and that a longer exposure duration would not exacerbate the observed effect or cause the appearance of some other adverse effect, the Agency may choose to use less-than-90-day studies as the basis of the RfD. Such values would have to be used with care because of the uncertainty in determining if other effects might be expressed if exposure was of greater duration than 90 days.

3.2.3.6 Use of Reproductive/Developmental, Immunotoxicity, and Neurotoxicity Data as the Basis for Deriving RfDs

All relevant toxicity data have some bearing on the RfD derivation and verification and are considered by EPA. The "critical" effect is the adverse effect most relevant to humans or, in the absence of an effect known to be relevant to humans, the adverse effect that occurs at the lowest dose in animal studies. If the critical effect is neurotoxicity, EPA will use that endpoint as the basis for the derivation and verification of an RfD, as it did for the RfD for acrylamide. Moreover, the Agency is continually revising its procedures for noncancer risk assessment. For example, EPA has released guidelines for deriving developmental RfDs (RfD_{DT}, USEPA, 1991a), for using reproductive toxicity (USEPA, 1996a), and neurotoxicity (USEPA, 1995) data

in risk assessments. The Agency is currently working on guidelines for using immunotoxicity data to derive RfDs. In addition, the Agency is proceeding with the process of generating acceptable emergency health levels for hazardous substances in acute exposure situations based on established guidelines (NRC, 1993).

3.2.3.7 Applicability of Toxicokinetic Data in Risk Assessment

All pertinent toxicity data should be used in the risk assessment process, including toxicokinetic and mechanistic data. The Agency has used toxicokinetic data in deriving the RfD for cadmium and other compounds and currently is using toxicokinetic data to better characterize human inhalation exposures from animal inhalation experiments during derivation/verification of RfCs. In analogy to the RfD, the RfC is considered to be an estimate of a concentration in the air that is not anticipated to cause adverse noncancer effects over a lifetime of inhalation exposure (USEPA, 1994; Jarabek, 1995a). For RfCs, different dosimetry adjustments are made to account for the differences between laboratory animals and humans in gas uptake and disposition or in particle clearance and retention. This procedure results in calculation of a "human equivalent concentration." Based on the use of these procedures, an interspecies UF of 3 (i.e., approximately $10^{0.5}$), instead of the standard factor of 10, is used in the RfC derivation (Jarabek, 1995b).

Toxicokinetics and toxicodynamics of a chemical each contribute to a chemical's observed toxicity, and specifically, to observed differences among species in sensitivity. Toxicokinetics describes the disposition (i.e., deposition, absorption, distribution, metabolism, and elimination of chemicals in the body) and can be approximated using toxicokinetic models. Toxicodynamics describes the toxic interaction of the agent with the target cell. In the absence of specific data on their relative contributions to the toxic effects observed in species, each is considered to account for approximately one-half of the difference in observed effects for humans compared with laboratory animals. The implication of this assumption is that an interspecies uncertainty factor of 3 rather than 10 could be used for deriving an RfD when valid toxicokinetic data and models can be applied to obtain an oral "human equivalent applied dose" (Jarabek, 1995b). If specific data exist on the relative contribution of either element to observed effects, that proportion will be used. The role exposure duration may play, and whether or not the chemical or its damage may accumulate over time in a particular scenario, also requires careful consideration (Jarabek, 1995c).

3.2.3.8 Consideration of Linearity (or Lack of a Threshold) for Noncarcinogenic Chemicals

It is quite possible that there are chemicals with noncarcinogenic endpoints that have no threshold for effects. For example, in the case of lead, it has not been possible to identify a threshold for effects on neurological development. Other examples could include genotoxic teratogens and germline mutagens. Genotoxic teratogens act by causing mutational events during organogenesis, histogenesis, or other stages of development. Germline mutagens interact with germ cells to produce mutations which may be transmitted to the zygote and expressed during one or more stages of development. However, there are few chemicals which currently have sufficient mechanistic information about these possible modes of action. It should be recognized that although an MOA consistent with linearity is possible (especially for agents

known to be mutagenic), this has yet to be reasonably demonstrated for most toxic endpoints other than cancer.

EPA has recognized the potential for nonthreshold noncarcinogenic endpoints and discussed this issue in the *Guidelines for Developmental Toxicity Risk Assessment* (USEPA, 1991a) and in the 1986 *Guidelines for Mutagenicity Risk Assessment* (USEPA, 1986). An awareness of the potential for such teratogenic/mutagenic effects should be established in order to deal with such data. However, without adequate data to support a genetic or mutational basis for developmental or reproductive effects, the default becomes a UF or MOA approach, which are procedures utilized for noncarcinogens assumed to have a threshold. Therefore, genotoxic teratogens and germline mutagens should be considered an exception while the traditional uncertainty factor approach is the general rule for calculating criteria or values for chemicals demonstrating developmental/reproductive effects. For the exceptional cases, since there is no well-established mechanism for calculating criteria protective of human health from the effects of these agents, criteria will be established on a case-by-case basis. Other types of nonthreshold noncarcinogens must also be handled on a case-by-case basis.

3.2.3.9 Minimum Data Guidance

For details on minimum data guidance for RfD development, see the Risk Assessment TSD (USEPA, 2000).

4. EXPOSURE

The derivation of AWQC for the protection of human health requires information about both the toxicological endpoints of concern for water pollutants and the pathways of human exposure to those pollutants. The two primary pathways of human exposure to pollutants present in a particular ambient waterbody that have been considered in deriving AWQC are direct ingestion of drinking water obtained from that waterbody and the consumption of fish/shellfish obtained from that waterbody. The water pathway also includes other exposures from household uses (e.g., showering). The derivation of an AWQC involves the calculation of the maximum water concentration for a pollutant (i.e., the water quality criteria level) that ensures drinking water and/or fish ingestion exposures will not result in human intake of that pollutant in amounts that exceed a specified level based upon the toxicological endpoint of concern.

The equation for noncancer effects is presented again here, in simplified form, to emphasize the exposure-related parameters (in bold). [Note: the RSC parameter also applies to nonlinear low-dose extrapolation for cancer effects and the other exposure parameters apply to all three of the equations (see Section 1.6).]

$$AWQC = RfD \bullet \boldsymbol{RSC} \bullet \frac{(\boldsymbol{BW})}{\left[\boldsymbol{DI} + (\boldsymbol{FI} \bullet BAF)\right]} \qquad \text{(Equation 4-1)}$$

where:

AWQC	=	Ambient Water Quality Criterion (mg/L)
RfD	=	Reference dose for noncancer effects (mg/kg-day)
RSC	=	Relative source contribution factor to account for non-water sources of exposure
BW	=	Human body weight (kg)
DI	=	Drinking water intake (L/day)
FI	=	Fish intake (kg/day)
BAF	=	Bioaccumulation factor (L/kg)

The following subsections discuss exposure issues relevant to the 2000 Human Health Methodology: exposure policy issues; consideration of non-water sources of exposure (the Relative Source Contribution approach); and the factors used in AWQC computation. In relevant sections, science policy and risk management decisions made by EPA are discussed.

4.1 EXPOSURE POLICY ISSUES

This section discusses broad policy issues related to exposure concerning the major objectives that the Agency believes should be met in setting AWQC.

An Exposure Assessment TSD provides greater detail on numerous topics discussed in this guidance: suggested sources of contaminant concentration and exposure intake information; suggestions of survey methods for obtaining and analyzing exposure data necessary for deriving AWQC; summaries of studies on fish consumption among sport fishers and subsistence fishers; more detailed presentation of parameter values (e.g., fish consumption rates, body weights); and additional guidance on the application of the RSC approach.

4.1.1 Sources of Exposure Associated With Ambient Water

4.1.1.1 Appropriateness of Including the Drinking Water Pathway in AWQC

EPA intends to continue including the drinking water exposure pathway in the derivation of its national default human health criteria (AWQC), as has been done since the 1980 AWQC National Guidelines were first published.

EPA recommends inclusion of the drinking water exposure pathway where drinking water is a designated use for the following reasons: (1) Drinking water is a designated use for surface waters under the CWA and, therefore, criteria are needed to assure that this designated use can be protected and maintained. (2) Although rare, there are some public water supplies that provide drinking water from surface water sources without treatment. (3) Even among the majority of water supplies that do treat surface waters, existing treatments may not necessarily be effective for reducing levels of particular contaminants. (4) In consideration of the Agency's goals of pollution prevention, ambient waters should not be contaminated to a level where the burden of achieving health objectives is shifted away from those responsible for pollutant discharges and placed on downstream users to bear the costs of upgraded or supplemental water treatment.

This policy decision has been supported by the States, most of the public stakeholders, and by external peer reviewers. As with the other exposure parameters, States and authorized Tribes have the flexibility to use alternative intake rates if they believe that drinking water consumption is substantively different than EPA's recommended default assumptions of 2 L/day for adults and 1 L/day for children. EPA recommends that States and authorized Tribes use an intake rate that would be protective of a majority of consumers and will consider whether an alternative assumption is adequately protective of a State's or Tribe's population based on the information or rationale provided at the time EPA reviews State and Tribal water quality standards submissions.

4.1.1.2 Setting Separate AWQC for Drinking Water and Fish Consumption

In conjunction with the issue of the appropriateness of including the drinking water pathway explicitly in the derivation of AWQC for the protection of human health, EPA intends to continue its practice of setting a single AWQC for both drinking water and fish/shellfish consumption, and a separate AWQC based on ingestion of fish/shellfish alone. This latter criterion applies in those cases where the designated uses of a waterbody include supporting fishable uses under Section 101(a) of the CWA and, thus, fish or shellfish for human consumption, but not as a drinking water supply source (e.g., non-potable estuarine waters).

EPA does not believe that national water quality criteria for protection of drinking water uses only are particularly useful for two reasons. First, State and Tribal standards for human health are set to protect Section 101(a) uses (e.g., "fishable, swimmable uses") under the CWA. Second, most waters have multiple designated uses. Additionally, the water quality standards program protects aquatic life. The 2000 Human Health Methodology revisions do not change EPA's policy to apply aquatic life criteria to protect aquatic species where they are more sensitive (i.e., when human health criteria would not be protective enough) or where human health via fish or water ingestion is not an issue.

4.1.1.3 Incidental Ingestion from Ambient Surface Waters

The 2000 Human Health Methodology does not routinely include criteria to address incidental ingestion of water from recreational uses. EPA has considered whether there are cases where water quality criteria for the protection of human health based only on fish ingestion (or only criteria for the protection of aquatic life) may not adequately protect recreational users from health effects resulting from incidental water ingestion.

EPA reviewed information that provided estimates of incidental water ingestion rates averaged over time. EPA generally believes that the averaged amount is negligible and will not have any impact on the chemical criteria values representative of both drinking water and fish ingestion. A lack of impact on the criteria values would likely also be true for chemical criteria based on fish consumption only, unless the chemical exhibits no bioaccumulation potential. However, EPA also believes that incidental/accidental water ingestion could be important for the development of microbial contaminant water quality criteria, and for either chemical or microbial criteria for States where recreational uses such as swimming and boating are substantially higher than the national average. EPA also notes that some States have indicated they already have established incidental ingestion rates for use in developing criteria. Therefore, although EPA will not use this intake parameter when deriving its national 304(a) chemical criteria, limited guidance is provided in the Exposure Assessment TSD volume in order to assist States and authorized Tribes that face situations where this intake parameter could be of significance.

4.2 CONSIDERATION OF NON-WATER SOURCES OF EXPOSURE WHEN SETTING AWQC

4.2.1 Policy Background

The 2000 Human Health Methodology uses different approaches for addressing non-water exposure pathways in setting AWQC for the protection of human health depending upon the toxicological endpoint of concern. With those substances for which the appropriate toxic endpoint is carcinogenicity based on a linear low-dose extrapolation, only the two water sources (i.e., drinking water and fish ingestion) are considered in the derivation of the AWQC. Non-water sources are not considered explicitly. In the case of carcinogens based on linear low-dose extrapolation, the AWQC is being determined with respect to the *incremental* lifetime risk posed by a substance's presence in water, and is not being set with regard to an individual's total risk from all sources of exposure. Thus, the AWQC represents the water concentration that would be

expected to increase an individual's lifetime risk of carcinogenicity from exposure to the particular pollutant by no more than one chance in one million, regardless of the additional lifetime cancer risk due to exposure, if any, to that particular substance from other sources.

Furthermore, health-based criteria values for one medium based on linear low-dose extrapolation typically vary from values for other media in terms of the concentration value, and often the associated risk level. Therefore, the RSC concept could not even theoretically apply unless all risk assessments for a particular carcinogen based on linear low-dose extrapolation resulted in the same concentration value and same risk level; that is, an apportionment would need to be based on a single risk value and level.

In the case of substances for which the AWQC is set on the basis of a carcinogen based on a nonlinear low-dose extrapolation or for a noncancer endpoint where a threshold is assumed to exist, non-water exposures are considered when deriving the AWQC using the RSC approach. The rationale for this approach is that for pollutants exhibiting threshold effects, the objective of the AWQC is to ensure that an individual's total exposure does not exceed that threshold level.

There has been some discussion of whether it is, in fact, necessary in most cases to explicitly account for other sources of exposure when computing the AWQC for pollutants exhibiting threshold effects. It has been argued that because of the conservative assumptions generally incorporated in the calculation of RfDs (or POD/UF values) used as the basis for the AWQC derivation, total exposures slightly exceeding the RfD are unlikely to produce adverse effects.

EPA emphasizes that the purpose of the RSC is to ensure that the level of a chemical allowed by a criterion or multiple criteria, when combined with other identified sources of exposure common to the population of concern, will not result in exposures that exceed the RfD or the POD/UF. The policy of considering multiple sources of exposure when deriving health-based criteria has become common in EPA's program office risk characterizations and criteria and standard-setting actions. Numerous EPA workgroups have evaluated the appropriateness of factoring in such exposures, and the Agency concludes that it is important for adequately protecting human health. Consequently, EPA risk management policy has evolved significantly over the last six years. Various EPA program initiatives and policy documents regarding aggregate exposure and cumulative risk have been developed, including the consideration of inhalation and dermal exposures. Additionally, accounting for other exposures has been included in recent mandates (e.g., the Food Quality Protection Act) and, thus, is becoming a requirement for the Agency. The Exposure Decision Tree approach has been shared with other EPA offices, and efforts to coordinate policies on aggregate exposure, where appropriate, have begun. EPA intends to continue developing policy guidance on the RSC issue and guidance to address the concern that human health may not be adequately protected if criteria allow for higher levels of exposure that, combined, may exceed the RfD or POD/UF. EPA also intends to refine the 2000 Human Health Methodology in the future to incorporate additional guidance on inhalation and dermal exposures. As stated previously, EPA is required to derive national water quality criteria under Section 304(a) of the CWA and does not intend to derive site-specific criteria. However, States and authorized Tribes have the flexibility to make alternative exposure and RSC estimates based on local data, and EPA strongly encourages this.

Uncertainty factors used in the derivation of the RfD (or POD/UF) to account for intra- and interspecies variability and the incompleteness of the toxicity data set(s)/animal studies are specifically relevant to the chemical's internal toxicological action, irrespective of the sources of exposure that humans may be experiencing. The Agency's policy is to consider and account for other sources of exposure in order to set protective health criteria. EPA believes that multiple route exposures may be particularly important when uncertainty factors associated with the RfD are small. Although EPA is well aware that RfDs are not all equivalent in their derivation, EPA does not believe that uncertainty in the toxicological data should result in less stringent criteria by ignoring exposure sources. However, the RSC policy approach does allow less stringent assumptions when multiple sources of exposure are not anticipated.

The AWQC are designed to be protective criteria, generally applicable to the waters of the United States. While EPA cannot quantitatively predict the actual human health risk associated with combined exposures above the RfD or POD/UF, a combination of health criteria for multiple media exceeding the RfD or POD/UF may not be sufficiently protective. Therefore, EPA's policy is to routinely account for all sources and routes of non-occupational exposure when setting AWQC for noncarcinogens and for carcinogens based on nonlinear low-dose extrapolations. EPA believes that maintaining total exposure below the RfD (or POD/UF) is a reasonable health goal and that there are circumstances where health-based criteria for a chemical should not exceed the RfD (or POD/UF), either alone (if only one criterion is relevant, along with other intake sources considered as background exposures) or in combination. EPA believes its RSC policy ensures this goal.

Also, given the inability to reasonably predict future changes in exposure patterns, the uncertainties in the exposure estimates due to typical data inadequacy, possible unknown sources of exposure, and the potential for some populations to experience greater exposures than indicated by the available data, EPA believes that utilizing the entire RfD (or POD/UF) does not ensure adequate protection.

4.2.2 The Exposure Decision Tree Approach

As indicated in Section 1, EPA has, in the past, used a "subtraction" method to account for multiple sources of exposure to pollutants. In the subtraction method, other sources of exposure (i.e., those other than the drinking water and fish exposures) are subtracted from the RfD (or POD/UF). However, EPA also previously used a "percentage" method for the same purpose. In this approach, the percentage of total exposure typically accounted for by the exposure source for which the criterion is being determined, referred to as the relative source contribution (RSC), is applied to the RfD to determine the maximum amount of the RfD "apportioned" to that source. With both procedures, a "ceiling" level of 80 percent of the RfD and a "floor level" of 20 percent of the RfD are applied.

The subtraction method is considered acceptable when only one criterion is relevant for a particular chemical. The percentage method is recommended in the context of the above goals when multiple media criteria are at issue. The percentage method does not simply depend on the amount of a contaminant in the prospective criterion source only. It is intended to reflect health considerations, the relative portions of other sources, and the likelihood for ever-changing levels

in each of those multiple sources (due to ever-changing sources of emissions and discharges). Rather than simply defaulting in every instance, the Agency attempts to compare multiple source exposures with one another to estimate their relative contribution to the total–given that understanding the degree to which their concentrations vary, or making any distributional analysis, is often not possible. The criteria levels, when multiple criteria are at issue, are based on the actual levels, with an assumption that there may be enough relative variability such that an apportionment (relating that percentage to the RfD) is a reasonable way of accounting for the uncertainty regarding that variability.

The specific RSC approach recommended by EPA, which we will use for the derivation of AWQC for noncarcinogens and carcinogens assessed using nonlinear low-dose extrapolation, is called the Exposure Decision Tree and is described below. To account for exposures from other media when setting an AWQC (i.e., non-drinking water/non-fish ingestion exposures, and inhalation or dermal exposures), the Exposure Decision Tree for determining proposed RfD or POD/UF apportionments represents a method of comprehensively assessing a chemical for water quality criteria development. This method considers the adequacy of available exposure data, levels of exposure, relevant sources/media of exposure, and regulatory agendas (i.e., whether there are multiple health-based criteria or regulatory standards for the same chemical). The Decision Tree addresses most of the disadvantages associated with the exclusive use of either the percentage or subtraction approaches, because they are not arbitrarily chosen prior to determining the following: specific population(s) of concern, whether these populations are relevant to multiple-source exposures for the chemical in question (i.e., whether the population is actually or potentially experiencing exposure from multiple sources), and whether levels of exposure, regulatory agendas, or other circumstances make apportionment of the RfD or POD/UF desirable. Both subtraction and percentage methods are potentially utilized under different circumstances with the Exposure Decision Tree approach, and the Decision Tree is recommended with the idea that there is enough flexibility to use other procedures if information on the contaminant in question suggests it is not appropriate to follow the Decision Tree. EPA recognizes that there may be other valid approaches in addition to the Exposure Decision Tree.

The Exposure Decision Tree approach allows flexibility in the RfD (or POD/UF) apportionment among sources of exposure. When adequate data are available, they are used to make protective exposure estimates for the population(s) of concern. When other sources or routes of exposure are anticipated but data are not adequate, there is an even greater need to make sure that public health protection is achieved. For these circumstances, a series of qualitative alternatives is used (with the less adequate data or default assumptions) that allow for the inadequacies of the data while protecting human health. Specifically, the Decision Tree makes use of chemical information when actual monitoring data are inadequate. It considers information on the chemical/physical properties, uses of the chemical, and environmental fate and transformation, as well as the likelihood of occurrence in various media. Review of such information, when available, and determination of a reasonable exposure characterization for the chemical will result in a water quality criterion that more accurately reflects exposures than automatically using a default value. Although the 20 percent default will still generally be used when information is not adequate, the need for using it should be reduced. There may also be some situations where EPA would consider the use of an 80 percent default (see Section 4.2.3).

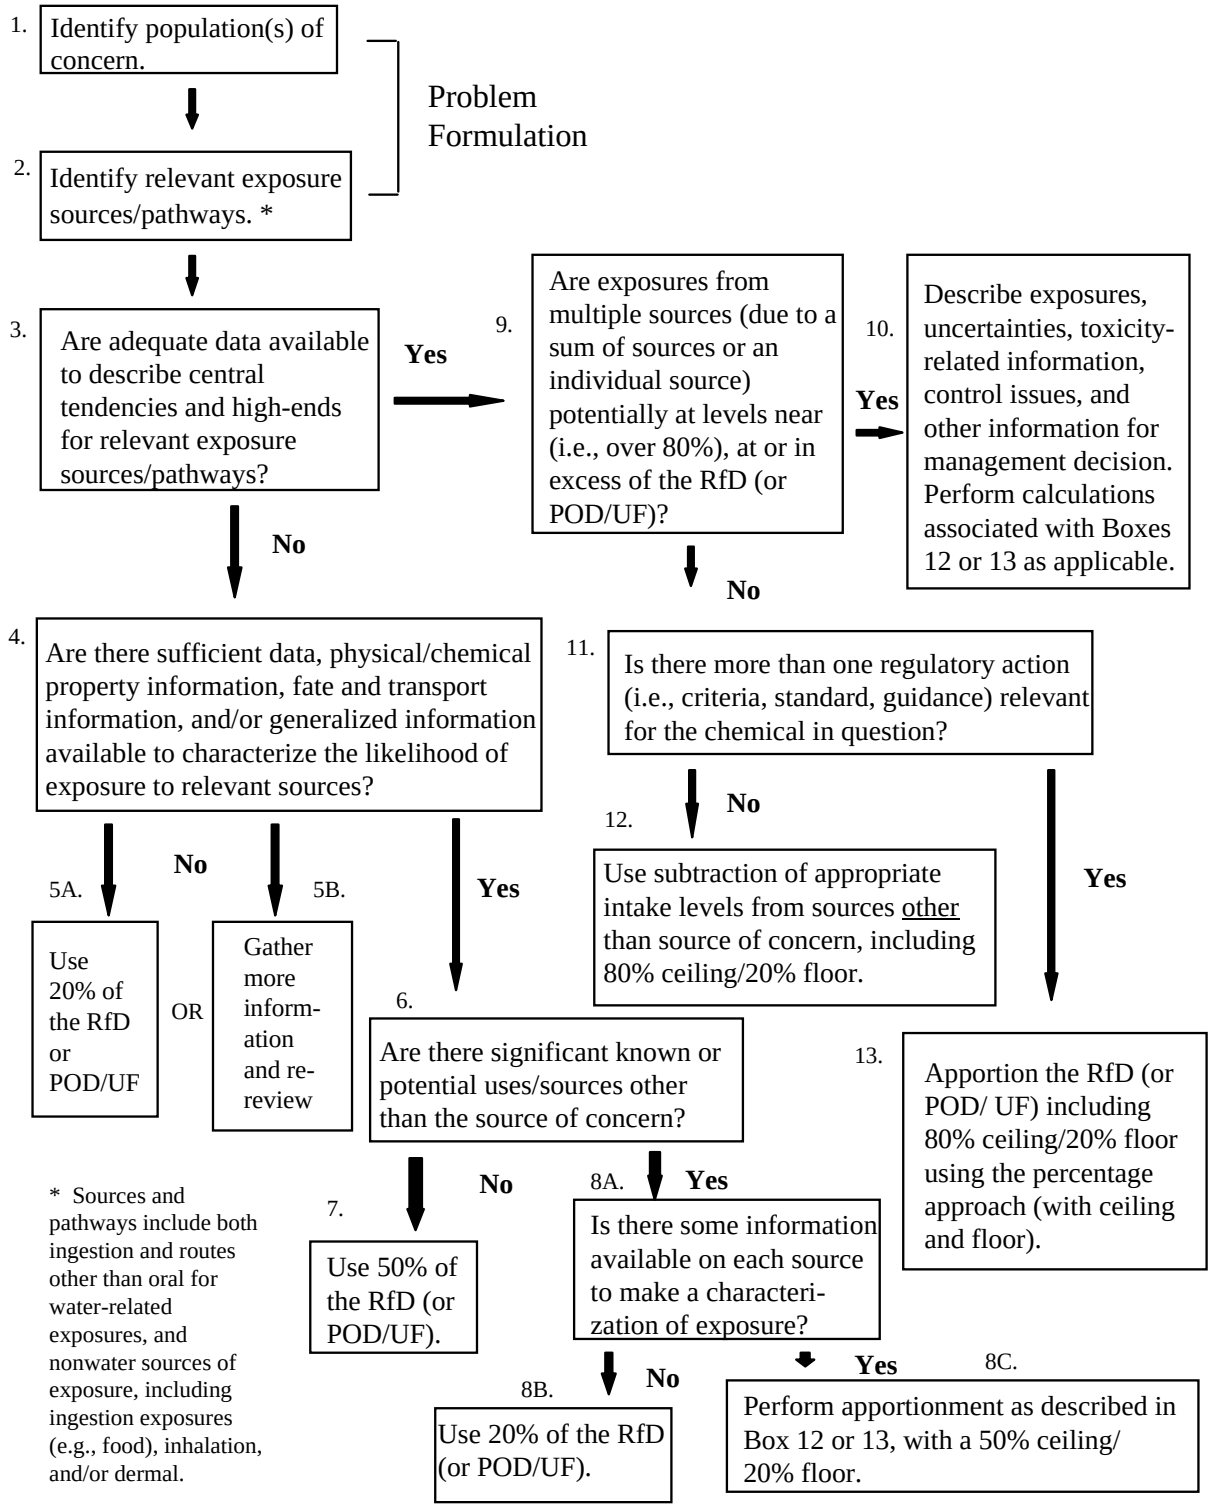
The Decision Tree also allows for use of either the subtraction or percentage method to account for other exposures, depending on whether one or more health-based criterion is relevant for the chemical in question. The subtraction method is considered acceptable when only one criterion is relevant for a particular chemical. In these cases, other sources of exposure can be considered "background" and can be subtracted from the RfD (or POD/UF).

EPA cautions States and Tribes when using the subtraction method in these circumstances. The subtraction method results in a criterion allowing the maximum possible chemical concentration in water after subtracting other sources. As such, it removes any cushion between pre-criteria levels (i.e., actual "current" levels) and the RfD, thereby setting criteria at the highest levels short of exceeding the RfD. It is somewhat counter to the goals of the CWA for maintaining and restoring the nation's waters. It is also directly counter to Agency policies, explicitly stated in numerous programs, regarding pollution prevention. EPA has advocated that it is good health policy to set criteria such that exposures are kept low when current levels are already low. The subtraction method generally results in criteria levels of a contaminant in a particular medium at significantly higher levels than the percentage method and, in this respect, is contradictory to such goals. In fact, many chemicals have pre-criteria levels in environmental media substantially lower (compared to the RfD) than the resulting criteria allow.

When more than one criterion is relevant to a particular chemical, apportioning the RfD (or POD/UF) via the percentage method is considered appropriate to ensure that the combination of criteria and, thus, the potential for resulting exposures do not exceed the RfD (or POD/UF). The Exposure Decision Tree (with numbered boxes) is shown in Figure 4-1. The explanation in the text on the following pages must be read in tandem with the Decision Tree figure; the text in each box of the figure only nominally identifies the process and conditions for determining the outcome for that step of the Decision Tree. The underlying objective is to maintain total exposure below the RfD (or POD/UF) while generally avoiding an extremely low limit in a single medium that represents just a nominal fraction of the total exposure. To meet this objective, all proposed numeric limits lie between 80 percent and 20 percent of the RfD (or POD/UF). Again, EPA will use the Exposure Decision Tree approach when deriving its AWQC but also recognizes that departures from the approach may be appropriate in certain cases. EPA understands that there may be situations where the Decision Tree procedure is not practicable or

Figure 4-1

Exposure Decision Tree for Defining Proposed RfD (or POD/UF) Apportionment



may be simply irrelevant after considering the properties, uses, and sources of the chemical in question. EPA endorses such flexibility by States and authorized Tribes when developing alternative water quality criteria in order to choose other procedures that are more appropriate for setting health-based criteria and, perhaps, apportioning the RfD or POD/UF, as long as reasons are given as to why it is not appropriate to follow the Exposure Decision Tree approach and as long as the steps taken to evaluate the potential sources and levels of exposure are clearly described. Often, however, the common situation of multiple exposure sources for a chemical is likely to merit a Decision Tree evaluation for the purpose of developing human health water quality criteria for a given chemical.

It is clear that this will be an interactive process; input by exposure assessors will be provided to, and received from, risk managers throughout the process, given that there may be significant implications regarding control issues (i.e., cost/feasibility), environmental justice issues, etc. In cases where the Decision Tree is not chosen, communication and concurrence about the decision rationale and the alternative water quality criteria are of great importance.

Descriptions of the boxes within the Decision Tree are separated by the following process headings to facilitate an understanding of the major considerations involved. The decision to perform, or not to perform, an apportionment could actually be made at several points during the Decision Tree process. Working through the process is most helpful for identifying possible exposure sources and the potential for exposure, determining the relevancy of the Decision Tree to developing an AWQC for a particular chemical and, possibly, determining the appropriateness of using an alternative approach to account for overall exposure. "Relevancy" here means determining whether more than one criterion, standard, or other guidance is being planned or is in existence for the chemical in question. Additional guidance for States and Tribes that wish to use the Exposure Decision Tree is provided in the Exposure Assessment TSD.

4.2.2.1 Problem Formulation

Initial Decision Tree discussion centers around the first two boxes: identification of population(s) of concern (Box 1) and identification of relevant exposure sources and pathways (Box 2). The term "problem formulation" refers to evaluating the population(s) and sources of exposure in a manner that allows determination of the potential for the population of concern to experience exposures from multiple sources for the chemical in question. Also, the data for the chemical in question must be representative of each source/medium of exposure and be relevant to the identified population(s). Evaluation includes determining whether the levels, multiple criteria or regulatory standards, or other circumstances make apportionment of the RfD or POD/UF reasonable. The initial problem formulation also determines the exposure parameters chosen, the intake assumptions chosen for each route, and any environmental justice or other social issues that aid in determining the population of concern. The term "data," as used here and discussed throughout this section, refers to ambient sampling data (whether from Federal, regional, State, or area-specific studies) and not internal human exposure measurements.

4.2.2.2 Data Adequacy

In Box 3, it is necessary that adequate data exist for the relevant sources/pathways of exposure if one is to avoid using default procedures. The adequacy of data is a professional judgment for each individual chemical of concern, but EPA recommends that the minimum acceptable data for Box 3 are exposure distributions that can be used to determine, with an acceptable 95 percent confidence interval, the central tendency and high-end exposure levels for each source. In fact, distributional data may exist for some or most of the sources of exposure.

There are numerous factors to consider in order to determine whether a dataset is adequate. These include: (1) sample size (i.e., the number of data points); (2) whether the data set is a random sample representative of the target population (if not, estimates drawn from it may be biased no matter how large the sample); (3) the magnitude of the error that can be tolerated in the estimate (estimator precision); (4) the sample size needed to achieve a given precision for a given parameter (e.g., a larger sample is needed to precisely estimate an upper percentile than a mean or median value); (5) an acceptable analytical method detection limit; and (6) the functional form and variability of the underlying distribution, which determines the estimator precision (e.g., whether the distribution is normal or lognormal and whether the standard deviation is 1 or 10). Lack of information may prevent assessment of each of these factors; monitoring study reports often fail to include background information or sufficient summary statistics (and rarely the raw data) to completely characterize data adequacy. Thus, a case-by-case determination of data adequacy may be necessary.

That being stated, there are some guidelines, as presented below, that lead to a rough rule-of-thumb on what constitutes an "adequate" sample size for exposure assessment. Again, first and foremost, the representativeness of the data for the population evaluated and the analytical quality of the data must be acceptable. If so, the primary objective then becomes estimating an upper percentile (e.g., say the 90th) and a central tendency value of some exposure distribution based on a random sample from the distribution. Assuming that the distribution of exposures is unknown, a nonparametric estimate of the 90th percentile is required. The required estimate, based on a random sample of *n* observations from a target population, is obtained by ranking the data from smallest to largest and selecting the observation whose rank is 1 greater than the largest integer in the product of 0.9 times *n*. For example, in a data set of 25 points, the nonparametric estimate of the 90th percentile is the 23rd largest observation.

In addition to this point estimate, it is useful to have an upper confidence bound on the 90th percentile. To find the rank of the order statistic that gives an upper 95 percent confidence limit on the 90th percentile, the smallest value of *r* that satisfies the following formula is determined:

$$0.95 \approx \sum_{i=0}^{r-1} \binom{n}{i} 0.9^{i}\ 0.1^{n-i} \qquad \text{(Equation 4-2)}$$

where:

r	=	the rank order of the observation
n	=	the number of observations
I	=	integer from 0 to r - 1

For relatively small data sets, the above formula will lead to selecting the largest observation as the upper confidence limit on the 90th percentile. However, the problem with using the maximum is that, in many environmental datasets, the largest observation is an outlier and would provide an unrealistic upper bound on the 90th percentile. It would, therefore, be preferable if the sample size *n* were large enough so that the formula yielded the second largest observation as the confidence limit (see for example Gibbons, 1971).

This motivates establishing the following criterion for setting an "adequate" sample size: pick the smallest *n* such that the nonparametric upper 95 percent confidence limit on the 90th percentile is the second largest value. Application of the above formula with *r* set to *n*-1 yields *n* = 45 for this minimum sample size.

For the upper 95 percent confidence limit to be a useful indicator of a high-end exposure, it must not be overly conservative (too large relative to the 90th percentile). It is, therefore, of interest to estimate the expected magnitude of the ratio of the upper 95 percent confidence limit to the 90th percentile. This quantity generally cannot be computed, since it is a function of the unknown distribution. However, to get a rough idea of its value, consider the particular case of a normal distribution. If the coefficient of variation (i.e., the standard deviation divided by the mean) is between 0.5 and 2.0, the expected value of the ratio in samples of 45 will be approximately 1.17 to 1.31; i.e., the upper 95 percent confidence limit will be only about 17 to 31 percent greater than the 90th percentile on the average.

It should be noted that the nonparametric estimate of the 95 percent upper confidence limit based on the second largest value can be obtained even if the data set has only two detects (it is assumed that the two detects are greater than the detection limit associated with all non-detects). This is an argument for using nonparametric rather than parametric estimation, since use of parametric methods would require more detected values. On the other hand, if non-detects were not a problem and the underlying distribution were known, a parametric estimate of the 90th percentile would generally be more precise.

As stated above, adequacy also depends on whether the samples are relevant to and representative of the population at risk. Data may, therefore, be adequate for some decisions and inadequate for others; this determination requires some professional judgment.

If the answer to Box 3 is no, based on the above determination of adequacy, then the decision tree moves to Box 4. As suggested by the separate boxes, the available data that will be reviewed as part of Box 4 do not meet the requirements necessary for Box 3. In Box 4, any limited data that are available (in addition to information about the chemical/physical properties, uses, and environmental fate and transformation, as well as any other information that would characterize the likelihood of exposure from various media for the chemical) are evaluated to

make a qualitative determination of the relation of one exposure source to another. Although this information should always be reviewed at the outset, it is recommended that this information also be used to estimate the health-based water quality criteria. The estimate should be rather conservative (as indicated in the Decision Tree), given that it is either not based on actual monitoring data or is based on data that has been considered to be inadequate for a more accurate quantitative estimate. Therefore, greater uncertainties exist and accounting for variability is not really possible. Whether the available data are adequate and sufficiently representative will likely vary from chemical to chemical and may depend on the population of concern. If there are some data and/or other information to make a characterization of exposure, a determination can be made as to whether there are significant known or potential uses for the chemical/sources of exposure other than the source of concern (i.e., in this case, the drinking water and fish intakes relevant to developing an AWQC) that would allow one to anticipate/quantify those exposures (Box 6). If there are not, then it is recommended that 50 percent of the RfD or POD/UF can be safely apportioned to the source of concern (Box 7). While this leaves half of the RfD or POD/UF unapportioned, it is recommended as the maximum apportionment due to the lack of data needed to more accurately quantify actual or potential exposures. If the answer to the question in Box 6 is yes (there is multiple source information available for the exposures of concern), and some information is available on each source of exposure (Box 8A), apply the procedure in either Box 12 or Box 13 (depending on whether one or more criterion is relevant to the chemical), using a 50 percent ceiling (Box 8C)–again due to the lack of adequate data. If the answer to the question in Box 8A is no (there is no available information to characterize exposure), then the 20 percent default of the RfD or POD/UF is used (Box 8B).

If the answer to the question in Box 4 is no; that is, there are not sufficient data/information to characterize exposure, EPA intends to generally use the "default" assumption of 20 percent of the RfD or POD/UF (Box 5A) when deriving or revising the AWQC. It may be better to gather more data or information and re-review when this information becomes available (Box 5B). EPA has done this on occasion when resources permit the acquisition of additional data to enable better estimates of exposure instead of the default. If this is not possible, then the assumption of 20 percent of the RfD or POD/UF (Box 5A) should be used. Box 5A is likely to be used infrequently with the Exposure Decision Tree approach, given that the information described in Box 4 should be available in most cases. However, EPA intends to use 20 percent of the RfD (or POD/UF), which has also been used in past water program regulations, as the default value.

4.2.2.3 Regulatory Actions

If there are adequate data available to describe the central tendencies and high ends from each exposure source/pathway, then the levels of exposure relative to the RfD or POD/UF are compared (Box 9). If the levels of exposure for the chemical in question are not near (currently defined as greater than 80 percent), at, or in excess of the RfD or POD/UF, then a subsequent determination is made (Box 11) as to whether there is more than one health-based criterion or regulatory action relevant for the given chemical (i.e., more than one medium-specific criterion,

standard or other guidance being planned, performed or in existence for the chemical). The subtraction method is considered acceptable when only one criterion (standard, etc.) is relevant for a particular chemical. In these cases, other sources of exposure can be considered "background" and can be subtracted from the RfD (or POD/UF). When more than one criterion is relevant to a particular chemical, apportioning the RfD (or POD/UF) via the percentage method is considered appropriate to ensure that the combination of health criteria, and thus the potential for resulting exposures, do not exceed the RfD (or POD/UF).

As indicated in Section 2, for EPA's national 304(a) criteria, the RSC intake estimates of non-water exposures (e.g., non-fish dietary exposures) will be based on arithmetic mean values when data are available. The assumed body weight used in calculating the national criteria will also be based on average values. The drinking water and fish intake values are 90th percentile estimates. EPA believes that these assumptions will be protective of a majority of the population and recommends them for State and Tribal use. However, States and authorized Tribes have the flexibility to choose alternative intake rate and exposure estimate assumptions to protect specific population groups that they have chosen.

4.2.2.4 Apportionment Decisions

If the answer to the question in Box 11 is no (there is not more than one relevant medium-specific criterion/regulatory action), then the recommended method for setting a health-based water quality criterion is to utilize a subtraction calculation (Box 12). Specifically, appropriate intake values for each exposure source other than the source of concern are subtracted out. EPA will rely on average values commonly used in the Agency for food ingestion and inhalation rates, combined with mean contaminant concentration values, for calculating RSC estimates to subtract. Alternatively, contaminant concentrations could be selected based on the variability associated with those concentrations for each source. This implies that a case-by-case determination of the variability and the resulting intake chosen would be made, as each chemical evaluated can be expected to have different variations in concentration associated with each source of intake. However, EPA anticipates that the available data for most contaminants will not allow this for determination (based on past experience). Guidance addressing this possibility is addressed in the Exposure Assessment TSD. EPA does not recommend that high-end intakes be subtracted for every exposure source, since the combination may not be representative of any actually exposed population or individual. The subtraction method would also include an 80 percent ceiling and a 20 percent floor.

If the answer to the question in Box 11 is yes (there is more than one medium-specific criterion/regulation relevant), then the recommended method for setting health-based water quality criteria is to apportion the RfD or POD/UF among those sources for which health-based criteria are being set (Box 13). This is done via a percentage approach (with a ceiling and floor). This simply refers to the percentage of overall exposure contributed by an individual exposure source. For example, if for a particular chemical, drinking water were to represent half of total exposure and diet were to represent the other half, then the drinking water contribution (or RSC) would be 50 percent. The health-based criteria would, in turn, be set at 50 percent of the RfD or POD/UF. This method also utilizes an appropriate combination of intake values for each

exposure source based on values commonly used in the Agency for food ingestion and inhalation rates, combined with mean contaminant concentration values.

Finally, if the levels of exposure for the chemical in question are near (currently defined as greater than 80 percent), at, or in excess of the RfD or POD/UF (i.e., the answer in Box 9 is yes), then the estimates of exposures and related uncertainties, recommended apportionment (either box 12 or 13), toxicity-related information, control issues, and other information are to be presented to managers for a decision (Box 10). The high levels referred to in Box 9 may be due to one source contributing that high level (while other sources contribute relatively little) or due to more than one source contributing levels that, in combination, approach or exceed the RfD or POD/UF. Management input may be necessary due to the control issues (i.e., cost and feasibility concerns), especially when multiple criteria are at issue. In practice, risk managers are routinely a part of decisions regarding regulatory actions and will be involved with any recommended outcome of the Exposure Decision Tree or, for that matter, any alternative to the Exposure Decision Tree. However, because exposures approach or exceed the RfD or POD/UF and because the feasibility of controlling different sources of exposure are complicated issues, risk managers will especially need to be directly involved in final decisions in these circumstances.

It is emphasized here that the procedures in these circumstances are not different than the procedures when exposures are not at or above the RfD (or POD/UF). Therefore, in these cases, estimates should be performed as with Boxes 11, 12, and 13. The recommendation should be made based on health-based considerations only, just as when the chemical in question was not a Box 10 situation. If the chemical is relevant to one health criterion or regulatory action only, the other sources of exposure could be subtracted from the RfD or POD/UF to determine if there is any leftover amount for setting the criterion. If the chemical is a multiple media criteria issue, then an apportionment should be made, even though it is possible that all sources would need to be reduced. Regardless of the outcome of Box 9, all apportionments made (via the methods of Boxes 12 or 13) should include a presentation of the uncertainty in the estimate and in the RfD or POD/UF for a more complete characterization.

The process for a Box 10 situation (versus a situation that is not) differs in that the presentations for Boxes 12 and 13 are based on apportionments (following the review of available information and a determination of appropriate exposure parameters) that must address additional control issues and may result in more selective reductions. With Box 10, one or several criteria possibilities ("scenarios") could be presented for comparison along with implications of the effects of various control options. It is appropriate to present information in this manner to risk managers given the complexity of these additional control issues.

4.2.3 Additional Points of Clarification on the Exposure Decision Tree Approach for Setting AWQC

As with Box 9, if a determination is made in Box 8A (i.e., information is available to characterize exposure) that exposures are near, at, or above the RfD (or POD/UF) based on the available information, the apportionments made need to be presented to risk managers for decision. If information is lacking on some of the multiple exposure sources, then EPA would use a default of 20 percent of the RfD or POD/UF (Box 8B).

Results of both Boxes 12 and 13 rely on the 80 percent ceiling and 20 percent floor. The 80 percent ceiling was implemented to ensure that the health-based goal will be low enough to provide adequate protection for individuals whose total exposure to a contaminant is, due to any of the exposure sources, higher than currently indicated by the available data. This also increases the margin of safety to account for possible unknown sources of exposure. The 20 percent floor has been traditionally rationalized to prevent a situation where small fractional exposures are being controlled. That is, below that point, it is more appropriate to reduce other sources of exposure, rather than promulgating standards for *de minimus* reductions in overall exposure.

If it can be demonstrated that other sources and routes of exposure are not anticipated for the pollutant in question (based on information about its known/anticipated uses and chemical/physical properties), then EPA would use the 80 percent ceiling. EPA qualifies this policy with the understanding that as its policy on cumulative risk assessment continues to develop, the 80 percent RSC may prove to be underprotective.

In the cases of pollutants for which substantial data sets describing exposures across all anticipated pathways of exposure exist, and probabilistic analyses have been conducted based on those data, consideration will be given to the results of those assessments as part of the Exposure Decision Tree approach for setting AWQC.

For many chemicals, the rate of absorption from ingestion can differ substantially from absorption by inhalation. There is also available information for some chemicals that demonstrates appreciable differences in gastrointestinal absorption depending on whether the chemical is ingested from water, soil, or food. For some contaminants, the absorption of the contaminant from food can differ appreciably for plant compared with animal food products. Regardless of the apportionment approach used, EPA recommends using existing data on differences in bioavailability between water, air, soils, and different foods when estimating total exposure for use in apportioning the RfD or POD/UF. The Agency has developed such exposure estimates for cadmium (USEPA, 1994). In the absence of data, EPA will assume equal rates of absorption from different routes and sources of exposure.

4.2.4 Quantification of Exposure

When selecting contaminant concentration values in environmental media and exposure intake values for the RSC analysis, it is important to realize that each value selected (including those recommended as default assumptions in the AWQC equation) may be associated with a distribution of values for that parameter. Determining how various subgroups fall within the distributions of overall exposure and how the combination of exposure variables defines what population is being protected is a complicated and, perhaps, unmanageable task, depending on the amount of information available on each exposure factor included. Many times, the default assumptions used in EPA risk assessments are derived from the evaluation of numerous studies and are considered to generally represent a particular population group or a national average. Therefore, describing with certainty the exact percentile of a particular population that is protected with a resulting criteria is often not possible.

By and large, the AWQC are derived to protect the majority of the general population from chronic adverse health effects. However, as stated above in Section 4.1.1.1, States and authorized Tribes are encouraged to consider protecting population groups that they determine are at greater risk and, thus, would be better protected using alternative exposure assumptions. The ultimate choice of the contaminant concentrations used in the RSC estimate and the exposure intake rates requires the use of professional judgment. This is discussed in greater detail in the Exposure Assessment TSD.

4.2.5 Inclusion of Inhalation and Dermal Exposures

EPA intends to develop policy guidelines to apply to this Methodology for explicitly incorporating inhalation and dermal exposures. When estimating overall exposure to pollutants for AWQC development, EPA believes that the sources of inhalation and dermal exposures considered should include, on a case-by-case basis, both non-oral exposures from water and other inhalation and dermal sources (e.g., ambient or indoor air, soil). When the policy guidelines are completed, this Methodology will be refined to include that guidance.

A number of drinking water contaminants are volatile and thus diffuse from water into the air where they may be inhaled. In addition, drinking water is used for bathing and, thus, there is at least the possibility that some contaminants in water may be dermally absorbed. Volatilization may increase exposure via inhalation and decrease exposure via ingestion and dermal absorption. The net effect of volatilization and dermal absorption upon total exposure to volatile drinking water contaminants is unclear in some cases and varies from chemical to chemical. Dermal exposures are also important to consider for certain population groups, such as children and other groups with high soil contact.

With regard to additional non-water related exposures, it is clear that the type and magnitude of toxicity produced via inhalation, ingestion, and dermal contact may differ; that is, the route of exposure can affect absorption of a chemical and can otherwise modify its toxicity. For example, an inhaled chemical such as hydrogen fluoride may produce localized effects on the lung that are not observed (or only observed at much higher doses) when the chemical is administered orally. Also, the active form of a chemical (and principal toxicity) can be the parent compound and/or one or more metabolites. With this Methodology, EPA recommends that differences in absorption and toxicity by different routes of exposure be determined and accounted for in dose estimates and applied to the exposure assessment. EPA acknowledges that the issue of whether the doses received from inhalation and ingestion exposures are cumulative (i.e., toward the same threshold of toxicity) is complicated. Such a determination involves evaluating the chemical's physical characteristics, speciation, and reactivity. A chemical may also exhibit different metabolism by inhalation versus oral exposure and may not typically be metabolized by all tissues. In addition, a metabolite may be much more or much less toxic than the parent compound. Certainly with a systemic effect, if the chemical absorbed via different routes enters the bloodstream, then there is some likelihood that it will contact the same target organ. Attention also needs to be given to the fact that both the RfD and RfC are derived based on the administered level. Toxicologists generally believe that the effective concentration of the active form of a chemical(s) at the site(s) of action determines the toxicity. If specific differences between routes of exposure are not known, it may be reasonable to assume that the

internal concentration at the site from any route contributes as much to the same effect as any other route. A default of assuming equal absorption has often been used. However, for many of the chemicals that the Agency has reviewed, there is a substantial amount of information already known to determine differences in rates of absorption. For example, absorption is, in part, a function of blood solubility (i.e., Henry's Constant) and better estimations than the default can be made.

The RSC analyses that accompany the 2000 Human Health Methodology accommodate inclusion of inhalation exposures. Even if different target organs are involved between different routes of exposure, a conservative policy may be appropriate to keep all exposures below a certain level. A possible alternative is to set allowable levels (via an equation) such that the total of ingestion exposures over the ingestion RfD added to the total of inhalation exposures over the inhalation RfC is not greater than 1 (Note: the RfD is typically presented in mg/kg-day and the RfC is in mg/m^3). Again, EPA intends to develop guidance for this Methodology to explicitly incorporate inhalation and dermal exposures, and will refine the Methodology when that guidance is completed.

4.3 EXPOSURE FACTORS USED IN THE AWQC COMPUTATION

This section presents values for the specific exposure factors that EPA will use in the derivation of AWQC. These include human body weight, drinking water consumption rates, and fish ingestion rates.

When choosing exposure factor values to include in the derivation of a criterion for a given pollutant, EPA recommends considering values that are relevant to population(s) that is (are) most susceptible to that pollutant. In addition, highly exposed populations should be considered when setting criteria. In general, exposure factor values specific to adults and relevant to lifetime exposures are the most appropriate values to consider when determining criteria to protect against effects from long-term exposure which, by and large, the human health criteria are derived to protect. However, infants and children may have higher rates of water and food consumption per unit body weight compared with adults and also may be more susceptible to some pollutants than adults (USEPA, 1997a). There may be instances where acute or subchronic developmental toxicity makes children the population group of concern. In addition, exposure of pregnant women to certain toxic chemicals may cause developmental effects in the fetus (USEPA, 1997b). Exposures resulting in developmental effects may be of concern for some contaminants and should be considered along with information applicable to long-term health effects when setting AWQC. (See Section 3.2 for further discussion of this issue.) Short-term exposure may include multiple intermittent or continuous exposures occurring over a week or so. Exposure factor values relevant for considering chronic toxicity, as well as exposure factor values relevant for short-term exposure developmental concerns, that could result in adverse health effects are discussed in the sections below. In appropriate situations, EPA may consider developing criteria for developmental health effects based on exposure factor values specific to children or to women of childbearing age. EPA encourages States and Tribes to do the same when health risks are associated with short-term exposures.

EPA believes that the recommended exposure factor default intakes for adults in chronic exposure situations are adequately protective of the population over a lifetime. In providing additional exposure intake values for highly exposed subpopulations (e.g., sport anglers, subsistence fishers), EPA is providing flexibility for States and authorized Tribes to establish criteria specifically targeted to provide additional protection using adjusted values for exposure parameters for body weight, drinking water intake, and fish consumption. The exposure factor values provided for women of childbearing age and children would only be used in the circumstances indicated above.

Each of the following sections recommends exposure parameter values for use in developing AWQC. These are based on both science policy decisions that consider the best available data, as well as risk management judgments regarding the overall protection afforded by the choice in the derivation of AWQC. These will be used by EPA to derive new, or revise existing, 304(a) national criteria.

4.3.1 Human Body Weight Values for Dose Calculations

The source of data for default human body weights used in deriving the AWQC is the third *National Health and Nutrition Examination Survey* (NHANES III). NHANES III represents a very large interview and examination endeavor of the National Center for Health Statistics (NCHS) and included participation from the Centers for Disease Control (CDC). The NHANES III was conducted on a nationwide probability sample of over 30,000 persons from the civilian, non-institutionalized population of the United States. The survey began in October 1988 and was completed in October 1994 (WESTAT, 2000; McDowell, 2000). Body weight data were taken from the NHANES III Examination Data File. Sampling weights were applied to all persons examined in the Mobile Examination Centers (MECs) or at home, as was recommended by the NHANES data analysts (WESTAT, 2000).

The NHANES III survey has numerous strengths and very few weaknesses. Its primary strengths are the national representativeness, large sample size, and precise estimates due to this large sample size. Another strength is its high response rate; the examination rate was 73 percent overall, 89 percent for children under 1 year old, and approximately 85 percent for children 1 to 5 years old (McDowell, 2000). Interview response rates were even higher, but the body weight data come from the NHANES examinations; that is, all body weights were carefully measured by survey staff, rather than the use of self-reported body weights. The only significant potential weakness of the NHANES data is the fact that the data are now between 6 and 12 years old. Given that there were upward trends in body weight from NHANES II to NHANES III, and that NCHS has indicated the prevalence of overweight people increased in all age groups, the data could underestimate current body weights if that trend has continued (WESTAT, 2000).

The NHANES III collected standard body measurements of sample subjects, including height and weight, that were made at various times of the day and in different seasons of the year. This technique was used because one's weight may vary between winter and summer and may fluctuate with recency of food and water intake and other daily activities (McDowell, 2000).

As with the other exposure assumptions, States and authorized Tribes are encouraged to use alternative body weight assumptions for population groups other than the general population and to use local or regional data over default values as more representative of their target population group(s).

4.3.1.1 Rate Protective of Human Health from Chronic Exposure

EPA recommends maintaining the default body weight of 70 kg for calculating AWQC as a representative average value for both male and female adults. As previously indicated, exposure factor values specific to adults are recommended to protect against effects from long-term exposure. The value of 70 kg is based on the following information. In the analysis of the NHANES III database, median and mean values for female adults 18-74 years old are 65.8 and 69.5 kg, respectively (WESTAT, 2000). For males in the same age range, the median and mean values are 79.9 and 82.1 kg, respectively. The mean body weight value for men and women ages 18 to 74 years old from this survey is 75.6 kg (WESTAT, 2000). This mean value is higher than the mean value for adults ages 20-64 years old of 70.5 kg from a study by the National Cancer Institute (NCI) which primarily measured drinking water intake (Ershow and Cantor, 1989). The NCI study is described in the subsection on Drinking Water Intake Rates that follows (Section 4.3.2). The value from the NHANES III database is also higher than the value given in the revised EPA *Exposure Factors Handbook* (USEPA, 1997b), which recommends 71.8 kg for adults, based on the older NHANES II data. The Handbook also acknowledges the commonly used 70 kg value and encourages risk assessors to use values which most accurately reflect the exposed population. However, the point is also made that the 70 kg value is used in the derivation of cancer slope factors and unit risks that appear in IRIS. Consistency is advocated between the dose-response relationship and exposure factors assumed. Therefore, if a value higher than 70 kg is used, the assessor needs to adjust the dose-response relationship as described in the Appendix to Chapter 1, Volume 1 of the Handbook (USEPA, 1997b).

4.3.1.2 Rates Protective of Developmental Human Health Effects

As noted above, pregnant women may represent a more appropriate population for which to assess risks from exposure to chemicals in ambient waters in some cases, because of the potential for developmental effects in fetuses. In these cases, body weights representative of women of childbearing age may be appropriate to adequately protect offspring from such health effects. To determine a mean body weight value appropriate to this population, separate body weight values for women in individual age groups within the range of 15 to 44 years old were analyzed from the NHANES III data (WESTAT, 2000). The resulting median and mean body weight values are 63.2 and 67.3 kg, respectively. Ershow and Cantor (1989) present body weight values specifically for pregnant women included in the survey; median and mean weights are 64.4 and 65.8 kilograms, respectively. Ershow and Cantor (1989), however, do not indicate the ages of these pregnant women. Based on this information for women of childbearing age and pregnant women, EPA recommends use of a body weight value of 67 kg in cases where pregnant women are the specific population of concern and the chemical of concern exhibits reproductive and/or developmental effects (i.e., the critical effect upon which the RfD or POD/UF is based). Using the 67 kg assumption would result in lower (more protective) criteria than criteria based on 70 kg.

As discussed earlier, because infants and children generally have a higher rate of water and food consumption per unit body weight compared with adults, a higher intake rate per unit body weight may be needed when comparing estimated exposure doses with critical doses when RfDs are based on health effects in children. To calculate intake rates relevant to such effects, the body weight of children should be used. As with the default body weight for pregnant women, EPA is not recommending the development of additional AWQC (i.e., similar to drinking water health advisories) that focus on acute or short-term effects, since these are not seen routinely as having a meaningful role in the water quality criteria program. However, there may be circumstances where the consideration of exposures for these groups is warranted. Although the AWQC generally are based on chronic health effects data, they are intended to also be protective with respect to adverse effects that may reasonably be expected to occur as a result of elevated shorter-term exposures. EPA acknowledges this as a potential course of action and is, therefore, recommending these default values which EPA would consider in an appropriate circumstance and for States and authorized Tribes to utilize in such situations.

EPA is recommending an assumption of 30 kg as a default child's body weight to calculate AWQC to provide additional protection for children when the chemical of concern indicates health effects in children are of predominant concern (i.e., test results show children are more susceptible due to less developed immune systems, neurological systems, and/or lower body weights). The value is based on the mean body weight value of 29.9 kg for children ages 1 to14 years old, which combines body weight values for individual age groups within this larger group. The mean value is based on body weight information from NHANES III for individual-year age groups between one and 14 years old (WESTAT, 2000). A mean body weight of 28 kg is obtained using body weight values from Ershow and Cantor (1989) for five age groups within this range of 0-14 years and applying a weighting method for different ages by population percentages from the U.S. Bureau of the Census. The 30 kg assumption is also consistent with the age range for children used with the estimated fish intake rates. Unfortunately, fish intake rates for finer age group divisions are not possible due to the limited sampling base from the fish intake survey; there is limited confidence in calculated values (e.g., the mean) for such fine age groups. Given this limitation, the broad age category of body weight for children is suitable for use with the default fish intake assumption.

Given the hierarchy of preferences regarding the use of fish intake information (see Section 4.3.3), States may have more comprehensive data and prefer to target a more narrow, younger age group. If States choose to specifically evaluate toddlers, EPA recommends using 13 kg as a default body weight assumption for children ages 1 to 3 years old. The median and mean values of body weight for children 1 to 3 years old are 13.2 and 13.1 kg, respectively, based on an analysis of the NHANES III database (WESTAT, 2000). The NHANES III median and mean values for females between 1 and 3 years old are 13.0 and 12.9 kg, respectively, and are 13.4 and 13.4 kg for males, respectively. Median and mean body weight values from the earlier Ershow and Cantor (1989) study for children ages 1 to 3 years old were 13.6 and 14.1 kg, respectively. Finally, if infants are specifically evaluated, EPA recommends a default body weight of 7 kg based on the NHANES III analysis. Median and mean body weights for both male and female infants (combined) 2 months old were 6.3 and 6.3 kg, respectively, and for infants 3 months old were 7.0 and 6.9 kg, respectively. With the broader age category of males and females 2 to 6 months old, median and mean body weights were 7.4 and 7.4 kg, respectively. The NHANES

analysis did not include infants under 2 months of age. Although EPA is not recommending body weight values for newborns, the NCHS National Vital Statistics Report indicates that, for 1997, the median birth weight ranged from 3 to 3.5 kg, according to WESTAT (2000).

Body weight values for individual ages within the larger range of 0-14 years are listed in the Exposure Assessment TSD for those States and authorized Tribes who wish to use body weight values for these individual groups. States and Tribes may wish to consider certain general developmental ages (e.g., infants, pre-adolescents, etc.), or certain specific developmental landmarks (e.g., neurological development in the first four years), depending on the chemical of concern. EPA encourages States and authorized Tribes to choose a body weight intake from the tables presented in the TSD, if they believe a particular age subgroup is more appropriate.

4.3.2 Drinking Water Intake Rates

The basis for the drinking water intake rates (also for the fish intake rates presented in Section 4.3.3) is the 1994-96 Continuing Survey of Food Intake by Individuals *(*CSFII) conducted by the U.S. Department of Agriculture (USDA, 1998). The CSFII survey collects dietary intake information from nationally representative samples of non-institutionalized persons residing in United States households. Households in these national surveys are sampled from the 50 states and the District of Columbia. Each survey collects daily consumption records for approximately 10,000 food codes across nine food groups. These food groups are (1) milk and milk products; (2) meat, poultry, and fish; (3) eggs; (4) dry beans, peas, legumes, nuts, and seeds; (5) grain products; (6) fruit; (7) vegetables; (8) fats, oils, and salad dressings; and (9) sweets, sugars, and beverages. The survey also asks each respondent how many fluid ounces of plain drinking water he or she drank during each of the survey days. In addition, the CSFII collects household information, including the source of plain drinking water, water used to prepare beverages, and water used to prepare foods. Data provide "up-to-date information on food intakes by Americans for use in policy formation, regulation, program planning and evaluation, education, and research." The survey is "the cornerstone of the National Nutritional Monitoring and Related Research Program, a set of related federal activities intended to provide regular information on the nutritional status of the United States population" (USDA, 1998).

The 1994-96 CSFII was conducted according to a stratified, multi-area probability sample organized using estimates of the 1990 United States population. Stratification accounted for geographic location, degree of urbanization, and socioeconomics. Each year of the survey consisted of one sample with oversampling for low-income households.

Survey participants provided two non-consecutive, 24-hour days of dietary data. Both days' dietary recall information was collected by an in-home interviewer. Interviewers provided participants with an instructional booklet and standard measuring cups and spoons to assist them in adequately describing the type and amount of food ingested. If the respondent referred to a cup or bowl in their own home, a 2-cup measuring cup was provided to aid in the calculation of the amount consumed. The sample person could fill their own bowl or cup with water to represent the amount eaten or drunk, and the interviewer could then measure the amount consumed by pouring it into the 2-cup measure. The Day 2 interview occurred three to 10 days

after the Day 1 interview, but not on the same day of the week. The interviews allowed participants "three passes" through the daily intake record to maximize recall (USDA, 1998). Proxy interviews were conducted for children aged six and younger and sampled individuals unable to report due to mental or physical limitations. The average questionnaire administration time for Day 1 intake was 30 minutes, while Day 2 averaged 27 minutes.

Two days of dietary recall data were provided by 15,303 individuals across the three survey years. This constitutes an overall two-day response rate of 75.9 percent. Survey weights were corrected by the USDA for nonresponse.

All three 1994-96 CSFII surveys are multistage, stratified-cluster samples. Sample weights, which project the data from a sampled individual to the population, are based on the probability of an individual being sampled at each stage of the sampling design. The sample weights associated with each individual reporting two days of consumption data were adjusted to correct for nonresponse bias.

The 1994-96 CSFII surveys have advantages and limitations for estimating per capita water (or fish) consumption. The primary advantage of the CSFII surveys is that they were designed and conducted by the USDA to support unbiased estimation of food consumption across the population in the United States and the District of Columbia. Second, the survey is designed to record daily intakes of foods and nutrients and support estimation of food consumption.

One limitation of the 1994-96 CSFII surveys is that individual food consumption data were collected for only two days–a brief period which does not necessarily depict "usual intake." Usual dietary intake is defined as "the long-run average of daily intakes by an individual." Upper percentile estimates may differ for short-term and longer-term data because short-term food consumption data tend to be inherently more variable. It is important to note, however, that variability due to duration of the survey does not result in bias of estimates of overall mean consumption levels. Also, the multistage survey design does not support interval estimates for many of the subpopulations of interest because of sparse representation in the sample. Subpopulations with sparse representation include Native Americans on reservations and certain ethnic groups. While these individuals are participants in the survey, they are not present in sufficient numbers to support consumption estimates.

Despite these limitations, the CSFII is considered one of the best sources of current information on consumption of water and fish-containing foods. The objective of estimating per capita water and fish consumption by the United States population is compatible with the statistical design and scope of the CSFII survey.

4.3.2.1 Rate Protective of Human Health from Chronic Exposure

EPA recommends maintaining the default drinking water intake rate of 2 L/day to protect most consumers from contaminants in drinking water. EPA believes that the 2 L/day assumption is representative of a majority of the population over the course of a lifetime. EPA also notes that there is comparatively little variability in water intake within the population compared with

fish intake (i.e., drinking water intake varies, by and large, by about a three-fold range, whereas fish intake can vary by 100-fold). EPA believes that the 2 L/day assumption continues to represent an appropriate risk management decision. The results of the 1994-96 CSFII analysis indicate that the arithmetic mean, 75th, and 90th percentile values for adults 20 years and older are 1.1, 1.5, and 2.2 L/day, respectively (USEPA, 2000a). The 2 L/day value represents the 86th percentile for adults. These values can also be compared to data from an older National Cancer Institute (NCI) study, which estimated intakes of tapwater in the United States based on the USDA's 1977-78 Nationwide Food Consumption Survey (NFCS). The arithmetic mean, 75th, and 90th percentile values for adults 20 - 64 years old were 1.4, 1.7, and 2.3 L/day, respectively (Ershow and Cantor, 1989). The 2 L/day value represents the 88th percentile for adults from the NCI study.

The 2 L/day assumption was used with the original 1980 AWQC National Guidelines and has also been used in EPA's drinking water program. EPA believes that the newer studies continue to support the use of 2 L/day as a reasonable and protective consumption rate that represents the intake of most water consumers in the general population. However, individuals who work or exercise in hot climates could have water consumption rates significantly above 2 L/day, and EPA believes that States and Tribes should consider regional or occupational variations in water consumption.

4.3.2.2 Rates Protective of Developmental Human Health Effects

Based on the 1994-96 CSFII study data, EPA also recommends 2 L/day for women of childbearing age. The analysis for women of childbearing age (ages 15-44) indicate mean, 75th, and 90th percentile values of 0.9, 1.3, and 2.0 L/day, respectively. These rates compare well with those based on an analysis of tapwater intake by pregnant and lactating women by Ershow et al. (1991), based on the older USDA data, for women ages 15-49. Arithmetic mean, 75th and 90th percentile values were 1.2, 1.5, and 2.2 L/day, respectively, for pregnant women. For lactating women, the arithmetic mean, 75th and 90th percentile values were 1.3, 1.7, and 1.9 L/day, respectively.

As noted above, because infants and children have a higher daily water intake per unit body weight compared with adults, a water consumption rate measured for children is recommended for use when RfDs are based on health effects in children. Use of this water consumption rate should result in adequate protection for infants and children when setting criteria based on health effects for this target population. EPA recommends a drinking water intake of 1 L/day to, again, represent a majority of the population of children that consume drinking water. The results of the 1994-96 CSFII analysis indicate that for children from 1 to 10 years of age, the arithmetic mean, 75th, and 90th percentile values are 0.4, 0.6, and 0.9 L/day, respectively (USEPA, 2000a). The 1 L/day value represents the 93rd percentile for this group. The arithmetic mean, 75th, and 90th percentile values for smaller children, ages 1 to 3 years, are 0.3, 0.5, and 0.7 L/day, respectively. The 1 L/day value represents the 97th percentile of the group ages 1 to 3 years old. For the category of infants under 1 year of age, the arithmetic mean, 75th, and 90th percentile values are 0.3, 0.7, and 0.9 L/day, respectively. These data can similarly be compared to those of the older National Cancer Institute (NCI) study. The arithmetic mean, 75th, and 90th percentile values for children 1 to 10 years old were 0.74, 0.96, and 1.3 L/day,

respectively. The mean, 75th, and 90th percentile values for children 1 to 3 years old in the NCI study were 0.6, 0.8, and 1.2 L/day, respectively. Finally, the mean, 75th, and 90th percentile values for infants less than 6 months old were 0.3, 0.3, and 0.6 L/day, respectively (Ershow and Cantor, 1989).

4.3.2.3 Rates Based on Combining Drinking Water Intake and Body Weight

As an alternative to considering body weight and drinking water intake rates separately, EPA is providing rates based on intake per unit body weight data (in units of ml/kg) in the Exposure Assessment TSD, with additional discussion on their use. These rates are based on self-reported body weights from the CSFII survey respondents for the 1994-96 data. While EPA intends to derive or revise national default criteria on the separate intake values and body weights, in part due to the strong input received from its State stakeholders, the ml/kg-BW/day values are provided in the TSD for States or authorized Tribes that prefer their use. It should be noted that in their 1993 review, EPA's Science Advisory Board (SAB) felt that using drinking water intake rate assumptions on a per unit body weight basis would be more accurate, but did not believe this change would appreciably affect the criteria values (USEPA, 1993).

4.3.3 Fish Intake Rates

The basis for the fish intake rates is the 1994-96 CSFII conducted by the USDA, and described above in Section 4.3.2.

4.3.3.1 Rates Protective of Human Health from Chronic Exposure

EPA recommends a default fish intake rate of 17.5 grams/day to adequately protect the general population of fish consumers, based on the 1994 to 1996 data from the USDA's CSFII Survey. EPA will use this value when deriving or revising its national 304(a) criteria. This value represents the 90th percentile of the 1994-96 CSFII data. This value also represents the uncooked weight estimated from the CSFII data, and represents intake of freshwater and estuarine finfish and shellfish only. For deriving AWQC, EPA has also considered the States' and Tribes' needs to provide adequate protection from adverse health effects to highly exposed populations such as recreational and subsistence fishers, in addition to the general population. Based on available studies that characterize consumers of fish, recreational fishers and subsistence fishers are two distinct groups whose intake rates may be greater than the general population. It is, therefore, EPA's decision to discuss intakes for these two groups, in addition to the general population.

EPA recommends default fish intake rates for recreational and subsistence fishers of 17.5 grams/day and 142.4 grams/day, respectively. These rates are also based on uncooked weights for fresh/estuarine finfish and shellfish only. However, because the level of fish intake in highly exposed populations varies by geographical location, EPA suggests a four preference hierarchy for States and authorized Tribes to follow when deriving consumption rates that encourages use of the best local, State, or regional data available. A thorough discussion of the development of this policy method and relevant data sources is contained in the Exposure Assessment TSD. The hierarchy is also presented here because EPA strongly emphasizes that States and authorized

Tribes should consider developing criteria to protect highly exposed population groups and use local or regional data over the default values as more representative of their target population group(s). The four preference hierarchy is: (1) use of local data; (2) use of data reflecting similar geography/population groups; (3) use of data from national surveys; and (4) use of EPA's default intake rates.

The recommended four preference hierarchy is intended for use in evaluating fish intake from fresh and estuarine species only. Therefore, to protect humans who additionally consume marine species of fish, the marine portion should be considered an *other source of exposure* when calculating an RSC for dietary intake. Refer to the Exposure Assessment TSD for further discussion. States and Tribes need to ensure that when evaluating overall exposure to a contaminant, marine fish intake is not double-counted with the other dietary intake estimate used. Coastal States and authorized Tribes that believe accounting for total fish consumption (i.e., fresh/estuarine and marine species) is more appropriate for protecting the population of concern may do so, provided that the marine intake component is not double-counted with the RSC estimate. Tables of fish consumption intakes based on the CSFII in the TSD provide rates for fresh/estuarine species, marine species, and total (combined) values to facilitate this option for States and Tribes. Throughout this section, the terms "fish intake" or "fish consumption" are used. These terms refer to the consumption of finfish and shellfish, and the CSFII survey includes both. States and Tribes should ensure that when selecting local or regionally-specific studies, both finfish and shellfish are included when the population exposed are consumers of both types.

EPA's first preference is that States and authorized Tribes use the results from fish intake surveys of local watersheds within the State or Tribal jurisdiction to establish fish intake rates that are representative of the defined populations being addressed for the particular waterbody. Again, EPA recommends that data indicative of fresh/estuarine species only be used which is, by and large, most appropriate for developing AWQC. EPA also recommends the use of uncooked weight intake values, which is discussed in greater detail with the fourth preference. States and authorized Tribes may use either high-end values (such as the 90^{th} or 95^{th} percentile values) or average values for an identified population that they plan to protect (e.g., subsistence fishers, sport fishers, or the general population). EPA generally recommends that arithmetic mean values should be the lowest value considered by States or Tribes when choosing intake rates for use in criteria derivation. When considering geometric mean (median) values from fish consumption studies, States and authorized Tribes need to ensure that the distribution is based on survey respondents who reported consuming fish because surveys based on both consumers and nonconsumers can often result in median values of zero. If a State or Tribe chooses values (whether the central tendency or high-end values) from studies that particularly target high-end consumers, these values should be compared to high-end fish intake rates for the general population to make sure that the high-end consumers within the general population would be protected by the chosen intake rates. EPA believes this is a reasonable procedure and is also consistent with the recent Great Lakes Water Quality Initiative (known as the "GLI") (USEPA, 1995). States and authorized Tribes may wish to conduct their own surveys of fish intake, and EPA guidance is available on methods to conduct such studies in *Guidance for Conducting Fish and Wildlife Consumption Surveys* (USEPA, 1998). Results from broader geographic regions in which the State or Tribe is located can also be used, but may not be as applicable as results from

local watersheds. Since such studies would ultimately form the basis of a State or Tribe's AWQC, EPA would review any surveys of fish intake for consistency with the principles of EPA's guidance as part of the Agency's review of water quality standards under Section 303(c).

If surveys conducted in the geographic area of the State or Tribe are not available, EPA's second preference is that States and authorized Tribes consider results from existing fish intake surveys that reflect similar geography and population groups (e.g., from a neighboring State or Tribe or a similar watershed type), and follow the method described above regarding target values to derive a fish intake rate. Again, EPA recommends the use of uncooked weight intake values and the use of fresh/estuarine species data only. Results of existing local and regional surveys are discussed in greater detail in the TSD.

If applicable consumption rates are not available from local, State, or regional surveys, EPA's third preference is that States and authorized Tribes select intake rate assumptions for different population groups from national food consumption surveys. EPA has analyzed one such national survey, the 1994-96 CSFII. As described in Section 4.3.2, this survey, conducted annually by the USDA, collects food consumption information from a probability sample of the population of all 50 states. Respondents to the survey provide two days of dietary recall data. A detailed description of the combined 1994-96 CSFII survey, the statistical methodology, and the results and uncertainties of the EPA analyses are provided in a separate EPA report (USEPA, 2000b). The Exposure Assessment TSD for this Methodology presents selected results from this report including point and interval estimates of combined finfish and shellfish consumption for the mean, 50^{th} (median), 90^{th}, 95^{th}, and 99^{th} percentiles. The estimated fish consumption rates are by fish habitat (i.e., freshwater/estuarine, marine and all habitats) for the following population groups: (1) all individuals; (2) individuals age 18 and over; (3) women ages 15-44; and (4) children age 14 and under. Three kinds of estimated fish consumption rates are provided: (1) per capita rates (i.e., rates based on consumers and nonconsumers of fish from the survey period– refer to the TSD for further discussion); (2) consumers-only rates (i.e., rates based on respondents who reported consuming finfish or shellfish during the two-day reporting period); and (3) per capita consumption by body weight (i.e., per capita rates reported as milligrams of fish per kilogram of body weight per day).

EPA's fourth preference is that States and authorized Tribes use as fish intake assumptions the following default rates, based on the 1994-96 CSFII data, that EPA believes are representative of fish intake for different population groups: 17.5 grams/day for the general adult population and sport fishers, and 142.4 grams/day for subsistence fishers. These are risk management decisions that EPA has made after evaluating numerous fish intake surveys. These values represent the uncooked weight intake of freshwater/estuarine finfish and shellfish. As with the other preferences, EPA requests that States and authorized Tribes routinely consider whether there is a substantial population of sport fishers or subsistence fishers when developing site-specific estimates, rather than automatically basing them on the typical individual. Because the combined 1994-96 CSFII survey is national in scope, EPA will use the results from this survey to estimate fish intake for deriving national criteria. EPA has recognized the data gaps and uncertainties associated with the analysis of the 1994-96 CSFII survey in the process of making its default recommendations. The estimated mean of freshwater and estuarine fish ingestion for adults is 7.50 grams/day, and the median is 0 grams/day. The estimated 90^{th}

percentile is 17.53 grams/day; the estimated 95th percentile is 49.59 grams/day; and the estimated 99th percentile is 142.41 grams/day. The median value of 0 grams/day may reflect the portion of individuals in the population who never eat fish as well as the limited reporting period (2 days) over which intake was measured. By applying as a default 17.5 grams/day for the general adult population, EPA intends to select an intake rate that is protective of a majority of the population (again, the 90th percentile of consumers and nonconsumers according to the 1994-96 CSFII survey data). Trophic level breakouts are: TL2 = 3.8 grams/day; TL3 = 8.0 grams/day; and TL4 = 5.7 grams/day. EPA further considers 17.5 grams/day to be indicative of the average consumption among sport fishers based on averages in the studies reviewed, which are presented in the Exposure Assessment TSD. Similarly, EPA believes that the assumption of 142.4 grams/day is within the range of average consumption estimates for subsistence fishers based on the studies reviewed. Experts at the 1992 National Workshop that initiated the effort to revise this Methodology acknowledged that the national survey high-end values are representative of average rates for highly exposed groups such as subsistence fishermen, specific ethnic groups, or other highly exposed people. EPA is aware that some local and regional studies indicate greater consumption among Native American, Pacific Asian American, and other subsistence consumers, and recommends the use of those studies in appropriate cases, as indicated by the first and second preferences. Again, States and authorized Tribes have the flexibility to choose intake rates higher than an average value for these population groups. If a State or authorized Tribe has not identified a separate well-defined population of high-end consumers and believes that the national data from the 1994-96 CSFII are representative, they may choose these recommended rates.

As indicated above, the default intake values are based on the uncooked weights of the fish analyzed. There has been some question regarding whether to use cooked or uncooked weights of fish intake for deriving the AWQC. Studies show that, typically, with a filet or steak of fish, the weight loss in cooking is about 20 percent; that is, the uncooked weight is approximately 20 percent higher (Jacobs et al., 1998). This obviously means that using uncooked weights results in a slightly higher intake rate and slightly more stringent AWQC. In researching consumption surveys for this proposal, EPA has found that some surveys have reported rates for cooked fish, others have reported uncooked rates, and many more are unclear as to whether cooked or uncooked rates are used. The basis of the CSFII survey was prepared or *as consumed* intakes; that is, the survey respondents estimated the weight of fish that they consumed. This was also true with the GLI (which was specifically based on studies describing consumption rates of cooked fish) and, by and large, cooked fish is what people consume. However, EPA's *Guidance For Assessing Chemical Contaminant Data For Use In Fish Advisories* recommends analysis and advisories based on uncooked fish (USEPA, 1997a). EPA considered the potential confusion over the fact that the uncooked weights are used in the fish advisory program. Further, the measures of a contaminant in fish tissue samples that are applicable to compliance monitoring and the permitting program are related to the uncooked weights. The choice of intakes is also complicated by factors such as the effect of the cooking process, the different parts of a fish where a chemical may accumulate, and the method of preparation.

After considering all of the above (in addition to public input received), EPA will derive its national default criteria based on the uncooked weight fish intakes. The Exposure

Assessment TSD provides additional guidance on site-specific modifications. Specifically, an alternate approach is described for calculating AWQC with the *as consumed* weight–which is more directly associated with human exposure and risk–and then adjusting the value by the approximate 20 percent loss to an uncooked equivalent (thereby representing the same relative risk as the *as consumed* value). This approach results in a different AWQC value (than using the uncooked weights) and represents a more direct translation of the *as consumed* risk to the uncooked equivalent. However, EPA understands that it is more scientifically rigorous and may be too intensive of a process for States and Tribes to rely on. The option is presented in the TSD to offer States and authorized Tribes greater flexibility with their water quality standards program.

The default fish intake values also reflect specific designations of species classified in accordance with information regarding the life history of the species or based on landings information form the National Marine Fisheries Service. Most significantly, salmon has been reclassified from a freshwater/estuarine species to a marine species. As marine harvested salmon represents approximately 99 percent of salmon consumption in the 1994-96 CSFII Survey, removal reduces the overall fresh/estuarine fish consumption rate by 13 percent. Although they represent a very small percentage of freshwater/estuarine intake, land-locked and farm-raised salmon consumed by 1994-96 CSFII respondents are still included. The rationale for the default intake species designations is explained in the Exposure Assessment TSD. Once again, EPA emphasizes the flexibility for States and authorized Tribes to use alternative assumptions based on local or regional data to better represent their population groups of concern.

4.3.3.2 Rates Protective of Developmental Human Health Effects

Exposures resulting in health effects in children or developmental effects in fetuses may be of primary concern. As discussed at the beginning of this section on exposure factors used, in a situation where acute or sub-chronic toxicity and exposure are the basis of an RfD (or POD/UF), EPA will consider basing its national default criteria on children or women of childbearing age, depending on the target population at greatest risk. EPA recommends that States and authorized Tribes use exposure factors for children or women of childbearing age in these situations. As stated previously, EPA is not recommending the development of additional AWQC but is acknowledging that basing a criterion on these population groups is a potential course of action and is, therefore, recommending the following default intake rates for such situations.

EPA's preferences for States and authorized Tribes in selecting values for intake rates relevant for children is the same as that discussed above for establishing values for average daily consumption rates for chronic effects; i.e., in decreasing order of preference, results from fish intake surveys of local watersheds, results from existing fish intake surveys that reflect similar geography and population groups, the distribution of intake rates from nationally based surveys (e.g., the CSFII), or lastly, the EPA default rates. When an RfD is based on health effects in children, EPA recommends a default intake rate of 156.3 grams/day for assessing those contaminants that exhibit adverse effects. This represents the 90th percentile consumption rate for actual consumers of freshwater/estuarine finfish and shellfish for children ages 14 and under using the combined 1994 to 1996 results from the CSFII survey. The value was calculated based

on data for only those children who ate fish during the 2-day survey period, and the intake was averaged over the number of days during which fish was actually consumed. EPA believes that by selecting the data for consumers only, the 90th percentile is a reasonable intake rate to approximate consumption of fresh/estuarine finfish and shellfish within a short period of time for use in assessments where adverse effects in children are of primary concern. As discussed previously, EPA will use a default body weight of 30 kg to address potential acute or subchronic effects from fish consumption by children. EPA is also providing these default intake values for States and authorized Tribes that choose to provide additional protection when developing criteria that they believe should be based on health effects in children. This is consistent with the rationale in the recent GLI (USEPA, 1995) and is an approach that EPA believes is reasonable. Distributional information on intake values relevant for assessing exposure when health effects to children are of concern is presented in the Exposure Assessment TSD.

There are also cases in which pregnant women may be the population of most concern, due to the possibility of developmental effects that may result from exposures of the mother to toxicants. In these cases, fish intake rates specific to females of childbearing age are most appropriate when assessing exposures to developmental toxicants. When an RfD is based on developmental toxicity, EPA proposes a default intake rate of 165.5 grams/day for assessing exposures for women of childbearing age from contaminants that cause developmental effects. This is equivalent to the 90th percentile consumption rate for actual consumers of freshwater/ estuarine finfish and shellfish for women ages 15 to 44 using the combined 1994 to1996 results from the CSFII survey. As with the rate for children, this value represents only those women who ate fish during the 2-day survey period. As discussed previously, EPA will use a default body weight of 67 kg for women of childbearing age.

4.3.3.3 Rates Based on Combining Fish Intake and Body Weight

As with the drinking water intake values, EPA is providing values for fish intake based on a per unit body weight basis (in units of mg/kg) in the Exposure Assessment TSD. These rates use the self-reported body weights of the 1994-96 CSFII survey. Again, while EPA intends to derive or revise national default criteria on the separate intake values and body weights, the mg/kg-BW/day values are provided in the TSD for States or authorized Tribes that prefer their use.

5. BIOACCUMULATION

5.1 INTRODUCTION

Aquatic organisms can accumulate certain chemicals in their bodies when exposed to these chemicals through water, their diet, and other sources. This process is called bioaccumulation. The magnitude of bioaccumulation by aquatic organisms varies widely depending on the chemical but can be extremely high for some highly persistent and hydrophobic chemicals. For such highly bioaccumulative chemicals, concentrations in aquatic organisms may pose unacceptable human health risks from fish and shellfish consumption even when concentrations in water are too low to cause unacceptable health risks from drinking water consumption alone. These chemicals may also biomagnify in aquatic food webs, a process whereby chemical concentrations increase in aquatic organisms of each successive trophic level due to increasing dietary exposures (e.g., increasing concentrations from algae, to zooplankton, to forage fish, to predatory fish).

In order to prevent harmful exposures to waterborne chemicals through the consumption of contaminated fish and shellfish, national 304(a) water quality criteria for the protection of human health must address the process of chemical bioaccumulation in aquatic organisms. For deriving national 304(a) criteria to protect human health, EPA accounts for potential bioaccumulation of chemicals in fish and shellfish through the use of national bioaccumulation factors (BAFs). A national BAF is a ratio (in L/kg) that relates the concentration of a chemical in water to its expected concentration in commonly consumed aquatic organisms in a specified trophic level. An illustration of how national BAFs are used in the derivation of 304(a) criteria for carcinogens using linear low-dose extrapolation is shown in the following equation:

$$AWQC = RSD \bullet \left(\frac{BW}{DI + \sum_{i=2}^{4} (FI_i \bullet BAF_i)} \right) \qquad \text{(Equation 5-1)}$$

where:

RSD	=	Risk specific dose (mg/kg-day)
BW	=	Human body weight (kg)
DI	=	Drinking water intake (L/day)
FI_i	=	Fish intake at trophic level I, where I=2, 3, and 4;
BAF_i	=	National bioaccumulation factor at trophic level I, where I=2, 3, and 4

The purpose of this chapter is to present EPA's recommended methodology for deriving national bioaccumulation factors for setting national 304(a) water quality criteria to protect human health. A detailed scientific basis of the recommended national BAF methodology is provided in the Bioaccumulation TSD. While the methodology detailed in this chapter is

intended to be used by EPA for deriving national BAFs, EPA encourages States and authorized Tribes to derive BAFs that are specific to certain regions or waterbodies, where appropriate. Guidance to States and authorized Tribes for deriving site-specific BAFs is provided in the Biaccumulation TSD.

5.1.1 Important Bioaccumulation and Bioconcentration Concepts

Several attributes of the bioaccumulation process are important to understand when deriving national BAFs for use in setting national 304(a) criteria. First, the term "bioaccumulation" refers to the uptake and retention of a chemical by an aquatic organism from all surrounding media (e.g., water, food, sediment). The term "bioconcentration" refers to the uptake and retention of a chemical by an aquatic organism from water only. For some chemicals (particularly those that are highly persistent and hydrophobic), the magnitude of bioaccumulation by aquatic organisms can be substantially greater than the magnitude of bioconcentration. Thus, an assessment of bioconcentration alone would underestimate the extent of accumulation in aquatic biota for these chemicals. Accordingly, EPA's guidelines presented in this chapter emphasize the measurement of chemical bioaccumulation by aquatic organisms, whereas EPA's 1980 Methodology emphasized the measurement of bioconcentration.

Another noteworthy aspect of bioaccumulation process is the issue of steady-state conditions. Specifically, both bioaccumulation and bioconcentration can be viewed simply as the result of competing rates of chemical uptake and depuration (chemical loss) by an aquatic organism. The rates of chemical uptake and depuration can be affected by various factors including the properties of the chemical, the physiology of the organism in question, water quality and other environmental conditions, ecological characteristics of the waterbody (e.g., food web structure), and the concentration and loadings history of the chemical. When the rates of chemical uptake and depuration are equal, tissue concentrations remain constant over time and the distribution of the chemical between the organism and its source(s) is said to be at steady-state. For constant chemical exposures and other conditions, the steady-state concentration in the organism represents the highest accumulation potential of the chemical in that organism under those conditions. The time required for a chemical to achieve steady state has been shown to vary according to the properties of the chemical and other factors. For example, some highly hydrophobic chemicals can require long periods of time to reach steady state between environmental compartments (e.g., many months), while highly hydrophilic chemicals usually reach steady-state relatively quickly (e.g., hours to days).

Since national 304(a) criteria for the protection of human health are typically designed to protect humans from harmful lifetime or long-term exposures to waterborne contaminants, the assessment of bioaccumulation that equals or approximates steady-state accumulation is one of the principles underlying the derivation of national BAFs. For some chemicals that require relatively long periods of time to reach steady-state in tissues of aquatic organisms, changes in water column concentrations may occur on a much more rapid time scale compared to the corresponding changes in tissue concentrations. Thus, if the system departs substantially from steady-state conditions and water concentrations are not averaged over a sufficient time period, the ratio of the tissue concentration to a water concentration may have little resemblance to the steady-state ratio and have little predictive value of long-term bioaccumulation potential.

Therefore, BAF measurements should be based on water column concentrations which are averaged over a sufficient period of time (e.g., a duration comparable to the time required for the chemical to reach steady-state). In addition, BAF measurements should be based on adequate spatial averaging of both tissue and water column concentrations for use in deriving 304(a) criteria for the protection of human health.

For this reason, a BAF is defined in this Methodology as representing the ratio (in L/kg-tissue) of a concentration of a chemical in tissue to its concentration in the surrounding water in situations where the organism and its food are exposed and the ratio does not change substantially over time (i.e., the ratio which reflects bioaccumulation at or near steady-state). A bioconcentration factor (BCF) is the ratio (in L/kg-tissue) of the concentration of a substance in tissue of an aquatic organism to its concentration in the ambient water, in situations where the organism is exposed through the water only and the ratio does not change substantially over time.

5.1.2 Goal of the National BAF

The goal of EPA's national BAF is to represent the long-term, average bioaccumulation potential of a chemical in edible tissues of aquatic organisms that are commonly consumed by humans throughout the United States. National BAFs are not intended to reflect fluctuations in bioaccumulation over short time periods (e.g., a few days) because 304(a) human health criteria are generally designed to protect humans from long-term exposures to waterborne chemicals. National BAFs are also intended to account for some major chemical, biological, and ecological attributes that can affect bioaccumulation in bodies of water across the United States. For example, separate procedures are provided for deriving national BAFs depending on the type of chemical (i.e., nonionic organic, ionic organic, inorganic and organometallic). In addition, EPA's national BAFs are derived separately for each trophic level to account for potential biomagnification of some chemicals in aquatic food webs and broad physiological differences between trophic levels that may influence bioaccumulation. Because lipid content of aquatic organisms and the amount of organic carbon in the water column have been shown to affect bioaccumulation of nonionic organic chemicals, EPA's national BAFs are adjusted to reflect the lipid content of commonly consumed fish and shellfish and the freely dissolved fraction of the chemical in ambient water for these chemicals.

5.1.3 Changes to the 1980 Methodology

Numerous scientific advances have occurred in the area of bioaccumulation since the publication of the 1980 Methodology for deriving AWQC for the protection of human health (USEPA, 1980). These advances have significantly increased our ability to assess and predict the bioaccumulation of chemicals in aquatic biota. As a result, EPA has revised the bioaccumulation portion of the 1980 Methodology to reflect the current state of the science and to improve accuracy in assessing bioaccumulation for setting 304(a) criteria for the protection of human health. The changes contained in the bioaccumulation portion of the 2000 Human Health Methodology are mostly designed to:

- Improve the ability to incorporate chemical exposure from sediments and aquatic food webs in assessing bioaccumulation potential,

- Expand the ability to account for site-specific factors which affect bioaccumulation, and

- Incorporate new data and assessment tools into the bioaccumulation assessment process.

A summary of the key changes that have been incorporated into the bioaccumulation portion of the 2000 Human Health Methodology and appropriate comparisons to the1980 Methodology are provided below.

5.1.3.1 Overall Approach

The 1980 Methodology for deriving 304(a) criteria for the protection of human health emphasized the assessment of bioconcentration (uptake from water only) through the use of the BCF. Based on the 1980 Methodology, measured BCFs were usually determined from laboratory data unless field data demonstrated consistently higher or lower accumulation compared with laboratory data. In these cases, "field BCFs" (currently termed field-measured BAFs) were recommended for use. For lipophilic chemicals where lab or field-measured data were unavailable, EPA recommended predicting BCFs from the octanol-water partition coefficient and the following equation from Veith et al. (1979): "log BCF = (0.85 log K_{ow}) - 0.70".

The 2000 Human Health Methodology revisions contained in this chapter emphasize the measurement of bioaccumulation (uptake from water, sediment, and diet) through the use of the BAF. Consistent with the 1980 Methodology, measured data are preferred over predictive approaches for determining the BAF (i.e., field-measured BAFs are generally preferred over predicted BAFs). However, the 2000 Human Health Methodology contains additional methods for deriving a national BAF that were not available in 1980. The preference for using the BAF methods also differs depending on the type and properties of the chemical. For example, the BAF derivation procedure differs for each of three broadly defined chemical categories: (1) nonionic organic, (2) ionic organic, and (3) inorganic and organometallic chemicals. Furthermore, within the category of nonionic organic chemicals, different procedures are used to derive the BAF depending on a chemicals' hydrophobicity and extent of chemical metabolism that would be expected to occur in aquatic biota.

5.1.3.2 Lipid Normalization

In the 1980 Methodology, BCFs for lipophilic chemicals were normalized by the lipid fraction in the tissue of fish and shellfish used to determine the BCF. Lipid normalization enabled BCFs to be averaged across tissues and organisms. Once the average lipid-normalized BCF was determined, it was adjusted by the consumption-weighted lipid content of commonly consumed aquatic organisms in the United States to obtain an overall consumption-weighted BCF. A similar procedure has been retained in the 2000 Human Health Methodology, whereby BAFs for nonionic organic chemicals are lipid normalized and adjusted by the consumption-weighted lipid content of commonly consumed organisms to obtain a BAF for criteria

calculations. However, the 2000 Human Health Methodology uses more up-to-date lipid data and consumption data for deriving the consumption-weighted BAFs.

5.1.3.3 Bioavailability

Bioconcentration factors derived according to the 1980 Methodology were based on the total concentration of the chemical in water, for both lipophilic and nonlipophilic chemicals. In the 2000 Human Health Methodology, BAFs for nonionic organic chemicals are derived using the most bioavailable fraction (i.e., the freely dissolved fraction) to account for the influence of particulate and dissolved organic carbon on a chemical's bioavailability. Such BAFs are then adjusted to reflect the expected bioavailability at the sites of interest (i.e., by adjusting for organic carbon concentrations at the sites of interest). Procedures for accounting for the effect of organic carbon on bioaccumulation were published previously by EPA under the Great Lakes Water Quality Initiative (GLWQI or GLI) rulemaking (USEPA, 1995a,b). Bioavailability is also considered in developing BAFs for the other chemical classes defined in the 2000 Human Health Methodology (e.g., ionic organics, inorganics/organometallics) but is done so on a chemical-by-chemical basis.

5.1.3.4 Trophic Level Considerations

In the 1980 Methodology, BCFs were determined and used for criteria derivation without explicit regard to the trophic level of the aquatic organism (e.g., benthic filter feeder, forage fish, predatory fish). Over the past two decades, much information has been assembled which demonstrates that an organism's trophic position in the aquatic food web can have an important effect on the magnitude of bioaccumulation of certain chemicals. In order to account for the variation in bioaccumulation that is due to trophic position of the organism, the 2000 Human Health Methodology recommends that BAFs be determined and applied on a trophic level-specific basis.

5.1.3.5 Site-Specific Adjustments

The 1980 Methodology contained little guidance for making adjustments to the national BCFs to reflect site- or region-specific conditions. The 2000 Human Health Methodology has greatly expanded the guidance to States and authorized Tribes for making adjustments to national BAFs to reflect local conditions. This guidance is contained in the Bioaccumulation TSD. In the Bioaccumulation TSD, guidance and data are provided for adjusting national BAFs to reflect the lipid content in locally consumed aquatic biota and the organic carbon content in the waterbodies of concern. This guidance also allows the use of appropriate bioaccumulation models for deriving site-specific BAFs. EPA also plans to publish detailed guidance on designing and conducting field bioaccumulation studies for measuring BAFs and biota-sediment accumulation factors (BSAFs). In general, EPA encourages States and authorized Tribes to make site-specific modifications to EPA's national BAFs provided such adjustments are scientifically defensible and adequately protect the designated use of the waterbody.

While the aforementioned revisions are new to EPA's Methodology for deriving national 304(a) criteria for the protection of human health, many of these refinements have been

incorporated in prior Agency guidance and regulations. For example, the use of food chain multipliers to account for the biomagnification of nonionic organic chemicals in aquatic food webs when measured data are unavailable was introduced by EPA in three documents*: Technical Support Document for Water Quality-Based Toxics Control* (USEPA, 1991), a draft document entitled *Assessment and Control of Bioconcentratable Contaminants in Surface Waters* (USEPA, 1993), and in the *Great Lakes Water Quality Initiative* (GLI) (USEPA, 1995b). Similarly, procedures for predicting BAFs using BSAFsand incorporating the effect of organic carbon on bioavailability were used to derive water quality criteria under the GLI.

5.1.4 Organization of This Section

The methodology for deriving national BAFs for use in deriving National 304(a) Human Health AWQC is provided in the following sections. Important terms used throughout this chapter are defined in Section 5.2. Section 5.3 provides an overview of the BAF derivation guidelines. Detailed procedures for deriving national BAFs are provided in Section 5.4 for nonionic organic chemicals, in Section 5.5 for ionic organic chemicals, and in Section 5.6 for inorganics and organometallic chemicals. Literature cited is provided in Section 5.7.

5.2 DEFINITIONS

The following terms and definitions are used throughout this chapter.

Bioaccumulation. The net accumulation of a substance by an organism as a result of uptake from all environmental sources.

Bioconcentration. The net accumulation of a substance by an aquatic organism as a result of uptake directly from the ambient water, through gill membranes or other external body surfaces.

Bioaccumulation Factor (BAF). The ratio (in L/kg-tissue) of the concentration of a substance in tissue to its concentration in the ambient water, in situations where both the organism and its food are exposed and the ratio does not change substantially over time. The BAF is calculated as:

$$BAF = \frac{C_t}{C_w} \qquad \text{(Equation 5-2)}$$

where:

C_t = Concentration of the chemical in the specified wet tissue
C_w = Concentration of chemical in water

Bioconcentration Factor (BCF). The ratio (in L/kg-tissue) of the concentration of a substance in tissue of an aquatic organism to its concentration in the ambient water, in situations where the organism is exposed through the water only and the ratio does not change substantially over time. The BCF is calculated as:

$$BCF = \frac{C_t}{C_w} \qquad \text{(Equation 5-3)}$$

where:

C_t = Concentration of the chemical in the specified wet tissue
C_w = Concentration of chemical in water

Baseline BAF (BAF_ℓ^{fd}). For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), a BAF (in L/kg-lipid) that is based on the concentration of freely dissolved chemical in the ambient water and the lipid normalized concentration in tissue.

Baseline BCF (BCF_ℓ^{fd}). For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), a BCF (in L/kg-lipid) that is based on the concentration of freely dissolved chemical in the ambient water and the lipid normalized concentration in tissue.

Biomagnification. The increase in tissue concentration of a chemical in organisms at successive trophic levels through a series of predator-prey associations, primarily through the mechanism of dietary accumulation.

Biomagnification Factor (BMF). The ratio (unitless) of the tissue concentration of a chemical in a predator at a particular trophic level to the tissue concentration in its prey at the next lower trophic level for a given waterbody and chemical exposure. For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), a BMF can be calculated using lipid-normalized concentrations in the tissue of organisms at two successive trophic levels as:

$$BMF_{(TL,\ n)} = \frac{C_{\ell\ (TL,\ n)}}{C_{\ell\ (TL,\ n-1)}} \qquad \text{(Equation 5-4)}$$

where:

$C_{\ell\ (TL,\ n)}$ = Lipid-normalized concentration in appropriate tissue of predator organism at a given trophic level (TL “n”)

$C_{\ell\ (TL,\ n-1)}$ = Lipid-normalized concentration in appropriate tissue of prey organism at the next lower trophic level from the predator (TL "n-1")

For inorganic, organometallic, and certain ionic organic chemicals where lipid and organic carbon partitioning does not apply, a BMF can be calculated using chemical concentrations in the tissue of organisms at two successive trophic levels as:

$$BMF_{(TL,\ n)} = \frac{C_{t\ (TL,\ n)}}{C_{t\ (TL,\ n-1)}} \qquad \text{(Equation 5-5)}$$

where:

$C_{t\ (TL,\ n)}$ = Concentration in appropriate tissue of predator organism at trophic level "n" (may be either wet weight or dry weight concentration so long as both the predator and prey concentrations are expressed in the same manner)

$C_{t\ (TL,\ n-1)}$ = Concentration in appropriate tissue of prey organism at the next lower trophic level from the predator (may be either wet weight or dry weight concentration so long as both the predator and prey concentrations are expressed in the same manner)

Biota-Sediment Accumulation Factor (BSAF). For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), the ratio of the lipid-normalized concentration of a substance in tissue of an aquatic organism to its organic carbon-normalized concentration in surface sediment (expressed as kg of sediment organic carbon per kg of lipid), in situations where the ratio does not change substantially over time, both the organism and its food are exposed, and the surface sediment is representative of average surface sediment in the vicinity of the organism. The BSAF is defined as:

$$BSAF = \frac{C_{\ell}}{C_{soc}} \qquad \text{(Equation 5-6)}$$

where:

C_{ℓ} = The lipid-normalized concentration of the chemical in tissues of the biota (µg/g lipid)

C_{soc} = The organic carbon-normalized concentration of the chemical in the surface sediment (µg/g sediment organic carbon)

Depuration. The loss of a substance from an organism as a result of any active or passive process.

Food Chain Multiplier (FCM). For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), the ratio of a baseline BAF_{ℓ}^{fd} for an organism of a particular trophic level to the baseline BCF_{ℓ}^{fd} (usually determined for organisms in trophic level one). For inorganic, organometallic, and certain ionic organic chemicals where lipid and organic carbon partitioning does not apply, a FCM is based on total (wet or dry weight) concentrations of the chemical in tissue.

Freely Dissolved Concentration. For nonionic organic chemicals, the concentration of the chemical that is dissolved in ambient water, excluding the portion sorbed onto particulate or dissolved organic carbon. The freely dissolved concentration is considered to represent the most bioavailable form of an organic chemical in water and, thus, is the form that best predicts bioaccumulation. The freely dissolved concentration can be determined as:

$$C_w^{fd} = (C_w^t) \cdot (f_{fd}) \qquad \text{(Equation 5-7)}$$

where:

C_w^{fd}	=	Freely dissolved concentration of the organic chemical in ambient water
C_w^t	=	Total concentration of the organic chemical in ambient water
f_{fd}	=	Fraction of the total chemical in ambient water that is freely dissolved

Hydrophilic. A term that refers to the extent to which a chemical is attracted to partitioning into the water phase. Hydrophilic organic chemicals have a greater tendency to partition into polar phases (e.g., water) compared to chemicals of hydrophobic chemicals.

Hydrophobic. A term that refers to the extent to which a chemical avoids partitioning into the water phase. Highly hydrophobic organic chemicals have a greater tendency to partition into nonpolar phases (e.g., lipid, organic carbon) compared with chemicals of lower hydrophobicity.

Lipid-normalized Concentration (C_{ℓ}). The total concentration of a contaminant in a tissue or whole organism divided by the lipid fraction in that tissue or whole organism. The lipid-normalized concentration can be calculated as:

$$C_{\ell} = \frac{C_t}{f_{\ell}} \qquad \text{(Equation 5-8)}$$

where:

C_t	=	Concentration of the chemical in the wet tissue (either whole organism or specified tissue)

f_ℓ = Fraction lipid content in the organism or specified tissue

Octanol-water Partition Coefficient (K_{ow}). The ratio of the concentration of a substance in the n-octanol phase to its concentration in the aqueous phase in an equilibrated two-phase octanol-water system. For log K_{ow}, the log of the octanol-water partition coefficient is a base 10 logarithm.

Organic Carbon-normalized Concentration (C_{soc}). For sediments, the total concentration of a contaminant in sediment divided by the fraction of organic carbon in sediment. The organic carbon-normalized concentration can be calculated as:

$$C_{soc} = \frac{C_s}{f_{oc}} \qquad \text{(Equation 5-9)}$$

where:

C_s = Concentration of chemical in sediment
f_{oc} = Fraction organic carbon in sediment

Uptake. Acquisition by an organism of a substance from the environment as a result of any active or passive process.

5.3 FRAMEWORK FOR DETERMINING NATIONAL BIOACCUMULATION FACTORS

5.3.1 Four Different Methods

Bioaccumulation factors used to derive national BAFs can be measured or predicted using some or all of the following four methods, depending on the type of chemical and its properties. These methods are:

(1) a measured BAF obtained from a field study (i.e., a field-measured BAF);

(2) a BAF predicted from a field-measured BSAF;

(3) a BAF predicted from a laboratory-measured BCF (with or without adjustment by an FCM); and

(4) a BAF predicted from a chemical's octanol-water partition coefficient (K_{ow}), with or without adjustment using an FCM.

A brief summary of each of the four methods is provided below. Additional details on the use of these four methods is provided in Section 5.4 (for nonionic organics), Section 5.5 (for ionic organics) and Section 5.6 (for inorganics and organometallics).

1. **Field-Measured BAF.** Use of a field-measured BAF, which is the most direct measure of bioaccumulation, is the only method that can be used to derive a national BAF for all types of chemicals (i.e., nonionic organic, ionic organic, and inorganic and organometallic chemicals). A field-measured BAF is determined from a field study using measured chemical concentrations in the aquatic organism and its surrounding water. Because field studies are conducted in natural aquatic ecosystems, a field-measured BAF reflects an organism's exposure to a chemical through all relevant exposure pathways (i.e., water, sediment, and diet). A field-measured BAF also reflects any metabolism of a chemical that might occur in the aquatic organism or its food web. Therefore, field-measured BAFs are appropriate for all chemicals, regardless of the extent of chemical metabolism in biota.

2. **Field-measured BSAF.** For nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies), a BAF can also be predicted from BSAFs. A BSAF is similar to a field-measured BAF in that the concentration of a chemical in biota is measured in the field and reflects an organism's exposure to all relevant exposure routes. A BSAF also reflects any chemical metabolism that might occur in the aquatic organism or its food web. However, unlike a field-measured BAF which references the biota concentration to the water concentration, a BSAF references the biota concentration to the sediment concentration. Use of the BSAF procedure is restricted to organic chemicals which are classified as being moderately to highly hydrophobic.

3. **Lab-measured BCF.** A laboratory-measured BCF can also be used to estimate a BAF for organic and inorganic chemicals. However, unlike a field-measured BAF or a BAF predicted from a field-measured BSAF, a laboratory-measured BCF only reflects the accumulation of chemical through the water exposure route. Laboratory-measured BCFs may therefore under estimate BAFs for chemicals where accumulation from sediment or dietary sources is important. In these cases, laboratory-measured BCFs can be multiplied by a FCM to reflect accumulation from non-aqueous (i.e., food chain) pathways of exposure. Since a laboratory-measured BCF is determined using the measured concentration of a chemical in an aquatic organism and its surrounding water, a laboratory-measured BCF reflects any metabolism of the chemical that occurs in the organism, but not in the food web.

4. **K_{ow}.** A chemical's octanol-water partition coefficient, or K_{ow}, can also be used to predict a BAF for nonionic organic chemicals. This procedure is appropriate only for nonionic organic chemicals (and certain ionic organic chemicals where similar lipid and organic carbon partitioning behavior applies). The K_{ow} has been extensively correlated with the BCF for nonionic organic chemicals that are poorly metabolized by aquatic organisms. Therefore, where substantial metabolism is known to occur in biota, the K_{ow} is not used

to predict the BAF. For nonionic organic chemicals where chemical exposure through the food web is important, use of the K_{ow} alone will under predict the BAF. In such cases, the K_{ow} is adjusted with a FCM similar to the BCF procedure above.

5.3.2 Overview of BAF Derivation Framework

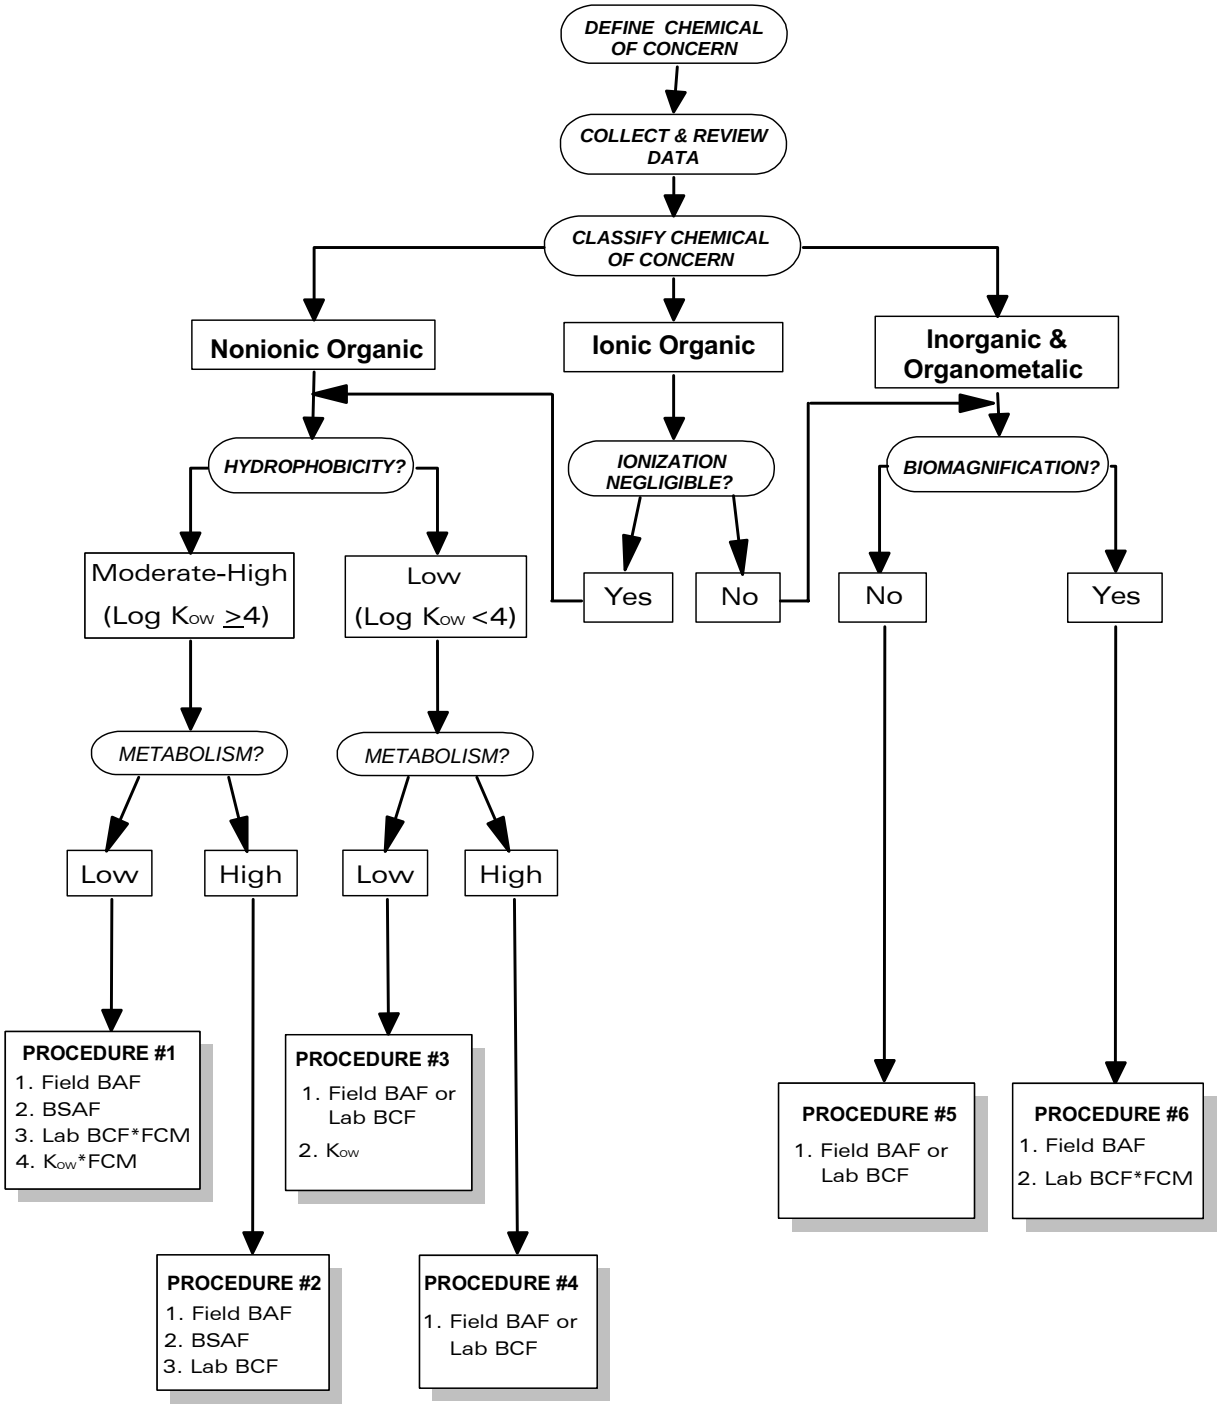
Although up to four methods can be used to derive a BAF as described in the previous section, it is evident that these methods do not apply equally to all types of chemicals. In addition, experience demonstrates that the required data will usually not be available to derive a BAF value using all of the applicable methods. As a result, EPA has developed the following guidelines to direct users in selecting the most appropriate method(s) for deriving a national BAF.

Figure 5-1 shows the overall framework of EPA's national BAF methodology. This framework illustrates the major steps and decisions that will ultimately lead to calculating a national BAF using one of six hierarchical procedures shown at the bottom of Figure 5-1. Each procedure contains a hierarchy of the BAF derivation methods discussed above, the composition of which depends on the chemical type and certain chemical properties (e.g., its degree of hydrophobicity and expected degree of metabolism and biomagnification). The number assigned to each BAF method within a procedure indicates its general order of preference for deriving a national BAF value. The goal of the framework and accompanying guidelines is to enable full use of available data and methods for deriving a national BAF value while appropriately restricting the use of certain methods to reflect their inherent limitations.

The first step in the framework is to define the chemical of concern. As described in Section 5.3.3, the chemical used to derive the national BAF should be consistent with the chemical used to derive the critical health assessment value. The second step is to collect and review all relevant data on bioconcentration and bioaccumulation of the chemical of concern (see Section 5.3.4). Once pertinent data are reviewed, the third step is to classify the chemical of concern into one of three broadly defined chemical categories: (1) nonionic organic chemicals, (2) ionic organic chemicals, and (3) and inorganic and organometallic chemicals. Guidance for classifying chemicals into these three categories is provided in Section 5.3.5.

After a chemical has been classified into one of the three categories, other information is used to select one of six hierarchical procedures to derive the national BAF. The specific procedures for deriving a BAF for each chemical group are discussed in Section 5.4 for nonionic organics, Section 5.5 for ionic organics, and Section 5.6 for inorganics and organometallics.

Figure 5-1. Framework for Deriving a National BAF



Detailed guidance concerning the first three steps of the derivation process (i.e, defining the chemical of concern, collecting and reviewing data, and classifying the chemical of concern) is provided in the following three sections.

5.3.3 Defining the Chemical of Concern

Defining the chemical of concern is the first step in deriving a national BAF. This step involves precisely defining the form(s) of the chemical upon which the national BAF value will be derived. Although this step is usually straightforward for single chemicals, complications can arise when the chemical of concern occurs as a mixture. The following guidelines should be followed for defining the chemical of concern.

1. Information for defining the chemical of concern should be obtained from the health and exposure assessment portions of the criteria derivation effort. The chemical(s) used to derive the national BAF should be consistent with the chemical(s) used to derive the reference dose (RfD), point of departure/uncertainty factor (POD/UF), or cancer potency factor.

2. In most cases, the RfD, POD/UF, or cancer potency factor will be based on a single chemical. In some cases, the RfD, POD/UF, or cancer potency factor will be based on a mixture of compounds, typically within the same chemical class (e.g., toxaphene, chlordane). In these situations, the national BAF should be derived in a manner that is consistent with the mixture used to express the health assessment.

    a. If sufficient data are available to reliably assess the bioaccumulation of each relevant compound contained in the mixture, then the national BAF(s) should be derived using the BAFs for the individual compounds of the mixture and appropriately weighted to reflect the mixture composition used to establish the RfD, POD/UF, or cancer potency factor. An example of this approach is shown in the derivation of BAFs for PCBs in the GLI Rulemaking (USEPA, 1997).

    b. If sufficient data are not available to reliably assess the bioaccumulation of individual compounds of the mixture, then the national BAF(s) should be derived using BAFs for the same or appropriately similar chemical mixture as that used to establish the RfD, POD/UF, or cancer potency value.

5.3.4 Collecting and Reviewing Data

The second step in deriving a national BAF is to collect and review all relevant bioaccumulation data for the chemical of concern. The following guidance should be followed for collecting and reviewing bioaccumulation data for deriving national BAFs.

1. All data on the occurrence and accumulation of the chemical of concern in aquatic animals and plants should be collected and reviewed for adequacy.

2. A comprehensive literature search strategy should be used for gathering bioaccumulation-related data. An example of a comprehensive literature search strategy is provided in the Bioaccumulation TSD.

3. All data that are used should contain sufficient supporting information to indicate that acceptable measurement procedures were used and that the results are probably reliable. In some cases it may be appropriate to obtain additional written information from the investigator.

4. Questionable data, whether published or unpublished, should not be used. Guidance for assessing the acceptability of bioaccumulation and bioconcentration studies is found in Sections 5.4, 5.5, and 5.6.

5.3.5 Classifying the Chemical of Concern

The next step in deriving a national BAF consists of classifying the chemical of concern into one of three categories: nonionic organic, ionic organic, and inorganic and organometallic (Figure 5-1). This step helps to determine which of the four methods described in Section 5.3.1 are appropriate for deriving BAFs. The following guidance applies for classifying the chemical of concern.

1. **Nonionic Organic Chemicals.** For the purposes of the 2000 Human Health Methodology, nonionic organic chemicals are those organic compounds that do not ionize substantially in natural bodies of water. These chemicals are also referred to as neutral or nonpolar organics in the scientific literature. Due to their neutrality, nonionic organic chemicals tend to associate with other neutral (or near neutral) compartments in aquatic ecosystems (e.g., lipid, organic carbon). Examples of nonionic organic chemicals which have been widely studied in terms of their bioaccumulation include polychlorinated biphenyls (PCBs), polychlorinated dibenzo-p-dioxins and furans, many chlorinated pesticides, and polynuclear aromatic hydrocarbons (PAHs). Procedures for deriving a national BAF for nonionic organic chemicals are provided in Section 5.4.

2. **Ionic Organic Chemicals.** For the purposes of the 2000 Human Health Methodology, ionic organic chemicals are considered to include those chemicals that contain functional groups with exchangeable protons such as hydroxyl, carboxylic, and sulfonic groups and functional groups that readily accept protons such as amino and aromatic heterocyclic nitrogen (pyridine) groups. Ionic organic chemicals undergo ionization in water, the extent of which depends on pH and the pKa of the chemical. Because the ionized species of these chemicals behave differently from the neutral species, separate guidance is provided for deriving BAFs for ionic organic chemicals. Procedures for deriving national BAFs for ionic organic chemicals are provided in Section 5.5.

3. **Inorganic and Organometallic Chemicals.** The inorganic and organometallic category is considered to include inorganic minerals, other inorganic compounds and elements, metals (e.g., copper, cadmium, chromium, zinc), metalloids (selenium, arsenic) and

organometallic compounds (e.g., methylmercury, tributyltin, tetraalkyllead). Procedures for deriving BAFs for inorganic and organometallic chemicals are provided in Section 5.6.

5.4 NATIONAL BIOACCUMULATION FACTORS FOR NONIONIC ORGANIC CHEMICALS

5.4.1 Overview

This section contains the methodology for deriving national BAFs for nonionic organic chemicals as defined in Section 5.3.5. The four general steps of this methodology are:

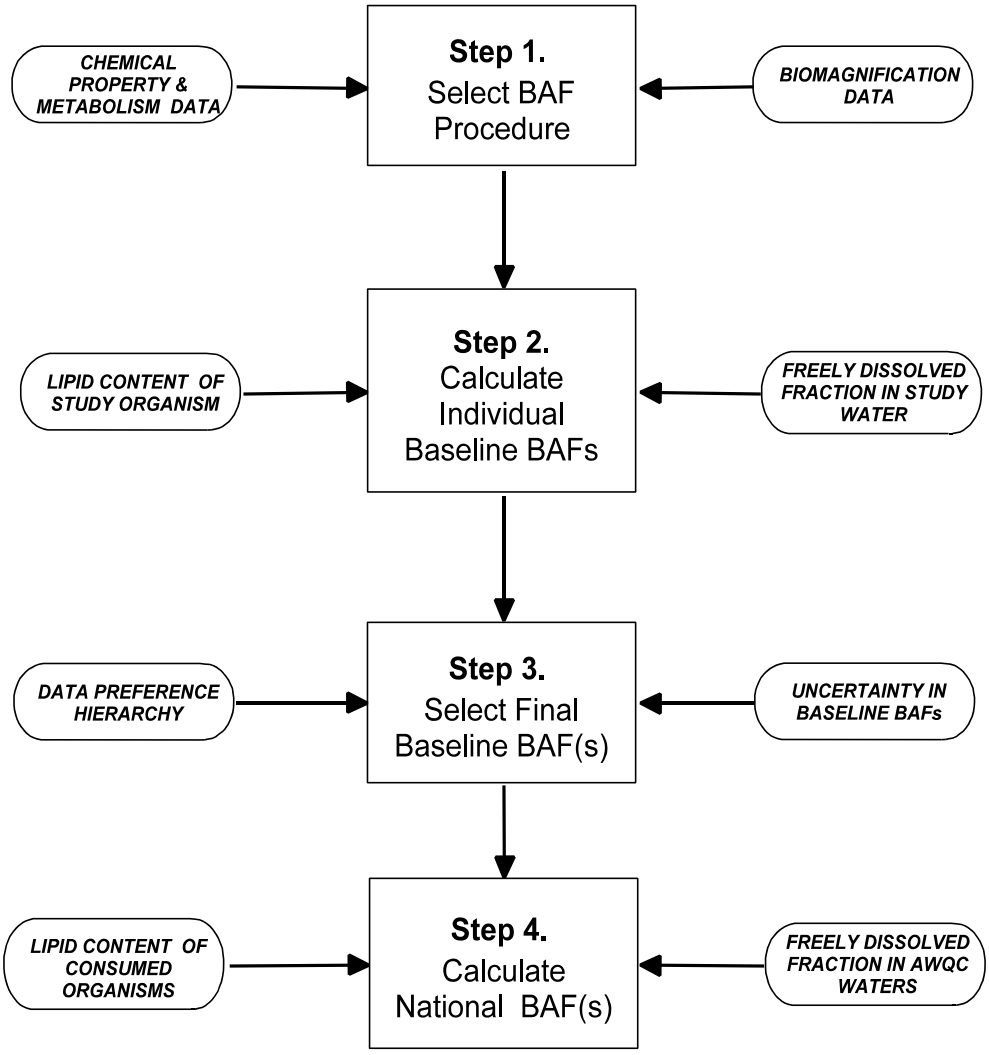
1. Selecting the BAF derivation procedure,
2. Calculating individual baseline BAF_{ℓ}^{fd}s,
3. Selecting the final baseline BAF_{ℓ}^{fd}s, and
4. Calculating the national BAFs from the final baseline BAF_{ℓ}^{fd}s.

A schematic of this four-step process is shown in Figure 5-2.

Step 1 of the methodology (selecting the BAF derivation procedure) determines which of the four BAF procedures summarized in Figure 5-1 will be appropriate for deriving the national BAF. Step 2 involves calculating individual, species-specific BAF_{ℓ}^{fd}s using all of the methods available within the selected BAF derivation procedure. Calculating the individual baseline BAF_{ℓ}^{fd}s involves using data from the field site or laboratory where the original data were collected to account for site-specific factors which affect the bioavailability of the chemical to aquatic organisms (e.g., lipid content of study organisms and freely dissolved concentration in study water). Step 3 of the methodology consists of selecting the final baseline BAF_{ℓ}^{fd}s from the individual baseline BAF_{ℓ}^{fd}s by taking into account the uncertainty in the individual BAFs and the data preference hierarchy selected in Step 1. The final step is to calculate a BAF (or BAFs) that will be used in the derivation of 304(a) criteria (i.e., referred to as the national BAF). This step involves adjusting the final baseline BAF_{ℓ}^{fd}(s) to reflect certain factors that affect bioavailablity of the chemical to aquatic organisms in waters to which the national 304(a) criteria will apply (e.g., the freely dissolved fraction expected in U.S. waters and the lipid content of consumed aquatic organisms). Baseline BAF_{ℓ}^{fd}s are not used directly in the derivation of the 304(a) criteria because they do not reflect the conditions that affect bioavailability in U.S. waters.

Section 5.4.2 below provides detailed guidance for selecting the appropriate BAF derivation procedure (Step 1 of the process). Guidance on calculating individual baseline BAF_{ℓ}^{fd}s, selecting the final baseline BAF, and calculating the national BAF (Steps 2 through 4 of the process) is provided in separate sections under each of the four BAF derivation procedures.

Figure 5-2. BAF Derivation for Nonionic Organic Chemicals



5.4.2 Selecting the BAF Derivation Procedure

This section describes the decisions that should be made to select one of the four available hierarchical procedures for deriving a national BAF for nonionic organic chemicals (Procedures #1 through #4 of Figure 5-1). As shown in Figure 5-1, two decision points exist in selecting the BAF derivation procedure. The first decision point requires knowledge of the chemical's hydrophobicity (i.e., the K_{ow} of the chemical). Guidance for selecting the K_{ow} for a chemical is provided in the Bioaccumulation TSD. The K_{ow} provides an initial basis for assessing whether biomagnification may be a concern for nonionic organic chemicals. The second decision point is based on the rate of metabolism for the chemical in the target organism. Guidance for assessing whether a high or low rate of metabolism is likely for a chemical of concern is provided below in Section 5.4.2.3. With the appropriate information for these two decision points, the BAF derivation procedure should be selected using the following guidelines.

5.4.2.1 <u>Chemicals with Moderate to High Hydrophobicity</u>

1. For the purposes of the 2000 Human Health Methodology, nonionic organic chemicals with log K_{ow} values equal to or greater than 4.0 should be classified as moderately to highly hydrophobic. For moderately to highly hydrophobic nonionic organic chemicals, available data indicate that exposure through the diet and other non-aqueous routes can become important in determining chemical residues in aquatic organisms (e.g., Russell et al., 1999; Fisk et al., 1998; Oliver and Niimi, 1983; Oliver and Niimi, 1988; Niimi, 1985; Swackhammer and Hites, 1988). Dietary and other non-aqueous exposure can become extremely important for those nonionic organic chemicals that are poorly metabolized by aquatic biota (e.g., certain PCB congeners, chlorinated pesticides, and polychlorinated dibenzo-p-dioxins and furans).

2. **Procedure #1** should be used to derive national BAFs for moderately to highly hydrophobic nonionic organic chemicals in cases where:

   (a) the rate of chemical metabolism by target aquatic organisms is expected to be sufficiently low such that biomagnification is of concern, or

   (b) the rate of chemical metabolism by target aquatic organisms is not sufficiently known.

   Procedure #1 accounts for non-aqueous exposure and the potential for biomagnification in aquatic food webs through the use of field-measured values for bioaccumulation (i.e., field measured BAF or BSAF) and FCMs when appropriate field data are unavailable. Guidance on deriving national BAFs using Procedure #1 is found below in Section 5.4.3.

3. **Procedure #2** should be used to derive the national BAFs for moderately to highly hydrophobic nonionic organic chemicals in cases where:

   (a) the rate of chemical metabolism by target aquatic organisms is expected to be sufficiently high such that biomagnification is not of concern.

Procedure #2 relaxes the requirement of using FCMs and eliminates the use of K_{ow}-based estimates of the BAF, two procedures that are most appropriate for poorly metabolized nonionic organic chemicals. Guidance on deriving national BAFs using Procedure #2 is found below in Section 5.4.4.

5.4.2.2 Chemicals with Low Hydrophobicity

1. For the purposes of these guidelines, nonionic organic chemicals with log K_{ow} values less than 4.0 should be classified as exhibiting low hydrophobicity. For nonionic organic chemicals that exhibit low hydrophobicity (i.e., log $K_{ow} < 4.0$), available information indicates that non-aqueous exposure to these chemicals is not likely to be important in determining chemical residues in aquatic organisms (e.g., Fisk et al., 1998; Gobas et al., 1993; Connolly and Pedersen, 1988; Thomann, 1989). For this group of chemicals, laboratory-measured BCFs and K_{ow}-predicted BCFs do not require adjustment with FCMs for determining the national BAF (Procedures #3 and #4), unless other appropriate data indicate differently.

   Other appropriate data include studies clearly indicating that non-aqueous exposure is important such that use of a BCF would substantially underestimate residues in aquatic organisms. In these cases, Procedure #1 should be used to derive the BAF for nonionic organic chemicals with log $K_{ow} < 4.0$. Furthermore, the data supporting the K_{ow} determination should be carefully reviewed for accuracy and appropriate interpretation, since the apparent discrepancy may be due to errors in determining K_{ow}.

2. **Procedure #3** should be used to derive national BAFs for nonionic organic chemicals of low hydrophobicity in cases where:

   (a) the rate of chemical metabolism by target aquatic organisms is expected to be negligible, such that tissue residues of the chemical of concern are not substantially reduced compared to an assumption of no metabolism, or

   (b) the rate of chemical metabolism by target aquatic organisms is not sufficiently known.

   Procedure #3 includes the use of K_{ow}-based estimates of the BCF to be used when lab or field data are absent. Guidance on deriving national BAFs using Procedure #3 is found below in Section 5.4.5.

3. **Procedure #4** should be used to derive national BAFs for nonionic organic chemicals of low hydrophobicity in cases where:

   (a) the rate of chemical metabolism by target aquatic organisms is expected to be sufficiently high, such that tissue residues of the chemical of concern are substantially reduced compared with an assumption of no metabolism.

Procedure #4 eliminates the option of using K_{ow}-based estimates of the BAF because the K_{ow} may over-predict accumulation when a chemical is metabolized substantially by an aquatic organism. Guidance on deriving national BAFs using Procedure #4 is found below in Section 5.4.6.

5.4.2.3 Assessing Metabolism

Currently, assessing the degree to which a chemical is metabolized by aquatic organisms is confounded by a variety of factors. First, conclusive data on chemical metabolism in aquatic biota are largely lacking. Such data include whole organism studies where the metabolic rates and breakdown products are quantified in fish and other aquatic organisms relevant to human consumption. However, the majority of information on metabolism is derived from *in vitro* liver microsomal preparations in which primary and secondary metabolites may be identified and their rates of formation may or may not be quantified. Extrapolating results from *in vitro* studies to the whole organism involves considerable uncertainty. Second, there are no generally accepted procedures for reliably predicting chemical metabolism by aquatic organisms in the absence of measured data. Third, the rate at which a chemical is metabolized by aquatic organisms can be species and temperature dependent. For example, PAHs are known to be metabolized readily by vertebrate aquatic species (primarily fish), although at rates much less than those observed for mammals. However, the degree of metabolism in invertebrate species is generally much less than the degree in vertebrate species (James, 1989). One hypothesis for this difference is that the invertebrate species lack the detoxifying enzymes and pathways that are present in many vertebrate species.

Given the current limitations on assessing the degree of chemical metabolism by aquatic organisms, the assessment of metabolism should be made on a case-by-case basis using a weight-of-evidence approach. When assessing a chemical's likelihood to undergo substantial metabolism in a target aquatic organism, the following data should be carefully evaluated:

(1) *in vivo* chemical metabolism data,
(2) bioconcentration and bioaccumulation data,
(3) data on chemical occurrence in target aquatic biota, and
(4) *in vitro* chemical metabolism data.

1. ***In vivo* Data.** *In vivo* data on metabolism in aquatic organisms are from studies of chemical metabolism using whole organisms. These studies are usually conducted using large fish from which blood, bile, urine, and individual tissues can be collected for the identification and quantification of metabolites formed over time. *In vivo* studies are considered the most useful for evaluating a chemical's degree of metabolism in an organism because both oxidative (Phase I) and conjugative (Phase II) metabolism can be assessed in these studies. Mass-balance studies, in which parent compound elimination is quantified separately from biotransformation and elimination of metabolites, allow calculation of conversion rate of parent to metabolite as well as metabolite elimination. This information might be used to estimate loss due to metabolism separately from that due to elimination of the parent compound for adjustment of K_{ow}-predicted BAFs. However, due to the analytical and experimental challenges these studies pose, data of

this type are limited. Less rigorous *in vivo* metabolism studies might include the use of metabolic blockers to demonstrate the influence of metabolism on parent compound kinetics. However, caution should be used in interpretation of absolute rates from these data due to the lack of specificity of mammalian derived blockers in aquatic species (Miranda et al., 1998).

2. **Bioconcentration or Bioaccumulation Data.** Data on chemical bioconcentration or bioaccumulation in aquatic organisms can be used indirectly for assessing metabolism. This assessment involves comparing acceptable lab-measured BCFs or field-measured BAFs (after converting to baseline values using procedures below) with the chemical's predicted value based on K_{ow}. The theoretical basis of bioconcentration and bioaccumulation for nonionic organic chemicals indicates that a chemical's baseline BCF should be similar to its K_{ow}-predicted value if metabolism is not occurring or is minimal (see the Bioaccumulation TSD). This theory also indicates that baseline BAFs should be similar to or higher than the K_{ow} for poorly metabolized organic chemicals, with highly hydrophobic chemicals often exhibiting higher baseline BAFs than K_{ow} values. Thus, if a chemical's baseline BCF or BAF is substantially lower than its K_{ow}, this may be an indication that the chemical is being metabolized by the aquatic organism of concern. Note, however, that this difference may also indicate problems in the experimental design or analytical chemistry, and that it may be difficult to discern the difference.

3. **Chemical Occurrence Data.** Although by no means definitive, data on the occurrence of chemicals in aquatic biota (i.e., residue studies) may offer another useful line of evidence for evaluating a chemical's likelihood to undergo substantial metabolism. Such studies are most useful if they have been conducted repeatedly over time and over wide geographical areas. Such studies might indicate a chemical is poorly metabolized if data show that the chemical is being biomagnified in the aquatic food web (i.e., higher lipid-normalized residues in successive trophic levels). Conversely, such studies might indicate a chemical is being metabolized substantially if residue data show a decline in residues with increasing trophic level. Again, other reasons for increases or decreases in concentrations with increasing trophic level might exist and should be carefully evaluated (e.g., incorrect food web assumptions, differences in exposure concentrations).

4. ***In vitro* Data.** *In vitro* metabolism data include data from studies where specific sub-cellular fractions (e.g., microsomal, cytosolic), cells, or tissues from an organism are tested outside the body (i.e., in test-tubes, cell- or tissue-culture). Compared with *in vivo* studies of chemical metabolism in aquatic organisms, *in vitro* studies are much more plentiful in the literature, with the majority of studies characterizing oxidative (Phase I) reactions de-coupled from conjugative (Phase II) metabolism. Cell, tissue, or organ level *in vitro* studies are less common but provide a more complete assessment of metabolism. While such studies are particularly useful for identifying the pathways, rates of formation, and metabolites formed, as well as the enzymes involved and differences in the temperature dependence of metabolism across aquatic species, they suffer from uncertainty when results are extrapolated to the whole organism. This uncertainty results from the fact that dosimetry (i.e., delivery of the toxicant to, and removal of metabolite

from, the target tissue) cannot currently be adequately reproduced in the laboratory or easily modeled.

When assessing chemical metabolism using the above information, the following guidelines apply.

a. A finding of substantial metabolism should be supported by two or more lines of evidence identified using the data described above.

b. At least one of the lines of evidence should be supported by either *in vivo* metabolism data or acceptable bioconcentration or bioaccumulation data.

c. A finding of substantial metabolism in one organism should not be extrapolated to another organism or another group of organisms unless data indicate similar metabolic pathways exist (or are very likely to exist) in both organisms. *In vitro* data may be particularly useful in cross-species extrapolations.

d. Finally, in situations where sufficient data are not available to properly assess the likelihood of significant metabolism in aquatic biota of concern, the chemical should be assumed to undergo little or no metabolism. This assumptions reflects a policy decision by EPA to err on the side of public health protection when sufficient information on metabolism is lacking.

5.4.3 Deriving National BAFs Using Procedure #1

This section contains guidance for calculating national BAFs for nonionic organic chemicals using Procedure #1 shown in Figure 5-1. The types of nonionic organic chemicals for which Procedure #1 is most appropriate are those that are classified as moderately to highly hydrophobic and subject to low (or unknown) rates of metabolism by aquatic biota (see Section 5.4.2 above). Non-aqueous contaminant exposure and subsequent biomagnification in aquatic food webs are of concern for chemicals that are classified in this category. Some examples of nonionic organic chemicals for which Procedure #1 is considered appropriate include:

- tetra-, penta- & hexachlorobenzenes;
- PCBs;
- octachlorostyrene;
- hexachlorobutadiene;
- endrin, dieldrin, aldrin;
- mirex, photomirex;
- DDT, DDE, DDD; and
- heptachlor, chlordane, nonachlor.

Under Procedure #1, the following four methods may be used in deriving a national BAF:

- using a BAF from an acceptable field study (i.e., a field-measured BAF);
- predicting a BAF from an acceptable field-measured BSAF;

- predicting a BAF from an acceptable laboratory-measured BCF and FCM; and
- predicting a BAF from an acceptable K_{ow} and FCM.

As shown in Figure 5-2, once the derivation procedure has been selected, the next steps in deriving a national BAF for a given trophic level include: calculating individual baseline BAF_{ℓ}^{fd}s (step 2), selecting the final baseline BAF_{ℓ}^{fd} (step 3), and calculating the national BAF from the final baseline BAF_{ℓ}^{fd} (step 4). Each of these three steps is discussed separately below.

5.4.3.1 Calculating Individual Baseline BAF_{ℓ}^{fd}s

Calculating an individual baseline BAF_{ℓ}^{fd} involves normalizing the field-measured BAF_{T}^{t} (or laboratory-measured BCF_{T}^{t}) which are based on total concentrations in tissue and water by the lipid content of the study organisms and the freely dissolved concentration in the study water. Both the lipid content in the organism and the freely dissolved concentration (as influenced by organic carbon in water) have been shown to be important factors that influence the bioaccumulation of nonionic organic chemicals (e.g., Mackay, 1982; Connolly and Pederson, 1988; Thomann, 1989, Suffet et al., 1994). Therefore, baseline BAF_{ℓ}^{fd}s (which are expressed on a freely dissolved and lipid-normalized basis) are considered more amenable to extrapolating between different species and bodies of water compared to BAFs expressed using the total concentration in the tissue and water. Because bioaccumulation can be strongly influenced by the trophic position of aquatic organisms (either due to biomagnification or physiological differences), extrapolation of baseline BAF_{ℓ}^{fd}s should not be performed between species of different trophic levels.

1. For each species for which acceptable data are available, calculate all possible baseline BAF_{ℓ}^{fd}s using each of the four methods shown above for Procedure #1.

2. Individual baseline BAF_{ℓ}^{fd}s should be calculated from field-measured BAF_{T}^{t}s, field-measured BSAFs, laboratory BCF_{T}^{t}s, and the K_{ow} according to the following procedures.

A. Baseline BAF_{ℓ}^{fd}s from Field-Measured BAFs

A baseline BAF_{ℓ}^{fd} should be calculated from each field-measured BAF_{T}^{t} using information on the lipid fraction in the tissue of concern for the study organism and the fraction of the total chemical that is freely dissolved in the study water.

1. **Baseline BAF_{ℓ}^{fd} Equation.** For each acceptable field-measured BAF_{T}^{t}, calculate a baseline BAF_{ℓ}^{fd} using the following equation:

$$\text{Baseline } BAF_{\ell}^{fd} = \left[\frac{\text{Measured } BAF_{T}^{t}}{f_{fd}} - 1 \right] \left(\frac{1}{f_{\ell}} \right) \qquad \text{(Equation 5-10)}$$

where:

Baseline BAF_{ℓ}^{fd}	=	BAF expressed on a freely dissolved and lipid-normalized basis
Measured BAF_{T}^{t}	=	BAF based on total concentration in tissue and water
f_{ℓ}	=	Fraction of the tissue that is lipid
f_{fd}	=	Fraction of the total chemical that is freely dissolved in the ambient water

The technical basis of Equation 5-10 is provided in the Bioaccumulation TSD. Guidance for determining each component of Equation 5-10 is provided below.

2. **Determining the Measured BAF_{T}^{t}.** The field-measured BAF_{T}^{t} shown in Equation 5-10 should be calculated based on the total concentration of the chemical in the appropriate tissue of the aquatic organism and the total concentration of the chemical in ambient water at the site of sampling. The equation to derive a measured BAF_{T}^{t} is:

$$\text{Measured } BAF_{T}^{t} = \frac{C_t}{C_w} \qquad \text{(Equation 5-11)}$$

where:

C_t	=	Total concentration of the chemical in the specified wet tissue
C_w	=	Total concentration of chemical in water

The data used to calculate a field-measured BAF_{T}^{t} should be reviewed thoroughly to assess the quality of the data and the overall uncertainty in the BAF value. The following general criteria apply in determining the acceptability of field-measured BAFs that are being considered for deriving national BAFs using Procedure #1.

a. Aquatic organisms used to calculate a field-measured BAF_{T}^{t} should be representative of aquatic organisms that are commonly consumed in the United States. An aquatic organism that is not commonly consumed in the United States can be used to calculate an acceptable field-measured BAF_{T}^{t} provided that the organism is considered to be a reasonable surrogate for a commonly consumed organism. Information on the ecology, physiology, and biology of the organism should be reviewed when assessing whether an organism is a reasonable surrogate of a commonly consumed organism.

b. The trophic level of the study organism should be determined by taking into account its life stage, diet, size, and the food web structure at the study location. Information from the study site (or similar sites) is preferred when evaluating trophic status. If such information is lacking, general information for assessing trophic status of aquatic organisms can be found in USEPA (2000a,b,c).

c. The percent lipid of the tissue used to determine the field-measured BAF_T^t should be either measured or reliably estimated to permit lipid-normalization of the chemical's tissue concentration.

d. The study from which the field-measured BAF_T^t is derived should contain sufficient supporting information from which to determine that tissue and water samples were collected and analyzed using appropriate, sensitive, accurate, and precise analytical methods.

e. The site of the field study should not be so unique that the BAF cannot be reasonably extrapolated to other locations where the BAF and resulting criteria will apply.

f. The water concentration(s) used to derive the BAF should reflect the average exposure of the aquatic organism that corresponds to the concentration measured in its tissue of concern. For nonionic organic chemicals, greater temporal and spatial averaging of chemical concentrations is required as the K_{ow} increases. In addition, as variability in water concentrations increase, greater temporal and spatial averaging is also generally required. Greater spatial averaging is also generally required for more mobile organisms.

g. The concentrations of particulate organic carbon and dissolved organic carbon in the study water should be measured or reliably estimated.

EPA is currently developing guidance for designing and conducting field studies for determining field-measured BAF_T^ts, including recommendations for minimum data requirements. A more detailed discussion of factors that should be considered when determining field-measured BAF_T^ts is provided in the Bioaccumulation TSD.

3. **Determining the Fraction Freely Dissolved (f_{fd}).** As illustrated by Equation 5-10, the fraction of the nonionic organic chemical that is freely dissolved in the study water is required for calculating a baseline BAF_ℓ^{fd} from a field-measured BAF_T^t. The freely dissolved fraction is the portion of the nonionic organic chemical that is not bound to particulate organic carbon or dissolved organic carbon. Together, the concentration of a nonionic organic chemical that is freely dissolved, bound to dissolved organic carbon, and bound to particulate organic carbon constitute its total concentration in water. As discussed further in the Bioaccumulation TSD, the freely dissolved fraction of a chemical is considered to be the best expression of the bioavailable form of nonionic organic chemicals to aquatic organisms (e.g., Suffet et al., 1994; USEPA, 1995b). Because the fraction of a nonionic organic chemical that is freely dissolved may vary among different bodies of water as a result of differences in dissolved and particulate organic carbon in the water, the bioavailability of the total chemical concentration in water is expected to vary from one body of water to another. Therefore, BAFs which are based on the freely dissolved concentration in water (rather than the total concentration in water) are considered to be more reliable for extrapolating and aggregating BAFs among different bodies of water. Currently, availability of BAFs based on measured freely dissolved

concentrations is very limited, partly because of difficulties in analytically measuring the freely dissolved concentration. Thus, if a BAF based on the total water concentration is reported in a given study, the fraction of the chemical that is freely dissolved should be predicted using information on the organic carbon content in the study water.

a. **Equation for Determining the Freely Dissolved Fraction.** If reliable measured data are unavailable to directly determine the freely dissolved fraction of the chemical in water, the freely dissolved fraction should be estimated using the following equation.

$$f_{fd} = \frac{1}{[1 + (POC \cdot K_{ow}) + (DOC \cdot 0.08 \cdot K_{ow})]} \qquad \text{(Equation 5-12)}$$

where:

POC = concentration of particulate organic carbon (kg/L)
DOC = concentration of dissolved organic carbon (kg/L)
K_{ow} = n-octanol water partition coefficient for the chemical

In Equation 5-12, K_{ow} is being used to estimate the partition coefficient to POC (i.e., K_{POC} in L/kg) and $0.08 \cdot K_{ow}$ is being used to estimate the partition coefficient to DOC (i.e., the K_{DOC} in L/kg). A discussion of the technical basis, assumptions, and uncertainty associated with the derivation and application of Equation 5-12 is provided in the Bioaccumulation TSD.

b. **POC and DOC Values.** When converting from the total concentration of a chemical to a freely dissolved concentration using Equation 5-12 above, the POC and DOC concentrations should be obtained from the original study from which the field-measured BAF is determined. If POC and DOC concentrations are not reported in the BAF study, reliable estimates of POC and DOC might be obtained from other studies of the same site used in the BAF study or closely related site(s) within the same water body. When using POC/DOC data from other studies of the same water body, care should be taken to ensure that environmental and hydrological conditions that might affect POC or DOC concentrations (i.e., runoff events, proximity to ground water or surface water inputs, sampling season) are reasonably similar to those in the BAF study. Additional information related to selecting POC and DOC values is provided in the Bioaccumulation TSD.

In some cases, BAFs are reported using the concentration of the chemical in filtered or centrifuged water. When converting these BAFs to a freely dissolved basis, the concentration of POC should be set equal to zero when using Equation 5-12. Particulates are removed from water samples by filtering or centrifuging the sample.

c. **Selecting K_{ow} Values.** A variety of techniques are available to measure or predict K_{ow} values. The reliability of these techniques depends to a large extent on the K_{ow} of the chemical. Because K_{ow} is an important input parameter for calculating the freely dissolved concentration of nonionic organic chemicals and for deriving BAFs using the other three methods of Procedure #1, care should be taken in selecting the most reliable K_{ow} value. The value of K_{ow} for use in estimating the freely dissolved fraction and other procedures used to derive national BAFs should be selected based on the guidance presented in the Bioaccumulation TSD.

4. **Determining the Fraction Lipid (f_ℓ).** Calculating a baseline BAF_ℓ^{fd} for a nonionic organic chemical using Equation 5-10 also requires that the total chemical concentration measured in the tissue used to determine the field-measured BAF_T^t be normalized by the lipid fraction (f_ℓ) in that same tissue. Lipid normalization of tissue concentrations reflects the assumption that BAFs (and BCFs) for nonionic organic chemicals are directly proportional to the percent lipid in the tissue upon which they are based. This assumption means that an organism with a two percent lipid content would be expected to accumulate twice the amount of a chemical at steady state compared with an organism with one percent lipid content, all else being equal. The assumption that aquatic organisms accumulate nonionic organic chemicals in proportion to their lipid content has been extensively evaluated in the literature (Mackay, 1982; Connell, 1988; Barron, 1990) and is generally accepted. Because the lipid content in aquatic organisms can vary both within and across species, BAFs that are expressed using the lipid-normalized concentration (rather than the total concentration in tissue) are considered to be the most reliable for aggregating multiple BAF values for a given species. Additional discussion of technical basis, assumptions, and uncertainties involved in lipid normalization is provided in the Bioaccumulation TSD.

a. The lipid fraction f_ℓ, is routinely reported in bioaccumulation studies involving nonionic organic chemicals. If the lipid fraction is not reported in the BAF study, it can be calculated using the following equation if the appropriate data are reported:

$$f_\ell = \frac{M_\ell}{M_t} \qquad \text{(Equation 5-13)}$$

where:

M_ℓ = Mass of lipid in specified tissue
M_t = Mass of specified tissue (wet weight)

b. Because lipid content can vary within an aquatic organism (and among tissues within that organism) due to several factors including the age and sex of the organism, changes in dietary composition, season of sampling and reproductive status, the lipid fraction used to calculate a baseline BAF_ℓ^{fd} should be measured in

the same tissue and organisms used to determine the field-measured BAF_T^t, unless comparability is demonstrated across organisms.

c. Experience has shown that different solvent systems used to extract lipids for analytical measurement can result in different quantities of lipids being extracted and measured in aquatic organisms (e.g., Randall et al.,1991, 1998). As a result, lipid measurements determined using different solvent systems might lead to apparent differences in lipid-normalized concentrations and lipid-normalized BAFs. The extent to which different solvent systems might affect lipid extractions (and lipid-normalized concentrations) is thought to vary depending on the solvent, chemical of concern, and lipid composition of the tissue being extracted. Guidance on measurement of lipid content, including the choice of solvent system and how different solvent systems may affect lipid content, is provided in the Bioaccumulation TSD.

B. Baseline BAF_ℓ^{fd} Derived from BSAFs

The second method of determining a baseline BAF_ℓ^{fd} for the chemical of concern in Procedure #1 involves the use of BSAFs. Although BSAFs may be used for measuring and predicting bioaccumulation directly from concentrations of chemicals in surface sediment, they may also be used to estimate BAFs (USEPA, 1995b; Cook and Burkhard, 1998). Since BSAFs are based on field data and incorporate effects of chemical bioavailability, food web structure, metabolism, biomagnification, growth, and other factors, BAFs estimated from BSAFs will incorporate the net effect of all these factors. The BSAF approach is particularly beneficial for developing water quality criteria for chemicals which are detectable in fish tissues and sediments, but are difficult to detect or measure precisely in the water column.

As shown by Equation 5-14 below, predicting baseline BAF_ℓ^{fd}s using BSAFs requires that certain types of data be used for the chemicals of interest (for which BAFs are to be determined) and reference chemicals (for which BAFs are measured) from a common sediment-water-organism data set. Differences between BSAFs for different organic chemicals are good measures of the relative bioaccumulation potentials of the chemicals. When calculated from a common organism-sediment sample set, chemical-specific differences in BSAFs reflect the net effect of biomagnification, metabolism, food chain, bioenergetics, and bioavailability factors on the degree of each chemical's equilibrium/disequilibrium between sediment and biota. At equilibrium, BSAFs are expected to be approximately 1.0. However, deviations from 1.0 (reflecting disequilibrium) are common due to: conditions where water is not at equilibrium with surface sediment; differences in organic carbon content of water and sediment; kinetic limitations for chemical transfer between sediments and water associated with specific biota; biomagnification; or biological processes such as growth or biotransformation. BSAFs are most useful (i.e., most predictable from one site to another) when measured under steady-state (or near steady-state) conditions. The use of non-steady-state BSAFs, such as found with new chemical loadings or rapid increases in loadings, increases uncertainty in this method for the relative degree of disequilibrium between the reference chemicals and the chemicals of interest. In general, the fact that concentrations of hydrophobic chemicals in sediment are less sensitive than concentrations in water to fluctuations in chemical loading and distribution makes the BSAF

method robust for estimating BAFs. Results from validation of the BAF procedure in Lake Ontario, the Fox River and Green Bay, Wisconsin, and the Hudson River, New York, demonstrate good agreement between observed and BSAF-predicted BAFs in the vast majority of comparisons made. Detailed results of the validation studies for the BSAF procedure are provided in the Bioaccumulation TSD.

Baseline BAF_{ℓ}^{fd}s should be calculated using acceptable BSAFs for chemicals of interest and appropriate sediment-to-water fugacity (disequilibrium) ratios $(\prod_{socw})_r/(K_{ow})_r$ for reference chemicals under the following guidelines.

1. **Baseline BAF_{ℓ}^{fd} Equation.** For each species with an acceptable field measured $(BSAF)_I$, a baseline BAF_{ℓ}^{fd} for the chemical of interest may be calculated using the following equation with an appropriate value of $(\prod_{socw})_r/(K_{ow})_r$:

$$(Baseline\ BAF_{\ell}^{fd})_i = (BSAF)_i \frac{(D_{i/r})\ (\prod_{socw})_r\ (K_{ow})_i}{(K_{ow})_r} \qquad \text{(Equation 5-14)}$$

where:

$(\text{Baseline } BAF_{\ell}^{fd})_I$	=	BAF expressed on a freely dissolved and lipid-normalized basis for chemical of interest "I"
$(BSAF)_I$	=	Biota-sediment accumulation factor for chemical of interest "I"
$(\prod_{socw})_r$	=	sediment organic carbon to water freely dissolved concentration ratio of reference chemical "r"
$(K_{ow})_I$	=	octanol-water partition coefficient for chemical of interest "I"
$(K_{ow})_r$	=	octanol-water partition coefficient for the reference chemical "r"
$D_{i/r}$	=	ratio between $\prod_{socw} / K_{ow}$ for chemicals "I" and "r" (normally chosen so that $D_{i/r} = 1$)

The technical basis, assumptions, and uncertainties associated with Equation 5-14 are provided in the Bioaccumulation TSD. Guidance for determining each component of Equation 5-14 is provided below.

2. **Determining Field-Measured BSAFs.** BSAFs should be determined by relating lipid-normalized concentrations of chemicals in an organism (C_{ℓ}) to organic carbon-normalized concentrations of the chemicals in surface sediment samples (C_{soc}) using the following equation:

$$BSAF = \frac{C_{\ell}}{C_{soc}} \qquad \text{(Equation 5-15)}$$

a. **Lipid-Normalized Concentration.** The lipid-normalized concentration of a chemical in an organism should be determined by:

$$C_{\ell} = \frac{C_t}{f_{\ell}} \qquad \text{(Equation 5-16)}$$

where:

C_t = Concentration of the chemical in the wet tissue (either whole organism or specified tissue) (µg/g)
f_{ℓ} = Fraction lipid content in the tissue

b. **Organic Carbon-Normalized Concentration.** The organic carbon-normalized concentration of a chemical in sediment should be determined by:

$$C_{soc} = \frac{C_s}{f_{oc}} \qquad \text{(Equation 5-17)}$$

where:

C_s = Concentration of chemical in sediment (µg/g sediment)
f_{oc} = Fraction organic carbon in sediment

The organic carbon-normalized concentrations of the chemicals in surface sediment samples should be associated with the average exposure environment of the organism.

3. **Sediment-to-Water Partition Coefficient** $(\prod_{socw})_r$. Sediment-to-water partition coefficients for reference chemicals should be determined by:

$$(\prod_{socw})_r = \frac{(C_{soc})_r}{(C_w^{fd})_r} \qquad \text{(Equation 5-18)}$$

where:

$(C_{soc})_r$ = Concentration of a reference chemical in sediment normalized to sediment organic carbon
$(C_w^{fd})_r$ = Concentration of the reference chemical freely dissolved in water

4. **Selecting Reference Chemicals.** Reference chemicals with $(\prod_{socw}) / (K_{ow})$ similar to that of the chemical of interest are preferred for this method. Theoretically, knowledge of the

difference between sediment-to-water fugacity ratios for two chemicals, "I" and "r" ($D_{i/r}$), could be used when reliable reference chemicals that meet the fugacity equivalence condition are not available. Similarity of $(\prod_{socw}) / (K_{ow})$ for two chemicals can be indicated on the basis of similar physical-chemical behavior in water (persistence, volatilization), similar mass loading histories, and similar concentration profiles in sediment cores.

Validation studies have demonstrated that choosing reference chemicals with well quantified concentrations in water is important because the uncertainty associated with measurement of barely detected chemicals is large (see the Bioaccumulation TSD). Similarity between K_{ow} values of the reference and target chemicals is generally desirable, although recent validation studies indicate that the accuracy of the method is not substantially decreased through use of reference chemicals with large differences in K_{ow}, as long as the chemicals are structurally similar and have similar persistence behavior in water and sediments.

5. The following data, procedural, and quality assurance requirements should be met for predicting baseline BAF_{ℓ}^{fd}s using field-measured BSAFs:

   a. Data on the reference chemicals and chemicals of interest should come from a common organism-water-sediment data set at a particular site.

   b. The chemicals of interest and reference chemicals should have similar physicochemical properties and persistence in water and sediment.

   c. The loadings history of the reference chemicals and chemicals of interest should be similar such that their expected sediment-water disequilibrium ratios $(\prod_{socw}/K_{ow})$ would not be expected to be substantially different (i.e., $D_{i/r} \sim 1$).

   d. The use of multiple reference chemicals is generally preferred for determining the value of $(\prod_{socw})_r$ so long as the concentrations are well quantified and the aforementioned conditions for selecting reference chemicals are met. In some cases, use of a single reference chemical may be necessary because of limited data.

   e. Samples of surface sediments (0-1 cm is ideal) should be from locations in which sediment is regularly deposited and is representative of average surface sediment in the vicinity of the organism.

   f. The K_{ow} value for the target and reference chemicals should be selected as described in the Bioaccumulation TSD.

   g. All other data quality and procedural guidelines described earlier for determining field-measured BAFs in Section 5.4.3.1(A) should be met.

Further details on the requirements for predicting BAFs from BSAF measurements, including the data, assumptions, and limitations of this approach are provided in the Bioaccumulation TSD.

C. Baseline BAF_{ℓ}^{fd} from a Laboratory-Measured BCF_T^t and FCM

The third method in Procedure #1 consists of using a laboratory-measured BCF_T^t (i.e., a BCF based on total concentrations in tissue and water) and FCMs to predict a baseline BAF_{ℓ}^{fd} for the chemical of concern. The BCF_T^t is used in conjunction with an FCM because non-aqueous routes of exposure and subsequent biomagnification is of concern for the types of chemicals applicable to Procedure #1. A laboratory-measured BCF inherently accounts for the effects of chemical metabolism that occurs in the organism used to calculate the BCF, but does not account for metabolism which may occur in other organisms of the aquatic food web.

1. **Baseline BAF_{ℓ}^{fd} Equation.** For each acceptable laboratory-measured BCF_T^t, calculate a baseline BAF_{ℓ}^{fd} using the following equation:

$$\text{Baseline } BAF_{\ell}^{fd} = (FCM) \cdot \left[\frac{\text{Measured } BCF_T^t}{f_{fd}} - 1 \right] \cdot \left(\frac{1}{f_{\ell}} \right) \qquad \text{(Equation 5-19)}$$

where:

Baseline BAF_{ℓ}^{fd}	=	BAF expressed on a freely dissolved and lipid-normalized basis
Measured BCF_T^t	=	BCF based on total concentration in tissue and water
f_{ℓ}	=	Fraction of the tissue that is lipid
f_{fd}	=	Fraction of the total chemical in the test water that is freely dissolved
FCM	=	The food chain multiplier either obtained from Table 5-1 by linear interpolation for the appropriate trophic level, or from appropriate field data

The technical basis for Equation 5-19 is provided in the Bioaccumulation TSD. Guidance for determining each component of Equation 5-19 is provided below.

2. **Determining the Measured BCF_T^t.** The laboratory-measured BCF_T^t shown in Equation 5-19 should be calculated using information on the total concentration of the chemical in the tissue of the organism and the total concentration of the chemical in the laboratory test water. The equation to derive a measured BCF_T^t is:

$$\text{Measured } BCF_T^t = \frac{C_t}{C_w} \qquad \text{(Equation 5-20)}$$

where:

C_t = Total concentration of the chemical in the specified wet tissue
C_w = Total concentration of chemical in the laboratory test water

The data used to calculate a laboratory-measured BCF_T^t should be reviewed thoroughly to assess the quality of the data and the overall uncertainty in the BCF value. The following general criteria apply in determining the acceptability of laboratory-measured BCF_T^t.

a. The test organism should not be diseased, unhealthy, or adversely affected by the concentration of the chemical because these attributes may alter accumulation of chemicals compared with healthy organisms.

b. The total concentration of the chemical in the water should be measured and should be relatively constant during the exposure period.

c. The organisms should be exposed to the chemical using a flow-through or renewal procedure.

d. The percent lipid of the tissue used to normalize the BCF_T^t should be either measured or reliably estimated to permit lipid normalization of chemical concentrations.

e. The concentrations of particulate organic carbon and dissolved organic carbon in the study water should be measured or reliably estimated.

f. Aquatic organisms used to calculate a laboratory-measured BCF_T^t should be representative of those aquatic organisms that are commonly consumed in the United States. An aquatic organism which is not commonly consumed in the United States can be used to calculate an acceptable laboratory-measured BCF_T^t provided that the organism is considered to be a reasonable surrogate for a commonly consumed organism. Information on the ecology, physiology, and biology of the organism should be reviewed when assessing whether an organism is a reasonable surrogate of a commonly consumed organism.

g. BCFs may be based on measurement of radioactivity from radiolabeled parent compounds only when the BCF is intended to include metabolites, when there is confidence that there is no interference due to metabolites of the parent compounds, or when studies are conducted to determine the extent of metabolism, thus allowing for a proper correction.

h. The calculation of the BCF_T^t should appropriately address growth dilution, which can be particularly important in affecting BCF_T^t determinations for poorly depurated chemicals.

I. Other aspects of the methodology used should be similar to those described by the American Society of Testing and Materials (ASTM, 1999) and USEPA *Ecological Effects Test Guidelines* (USEPA, 1996).

j. In addition, the magnitude of the K_{ow} and the availability of corroborating BCF data should be considered. For example, if the steady-state method is used for the BCF_T^t determination, exposure periods longer than 28 days will generally be required for highly hydrophobic chemicals to reach steady state between the water and the organism.

k. If a baseline BCF_ℓ^{fd} derived from a laboratory-measured BCF_T^t consistently increases or decreases as the chemical concentration increases in the test solutions for the test organisms, the BCF_T^t should be selected from the test concentration(s) that would most closely correspond to the 304(a) criterion. Note: a BCF_T^t should not be calculated from a control treatment.

3. **Selecting Food Chain Multipliers.** An FCM reflects a chemical's tendency to biomagnify in the aquatic food web. Values of FCMs greater than 1.0 are indicative of biomagnification and typically apply to organic chemicals with log K_{ow} values between 4.0 and 9.0. For a given chemical, FCMs tend to be greater at higher trophic levels, although FCMs for trophic level three can be higher than those for trophic level four.

Food chain multipliers used to derive baseline BAF_ℓ^{fd}s using Procedure #1 can be selected from model-derived or field-derived estimates.

a. **Model-Derived FCMs.** For nonionic organic chemicals appropriate for Procedure #1, EPA has calculated FCMs for various K_{ow} values and trophic levels using the bioaccumulation model of Gobas (1993). The FCMs shown in Table 5-1 were calculated using the Gobas model as the ratio of the baseline BAF_ℓ^{fd}s for trophic levels 2, 3, and 4 to the baseline BCF_ℓ^{fd}.

EPA recommends using the biomagnification model by Gobas (1993) to derive FCMs for nonionic organic chemicals for several reasons. First, the Gobas model includes both benthic and pelagic food chains, thereby incorporating exposure of organisms to chemicals from both the sediment and the water column. Second, the input data needed to run the model can be readily defined. Third, the predicted BAFs using the model are in agreement with field-measured BAFs for chemicals, even those with very high log K_{ow}s. Finally, the model predicts chemical residues in benthic organisms using equilibrium partitioning theory, which is consistent with EPA's equilibrium partitioning sediment guidelines (USEPA, 2000d).

The Gobas model requires input of specific data on the structure of the food chain and the water quality characteristics of the water body of interest. For calculating national BAFs, a mixed pelagic/benthic food web structure consisting of four trophic levels is assumed. Trophic level 1 is phytoplankton, trophic level 2 is

zooplankton, trophic level 3 is forage fish (e.g., sculpin and smelt), and trophic level 4 are predatory fish (e.g., salmonids). Additional assumptions are made regarding the composition of the aquatic species' diets (e.g., salmonids consume 10 percent sculpin, 50 percent alewives, and 40 percent smelt), the physical parameters of the aquatic species (e.g., lipid values), and the water quality characteristics (e.g., water temperature, sediment organic carbon).

A mixed pelagic/benthic food web structure has been assumed for the purpose of calculating FCMs because it is considered to be most representative of the types of food webs that occur in aquatic ecosystems. FCMs derived using the mixed pelagic/benthic structure are also about mid-range in magnitude between a 100% pelagic and 100% benthic driven food web (see the Bioaccumulation TSD). The validity of FCMs derived using the mixed pelagic/benthic food web structure has

Table 5-1
Food-Chain Multipliers for Trophic Levels 2, 3 and 4
(Mixed Pelagic and Benthic Food Web Structure and $\prod_{socw} / K_{OW} = 23$)

Log K_{OW}	Trophic Level 2	Trophic Level 3	Trophic Level 4	Log K_{OW}	Trophic Level 2	Trophic Level 3	Trophic Level 4

6.5	1.00	12.6	22.8				

been evaluated in several different ecosystems including Lake Ontario, the tidally influenced Bayou D'Inde in Louisiana, the Fox River and Green Bay, Wisconsin, and the Hudson River in New York. Additional details of the validation of EPA's national default FCMs and the assumptions, uncertainties, and input parameters for the model are provided in the Bioaccumulation TSD.

Although EPA uses the FCMs in Table 5-1 to derive its national 304(a) criteria, EPA recognizes that food webs of other waterbodies might differ from the assumptions used to calculate national BAFs. In these situations, States and authorized Tribes may wish to use alternate food web structures for calculating FCMs for use in setting State or Tribal water quality criteria. Additional guidance on the use of alternate food web structures for calculating State, Tribal, or site-specific criteria is provided in the Bioaccumulation TSD.

b. **Field-Derived FCMs.** In addition to model-derived estimates of FCMs, field data may also be used to derive FCMs. Currently, the use of field-derived FCMs is the only method recommended for estimating FCMs for inorganic and organometalic chemicals because appropriate model-derived estimates are not yet available (see Section 5.6). In contrast to the model-based FCMs described previously, field-derived FCMs account for any metabolism of the chemical of concern by the aquatic organisms used to calculate the FCM.

Field-derived FCMs should be calculated using lipid-normalized concentrations of the nonionic organic chemical in appropriate predator and prey species using the following equations.

$$FCM_{TL2} = BMF_{TL2} \quad \text{(Equation 5-21)}$$

$$FCM_{TL3} = (BMF_{TL3})\,(BMF_{TL2}) \quad \text{(Equation 5-22)}$$

$$FCM_{TL4} = (BMF_{TL4})\,(BMF_{TL3})\,(BMF_{TL2}) \quad \text{(Equation 5-23)}$$

where:

FCM = Food chain multiplier for designated trophic level (TL2, TL3, or TL4)
BMF = Biomagnification factor for designated trophic level (TL2, TL3, or TL4)

The basic difference between FCMs and BMFs is that FCMs relate back to trophic level one (or trophic level two as assumed by the Gobas (1993) model), whereas BMFs always relate back to the next lowest trophic level. For nonionic organic chemicals, BMFs can be calculated from tissue residue concentrations determined in biota at a site according to the following equations.

$$BMF_{TL2} = (C_{\ell, TL2}) / (C_{\ell, TL1}) \quad \text{(Equation 5-24)}$$

$$BMF_{TL3} = (C_{\ell, TL3}) / (C_{\ell, TL2}) \quad \text{(Equation 5-25)}$$

$$BMF_{TL4} = (C_{\ell, TL4}) / (C_{\ell, TL3}) \quad \text{(Equation 5-26)}$$

where:

C_ℓ = Lipid-normalized concentration of chemical in tissue of appropriate biota that occupy the specified trophic level (TL2, TL3, or TL4)

In addition to the acceptability guidelines pertaining to field-measured BAFs, the following procedural and quality assurance requirements apply to field-measured FCMs.

(1) Information should be available to identify the appropriate trophic levels for the aquatic organisms and appropriate predator-prey relationships for the site from which FCMs are being determined. General information on determining trophic levels of aquatic organisms can be found in USEPA 2000a,b,c.

(2) The aquatic organisms sampled from each trophic level should reflect the most important exposure pathways leading to human exposure via consumption of aquatic organisms. For higher trophic levels (e.g., 3 and 4), aquatic species should also reflect those that are commonly consumed by humans.

(3) The studies from which the FCMs are derived should contain sufficient supporting information from which to determine that tissue samples were collected and analyzed using appropriate, sensitive, accurate, and precise methods.

(4) The percent lipid should be either measured or reliably estimated for the tissue used to determine the FCM.

(5) The tissue concentrations should reflect average exposure over the approximate time required to achieve steady-state in the target species.

D. Baseline BAF_ℓ^{fd} from a K_{ow} and FCM

The fourth method in Procedure #1 consists of using a K_{ow} and an appropriate FCM for estimating the baseline BAF_ℓ^{fd}. In this method, the K_{ow} is assumed to be equal to the baseline BCF_ℓ^{fd}. Numerous investigations have demonstrated a linear relationship between the logarithm of the BCF and the logarithm of the octanol-water partition coefficient (K_{ow}) for organic chemicals for fish and other aquatic organisms. Isnard and Lambert (1988) list various regression equations that illustrate this linear relationship. When the regression equations are constructed using lipid-normalized BCFs, the slopes and intercepts are not significantly different from one and zero, respectively (e.g., de Wolf, et al., 1992). The underlying assumption for the linear relationship between the BCF and K_{ow} is that the bioconcentration process can be viewed as the partitioning of a chemical between the lipid of the aquatic organisms and water and that the K_{ow} is a useful surrogate for this partitioning process (Mackay, 1982). To account for biomagnification, Procedure #1 requires the K_{ow} value be used in conjunction with an appropriate FCM.

1. **Baseline BAF_{ℓ}^{fd} Equation.** For each acceptable K_{ow} value and FCM for the chemical of concern, calculate a baseline BAF_{ℓ}^{fd} using the following equation.

$$\text{Baseline } BAF_{\ell}^{fd} = (FCM) \cdot (K_{ow}) \qquad \text{(Equation 5-27)}$$

where:

Baseline BAF_{ℓ}^{fd}	=	BAF expressed on a freely dissolved and lipid-normalized basis for a given trophic level
FCM	=	The food chain multiplier for the appropriate trophic level obtained from Table 5-1 by linear interpolation or from appropriate field data (used with Procedure #1 only)
K_{ow}	=	Octanol-water partition coefficient

The BCF-K_{ow} relationship has been developed primarily for nonionic organic chemicals that are not readily metabolized by aquatic organisms and thus is most appropriate for poorly-metabolized nonionic organic chemicals (i.e., Procedures #1 and #3 as depicted in Figure 5-1). For poorly-metabolized nonionic organic chemicals with large log K_{ow}s (i.e., > 6), reported log BCFs are often not equal to log K_{ow}. EPA believes that this nonlinearity is primarily due to not accounting for several factors which affect the BCF determination. These factors include not basing BCFs on the freely dissolved concentration in water, not accounting for growth dilution, not assessing BCFs at steady-state, inaccuracies in measurements of uptake and elimination rate constants, and complications from the use of solvent carriers in the exposure. Application of Equation 5-27 for predicting BAFs has been conducted in several different ecosystems including Lake Ontario, the tidally influenced Bayou D'Inde in Louisiana, the Fox River and Green Bay, Wisconsin, and the Hudson River in New York. Additional detail on the validation, technical basis, assumptions, and uncertainty associated with Equation 5-27 and is provided in the Bioaccumulation TSD.

2. **FCMs and K_{ow}s**. Food chain multipliers and K_{ow} values should be selected as described previously in Procedure #1.

5.4.3.2 Selecting Final Baseline BAF_{ℓ}^{fd}s

After calculating individual baseline BAF_{ℓ}^{fd}s using as many of the methods in Procedure #1 as possible, the next step is to determine a final baseline BAF_{ℓ}^{fd} for each trophic level from the individual baseline BAF_{ℓ}^{fd}s (see Figures 5-1 and 5-2). The final baseline BAF_{ℓ}^{fd} will be used in the last step to determine the national BAF for each trophic level. The final baseline BAF_{ℓ}^{fd} for each trophic level should be determined from the individual baseline BAF_{ℓ}^{fd}s by considering the data preference hierarchy defined by Procedure #1 and uncertainty in the data. The data preference hierarchy for Procedure #1 is (in order of preference):

1. a baseline BAF_{ℓ}^{fd} from an acceptable field-measured BAF (method 1)

2. a baseline BAF_{ℓ}^{fd} predicted from an acceptable field-measured BSAF (method 2),
3. a baseline BAF_{ℓ}^{fd} predicted from an acceptable BCF and FCM (method 3), or
4. a baseline BAF_{ℓ}^{fd} predicted from an acceptable K_{ow} and FCM (method 4).

This data preference hierarchy reflects EPA's preference for BAFs based on field-measurements of bioaccumulation (methods 1 and 2) over those based on laboratory-measurements and/or predictions of bioaccumulation (methods 3 and 4). However, this data preference hierarchy should not be considered inflexible. Rather, it should be used as a guide for selecting the final baseline BAF_{ℓ}^{fd}s when the uncertainty is similar among two or more baseline BAF_{ℓ}^{fd}s derived using different methods. The following steps and guidelines should be followed for selecting the final baseline BAF_{ℓ}^{fd}s using Procedure #1.

1. **Calculate Species-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method where more than one acceptable baseline BAF_{ℓ}^{fd} is available for a given species, calculate a species-mean baseline BAF_{ℓ}^{fd} as the geometric mean of all available individual baseline BAF_{ℓ}^{fd}s. When calculating a species-mean baseline BAF_{ℓ}^{fd}, individual baseline BAF_{ℓ}^{fd}s should be reviewed carefully to assess the uncertainty in the BAF values. For highly hydrophobic chemicals applicable to Procedure #1, particular attention should be paid to whether sufficient spatial and temporal averaging of water and tissue concentrations was likely achieved in the BAF, BSAF, or BCF study. Highly uncertain baseline BAF_{ℓ}^{fd}s should not be used. Large differences in individual baseline BAF_{ℓ}^{fd}s for a given species (e.g., greater than a factor of 10) should be investigated further. In such cases, some or all of the baseline BAF_{ℓ}^{fd}s for a given species might not be used. Additional discussion on evaluating acceptability of BAF values is provided in the Bioaccumulation TSD.

2. **Calculate Trophic-Level-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method where more than one acceptable species-mean baseline BAF_{ℓ}^{fd} is available within a given trophic level, calculate a trophic-level-mean baseline BAF_{ℓ}^{fd} as the geometric mean of acceptable species-mean baseline BAF_{ℓ}^{fd}s in that trophic level. Trophic-level-mean baseline BAF_{ℓ}^{fd}s should be calculated for trophic levels two, three, and four because available data on U.S. consumers of fish and shellfish indicate significant consumption of organisms in these trophic levels.

3. **Select a Final Baseline BAF_{ℓ}^{fd} for Each Trophic Level.** For each trophic level, select the final baseline BAF_{ℓ}^{fd} using best professional judgment by considering: (1) the data preference hierarchy shown previously, (2) the relative uncertainty in the trophic-level-mean baseline BAF_{ℓ}^{fd}s derived using different methods, and (3) the weight of evidence among the four methods.

    a. In general, when more than one trophic-level-mean baseline BAF_{ℓ}^{fd} is available for a given trophic level, the final trophic-level-mean baseline BAF_{ℓ}^{fd} should be selected from the most preferred BAF method defined by the data preference hierarchy for Procedure #1.

    b. If uncertainty in a trophic-level-mean baseline BAF based on a higher tier (more preferred) method is judged to be substantially greater than a trophic-level-mean

baseline BAF from a lower tier method, and the weight of evidence among the various methods suggests that a BAF value from lower tier method is likely to be more accurate, then the final baseline BAF_{ℓ}^{fd} should be selected using a trophic level-mean baseline BAF_{ℓ}^{fd} from a lower tier method.

c. When considering the weight of evidence among the various BAF methods, greater confidence in the final baseline BAF_{ℓ}^{fd} is generally assigned when BAFs from a greater number of methods are in agreement for a given trophic level. However, lack of agreement among methods does not necessarily indicate less confidence if such disagreements can be adequately explained. For example, if the chemical of concern is metabolized by aquatic organisms represented by a BAF value, one would expect disagreement between a field-measured BAF (the highest priority data) and a predicted BAF using a K_{ow} and model-derived FCM. Thus, field-measured BAFs should generally be given the greatest weight among methods because they reflect direct measures of bioaccumulation and incorporate any metabolism which might occur in the organism and its food web.

d. The above steps should be performed for each trophic level until a final baseline BAF_{ℓ}^{fd} is selected for trophic levels two, three, and four.

5.4.3.3 Calculating National BAFs

The last step in deriving a national BAF for each trophic level is to convert the final baseline BAF_{ℓ}^{fd} determined in the previous step to a BAF that reflects conditions to which the national 304(a) criteria will apply (Figure 5-2). Since a baseline BAF_{ℓ}^{fd} is by definition normalized by lipid content and expressed on a freely dissolved basis, it needs to be adjusted to reflect the lipid fraction of aquatic organisms commonly consumed in the U.S. and the freely dissolved fraction expected in U.S. bodies of water. Converting a final baseline BAF_{ℓ}^{fd} to a national BAF requires information on: (1) the percent lipid of the aquatic organisms commonly consumed by humans, and (2) the freely dissolved fraction of the chemical of concern that would be expected in the ambient waters of interest. For each trophic level, a national BAF should be determined from a final baseline BAF_{ℓ}^{fd} according to the following guidelines.

1. **National BAF Equation.** For each trophic level, calculate a national BAF using the following equation.

$$\text{National BAF}_{(TL\ n)} = [(\text{Final Baseline BAF}_{\ell}^{fd})_{TL\ n} \cdot (f_{\ell})_{TL\ n} + 1] \cdot (f_{fd}) \qquad \text{(Equation 5-28)}$$

where:

Final Baseline BAF_{ℓ}^{fd} = Final trophic-level-mean baseline BAF expressed on a freely dissolved and lipid-normalized basis for trophic level "n"

$f_{\ell(TL\ n)}$	=	Lipid fraction of aquatic species consumed at trophic level "n"
f_{fd}	=	Fraction of the total chemical in water that is freely dissolved

The technical basis of Equation 5-28 is provided in the Bioaccumulation TSD. Guidance for determining each component of Equation 5-28 is provided below.

2. **Determining the Final Baseline BAF_{ℓ}^{fd}.** The final trophic-level-mean baseline BAF_{ℓ}^{fd}s used in this equation are those which have been determined using the guidance presented in Section 5.4.3.2 for selecting the final baseline BAF_{ℓ}^{fd}s.

3. **Lipid Content of Commonly Consumed Aquatic Species.** As illustrated by Equation 5-28, the percent lipid of the aquatic species consumed by humans is needed to accurately characterize the potential exposure to a chemical from ingestion of aquatic organisms.

   a. **National Default Lipid Values.** For the purposes of calculating a national 304(a) criterion, the following national default values for lipid fraction should be used: 1.9% (for trophic level two organisms), 2.6% (for trophic level three organisms), and 3.0% (for trophic level four organisms).

      These national default values for lipid content reflect national per capita average patterns of fish consumption in the United States. Specifically, they were calculated using the consumption-weighted mean lipid content of commonly consumed fish and shellfish as identified by the USDA Continuing Survey of Food Intake by Individuals (CSFII) for 1994 through 1996. This same national survey data was used to derive national default values of fish consumption. To maintain consistency with the fish consumption assumptions, only freshwater and estuarine organisms were included in the derivation of the national default lipid values. Additional details on the technical basis, assumptions, and uncertainty in the national default values of lipid fraction are provided in the Bioaccumulation TSD.

      Although national default lipid values are used by EPA to set national 304(a) criteria, EPA encourages States and authorized Tribes to use local or regional data on lipid content of consumed aquatic species when adopting criteria into their water quality standards because local or regional consumption patterns (and lipid content) can differ from national consumption patterns. Additional guidance on developing site-specific values of lipid content, including a database of lipid content for many commonly consumed aquatic organisms, is found in the Bioaccumulation TSD.

4. **Freely Dissolved Fraction.** The third piece of information required for deriving a national BAF is the freely dissolved fraction of the chemical of concern that is expected

in waters of the United States. As noted previously, expressing BAFs on the freely dissolved concentration in water allows a common basis for averaging BAFs from several studies. However, for use in criteria development, these BAFs should be converted back to values based on the total concentration in the water to be consistent with monitored water column and effluent concentrations, which are typically based on total concentrations of chemicals in the water. This should be done by multiplying the freely dissolved baseline BAF_{ℓ}^{fd} by the fraction of the freely dissolved chemical expected in water bodies of the United States where criteria are to be applied, as shown in Equation 5-29.

$$f_{fd} = \frac{1}{[1 + (POC \cdot K_{ow}) + (DOC \cdot 0.08 \cdot K_{ow})]} \qquad \text{(Equation 5-29)}$$

where:

POC	=	national default value for the particulate organic carbon concentration (kg/L)
DOC	=	national default value for the dissolved organic carbon concentration (kg/L)
K_{ow}	=	n-octanol water partition coefficient for the chemical

Equation 5-29 is identical to Equation 5-12, which was used to determine the freely dissolved fraction for deriving baseline BAF_{ℓ}^{fd}s from field-measured BAFs. However, the POC and DOC concentrations used in Equation 5-29 reflect those values that are expected in U.S. bodies of water, not the POC and DOC values in the study water used to derive the BAF. Guidance for determining each component of Equation 5-29 follows.

a. **National Default Values of POC and DOC.** For estimating the freely dissolved fraction of the chemical of concern that is expected in U.S. water bodies, national default values of 0.5 mg/L (5×10^{-7} kg/L) for POC and 2.9 mg/L (2.9×10^{-6} kg/L) for DOC should be used. These values are 50th percentile values (medians) based on an analysis of over 110,000 DOC values and 85,000 POC values contained in EPA's STORET database from 1980 through 1999. These default values reflect a combination of values for streams, lakes and estuaries across the United States. Additional details on the technical basis, assumptions, and uncertainty in the derivation and application of the national default values of POC and DOC are provided in the Bioaccumulation TSD.

   Although national default values of POC and DOC concentrations are used by EPA to set national 304(a) criteria as described by this document, EPA encourages States and authorized Tribes to use local or regional data on POC and DOC when adopting criteria into their water quality standards. EPA encourages States and Tribes to consider local or regional data on POC and DOC because local or regional conditions may result in differences in POC or DOC

concentrations compared with the values used as national defaults. Additional guidance on developing local or regional values of POC and DOC, including a database of POC and DOC values segregated by waterbody type, is found in the Bioaccumulation TSD.

b. **K_{ow} Value.** The value selected for the K_{ow} of the chemical of concern should be the same value used in earlier calculations (e.g., for calculating baseline BAF_{ℓ}^{fd}s and FCMs). Guidance for selecting the K_{ow} value is found in the Bioaccumulation TSD.

5.4.4 Deriving National BAFs Using Procedure #2

This section provides guidance for calculating national BAFs for nonionic organic chemicals using Procedure #2 shown in Figure 5-1. The types of nonionic organic chemicals for which Procedure #2 is most appropriate are those that are classified as moderately to highly hydrophobic and subject to high rates of metabolism by aquatic biota (see Section 5.4.2 above). Non-aqueous contaminant exposure and subsequent biomagnification in aquatic food webs are not generally of concern for chemicals that are classified in this category. As a result, FCMs are not used in this procedure. In addition, K_{ow} -based predictions of bioconcentration are not used in this procedure since the K_{ow} /BCF relationship is primarily based on poorly metabolized chemicals. Some nonionic organic chemicals for which Procedure #2 is probably appropriate include certain PAHs which are believed to be metabolized substantially by fish (e.g., benzo[a]pyrene, phenanthrene, fluoranthene, pyrene, benzo[a]anthracene and chrysene/triphenylene; USEPA, 1980; Burkhard and Lukasewycz, 2000).

According to Procedure #2, the following three methods can be used in deriving a national BAF:

- using a BAF from an acceptable field study (i.e., a field-measured BAF) (method 1),
- predicting a BAF from an acceptable BSAF (method 2), and
- predicting a BAF from an acceptable BCF (method 3).

Each of these three methods relies on measured data for assessing bioaccumulation and therefore, includes the effects of chemical metabolism by the study organism in the BAF estimate. The field-measured BAF and BSAF methods also incorporate any metabolism which occurs in the aquatic food web.

As shown in Figure 5-2, the next steps in deriving a national BAF after selecting the derivation procedure are: (1) calculating individual baseline BAF_{ℓ}^{fd}s, (2) selecting the final baseline BAF_{ℓ}^{fd}s, and (3) calculating the national BAFs. Each of these three steps is discussed separately below.

5.4.4.1 Calculating Individual Baseline BAF_{ℓ}^{fd}s

As described previously in Procedure #1, calculating individual baseline BAF_{ℓ}^{fd}s involves normalizing the measured BAF_{T}^{t} or BCF_{T}^{t} (which are based on the total chemical in water and

tissue) by the lipid content of the study organisms and the freely dissolved fraction of the chemical in the study water. Converting measured BAF_T^t (or BCF_T^t) values to baseline BAF_ℓ^{fd} (or BCF_ℓ^{fd}) values is designed to account for variation in measured BAF_T^ts that is caused by differences in lipid content of study organisms and differences in the freely dissolved fraction of chemical in study waters. Therefore, baseline BAF_ℓ^{fd}s are considered more amenable for extrapolating and averaging BAFs across different species and different study waters compared with total BAF_T^ts.

1. For each species where acceptable data are available, calculate all possible baseline BAF_ℓ^{fd}s using each of the three methods shown above for Procedure #2.

2. Individual baseline BAF_ℓ^{fd}s should be calculated from field-measured BAF_T^ts, field-measured BSAFs, and laboratory BCF_T^ts according to the following procedures.

A. Baseline BAF_ℓ^{fd} from Field-Measured BAFs

1. Except where noted below, a baseline BAF_ℓ^{fd} should be calculated from a field-measured BAF_T^t using the guidance and equations outlined in Section 5.4.3.1(A) for determining baseline BAF_ℓ^{fd}s from field-measured BAFs in Procedure #1.

2. Because nonionic organic chemicals applicable to Procedure #2 have relatively high rates of metabolism in aquatic organisms, they will tend to reach steady state more quickly than nonionic organic chemicals with similar K_{ow} values but which undergo little or no metabolism. Therefore, less temporal averaging of chemical concentrations would generally be required for determining field-measured BAF_T^ts with highly metabolizable chemicals compared with chemicals that are poorly metabolized by aquatic biota.

B. Baseline BAF_{ℓ}^{fd} Derived from Field-measured BSAFs

1. A baseline BAF_{ℓ}^{fd} should be calculated from a field-measured BSAF using the guidance and equations outlined in Section 5.4.3.1(B) for determining baseline BAF_{ℓ}^{fd}s from field-measured BSAFs in Procedure #1.

C. Baseline BAF_{ℓ}^{fd} from a Laboratory-Measured BCF

1. Except where noted below, a baseline BAF_{ℓ}^{fd} should be calculated from a laboratory-measured BCF_{T}^{t} using the guidance and equations outlined in Section 5.4.3.1(c) for determining baseline BAF_{ℓ}^{fd}s from a laboratory-measured BCF and FCM in Procedure #1.

2. Because biomagnification is not an overriding concern for nonionic organic chemicals applicable to Procedure #2, food chain multipliers are not used in the derivation of a baseline BAF_{ℓ}^{fd} from a laboratory-measured BCF_{T}^{t} .

5.4.4.2 Selecting Final Baseline BAF_{ℓ}^{fd}s

After calculating individual, baseline BAF_{ℓ}^{fd}s using as many of the methods in Procedure #2 as possible, the next step is to determine a final baseline BAF_{ℓ}^{fd} for each trophic level from the individual baseline BAF_{ℓ}^{fd}s. The final baseline BAF_{ℓ}^{fd} will be used in the last step to determine the national BAF for each trophic level. A final baseline BAF_{ℓ}^{fd} for each trophic level should be determined from the individual baseline BAF_{ℓ}^{fd}s by considering the data preference hierarchy defined by Procedure #2 and uncertainty in the data. The data preference hierarchy for Procedure #2 is (in order of preference):

1. a baseline BAF_{ℓ}^{fd} from an acceptable field-measured BAF (method 1),
2. a baseline BAF_{ℓ}^{fd} from an acceptable field-measured BSAF (method 2), or
3. a baseline BAF_{ℓ}^{fd} from an acceptable laboratory-measured BCF (method 3).

This data preference hierarchy reflects EPA's preference for BAFs based on field-measurements of bioaccumulation (methods 1 and 2) over those based on laboratory-measurements (method 3). However, as explained in Procedure #1, this data preference hierarchy should not be considered inflexible. Rather, it should be used as a guide for selecting the final baseline BAF_{ℓ}^{fd}s when the underlying uncertainty is similar among two or more baseline BAF_{ℓ}^{fd}s derived using different methods. Although biomagnification is not generally a concern for chemicals subject to Procedure #2, trophic level differences in bioaccumulation might be substantial to the extent that the rate of chemical metabolism by organisms in different trophic levels differs. For example, certain PAHs have been shown to be metabolized to a much greater extent by some fish compared with some invertebrate species (James, 1989). Therefore, final baseline BAF_{ℓ}^{fd}s for chemicals applicable to Procedure #2 should be determined on a trophic-level-specific basis according to the following guidelines.

1. The final baseline BAF_{ℓ}^{fd}s in Procedure #2 should be selected according to the same steps described in Procedure #1 but with the substitution of the data preference hierarchy described above for Procedure #2. Specifically, the species-mean baseline BAF_{ℓ}^{fd}s,

trophic-level-mean baseline BAF_{ℓ}^{fd}s, and the final baseline BAF_{ℓ}^{fd}s should be determined according to the guidelines presented in Procedure #1 (Section 5.4.3.2, Steps 1, 2, and 3).

5.4.4.3 Calculating the National BAFs

As described in Procedure #1, the last step in deriving national BAFs for nonionic organic chemicals is to convert the final baseline BAF_{ℓ}^{fd}s determined in the previous step to BAFs which reflect conditions to which the national 304(a) criteria will apply (Figure 5-2).

1. For trophic levels two, three, and four, national BAFs should be calculated from the final baseline BAF_{ℓ}^{fd}s using the same equation and procedures described previously in Procedure #1 (see Section 5.4.3.3 entitled "Calculating the National BAFs").

5.4.5 Deriving National BAFs Using Procedure #3

This section provides guidance for calculating national BAFs for nonionic organic chemicals using Procedure #3 shown in Figure 5-1. The types of nonionic organic chemicals for which Procedure #3 is most appropriate are those that are classified as low in hydrophobicity (i.e., log K_{ow} values less than 4.0) and subject to low (or unknown) rates of metabolism by aquatic biota (see Section 5.4.2 above). Non-aqueous contaminant exposure and subsequent biomagnification in aquatic food webs are not generally of concern for chemicals that are classified in this category (Fisk et al., 1998; Gobas et al., 1993; Connolly and Pedersen, 1988; Thomann, 1989). As a result, FCMs are not used in this procedure.

According to Procedure #3, the following three methods can be used in deriving a national BAF:

- using a BAF from an acceptable field study (i.e., a field-measured BAF),
- predicting a BAF from an acceptable laboratory-measured BCF, and
- predicting a BAF from an acceptable K_{ow}.

After selecting the derivation procedure, the next steps in deriving a national BAF at a given trophic level for nonionic organic chemicals are: (1) calculating individual baseline BAF_{ℓ}^{fd}s, (2) selecting the final baseline BAF_{ℓ}^{fd}, and (3) calculating the national BAF (Figure 5-2). Each of these three steps is discussed separately below.

5.4.5.1 Calculating Individual Baseline BAF_{ℓ}^{fd}s

Calculating individual baseline BAF_{ℓ}^{fd}s involves normalizing each measured BAF_{T}^{t} or BCF_{T}^{t} (which are based on the total chemical in water and tissue) by the lipid content of the study organism and the freely dissolved fraction of the chemical in the study water. For additional discussion of the technical basis for calculating baseline BAF_{ℓ}^{fd}s, see Section 5.4.3.1 in Procedure #1.

1. For each species where acceptable data are available, calculate all possible baseline BAF_{ℓ}^{fd}s using each of the three methods shown above for Procedure #3.

2. An individual baseline BAF_{ℓ}^{fd} should be calculated from field-measured BAF_{T}^{t}s, laboratory-measured BCF_{T}^{t}s, and K_{ow} values according to the following procedures.

A. Baseline BAF_{ℓ}^{fd} from Field-Measured BAFs

1. Except where noted below, a baseline BAF_{ℓ}^{fd} should be calculated from a field-measured BAF_{T}^{t} using the guidance and equations outlined in Section 5.4.3.1(A) in Procedure #1.

2. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log $K_{ow} < 4.0$), nonionic organic chemicals applicable to Procedure #3 are expected to remain almost entirely in the freely dissolved form in natural waters with dissolved and particulate organic carbon concentrations typical of most field BAF studies. Therefore, the freely dissolved fraction should be assumed to be equal to 1.0, unless the concentrations of DOC and POC are very high in the field BAF study. For studies with very high DOC or POC concentrations, (e.g., about 100 mg/L or higher for DOC or 10 mg/L or higher for POC), the freely dissolved fraction may be substantially lower than 1.0 and therefore should be calculated using Equation 5-12.

3. **Temporal Averaging of Concentrations.** Also due to their low hydrophobicity, nonionic organic chemicals appropriate to Procedure #3 will also tend to reach steady state quickly compared with those chemicals to which Procedure #1 applies. Therefore, the extent of temporal averaging of tissue and water concentrations is typically much less than that required for highly hydrophobic chemicals to which Procedure #1 is applied. In addition, field studies used to calculate BAFs for these chemicals should have sampled water and tissue at similar points in time because tissue concentrations respond more rapidly to changes in water concentrations. EPA will be providing additional guidance on appropriate BAF study designs for nonionic organic chemicals (including those appropriate to Procedure #3) in its forthcoming guidance document on conducting field BAF and BSAF studies.

B. Baseline BAF_{ℓ}^{fd} from a Laboratory-Measured BCF

1. Except where noted below, a baseline BAF_{ℓ}^{fd} should be calculated from a laboratory-measured BCF_{T}^{t} using the guidance and equations outlined in Section 5.4.3.1(c) of Procedure #1.

2. **Food Chain Multipliers.** Because biomagnification is not an overriding concern for the minimally hydrophobic chemicals applicable to Procedure #3, FCMs are not used in the derivation of a baseline BAF_{ℓ}^{fd} from a laboratory-measured BCF_{T}^{t}.

3. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log $K_{ow} < 4.0$), nonionic organic chemicals to which Procedure #3 is applied are expected to remain

almost entirely in the freely dissolved form in waters containing dissolved and particulate organic carbon concentrations typical of laboratory BCF studies. Therefore, the freely dissolved fraction should usually be assumed equal to 1.0. The freely dissolved fraction will be substantially less than 1.0 only in situations where unusually high concentrations of DOC and POC are present in the laboratory BCF study (e.g., above about 100 mg/L for DOC or about 10 mg/L for POC). In this situation, the freely dissolved fraction should be calculated according to Equation 5-12.

C. Baseline BAF_{ℓ}^{fd} from a K_{ow}

1. Except where noted below, a baseline BAF_{ℓ}^{fd} should be calculated from an acceptable K_{ow} using the guidance and equations outlined in Section 5.4.3.1(D) in Procedure #1.

2. Because biomagnification is not an overriding concern for nonionic organic chemicals with low hydrophobicity (i.e., log K_{ow} < 4.0), food chain multipliers are not used in Procedure #3 for deriving the baseline BAF_{ℓ}^{fd} from a K_{ow}.

5.4.5.2 Selecting Final Baseline BAF_{ℓ}^{fd}s

After calculating individual baseline BAF_{ℓ}^{fd}s using as many of the methods in Procedure #3 as possible, the next step is to determine a final baseline BAF_{ℓ}^{fd} for each trophic level from the individual baseline BAF_{ℓ}^{fd}s (Figure 5-2). The final baseline BAF_{ℓ}^{fd} will be used in the last step to determine the national BAF for each trophic level. The final baseline BAF_{ℓ}^{fd} for each trophic level should be determined from the individual baseline BAF_{ℓ}^{fd}s by considering the data preference hierarchy defined by Procedure #3 and uncertainty in the data. The data preference hierarchy for Procedure #3 is (in order of preference):

1. a baseline BAF_{ℓ}^{fd} from an acceptable field-measured BAF or laboratory-measured BCF, or
2. a baseline BAF_{ℓ}^{fd} predicted from an acceptable K_{ow} value.

This data preference hierarchy reflects EPA's preference for BAFs that are based on measured data (field-measured BAFs and laboratory-measured BCFs) over BAFs based on predictive methods (K_{ow}). This data preference hierarchy should be used as a guide for selecting the final baseline BAF_{ℓ}^{fd}s when the uncertainty is similar among two or more baseline BAF_{ℓ}^{fd}s derived using different methods. Since bioaccumulation via dietary uptake and subsequent biomagnification generally are not of concern for chemicals subject to Procedure #3, field-measured BAFs and laboratory-measured BCFs are considered equally in determining the national BAF.

Final baseline BAF_{ℓ}^{fd}s should be selected for each trophic level using the following steps and guidelines.

1. **Calculate Species-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method (i.e., field-measured BAF, BAF from a lab-measured BCF, or BAF from a K_{ow}) where more than one

acceptable baseline BAF_{ℓ}^{fd} is available for a given species, calculate a species-mean baseline BAF_{ℓ}^{fd} according to the guidance described previously in Procedure #1.

2. **Calculate Trophic-Level-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method where more than one acceptable species-mean baseline BAF_{ℓ}^{fd} is available within a given trophic level, calculate the trophic-level-mean baseline BAF_{ℓ}^{fd} as the geometric mean of acceptable species-mean baseline BAF_{ℓ}^{fd}s in that trophic level.

3. **Select a Final Baseline BAF_{ℓ}^{fd} for Each Trophic Level.** For each trophic level, select the final baseline BAF_{ℓ}^{fd} using best professional judgment by considering: (1) the data preference hierarchy, (2) the relative uncertainties among trophic-level-mean baseline BAF_{ℓ}^{fd}s derived using different methods, and (3) the weight of evidence among the three methods.

    a. In general, when more than one trophic-level-mean baseline BAF_{ℓ}^{fd} is available within a given trophic level, the final baseline BAF_{ℓ}^{fd} should be selected from the most preferred BAF method defined by the data preference hierarchy for Procedure #3. Within the first data preference tier, field-measured BAFs and laboratory-measured BCFs are considered equally desirable for deriving a final trophic-level-mean baseline BAF_{ℓ}^{fd} using Procedure #3. If a trophic-level-mean baseline BAF_{ℓ}^{fd} is available from both a field-measured BAF and a laboratory-measured BCF, the final baseline BAF_{ℓ}^{fd} should be selected using the trophic-level-mean baseline BAF_{ℓ}^{fd} or BCF_{ℓ}^{fd} with the least overall uncertainty.

    b. If uncertainty in a trophic-level-mean baseline BAF_{ℓ}^{fd} based on a higher tier (more preferred) method is judged to be substantially greater than a trophic-level-mean baseline BAF_{ℓ}^{fd} from a lower tier method, then the final baseline BAF_{ℓ}^{fd} should be selected using a trophic-level-mean baseline BAF_{ℓ}^{fd} from a lower tier method.

    c. The above steps should be performed for each trophic level until a final baseline BAF_{ℓ}^{fd} is selected for trophic level two, three, and four.

5.4.5.3 Calculating the National BAFs

As described in Procedure #1, the last step in deriving a national BAF for a given trophic level for nonionic organic chemicals is to convert the final baseline BAF_{ℓ}^{fd} determined in the previous step to a BAF that reflect conditions to which the national 304(a) criterion will apply (Figure 5-2). Each national BAF should be determined from a final baseline BAF_{ℓ}^{fd} according to the following guidelines.

1. **National BAF Equation.** Except where noted below, national BAFs for trophic levels two, three, and four should be calculated from the final, trophic-level-mean baseline BAF_{ℓ}^{fd}s using Equation 5-28 and associated guidance described in Procedure #1 (see Section 5.4.3.3).

2. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log K_{ow} < 4.0), a freely dissolved fraction of 1.0 should be assumed for calculating national BAFs for nonionic organic chemicals using Procedure #3. A freely dissolved fraction of 1.0 should be assumed because at a log K_{ow} of less than 4.0, nonionic organic chemicals are expected to remain over 99 percent in the freely dissolved form at POC and DOC concentrations corresponding to national default values for U.S. bodies of water (i.e., 0.5 mg/L and 2.9 mg/L, respectively).

5.4.6 Deriving National BAFs Using Procedure #4

This section provides guidance for calculating national BAFs for nonionic organic chemicals using Procedure #4 shown in Figure 5-1. The types of nonionic organic chemicals for which Procedure #4 is most appropriate are those that are classified as having low hydrophobicity and subject to high rates of metabolism by aquatic biota (see Section 5.4.2 above). Non-aqueous contaminant exposure and subsequent biomagnification in aquatic food webs are not generally of concern for chemicals that are classified in this category. As a result, FCMs are not used in this procedure. In addition, K_{ow} -based predictions of bioconcentration are not used in this procedure since the K_{ow} /BCF relationship is primarily based on poorly metabolized chemicals. One example of a nonionic organic chemical for which Procedure #4 appears appropriate is butyl benzyl phthalate in fish. Using radiolabeling techniques with confirmation by chromatographic analysis, Carr et al. (1997) present evidence that indicates butyl benzyl phthalate is extensively metabolized in sunfish. Carr et al. (1997) also report measured BCFs (and subsequently lipid-normalized BCFs) which are substantially below predicted BCFs based on log $K_{ow.}$ In a study of chlorinated anilines (which would be essentially un-ionized at ambient pH), de Wolf et al. (1992) reported measured BCFs substantially lower than those predicted based on K_{ow}. The authors suggested that biotransformation (metabolism) involving the amine (NH_2) was responsible for the lower measured BCFs.

According to Procedure #4, the following two methods can be used in deriving a national BAF:

- using a BAF from an acceptable field study (i.e., a field-measured BAF), and
- predicting a BAF from an acceptable BCF.

After selecting the derivation procedure, the next steps in deriving a national BAF for a given trophic level for nonionic organic chemicals are: (1) calculating individual baseline BAF_{ℓ}^{fd}s, (2) selecting the final baseline BAF_{ℓ}^{fd}, and (3) calculating the national BAF (Figure 5-2). Each of these three steps is discussed separately below.

5.4.6.1 Calculating Individual Baseline BAF_{ℓ}^{fd}s

Calculating individual baseline BAF_{ℓ}^{fd}s involves normalizing the measured BAF_T^t or BCF_T^t (which are based on the total chemical in water and tissue) by the lipid content of the study organism and the freely dissolved fraction of the chemical in the study water. For additional discussion of the technical basis for calculating baseline BAF_{ℓ}^{fd}s, see Section 5.4.3.1 in Procedure #1.

1. For each species where acceptable data are available, calculate all possible baseline BAF_{ℓ}^{fd}s using each of the two methods shown above for Procedure #4.

2. Individual baseline BAF_{ℓ}^{fd}s should be calculated from field-measured BAF_{T}^{t}s and laboratory-measured BCF_{T}^{t}s according to the following procedures.

A. Baseline BAF_{ℓ}^{fd} from Field-Measured BAFs

1. A baseline BAF_{ℓ}^{fd} should be calculated from a field-measured BAF_{T}^{t} using the guidance and equations outlined in Section 5.4.3.1(A) in Procedure #1.

2. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log K_{ow} < 4.0), nonionic organic chemicals applicable to Procedure #4 are expected to remain almost entirely in the freely dissolved form in natural waters with dissolved and particulate organic carbon concentrations typical of most field BAF studies. Therefore, the freely dissolved fraction should be assumed equal to 1.0 unless the concentrations of DOC and POC are very high in the field BAF study. For studies with very high DOC or POC concentrations, (e.g., about 100 mg/L or higher for DOC or 10 mg/L or higher for POC), the freely dissolved fraction may be substantially lower than 1.0 and therefore should be calculated using Equation 5-12.

3. **Temporal Averaging of Concentrations.** Also due to their low hydrophobicity, nonionic organic chemicals appropriate to Procedure #4 will also tend to reach steady-state quickly compared with those chemicals to which Procedure #1 applies. Therefore, the extent of temporal averaging of tissue and water concentrations is typically much less than that required for highly hydrophobic chemicals to which Procedure #1 is applied. In addition, field studies used to calculate BAFs for these chemicals should have sampled water and tissue at similar points in time because tissue concentrations should respond rapidly to changes in water concentrations. EPA will be providing additional guidance on appropriate BAF study designs for nonionic organic chemicals (including those appropriate to Procedure #4) in its forthcoming guidance document on conducting field BAF and BSAF studies.

B. Baseline BAF_{ℓ}^{fd} from a Laboratory-Measured BCF

1. Except where noted below, a baseline BAF_{ℓ}^{fd} should be calculated from a laboratory-measured BCF_{T}^{t} using the guidance and equations outlined in Section 5.4.3.1(c) of Procedure #1.

2. **Food Chain Multipliers.** Because biomagnification is not an important concern for the minimally hydrophobic chemicals applicable to Procedure #4, FCMs are not used in the derivation of a baseline BAF_{ℓ}^{fd} from a laboratory-measured BCF_{T}^{t}.

3. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log K_{ow} < 4.0), nonionic organic chemicals to which Procedure #4 is applied are expected to remain

almost entirely in the freely dissolved form in waters containing dissolved and particulate organic carbon concentrations typical of laboratory BCF studies. Therefore, the freely dissolved fraction should usually be assumed to be equal to 1.0. The freely dissolved fraction will be substantially less than 1.0 only in situations where unusually high concentrations of DOC and POC are present in the lab BCF study (e.g., above about 100 mg/L for DOC or about 10 mg/L for POC). In this situation, the freely dissolved fraction should be calculated according to Equation 5-12.

5.4.6.2 Selecting Final Baseline BAF_{ℓ}^{fd}s

After calculating individual baseline BAF_{ℓ}^{fd}s using as many of the methods in Procedure #4 as possible, the next step is to determine a final baseline BAF_{ℓ}^{fd} for a given trophic level from the individual baseline BAF_{ℓ}^{fd}s (Figure 5-2). The final baseline BAF_{ℓ}^{fd} will be used in the last step to determine the national BAF for each trophic level. A final baseline BAF_{ℓ}^{fd} should be determined for each trophic level from the individual baseline BAF_{ℓ}^{fd}s by considering the data preference hierarchy defined by Procedure #4 and uncertainty in the data. The data preference hierarchy for Procedure #4 is:

1. a baseline BAF_{ℓ}^{fd} from an acceptable field-measured BAF or predicted from an acceptable laboratory-measured BCF.

Since bioaccumulation via dietary uptake and subsequent biomagnification generally are not of concern for chemicals subject to Procedure #4, field-measured BAFs and laboratory-measured BCFs are considered equally in determining the national BAF.

Final baseline BAF_{ℓ}^{fd}s should be selected for each trophic level using the following steps and guidelines.

1. **Calculate Species-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method (i.e., field-measured BAF or a BAF from a lab-measured BCF) where more than one acceptable baseline BAF_{ℓ}^{fd} is available for a given species, calculate a species-mean baseline BAF_{ℓ}^{fd} according to the guidance described previously in Procedure #1.

2. **Calculate Trophic-Level-Mean Baseline BAF_{ℓ}^{fd}s.** For each BAF method where more than one acceptable species-mean baseline BAF_{ℓ}^{fd} is available within a given trophic level, calculate the trophic-level-mean baseline BAF_{ℓ}^{fd} as the geometric mean of acceptable species-mean baseline BAF_{ℓ}^{fd}s for that trophic level.

3. **Select a Final Baseline BAF_{ℓ}^{fd} for Each Trophic Level.** For each trophic level, select the final baseline BAF_{ℓ}^{fd} using best professional judgment by considering: (1) the data preference hierarchy, and (2) the relative uncertainties among trophic-level-mean BAFs derived using different methods.

    a. As discussed above, field-measured BAFs and laboratory-measured BCFs are considered equally desirable for deriving a final trophic-level-mean baseline

BAF_{ℓ}^{fd} using Procedure #4. If a trophic-level-mean baseline BAF_{ℓ}^{fd} is available from both a field-measured BAF and a laboratory-measured BCF, the final baseline BAF_{ℓ}^{fd} should be selected using the trophic-level-mean baseline BAF_{ℓ}^{fd} or BCF_{ℓ}^{fd} with the least overall uncertainty.

b. The above steps should be performed for each trophic level until a final baseline BAF_{ℓ}^{fd} is selected for trophic levels two, three, and four.

5.4.6.3 Calculating National BAFs

As described in Procedure #1, the last step in deriving a national BAF for a given trophic level for nonionic organic chemicals is to convert the final baseline BAF_{ℓ}^{fd} determined in the previous step to a BAF that reflects conditions to which the national 304(a) criterion will apply (Figure 5-2). Each national BAF should be determined from a final baseline BAF_{ℓ}^{fd} according to the following guidelines.

1. **National BAF Equation.** Except where noted below, national BAFs for trophic-levels two, three, and four should be calculated from the final, trophic-level-mean baseline BAF_{ℓ}^{fd}s using the same equation and procedures described previously in Procedure #1 (see Section 5.4.3.3 in Procedure #1).

2. **Freely Dissolved Fraction**. Due to their low hydrophobicity (i.e., log $K_{ow} < 4.0$), a freely dissolved fraction of 1.0 should be assumed for calculating national BAFs for nonionic organic chemicals using Procedure #4. A freely dissolved fraction of 1.0 should be assumed because at a log K_{ow} value of less than 4.0, nonionic organic chemicals are expected to remain over 99 percent in the freely dissolved form at POC and DOC concentrations corresponding to national default values for U.S. bodies of water (i.e., 0.5 mg/L and 2.9 mg/L, respectively).

5.5 NATIONAL BIOACCUMULATION FACTORS FOR IONIC ORGANIC CHEMICALS

This section contains guidelines for deriving national BAFs for ionic organic chemicals (i.e., organic chemicals which undergo significant ionization in water). As defined in Section 5.3.5, ionic organic chemicals contain functional groups which can either readily donate protons (e.g., organic acids with hydroxyl, carboxylic, and sulfonic groups) or readily accept protons (e.g., organic bases with amino and aromatic heterocyclic nitrogen groups). Some examples of ionic organic compounds include:

- chlorinated phenols (e.g., 2,4,6-trichlorophenol, pentachlorophenol),
- chlorinated phenoxyalkanoic acids (e.g., 2,4-dichlorophenoxyacetic acid [2,4-D]),
- nitrophenols (e.g., 2-nitrophenol, 2,4,6-trinitrophenol),
- cresols (e.g., 2,4-dinitro-*o*-cresol [DNOC]),
- pyridines (e.g., 2,4-dimethypyidine),
- aliphatic and aromatic amines (e.g., trimethylamine, aniline), and

- linear alkylbenzenesulfonate (LAS) surfactants.

Ionic organic chemicals are considered separately for deriving national BAFs because the anionic or cationic species of these chemicals behave much differently in the aquatic environment compared with their neutral (un-ionized) counterparts. The neutral species of ionic organic chemicals are thought to behave in a similar manner as nonionic organic compounds (e.g., partitioning to lipids and organic carbon as a function of hydrophobicity). However, the ionized (cationic, anionic) species exhibit a considerably more complex behavior involving multiple environmental partitioning mechanisms (e.g., ion exchange, electrostatic, and hydrophobic interactions) and a dependency on pH and other factors including ionic strength and ionic composition (Jafvert et al., 1990; Jafvert 1990; Schwarzenbach, et al., 1993). As a consequence, methods to predict the environmental partitioning of organic cations and anions are less developed and validated compared with methods for nonionic organic chemicals (Spacie, 1994; Suffet et al., 1994).

Given the current limitations in the state of the science for predicting the partitioning and bioaccumulation of the ionized species of ionic organic chemicals, procedures for deriving national BAFs for these chemicals differ depending on the extent to which the fraction of the total chemical is likely to be represented by the ionized (cationic, anionic) species in U.S. surface waters. When a significant fraction of the total chemical concentration is expected to be present as the ionized species in water, procedures for deriving the national BAF rely on empirical (measured) methods (i.e., Procedures #5 and 6 in Section 5.6). When an insignificant fraction of the total chemical is expected to be present as the ionized species (i.e., the chemical exists essentially in the neutral form), procedures for deriving the national BAF will follow those established for nonionic organic chemicals (e.g., Procedures #1 through #4 in Section 5.4). The following guidelines apply for assessing the occurrence of cationic and anionic forms at typical environmental pH ranges.

1. For the ionic organic chemical of concern, the dissociation constant, pK_a, should be compared to the range of pH values expected in fresh and estuarine waters of the U.S. At pH equal to the pK_a, 50% of the organic acid or base is expected to be present in the ionized species. The pH values for U.S. fresh and estuarine waters typically range between 6 and 9, although somewhat higher and lower values can occur in some bodies of water (e.g., acidic bogs and lakes, highly alkaline and eutrophic systems, etc.).

2. For organic acids, the chemical will exist almost entirely in its un-ionized form when pH is about 2 or more units below the pK_a. For organic bases, the chemical will exist almost entirely in its un-ionized form when pH is about 2 or more units above the pK_a. In these cases, the aqueous behavior of the chemical would be expected to be similar to nonionic organic chemicals. Therefore, national BAF should usually be derived using Procedures #1 through #4 in Section 5.4.

3. When pH is greater than the pK_a minus 2 for organic acids (or less than the pKa plus 2 for organic bases), the fraction of the total chemical that is expected to exist in its ionized form can become significant (i.e., $\geq$1% in the ionized). In these cases, the national BAF should usually be derived using Procedures #5 and #6 in Section 5.6.

4. In general, most organic acids (e.g., pentachlorophenol and silvex), exist primarily in the ionized form in ambient waters because their pK_a's (4.75 and 3.07, respectively) are much smaller than the pH of the ambient waters. Conversely, most organic bases, (e.g., aniline) exist mostly in the un-ionized form in ambient waters because their pK_a's (4.63 for aniline) are much smaller than the pH of the ambient waters.

5. The above guidelines are intended to be a general guide for deriving national BAFs for ionic organic chemicals, not an inflexible rule. Modifications to these guidelines should be considered on a case-by-case basis, particularly when such modifications are strongly supported by measured bioaccumulation or bioconcentration data. For example, initial models have been developed for predicting the solid and organic-phase partitioning of certain organic acids (e.g., Jafvert 1990, Jafvert et al., 1990). As these or other models become more fully developed and appropriately validated in the future, they should be considered in the development of national BAFs. In addition, since pH is a controlling factor for dissociation and subsequent partitioning of ionic organic chemicals, consideration should be given to expressing BAFs or BCFs as a function of pH (or other factors) where sufficient data exist to reliably establish such relationships.

5.6 NATIONAL BIOACCUMULATION FACTORS FOR INORGANIC AND ORGANOMETALLIC CHEMICALS

This section contains guidelines for deriving national BAFs for inorganic and organometallic chemicals as defined in Section 5.3.5. The derivation of BAFs for inorganic and organometallic chemicals differs in several ways from procedures for nonionic organic chemicals. First, lipid normalization of chemical concentrations in tissues does not generally apply for inorganic and organometallic chemicals. Thus, BAFs and BCFs cannot be extrapolated from one tissue to another based on lipid-normalized concentrations as is done for nonionic organic chemicals. Second, the bioavailability of inorganics and organometallics in water tends to be chemical-specific and thus, the techniques for expressing concentrations of nonionic organic chemicals based on the freely dissolved form do not generally apply. Third, at the present time there are no generic bioaccumulation models that can be used to predict BAFs for inorganic and organometallic chemicals as a whole, unlike the existence of K_{ow}-based models for nonionic organic chemicals. While some chemical-specific bioaccumulation models have been developed for inorganic and organometallic chemicals (e.g., Mercury Cycling Model by Hudson et. al, 1994), those models currently tend to require site-specific data for input to the model and are restricted to site-specific applications. As the models become more fully developed and validated in the future, they should be considered on a case-by-case basis in conjunction with the following procedures for deriving national BAFs.

5.6.1 Selecting the BAF Derivation Procedure

As shown in Figure 5-1, national BAFs can be derived using two procedures for inorganic and organometallic chemicals (Procedures #5 and #6). The choice of the BAF derivation procedure depends on whether or not the chemical undergoes biomagnification in aquatic food webs.

1. For many inorganic and organometallic chemicals, biomagnification does not occur and the BCF will be equal to the BAF. For these types of chemicals, Procedure #5 should be used to derive the national BAF. Procedure #5 considers BAFs and BCFs to be of equal value in determining the national BAF and does not require the use of FCMs with BCF measurements. Guidance for deriving BAFs using Procedure #5 is provided in Section 5.6.3.

2. For some inorganic and organometallic chemicals (e.g., methylmercury), biomagnification does occur and Procedure #6 should be used to determine the national BAF. Procedure #6 gives general preference to the use of field-measured BAFs over laboratory-measured BCFs and requires FCMs to be used with BCF measurements for predicting BAFs. Guidance for deriving BAFs using Procedure #6 is provided in Section 5.6.4.

3. Determining whether or not biomagnification occurs for inorganic and organometallic chemicals requires chemical-specific data on measured concentrations of the chemical in aquatic organisms and their prey. Concentrations in aquatic organisms that increase substantially at successive trophic levels of a food web suggest that biomagnification is

occurring. Concentrations in aquatic organisms that remain about the same or decrease at successive trophic levels of a food web suggest that biomagnification is not occurring. When comparing tissue concentrations for assessing biomagnification, care should be taken to ensure that the aquatic organisms chosen actually represent functional predator-prey relationships and that all major prey species are considered in the comparisons.

5.6.2 Bioavailability

The chemical-specific nature of inorganic and organometallic bioavailability is likely due in part to chemical-specific differences in several factors which affect bioavailability and bioaccumulation. These factors include differences in the mechanisms for chemical uptake by aquatic organisms (e.g., passive diffusion, facilitated transport, active transport), differences in sorption affinities to biotic and abiotic ligands, and differences in chemical speciation in water. Some inorganic and organometallic chemicals exist in multiple forms and valence states in aquatic ecosystems that can differ in their bioavailability to aquatic organisms and undergo conversions between forms. For example, selenium can exist in various forms in aquatic ecosystems, including inorganic selenite($^{+4}$) and selenate($^{+6}$) oxyanions, elemental selenium (^{0}) under reducing conditions (primarily in sediments), and organoselenium compounds of selenide ($^{-2}$). Dominant forms of mercury in natural, oxic waters include inorganic ($^{+2}$) mercury compounds and methylmercury; the latter is generally considered to be substantially more bioavailable than inorganic mercury compounds to higher trophic level organisms. Although a generic analogue to the "freely dissolved" conversion for nonionic organic chemicals does not presently exist for inorganic and organometallic chemicals as a whole, the occurrence and bioavailability of different forms of these chemicals should be carefully considered when deriving national BAFs.

1. If data indicate that: (1) a particular form (or multiple forms) of the chemical of concern largely governs its bioavailability to target aquatic organisms, and (2) BAFs are more reliable when derived using the bioavailable form(s) compared with using other form(s) of the chemical of concern, then BAFs and BCFs should be based on the appropriate bioavailable form(s).

2. Because different forms of many inorganic and organometallic chemicals may interconvert once released to the aquatic environment, regulatory and mass balance considerations typically require an accounting of the total concentration in water. In these cases, sufficient data should be available to enable conversion between total concentrations and the other (presumably more bioavailable) forms in water.

5.6.3 Deriving BAFs Using Procedure #5

This section contains guidance for calculating national BAFs for inorganic and organometallic chemicals using Procedure #5 as shown in Figure 5-1. The types of inorganic and organometallic chemicals for which Procedure #5 is appropriate are those that are not likely to biomagnify in aquatic food webs (see Section 5.1 above). In Procedure #5, two methods are available to derive the national BAF for a given trophic level:

- using a BAF from an acceptable field study (i.e., field-measured BAF), or
- predicting a BAF from an acceptable laboratory-measured BCF.

Individual BAFs should be determined from field-measured BAFs or laboratory-measured BCFs according to the following guidelines.

5.6.3.1 Determining Field-Measured BAFs

1. Except where noted below, field-measured BAFs should be determined using the guidance provided in Section 5.4.3.1(A) of Procedure #1.

2. As described previously, conversion of field-measured BAFs to baseline BAF_{ℓ}^{fd}s based on lipid-normalized and freely-dissolved concentrations does not apply for inorganic and organometallic chemicals. Therefore, the guidance and equations provided in Procedure #1 which pertain to converting field-measured BAFs to baseline BAF_{ℓ}^{fd}s and subsequently to national BAFs do not generally apply to inorganic chemicals. As discussed in Section 5.6.2 above, an analogous procedure in concept might be required for converting total BAFs to BAFs based on the most bioavailable form(s) for some inorganic and organometallic chemicals of concern. Such procedures should be applied on a chemical-specific basis.

3. BAFs should be expressed on a wet-weight basis; BAFs reported on a dry-weight basis can be used only if they are converted to a wet-weight basis using a conversion factor that is measured or reliably estimated for the tissue used in the determination of the BAF.

4. BAFs should be based on concentrations in the edible tissue(s) of the biota unless it is demonstrated that whole-body BAFs are similar to edible tissue BAFs. For some finfish and shellfish species, whole body is considered to be the edible tissue.

5. The concentrations of an inorganic or organometallic chemical in a bioaccumulation study should be greater than normal background levels and greater than levels required for normal nutrition of the test species if the chemical is a micronutrient, but below levels that adversely affect the species. Bioaccumulation of an inorganic or organometallic chemical that is essential to the nutrition of aquatic organisms might be overestimated if concentrations are at or below normal background levels due to selective accumulation by the organisms to meet their nutritional requirements.

5.6.3.2 Determining Laboratory-Measured BCFs

1. Except where noted below, BAFs should be predicted from laboratory-measured BCFs using the guidance provided in Section 5.4.3.1(c) of Procedure #1.

2. As described previously, conversion of laboratory-measured BCFs to baseline BCF_{ℓ}^{fd}s based on lipid-normalized and freely dissolved concentrations does not apply for inorganic and organometallic chemicals. Therefore, the guidance and equations provided in Procedure #1 which pertain to converting laboratory-measured BCFs to baseline BCF_{ℓ}^{fd}s and subsequently to national BCFs do not generally apply to inorganic and organometallic chemicals. As discussed in Section 5.6.2 above, an analogous procedure in concept might be required for converting total BCFs to BCFs based on the most bioavailable form(s) of some inorganic and organometallic chemicals of concern. Such procedures should be applied on a chemical-specific basis. In addition, the use of FCMs with BCFs does not apply to chemicals applicable to Procedure #5.

3. BCFs should be expressed on a wet-weight basis; BCFs reported on a dry-weight basis can be used only if they are converted to a wet-weight basis using a conversion factor that is measured or reliably estimated for the tissue used in the determination of the BCF.

4. BCFs should be based on concentrations in the edible tissue(s) of the biota unless it is demonstrated that whole-body BCFs are similar to edible tissue BCFs. For some finfish and shellfish species, whole body is considered to be the edible tissue.

5. The concentrations of an inorganic or organometallic chemical in a bioconcentration test should be greater than normal background levels and greater than levels required for normal nutrition of the test species if the chemical is a micronutrient, but below levels that adversely affect the species. Bioaccumulation of an inorganic or organometallic chemical that is essential to the nutrition of aquatic organisms might be overestimated if concentrations are at or below normal background levels due to selective accumulation by the organisms to meet their nutritional requirements.

5.6.3.3 Determining the National BAFs

After calculating individual BAFs using as many of the methods in Procedure #5 as possible, the next step is to determine national BAFs for each trophic level from the individual BAFs. The national BAFs will be used to determine the national 304(a) criteria. The national BAFs should be determined from the individual BAFs by considering the data preference hierarchy defined for Procedure #5 and uncertainty in the data. The data preference hierarchy for Procedure #5 is:

1. a BAF from an acceptable field-measured BAF or predicted from an acceptable laboratory-measured BCF.

Since bioaccumulation via dietary uptake and subsequent biomagnification are not of concern for chemicals subject to Procedure #5, field-measured BAFs and laboratory-measured

BCFs are considered equally in determining the national BAFs. The national BAFs should be selected for each trophic level using the following steps and guidelines.

1. **Calculate Species-Mean BAFs.** For each BAF method where more than one acceptable field-measured BAF (or a BAF predicted from a BCF) is available for a given species, calculate the species-mean BAF as the geometric mean of all acceptable individual measured or BCF-predicted BAFs. When calculating species-mean BAFs, individual measured or BCF-predicted BAFs should be reviewed carefully to assess uncertainties in the BAF values. Highly uncertain BAFs should not be used. Large differences in individual BAFs for a given species (e.g., greater than a factor of 10) should be investigated further and in such cases, some or all of the BAFs for a given species might not be used. Additional discussion on evaluating the acceptability of BAF and BCF values is provided in the Bioaccumulation TSD.

2. **Calculate Trophic-Level-Mean BAFs.** For each BAF method where more than one acceptable species-mean BAF is available within a given trophic level, calculate the trophic-level-mean BAF as the geometric mean of acceptable species-mean BAFs in that trophic level. Trophic-level-mean BAFs should be calculated for trophic levels two, three and four because available data on U.S. consumers of fish and shellfish indicate significant consumption of organisms in these trophic levels.

3. **Select a Final National BAF for Each Trophic Level.** For each trophic level, select the final national BAF using best professional judgment by considering: (1) the data preference hierarchy in Procedure #5, and (2) the relative uncertainties among trophic level-mean BAFs derived using different methods.

    a. As discussed above, field-measured BAFs and laboratory-measured BCFs are considered equally desirable for deriving a final national BAF using Procedure #5. If a trophic-level-mean BAF is available from both a field-measured BAF and a laboratory-measured BCF, the final national BAF should be selected using the trophic-level-mean BAF with the least overall uncertainty.

    b. The above steps should be performed for each trophic level until a national BAF is selected for trophic levels two, three, and four.

5.6.4 Deriving BAFs Using Procedure #6

This section contains guidance for calculating national BAFs for inorganic and organometallic chemicals using Procedure #6 as shown in Figure 5-1. The types of inorganic and organometallic chemicals for which Procedure #6 is appropriate are those that are considered likely to biomagnify in aquatic food webs (see Section 5.6.1 above). Methylmercury is an example of an organometallic chemical to which Procedure #6 applies. In Procedure #6, two methods are available to derive the national BAF:

- using a BAF from an acceptable field study (i.e., field-measured BAF), or

- predicting a BAF from an acceptable laboratory-measured BCF and a FCM.

Individual BAFs should be determined from field-measured BAFs or laboratory-measured BCFs and FCMs according to the following guidelines.

5.6.4.1 Determining Field-Measured BAFs

1. Field-measured BAFs should be determined using the guidance provided in Section 5.6.3.1 of Procedure #5.

5.6.4.2 Determining Laboratory-Measured BCFs

1. Except where noted below, BAFs should be predicted from laboratory-measured BCFs using the guidance provided in Section 5.6.3.2 of Procedure #5.

2. Because biomagnification is of concern for chemicals applicable to Procedure #6, BAFs should be predicted from laboratory-measured BCF using FCMs. Currently, there are no generic models from which to predict FCMs for inorganic or organometallic chemicals. Therefore, FCMs should be determined using field data as described in the section entitled: "Field-Derived FCMs" in Section 5.4.3.1(c) of Procedure #1. Unlike nonionic organic chemicals, field-derived FCMs for inorganic and organometallic chemicals are not based on lipid-normalized concentrations in tissues. For calculating FCMs for inorganic and organometallic chemicals, concentrations in tissues should be based on the consistent use of either wet-weight or dry-weight concentrations in edible tissues. FCMs should be derived for trophic levels two, three, and four.

5.6.4.3 Determining the National BAF

After calculating individual BAFs using as many of the methods in Procedure #6 as possible, the next step is to determine national BAFs for each trophic level from the individual BAFs. The national BAFs will be used to determine the national 304(a) criteria. The national BAFs should be determined from the individual BAFs by considering the data preference hierarchy defined for Procedure #6 and uncertainty in the data. The data preference hierarchy for Procedure #6 is (in order of preference):

1. a BAF from an acceptable field-measured BAF, or
2. a predicted BAF from an acceptable laboratory-measured BCF and FCM.

This data preference hierarchy reflects EPA's preference for field-measured BAFs over BAFs predicted from a laboratory-measured BCF and FCM, because field-measured BAFs are direct measures of bioaccumulation and biomagnification in aquatic food webs. BAFs predicted from laboratory-measured BCFs and FCMs indirectly account for biomagnification through the use of the FCM. For each trophic level, the national BAFs should be determined using the following steps and guidelines.

1. **Calculate Species-Mean BAFs.** For each BAF method where more than one acceptable field-measured BAF or BAF predicted using a BCF and FCM is available, calculate a species-mean BAF according to the guidance described previously in Procedure #5.

2. **Calculate Trophic Level-Mean BAFs.** For each BAF method where more than one acceptable species-mean BAF is available within a given trophic level, calculate the trophic level-mean BAF according to guidance described previously in Procedure #5.

3. **Select a Final National BAF for Each Trophic Level.** For each trophic level, select the final national BAF using best professional judgment by considering: (1) the data preference hierarchy in Procedure #6, and (2) the relative uncertainties among trophic level-mean BAFs derived using different methods.

    a. When a trophic-level mean BAF is available using both methods for a given trophic level (i.e., a field-measured BAF and a BAF predicted from a BCF and FCM), the national BAF should usually be selected using the field-measured BAF which is the preferred BAF method in the data preference hierarchy in Procedure #6.

    b. If uncertainty in the trophic-level mean BAF derived using field-measured BAFs is considered to be substantially greater than a trophic-level mean BAF derived using a BCF and FCM, the national BAF for that trophic level should be selected from the second tier (BCF · FCM) method.

    c. The above steps should be performed for each trophic level until a national BAF is selected for trophic levels two, three, and four.

June 2015

Human Health Ambient Water Quality Criteria: 2015 Update

Summary

EPA published final updated ambient water quality criteria for the protection of human health for 94 chemical pollutants. These updated recommendations reflect the latest scientific information and EPA policies, including updated body weight, drinking water consumption rate, fish consumption rate, bioaccumulation factors, health toxicity values, and relative source contributions. EPA accepted written scientific views from the public from May to August 2014 on the draft updated human health criteria and has published responses to those comments. EPA water quality criteria serve as recommendations to states and tribes authorized to establish water quality standards under the Clean Water Act.

Background

Ambient water quality criteria developed by EPA under Clean Water Act section 304(a) represent specific levels of chemicals or conditions in a water body that are not expected to cause adverse effects to human health. EPA is required to develop and publish water quality criteria that reflect the latest scientific knowledge. These criteria are not rules, nor do they automatically become part of a state's water quality standards. States may adopt the criteria that EPA publishes, modify EPA's criteria to reflect site-specific conditions, or adopt different criteria based on other scientifically-defensible methods. EPA must, however, approve any new water quality standards adopted by a state before they can be used for Clean Water Act purposes.

In this 2015 update, EPA revised 94 of the existing human health criteria to reflect the latest scientific information, including updated exposure factors (body weight, drinking water consumption rates, fish consumption rate), bioaccumulation factors, and toxicity factors (reference dose, cancer slope factor). The criteria have also been updated to follow the current EPA methodology for deriving human health criteria (USEPA 2000). EPA also developed chemical-specific science documents for each of the 94 chemical pollutants. The science documents detail the latest scientific information supporting the updated final human health criteria, particularly the updated toxicity and exposure input values. Specific updates are described below.

Due to outstanding technical issues, EPA did not update human health criteria for the following chemical pollutants at this time: antimony, arsenic, asbestos, barium, beryllium, cadmium, chromium (III or VI), copper, manganese, methylmercury, nickel, nitrates, nitrosamines, N-nitrosodibutylamine, N-nitrosodiethylamine, N-nitrosopyrrolidine, N-nitrosodimethylamine, N-nitrosodi-n-propylamine, N-nitrosodiphenylamine, polychlorinated biphenyls (PCBs), selenium, thallium, zinc, or 2,3,7,8-TCDD (dioxin).

It is important for states and authorized tribes to consider any new or updated section 304(a) criteria as part of their triennial review to ensure that state or tribal water quality standards reflect current science and protect applicable designated uses. EPA recently proposed revisions to its water quality

standards regulations that would, if finalized without substantive change, require states during their triennial reviews to consider new or updated section 304(a) recommended criteria and, if they do not adopt new or revised criteria for such pollutants, provide an explanation to EPA as to why the state did not do so. These final updated human health criteria recommendations supersede EPA's previous recommendations.

Updated Exposure Inputs

Body Weight

EPA updated the default body weight for human health criteria to 80 kilograms based on National Health and Nutrition Examination Survey (NHANES) data from 1999 to 2006 (USEPA 2011). This represents the mean body weight for adults ages 21 and older. EPA's previously recommended default body weight was 70 kilograms, which was based on the mean body weight of adults from the NHANES III database (1988-1994).

Drinking Water

EPA updated the default drinking water consumption rate to 2.4 liters per day based on NHANES data from 2003 to 2006 (USEPA 2011). This represents the per capita estimate of community water ingestion at the 90th percentile for adults ages 21 and older. EPA previously recommended a default drinking water consumption rate of 2 liters per day, which represented the per capita community water ingestion rate at the 86th percentile for adults surveyed in the US Department of Agriculture's 1994-1996 Continuing Survey of Food Intake by Individuals (CSFII) analysis and the 88th percentile of adults in the National Cancer Institute study of the 1977-1978 Nationwide Food Consumption Survey.

Fish Consumption

EPA updated the default fish consumption rate to 22 grams per day. This rate represents the 90th percentile consumption rate of fish and shellfish from inland and nearshore waters for the U.S. adult population 21 years of age and older, based on NHANES data from 2003 to 2010 (USEPA 2014). EPA's previously recommended rate of 17.5 grams per day was based on the 90th percentile consumption rate of fish and shellfish from inland and nearshore waters for the U.S. adult population and was derived from 1994-1996 CSFII data.

As described in EPA's human health criteria methodology (USEPA 2000), the level of fish consumption in highly exposed populations varies by geographical location. Therefore, EPA suggests a four preference hierarchy for states and authorized tribes that encourages use of the best local, state, or regional data available to derive fish consumption rates. EPA recommends that states and authorized tribes consider developing criteria to protect highly exposed population groups and use local or regional data in place of a default value as more representative of their target population group(s). The preferred hierarchy is: (1) use of local data; (2) use of data reflecting similar geography/ population groups; (3) use of data from national surveys; and (4) use of EPA's default consumption rates.

Bioaccumulation Factors

EPA's methodology for deriving human health criteria emphasizes using, when possible, measured or estimated bioaccumulation factors (BAFs), which account for chemical accumulation in aquatic organisms from all potential exposure routes (USEPA 2000). Unlike bioconcentration factors, BAFs account for more exposure pathways than direct water contact. As a result, the updated criteria will better represent exposures to pollutants that affect human health. In order to account for the variation in bioaccumulation that is due to trophic position of the organism, EPA's methodology (USEPA 2000) recommends that BAFs be determined and applied to three trophic levels of fish.

EPA selected BAFs using a framework for deriving national trophic level-specific BAFs (USEPA 2000; USEPA 2003). EPA used field-measured BAFs and laboratory-measured bioconcentration factors available from peer-reviewed, publicly available databases to develop national BAFs. If this information was not available, EPA selected octanol-water partition coefficients (Kow values) from peer-reviewed sources for use in calculating national BAFs. As an additional line of evidence, EPA reported model-estimated BAFs for every chemical based on

the Estimation Program Interface (EPI) Suite (USEPA 2012) to support the field-measured or predicted BAFs.

Updated Health Toxicity Values

EPA considered all available toxicity values for both noncarcinogenic and carcinogenic toxicological effects to develop the updated human health criteria. EPA's Integrated Risk Information System (IRIS) was the primary source for reference dose and cancer slope factors for this update. For some pollutants, however, more recent toxicity assessments were provided by EPA's Office of Water, EPA's Office of Pesticide Programs, and international or state agencies. EPA followed a systematic process to search for and select the toxicity values used to derive the final updated human health criteria for noncarcinogenic and carcinogenic effects.

Relative Source Contribution

EPA updated the human health criteria to reflect chemical-specific relative source contributions (RSC) ranging from 20 to 80 percent following the Exposure Decision Tree approach described in EPA's methodology (USEPA 2000). EPA recommends inclusion of an RSC when developing human health criteria for threshold non-carcinogens or non-linear carcinogens. The RSC allows a percentage of the reference dose's exposure to be attributed to ambient water and fish consumption (including fish and shellfish from inland and nearshore waters) when there are other potential exposure sources. The rationale for this approach is that the objective of the water quality criteria is to ensure that an individual's total exposure from all sources does not exceed the criteria. Exposures outside of the RSC include, but are not limited to, exposure to a particular pollutant from ocean fish consumption (not included in the fish consumption rate), non-fish food consumption (meats, poultry, fruits, vegetables, and grains), dermal exposure, and respiratory exposure.

Where can I find more information?

To access the Federal Register notice, the final updated criteria, and supporting documents visit EPA's National Recommended Human Health Criteria website at: http://water.epa.gov/scitech/swguidance/standards/criteria/health/.

This report is the product of the efforts of many people. The Seafood Consumption Task Force guided this study through its many challenging phases, and its members' contributions are gratefully acknowledged. We greatly appreciate the numerous comments and suggestions from many reviewers and the efforts by key Regional Monitoring Program participants in helping develop communication tools to disseminate important study results.

San Francisco Bay
Seafood Consumption Study

I. Background/Goals

A. Overview

Elevated levels of mercury and organochlorine compounds in fish from San Francisco Bay have raised public concern regarding potential health risks to those who catch and consume fish from the Bay. In response to this concern, the Regional Monitoring Program for Trace Substances (RMP) decided to conduct a comprehensive Seafood Consumption Study of people who catch and consume fish and shellfish from the Bay. The San Francisco Estuary Institute (SFEI), which administers the RMP, contracted with the Environmental Health Investigations Branch (EHIB) of the California Department of Health Services and Impact Assessment, Inc. to conduct this study. Information gathered through the study will be used to assess anglers' exposures to chemicals from eating Bay fish and to identify highly exposed populations. Additionally, the findings will provide information for improving outreach and education to different segments of the fishing population and for guiding contaminant studies to monitor fish that people consume.

B. Study Area

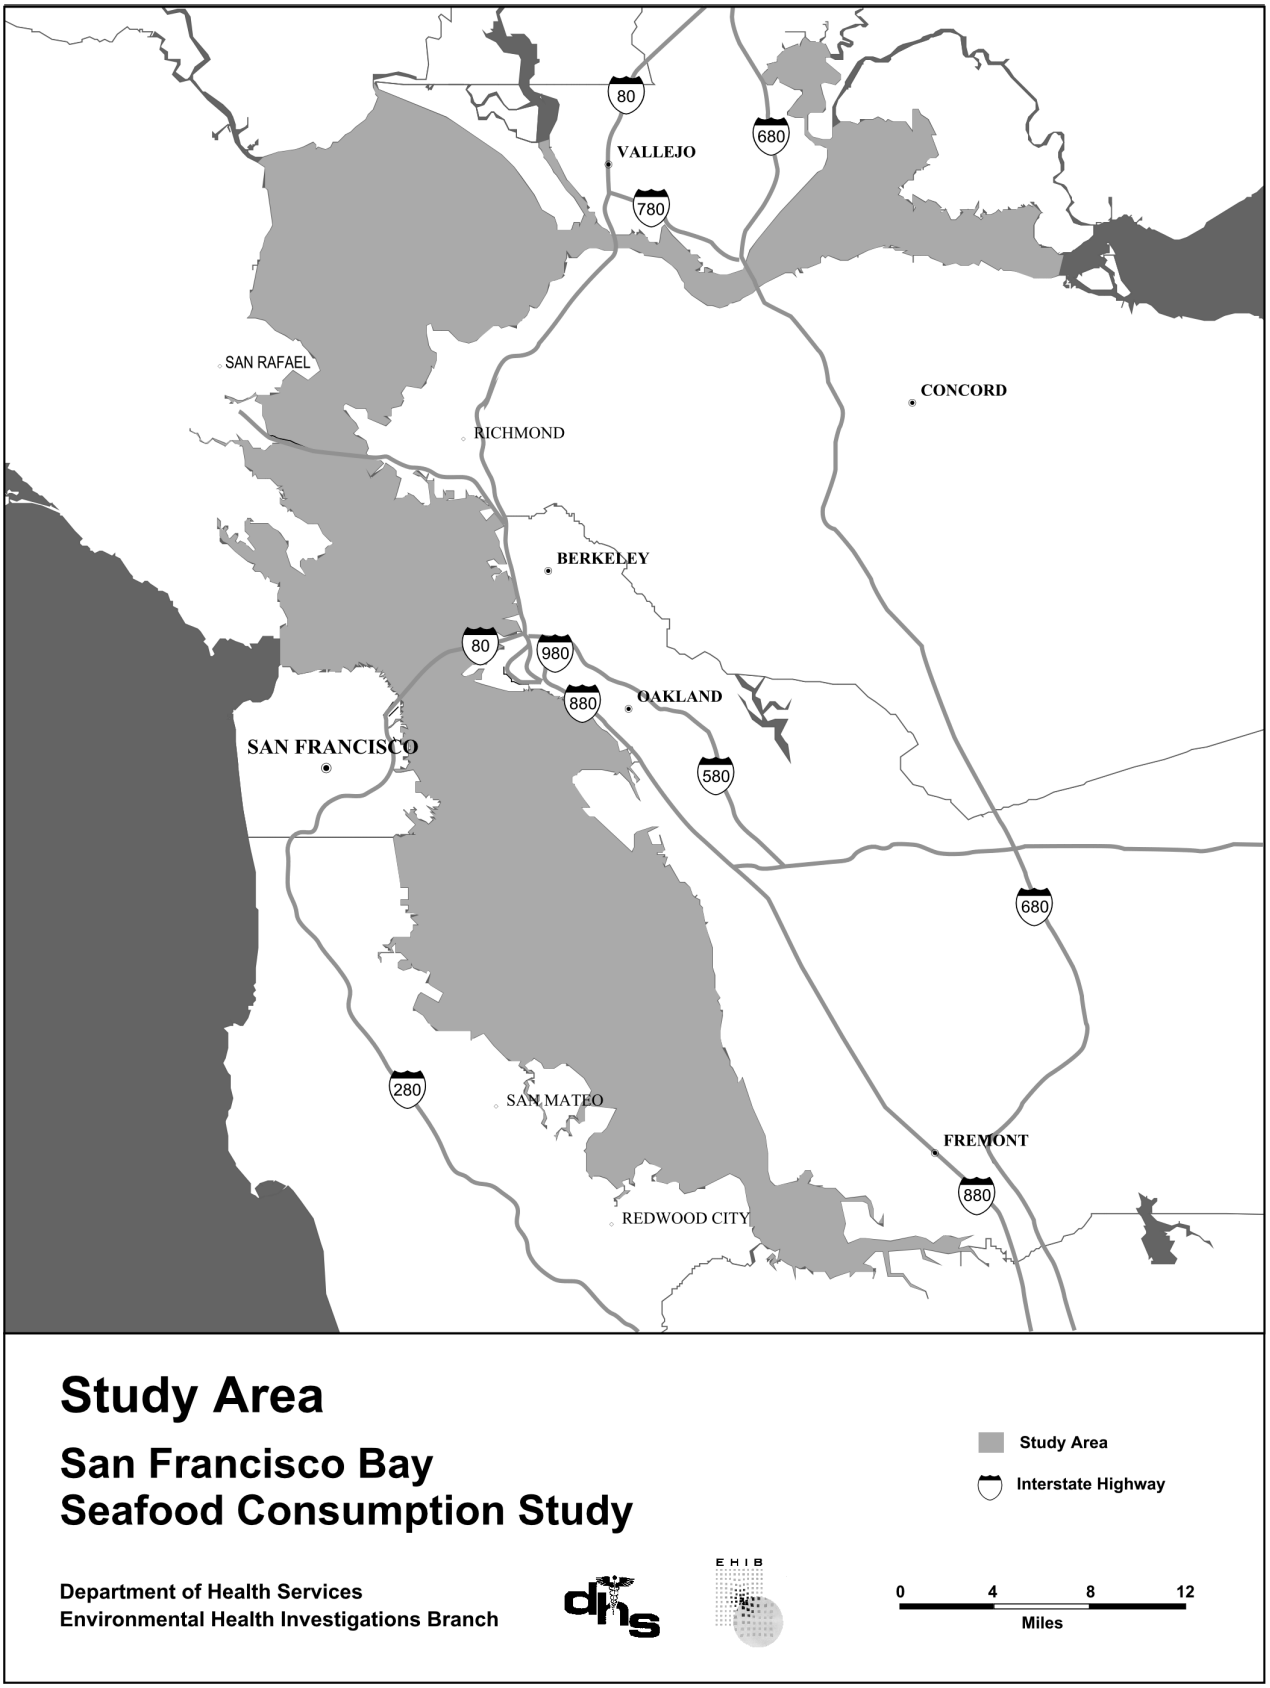
San Francisco Bay (SF Bay) is an important recreational fishing area in California. The Bay covers 478 square miles (marine and estuarine waters) and the nine counties bordering the Bay support a population of over six million (ABAG 2000, CDOF 2000). The study area was defined to include the San Francisco Bay within the Golden Gate Bridge, including San Pablo Bay in the north (see Figure 1). To the east, the study area included the Carquinez Straits and Suisun Bay to Chipps Island (near the city of Pittsburg).

C. Study Justification

Nationwide, there is increasing analytical evidence and growing public concern that fish and shellfish caught and consumed by anglers may contain chemical contaminants that pose health risks (USEPA 1998). To quantify these risks, contaminant levels in fish and the consumption patterns of the fishing population must be understood. To date the Santa Monica Bay Study (Allen *et al.*1996, SCCWRP/MBC 1994) of a Los Angeles area population has provided the best available data set for estimating consumption of sport fish in a California population (Gassel 1997). However, the United States Environmental Protection Agency (USEPA 1998) recommends using or collecting data on regional consumption patterns and population characteristics in order to estimate exposure for the local population(s) of concern. Although several studies have begun to characterize levels of contaminants known to pose health risks in Bay fish (SFEI 1999, SFRWQCB 1995), information that describes the consumption patterns of Bay anglers has been more limited and mostly focused on selected populations (Karras 1998, Ujihara 1997, Wong *et al.*1997, Cohen 1995, EHIB 1994). Consumption patterns include the quantity of fish consumed over time, the species and the parts of the fish consumed, and the preparation and cooking methods used.

Furthermore, little is known about the demographic characteristics of the people who eat Bay fish and how well they understand health advisories for SF Bay fish. Demographic information is needed so that health advisories on fish may be communicated appropriately and effectively. Gathering both consumption and demographic information from people fishing in San Francisco Bay will enable outreach and educational efforts to target populations facing the highest health risks. Because comprehensive data on fish consumption patterns of SF Bay anglers did not exist, we undertook this study to provide this information.

Figure 1. Study Area



D. Goals and Objectives of the San Francisco Bay Seafood Consumption Study

Goals:

1. To gather quantitative data that can be used to characterize exposures of the general fishing population of San Francisco Bay to chemical contaminants from consumption of Bay-caught fish and shellfish
2. To identify highly exposed fish and shellfish consuming sub-populations
3. To gather information needed to develop educational messages for targeted sub-populations

Objectives:

1. Develop estimates of exposure assessment parameters (fish and shellfish consumption, frequency, duration of exposure, and portion size) for San Francisco Bay anglers
2. Characterize pier, boat, and shore fishing populations by age, sex, income, ethnic composition, education, mode of fishing, and consumption rates
3. Characterize consumption of fish tissues other than muscle, such as skin and organs, and preparation/cooking methods
4. Determine which species are most commonly consumed; assess frequency of consumption of white croaker, striped bass, and leopard shark
5. Characterize what people do with the fish they catch and the shellfish they harvest (e.g., release it, eat it themselves, share it with family or friends, etc.)
6. Characterize seasonal variation in consumption and demographics
7. Characterize frequency of consumption of fish from stores and markets, and of fish and shellfish obtained from fishing outside of San Francisco Bay (including freshwater and marine locations)
8. Assess awareness of current health advisories and changes in behavior as a result of awareness (e.g., decreased consumption)
9. Identify how people currently are informed about advisories and their preferred mechanisms for obtaining information
10. Identify anglers' reasons for catching and consuming fish and shellfish
11. Determine whether anglers think the term "sportfish" refers to the fish they catch from San Francisco Bay

E. Previous and Ongoing Studies and Outreach Activities

In 1994, the San Francisco Bay Regional Water Quality Control Board (Regional Board) conducted a pilot study to determine the levels of chemicals found in fish commonly caught in San Francisco Bay (SFBRWQCB 1995). Over 100 chemicals were measured, but only six (mercury, polychlorinated biphenyls (PCBs), dioxins, dieldrin, chlordane, and DDT) were found in concentrations of potential health concern to people who regularly consume fish from the Bay. Of the eight species of fish sampled, white croaker, commonly referred to as kingfish, had the highest concentrations of organochlorines, while shark and striped bass had the highest concentrations of mercury.

In 1997, the Regional Board and the RMP conducted a follow-up contaminant study of SF Bay fish. The results of this study indicated that persistent toxic chemicals (mercury, PCBs, and other organochlorine compounds) in SF Bay fish remain at levels of human health concern (SFEI 1999). In 1999 the Regional Board and the RMP decided to incorporate monitoring bioaccumulative contaminants in fish tissue into the status and trends monitoring component of the RMP on a three-year cycle. The RMP and the Regional Board are planning additional projects to: 1) develop food web and mass balance models, 2) identify and quantify sources and loadings of mercury and PCBs, and 3) develop implementation plans for the reduction of mercury and PCBs (SFEI 2000).

In response to the results of the Regional Board's 1994 pilot study, the Office of Environmental Health Hazard Assessment (OEHHA) within the California Environmental Protection Agency issued an interim health advisory for SF Bay in 1994 (OEHHA 1994). This advisory replaced an earlier advisory issued in 1972 for SF Bay and the Delta region that recommended limits on striped bass consumption due to mercury contamination. The 1994 interim advisory recommends that adults limit their consumption of most species of fish caught from SF Bay to no more than two meals per month. Pregnant and breastfeeding women, women who may become pregnant, and children under six years of age are advised to eat no more than one meal per month. The health advisory recommends that meal size should be adjusted according to body weight, with roughly 1 ounce of fish per 20 pounds of body weight. Thus, meal size for an adult weighing 154 pounds (70 kg) is considered to be an 8-ounce portion prior to cooking (see Appendix A for the full advisory).

Limited data characterizing fishing populations and their consumption patterns exist for the San Francisco Bay Area. A few small surveys have gathered consumption and demographic data on selected populations at fishing piers or shores (Karras 1998, Ujihara 1997, Wong *et al.* 1997, Cohen 1995, EHIB 1994). A household-based survey of Laotians in Contra Costa County also found that the majority of households had members who fished in the Bay (Chiang 1998). The surveys conducted by Save San Francisco Bay Association and Communities for a Better Environment (Karras 1998, Wong *et al.* 1997, Cohen 1995) suggested that health risks from consumption of San Francisco Bay fish may be quite high for certain populations. Additionally they highlighted the need for expanded outreach and education to certain populations. However, the restricted scope of these surveys limits their usefulness for characterizing exposures of the overall fish-consuming population in SF Bay.

A 1991-92 survey, commonly referred to as the Santa Monica Bay Study, provided detailed consumption data for the population fishing in the marine waters of the Los Angeles area, namely the Santa Monica Bay, Palos Verdes Peninsula, and Los Angeles/Long Beach Harbor areas (Allen *et al.*1996, SCCWRP/MBC 1994). OEHHA has recommended using the distribution of consumption rates derived from the Santa Monica Bay Study as default values for California fishing populations when local consumption data are not available (Gassel 1997). However, due to differences in the types of fish commonly caught, the ethnic composition of the population, and other factors, the Santa Monica Bay Study results may not accurately characterize the SF Bay fishing population.

An ongoing survey, the Marine Recreational Fishery Statistics Survey (MRFSS), which in California is implemented by the Pacific States Marine Fisheries Commission for the National Marine Fisheries Service, covers a broad range of fishing activity and focuses on the species and quantity of fish caught by sport anglers. No consumption data are collected and only limited demographic information is obtained for the fishing population (NOAA/PSMFC 1997, Karpov *et al.* 1995).

With respect to outreach and education activities, in 1993, OEHHA originally convened the Education and Outreach Task Force on Fish Consumption and Fish Contamination Issues. The task force was initiated in response to concerns raised by environmental and community groups about the

lack of accessible information to anglers on health advisories in SF Bay. In particular, concerns focused on the lack of posted signs, lower literacy educational materials, and education and outreach materials in languages other than English. In 1997, EHIB assumed responsibility for coordinating the Education and Outreach Task Force on Fish Consumption and Fish Contamination Issues. The Task Force members currently include individuals representing environmental and community groups, and local, county, and state agencies (see Appendix B). A variety of educational activities has been conducted by Task Force members, including presentations to adult groups taking English as a second language classes, fish cleaning and cooking demonstrations, creating displays for community fairs, and development and distribution of signs, informational brochures, and postcards with health advisory information available in multiple languages. In particular, Save San Francisco Bay Association's Seafood Consumption Information Project conducted extensive outreach and education activities prior to the implementation of the SF Bay Seafood Consumption Study (Wong *et al.* 1997). OEHHA has also translated the SF Bay advisory into Chinese, Vietnamese, Korean, Cambodian, and Spanish, and developed other educational materials. In 1995, OEHHA staff conducted a survey to assess sign effectiveness and angler awareness at Berkeley Pier (Russell *et al.*1997). To date, Task Force members have arranged for signs publicizing the health advisory to be posted at 21 fishing sites.

II. Study Design, Implementation, and Management

A. Study Administration and Staff

The RMP formed a Seafood Consumption Advisory Task Force to provide technical support and to review all aspects of the study. The Task Force originated as a subgroup of the RMP's Fish Contamination Committee that provided technical support for designing and implementing fish sampling and contamination studies. Extensive efforts were made to expand the Task Force's membership to include all interested parties in the planning of the study, such as angler groups, environmental organizations, and community groups. Unfortunately, time and resource constraints limited the full participation of some of these groups. Members of the Task Force included representatives from federal, state, and local governmental agencies, academic institutions, environmental organizations, fishing groups, and industry groups (see Appendix C).

Project staff and Task Force members expended considerable time and effort to develop a study design that would allow for the study objectives to be met and also allow for the study to be carried out within the allocated budgetary resources. Project staff reviewed materials available from the United States Environmental Protection Agency (USEPA 1992), the American Fisheries Society (Pollock 1994), and methods and information available from other angler studies. These mainly included studies of SF Bay anglers (Ujihara 1997, Wong *et al.* 1997), the MRFS Survey (NOAA/PSMFC 1997), and the Santa Monica Bay Study (SCCWRP/MBC 1994). Project staff also consulted with recognized experts in areas such as biostatistics, survey design, questionnaire development, and fisheries management. During the study design phase (October 1997 through June 1998), Task Force members reviewed all study protocols and materials developed by project staff.

During the study implementation and data collection phase (July 1998 through June 1999), project staff provided progress reports and preliminary data to Task Force members on a regular basis. From July 1999 through December 2000 (data analysis and report generation phase), Task Force members also reviewed data analysis methods and drafts of this report.

The study was primarily conducted under the direction of staff within the Environmental Health Investigations Branch (EHIB) of the California Department of Health Services. None of the state staff were supported with contract funds. Contract funds were used to support a community relations coordinator (10% FTE), a graphic artist (5% FTE), a team of interviewers, and a half-time field coordinator. A research specialist conducted data analysis after all field data collection activities were completed.

Ten field interviewers were hired beginning in May 1998. They included five Spanish-speaking field interviewers, two Vietnamese-speaking interviewers, and two Chinese (Cantonese and Mandarin) speaking interviewers. One solely English-speaking interviewer had previous experience interviewing party boat anglers and was hired to conduct interviews of party boat anglers. The RMP also allocated a staff person who was solely English speaking to serve as a back-up interviewer when none of the regular interviewer staff were available.

Orientation and training of field interviewers occurred during May and June 1998 and included visits to all sampling sites. Interviewers practiced administering the questionnaire initially with project staff and in the field at sites not included in the sampling plan.

B. Sampling Plan

In order to derive exposure estimates applicable to the overall population of SF Bay anglers, we developed a sampling plan that would allow us to interview a representative sample of all anglers fishing in SF Bay. The key elements of our sampling plan are described below. A more detailed description is also provided in Appendix D.

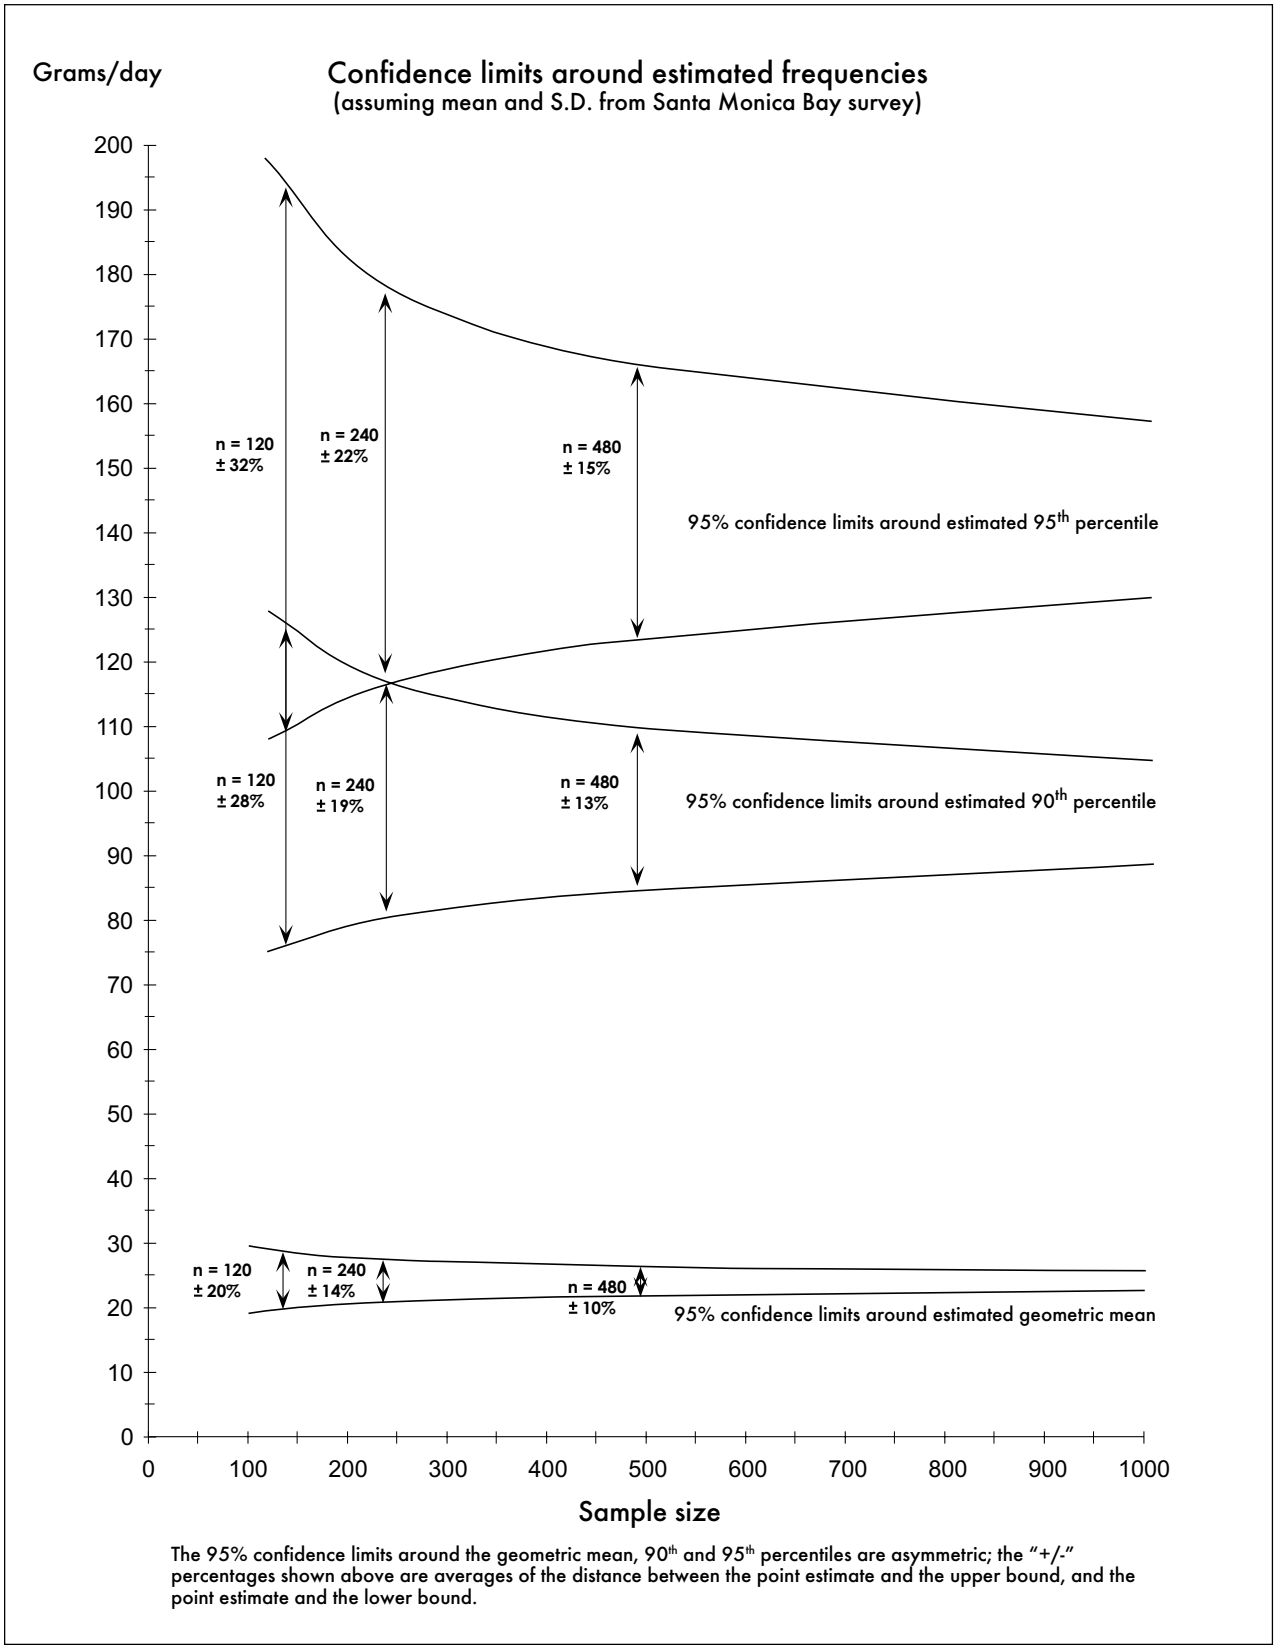
1. Survey Method

We chose on-site personal interviews as the survey method to gather fish consumption and demographic information from anglers. These interviews were conducted over a twelve-month period (July 1998 through June 1999) at selected fishing sites throughout SF Bay. Off-site methods such as mail and phone surveys were not selected because in California, no comprehensive list of anglers from fishing licenses or other sources was available when this study was being planned. Even if such a list had been available, it would not be complete for SF Bay anglers because fishing licenses are not required for fishing at public piers in California (CDFG 2000). A significant amount of fishing activity occurs on public piers in SF Bay, and the proportion of pier anglers with licenses is not known. Additionally, on-site personal interviews conducted by bilingual interviewers would enhance participation of respondents who may have difficulty understanding written questionnaires due to cultural or language barriers or low literacy. Finally, because of the importance of estimating consumption rate, we chose to use a physical model of a fish fillet in order to elicit information about the quantity of fish typically eaten by the angler. The use of the fillet model required personal interviews.

2. Sample Size Estimate

We set a sample size target based on the minimum number of interviews needed to estimate a reasonably precise mean consumption rate. The consumption rate was derived from the subset of anglers who consumed fish caught from SF Bay in the four weeks prior to the interview — a group we refer to as "recent consumers." In choosing a four-week time period, we sought to maximize the time period over which a consumption rate estimate could be made while minimizing recall bias. In addition, to date the Santa Monica Bay Study (SCCWRP/MBC 1994) has provided the best estimates of fish consumption rates from a California population. This study also used a four-week recall to estimate consumption rate. By using a similar method to define consumption rate, we could compare rates derived from both studies.

Figure 2. Confidence Limits



The 95% confidence limits around the geometric mean, 90th and 95th percentiles are asymmetric; the "+/-" percentages shown above are averages of the distance between the point estimate and the upper bound, and the point estimate and the lower bound.

We used consumption rate data from the Santa Monica Bay Study to estimate a target sample size for this study. Using the mean and standard deviation from the Santa Monica Bay Study, we calculated confidence limits around a geometric mean and upper percentiles (90th and 95th) for different sample sizes (Hahn and Meeker 1991). Figure 2 shows that for a sample size of n = 480, the 95% confidence limits average +/-10% around a geometric mean. At n = 480, the 95% confidence limits around the 90th and 95th percentiles are slightly larger (+/-13-15%). As can be expected, the width of the confidence limits decreases as the sample size increases. Figure 2 also shows that as the sample size increases beyond n = 480, little increase in precision of the consumption rate estimate is gained. We considered a 95% confidence limit of +/-10-15% to be reasonable and thus selected n = 480, or n ~ 500, as our target sample size for the group of recent consumers.

Based on our target number for recent consumers, we then estimated the number of anglers we would need to approach to obtain completed interviews of 500 recent consumers. Based on information from the Santa Monica Bay Study and two small shore-based angler surveys conducted in SF Bay (Ujihara 1997, Wong *et al.* 1997), we estimated that 25% of attempted interviews with anglers would yield interviews of recent consumers. Thus, we would need to attempt about 2000 interviews to reach our goal of interviews of 500 recent consumers.

We did not plan the study to obtain sample sizes of subgroups that would be large enough to show consumption rate differences between subgroups, such as ethnic groups. To be able to detect statistically significant differences in consumption rates between subgroups, consumption rate differences or the subgroup size would need to be relatively large. Based on data from the Santa Monica Bay Study, we estimated that a subgroup of 50 or more would be needed to detect a two-fold difference in consumption rates, or a subgroup of 100 or more would be needed to detect a 1.5 fold difference.

3. Allocation of Sampling Effort

The two key elements of our sampling plan were: (1) the sample would reflect the relative amount of fishing activity among fishing modes and other factors, and (2) the study expenses would not exceed our budgetary resources. We developed target numbers of interview attempts for each of three fishing modes based on the relative proportion of fishing activity for each mode within SF Bay. The three modes were defined as shore-based (which included pier and beach and bank sites), private boat, and party boat. Using fishing pressure estimates developed by the MRFSS (Roper 1997), we estimated about 62% of SF Bay fishing activities were conducted from shore-based sites, 28% from private boats, and 10% from party boats.

We also estimated the field interviewer hours available to conduct interviews and allocated these to the three modes. Budgetary limitations resulted in a reduction from our original target of 2000 interview attempts to 1774. Table 1 shows the targeted number of interviews for each of the three modes. These estimates reflected what we expected to achieve given the relative amount of fishing activity among the modes and our budgetary resources.

Table 1. Target Number of Interviews and Interviewer Hours by Fishing Mode

	Mode			
	Shore-Based[a]	Private Boat	Party Boat	Total
Targeted No. of Interviews	1151	407	216	1774
Projected No. of Interviewer Hours	1042	510	162	1714

[a]shore-based sites include pier, and beach and bank sites

4. Site Selection

The list of fishing sites used in the study was primarily drawn from the Marine Recreational Fisheries Statistics Survey (MRFSS) site list (Roper 1997). The 1997 MRFSS site list for SF Bay identified 47 shored-based sites, 24 sites with private boat access, and 8 with party boat access. We also consulted with Task Force members, staff from the California Department of Fish and Game, and other sources to assist with identifying fishing sites.

For shore-based sites, we selected public piers with the highest fishing activity. To reach our target sample size and stay within our budgetary resources, most sites with low fishing activity were excluded from the sampling plan. There was consensus among the Task Force members and external reviewers of the study design that this would not unduly bias the sampling results (see Appendix D). In general, low-activity areas were included only if they were adjacent to a high-activity site and could feasibly be surveyed at the same time. For example, we included beach or bank areas with low activity next to a busy fishing pier.

For the final site combination of shore-based sites, we selected 14 public piers with adjacent beach or bank areas to be sampled once each month. Interviewers were instructed to interview all anglers present at shore-based sites. Thus, the relative amount of fishing activity at a site was reflected in the number of interviews attempted at that site over time (i.e., the one year sampling period). The sites were grouped into pairs based on geographic proximity and site pairs were sampled on the same day. Two sites were specifically included to improve geographic coverage. The Martinez Pier was added because it is located in the Carquinez Straits area, which is not included in the MRFSS. Also, Dumbarton Bridge was added to replace the San Mateo Bridge pier site. The San Mateo Bridge pier site is one of the most heavily used sites in the Bay but was closed during the duration of the survey. The 14 selected shore-based sites sampled in the survey are shown in Figure 3.

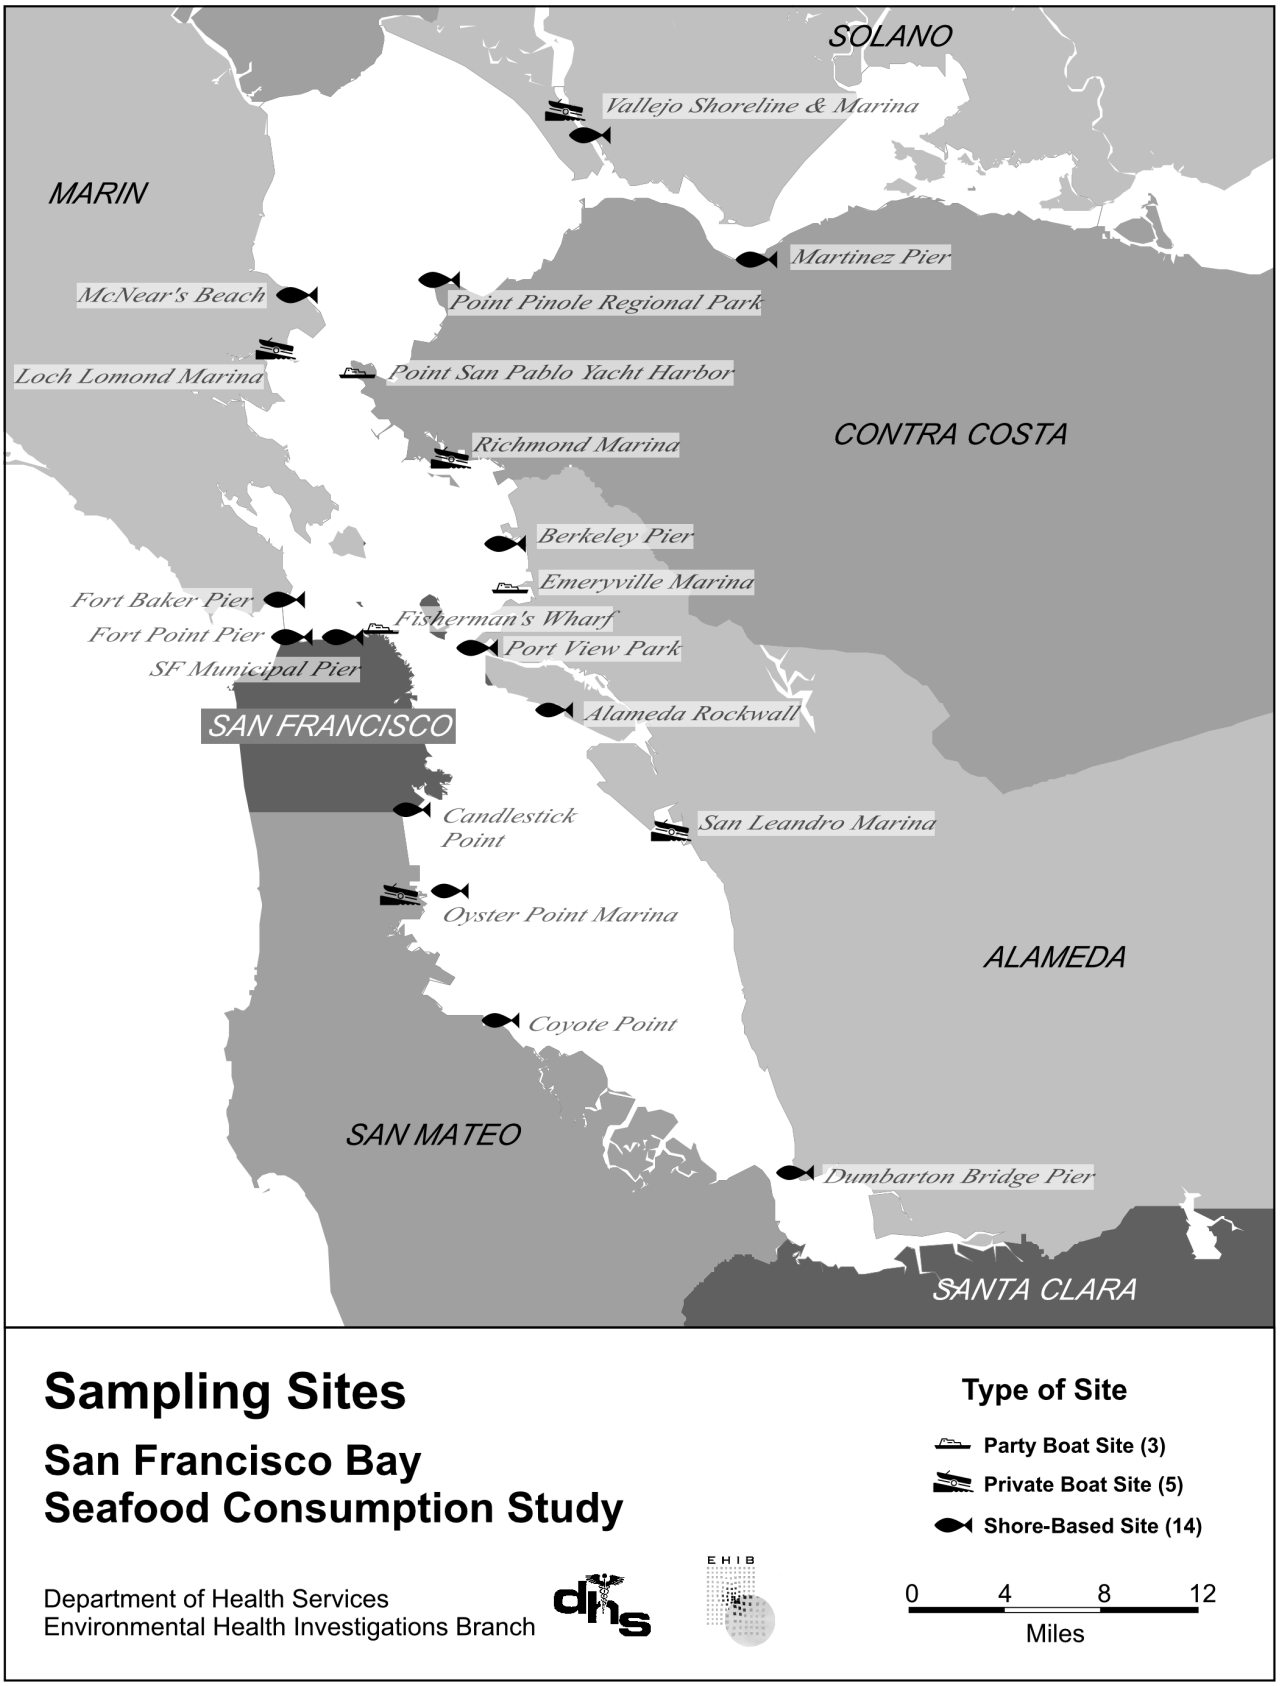
For private boat sites, we selected five boat launch sites with the highest fishing activity. As shown in Figure 3, the five sites provided reasonable geographic distribution of the Bay. We assigned an interview shift that was proportional to the relative amount of fishing activity at each selected site. Thus, interviewers had longer shifts at the more active sites and times. Interviewers attempted to interview all anglers using the site during their shift. In order to conserve on resources, we chose not to sample at one site, San Leandro Marina, on weekdays because this site had very low weekday activity.

For party boats, we examined data collected by the California Department of Fish and Game on party boat activities (CDFG 1998). These data showed that party boat activities within SF Bay were heaviest during warm weather months (from May to August) and lightest in January and December. Based on our estimate of available field interviewer resources, we allocated 18 party boat sampling trips by assigning three sampling trips per month for the busiest months and fewer sampling trips for less busy months.

5. Sampling Days and Times

Another key element of the sampling plan was to randomly select sampling days for shore-based and private boat sites. Because of the difficulty in scheduling more than one interview team per day, sampling days for both shore-based sites and private boat sites were selected without replacement from the same pool. Thus, only one type of site, either shore-based or private boat, could be sampled on a given day. Half the sites each month were designated for weekday sampling and the other half designated for weekend sampling. Weekday/weekend designations alternated every month. Sampling days were re-

Figure 3. Sampling Sites



scheduled if MRFSS staff planned to survey at the same site and day in order to avoid the possibility that anglers would be interviewed for both surveys on the same day.

To ensure coverage of the sampling day, shore-based sites were assigned morning or afternoon shifts. For safety reasons, we assigned sampling times only during daylight hours for both shore-based and private boat sites. In order to maximize coverage of daylight hours, shifts at shore-based sites began earlier and ended later during the longer summer months.

For private boats, sampling times were always in the afternoon to maximize the likelihood of interviewers intercepting anglers returning from their fishing trip. Although interviewers attempted to interview all private boat anglers during their shift, not just those returning, we believed anglers returning from their fishing trip would be more willing to be interviewed than those leaving on a trip.

For party boats, because we had to rely on the party boat captains to allow the interviewer access to their boats, we did not attempt to randomly select sampling days.

C. Survey Instruments

1. Questionnaire

The survey questionnaire was designed to gather information needed to address the specific objectives listed in Section I.D. The questionnaire included questions on ethnicity, income, education, age, fishing frequency, amount of fish eaten, types of fish eaten, preparation and cooking methods, others in the household who eat Bay fish, and awareness and knowledge of the state health advisory. (See Appendix E for a copy of the final questionnaire.) Trained interviewers personally administered the questionnaire to anglers at selected sites. The questionnaire was created using Teleform, Version 5.4, an automatic forms processing software, which allowed us to optically scan the data on the paper questionnaires to create an electronic data base (Teleform 1998). In order to facilitate administration and data entry, the questions mainly followed a partially closed-end question format, with discrete response categories, and an “other” category as needed for a write-in response. Initial drafts were prepared and submitted to the Task Force for review beginning in January 1998.

We also held a discussion group in March 1998 with five individuals (one African American male, one Chinese male, one Hispanic male, one Caucasian male, and one African American female) who fished frequently to solicit input and recommendations for the questionnaire. These individuals were recruited through notices distributed to fishing and community organizations. Field interviewers field-tested the questionnaire at sites not included in the sampling plan in May and June 1998. Revisions primarily served to improve clarity of questions, minimize response biases, maximize recall, and reduce interview time. Final forms were printed with unique identification numbers on water-resistant paper.

A Spanish translation of the questionnaire was also created. No separate interview tools were created for Vietnamese or Chinese interviews, but the interviewers practiced with each other and with other native-speaking individuals and agreed upon consistent terms and phrases to use. If an interview was conducted using the Spanish translated form, the responses were later copied onto a form created with Teleform (English only) to allow for optical scanning. Both the English and Spanish versions were turned in and reviewed by the field coordinator (who was also Spanish literate) prior to scanning.

2. Fish Pictures

For questions about specific fish species, interviewers showed respondents color pictures of 13 species of fish and three types of shellfish during the interview to help them identify the specific SF Bay fish they consumed. Pictures were obtained primarily from the California Department of Fish and Game. We selected the 13 most frequently caught species in the SF Bay using data from the MRFSS. The pictured

species are identified in Appendix F. Consumption practices for white croaker, leopard shark, and striped bass were of particular interest due to the higher levels of contaminants found in these species (organochlorine compounds in white croaker, and mercury in leopard shark and striped bass).

3. Fish Fillet Model

For the question on portion size, interviewers showed a cast plastic model of an 8-ounce raw fish fillet to help the respondent estimate the amount of fish consumed at one time. The respondent was asked "When you eat fish from anywhere (the Bay, other places, stores, restaurants), is the amount that you eat about this size, more or less?" Further probing by the interviewer took place as necessary to determine the respondent's usual portion size.

4. Census Form

At shore-based sites only, interviewers conducted a census of all anglers with fishing poles present at the beginning of the survey shift. Site code, mode, date, and start time were recorded, as well as the numbers of anglers who appeared over 18 years of age and less than 18 years of age.

5. Site Summary Form

Interviewers recorded site code, start and end time for each site, and total number of interview attempts per site on this form for each sampling day.

6. Survey Incentives

In order to promote participation by anglers and to prevent repeat interviews of anglers, a unique survey logo was created and imprinted on clipboards, binders, and name badges, hats, and vests worn by all field interviewers. Also as an incentive for participating, all respondents were given a key chain with a tape measure imprinted with the logo at the conclusion of the interview.

As an incentive for providing information that would allow us to contact them in the future for follow-up activities, respondents were also invited to enter a monthly drawing, making them eligible to receive a $20 gift certificate. They were also asked whether they would like information about the results of the survey sent to them and whether they could be contacted further.

7. Survey Tools

All field interviewers were provided with the following materials:

- Field Interviewer Training Manual
- Name badge, hat and vest with survey logo
- Site maps and directions
- Clipboards with survey logo
- Survey questionnaires
- Census and site summary forms
- Binder with map of San Francisco Bay and pictures of 13 species of fish and three species of shellfish commonly caught from the Bay
- Plastic model of an 8-ounce portion of raw fish fillet
- Health advisories (SF Bay specific health advisory and general fishing advisory available in six different languages)

- Key chain with tape measures imprinted with survey logo

Pictures of some of the above listed survey tools are included in Appendix F.

D. Field Survey Methods

Field survey methods are fully documented in the Field Interviewer Training Manual (see Appendix G) and are summarized briefly here.

For pier and beach and bank sites, the field coordinator assigned two interviewers to visit a site in pairs. Occasionally a third interviewer was assigned as needed. Attempts were made to match assignments with anticipated language requirements (e.g., Chinese speaking interviewers for San Francisco sites). The protocol required interviewers to conduct a census at the start of the shift and attempt to interview all anglers present at a site. If no anglers were present upon arrival, interviewers were required to stay on-site for one hour before leaving. Interviewers surveyed anglers in a sequential fashion. For example, interviewers worked one side of a pier at a time. If new arrivals appeared in areas where they had already interviewed, interviewers surveyed them only if they could keep track of all new arrivals (possible in relatively contained areas) in order to avoid selective interviewing.

For private boat sites, two interviewers were assigned to stay at a designated boat launch site for a preset number of hours. Interviewers screened boat anglers for whether or not they had been fishing or planned to go fishing and their designated fishing location. Only those who reported fishing or planning to fish at least half of their time in the Bay were interviewed.

At the conclusion of all pier, beach and bank, and private boat interviews, the interviewer read a summary of the health advisory for SF Bay and asked the respondent if he or she wanted to receive written information on the health advisory, which was available in six different languages.

For interviewing party boat anglers, the designated field interviewer contacted party boat captains who fish predominantly in SF Bay and had previously indicated their willingness to allow an interviewer to ride their boats. If the captain planned to fish in SF Bay, space was available, and the captain was willing, the interviewer accompanied the boat on the fishing trip. On the party boat survey form (see Appendix F), the interviewer recorded the marina from which the boat left, the boat name, and target species. If the captain took the boat outside the Bay during the trip, the interviewer also recorded the approximate amount of fishing activity that occurred outside SF Bay. While on board, the interviewer attempted to interview all anglers on the trip. Health advisory questions and information were excluded from interviews with party boat anglers in order to improve cooperation from party boat captains.

A revised protocol was implemented in April 1999 as party boat captains became less willing to let interviewers board their boats. Interviewers were assigned to interview party boat anglers after they exited the party boat. Determination of whether the boat planned to go inside or outside the Bay and the estimated time of return was made prior to sending interviewers out. Only party boats fishing in SF Bay at least some of the trip were included. Interviewers attempted to interview all exiting anglers who were at least 18 years old. Questions and information about health advisories were omitted from the interview.

If problems arose during a shift, field interviewers contacted the field coordinator. A cell phone was provided to the interviewers for this purpose. For example, interviewers contacted the field coordinator when an additional interviewer was needed because a site was particularly busy, or when a shift had to be terminated due to bad weather. Interviewers reviewed all questionnaires used for interviews they had conducted for completeness and clarity at the end of their shift.

E. Field Activities Summary

At the conclusion of each sampling shift, the interviewer completed the Site Summary Form and returned the form and completed interview forms to the field coordinator. The field coordinator created a monthly summary of field activities. Appendix H contains copies of the monthly summaries as well as a 12-month summary.

We completed 89 days of field surveying at shore-based sites, and 59 survey days at private boat sites. There were 47 weekday days and 42 weekend/holiday days at shore-based sites, and 28 weekday days and 31 weekend/holiday days at private boat sites. As documented in the field summaries, about a fifth of all shore-based and private boat sampling days needed to be rescheduled. Reasons for rescheduling included bad weather, conflict with a MRFSS sampling day, inability of interviewers to complete a site, or unavailability of interviewers. Rescheduled sampling days were conducted as close to the original sampling day as possible and were on the same day type (weekend or weekday).

For party boats, we originally scheduled 18 party boat sampling days. Because we had limited access to party boat anglers, we made 22 total attempts to board a party boat and 10 attempts to interview party boat anglers as they exited the boat. We were able to conduct interviews for about a third of all party boat attempts. Party boat interviews were conducted with anglers on boats departing from Pt. San Pablo Yacht Harbor, Emeryville Marina, and San Francisco Fisherman's Wharf. Party boats were mainly sampled on weekend days.

III. Data Management, Quality Assurance and Control, and Data Analysis

A. Data Management

As interviewers returned completed survey questionnaires, the field coordinator manually reviewed and corrected them as needed. Using Teleform, trained staff scanned the forms and visually reviewed each scanned page of the survey instrument. Categorical responses were optically read and coded. All handwritten entries (e.g., numbers and text) were visually reviewed and manually corrected as needed. After all pages were verified, the data was committed to a Microsoft Access database. Since each survey form was uniquely numbered, duplicate entries could be easily identified. Text entries were manually coded into predefined categories (see Appendix I). Separate Access data base files were created for each month of data collection and converted to a data file compatible with SAS version 7 (SAS 1998). After confirming that data integrity had been maintained, monthly data sets were merged to form the full data set. Data editing and data analyses using SAS were performed on the full data set.

B. Verification of Interviews by Phone

In order for us to independently verify that the interviews actually took place, we attempted to contact by phone a subset of persons interviewed. When interviewed in the field, respondents were asked if a supervisor could contact them. Of persons agreeing to be contacted (approximately half of all respondents), we attempted to contact 94 respondents (7% of all respondents). These respondents were chosen randomly. We were able to reach 67 respondents (71% of those we tried to reach and 5% of all respondents) after making up to three attempts. All 67 confirmed that they had been interviewed at the stated day and place. No attempt was made to verify their responses to the interview.

C. Quality Assurance (QA) and Quality Control (QC) Measures

A variety of QA/QC measures were incorporated in order to minimize measurement errors or other biases.

QA procedures put into place prior to data collection included:

- Obtaining review and input on all study materials and protocols by Seafood Consumption Study Advisory Task Force members
- Field testing of survey instrument
- Thorough training of interviewers in all aspects of survey administration
- Incorporating visual cues and tools to maximize recall during the interview

QC measures undertaken throughout the data collection phase included:

- Self-review of all forms completed by interviewer at end of shift
- On-site field audits of interviewing activities by the field coordinator or other project staff on 49 sampling days (31% of all sampling days).
- Manual review of all completed survey questionnaires by field coordinator for completeness and correct coding
- Regular verbal and written feedback to interviewers individually as needed
- Scheduled group meetings to provide periodic updates and to review procedures
- Phone calls to 5% of all respondents to verify that the interviews did take place
- Data review and editing to detect inadmissible and out-of-range values
- Inclusion of redundant questions worded differently to check consistency of answers

D. Data Analysis

1. Avidity Bias

How frequently anglers go fishing (i.e., their avidity) can vary widely among anglers. Some may fish daily while others may fish only once per year. In on-site surveys such as this study, how often an angler goes fishing determines how likely he or she will be included in the survey. Generally, avid anglers will be over represented in the sample and infrequent anglers will be under represented. Several authors have described this bias, called avidity bias (ATES/OEHHA 2000, Ossiander 1999, USEPA 1997, Pollock 1994, Price 1994, Thomson 1991).

Avidity bias presents a concern when an angler's avidity is correlated with important parameters that are being studied, such as consumption rate. If no correlation exists, there is no bias and data adjustments will not change the results. However, if correlation exists, the sample will not accurately reflect the overall angler population. Because one of the main goals of the study is to characterize exposures of the general population of San Francisco Bay anglers, adjusting for avidity bias allows for the results to more closely reflect this general population.

In this study, sample data were adjusted for avidity bias by weighting the respondents in proportion to the inverse of their sampling probability. This type of adjustment is a common and standard practice in the field of survey sampling (Stuart *et al.* 1976, Snedecor and Cochran 1989)). To estimate sampling

probability, we used the angler's fishing frequency, i.e., the number of times the angler reported fishing in the four week prior to the interview.

The fishing frequency response was used to adjust consumption rates of recent consumers (anglers who reported consuming SF Bay fish in the four weeks prior to the interview, see Appendix J), as well as other consumption rate variables such as meal frequency and portion size. Consumption rates based on consumption in the 12-month period prior to the interview could not be adjusted for avidity bias because information on fishing frequency over the same time period was not obtained. We also adjusted categorical variables such as mode, ethnicity and income for avidity bias. For these variables, the avidity bias adjustment was applied to the overall proportions of the variable subgroups.

In the equation below, we describe how the avidity bias adjustment was applied to an estimate of a mean consumption rate:

Weighted mean, $cw = \frac{\sum i \, wi \, \chi i}{\sum i \, wi}$ (SAS 1988)

The weighting factor, *w*, is the inverse of the angler's fishing frequency, and *x* is the angler's consumption rate. The angler's fishing frequency value was increased by one to include the trip during which the interview took place. Thus, an angler who did not fish in the 4 weeks prior to the interview would have a fishing frequency of 1 (zero fishing trips in the last 4 weeks plus one trip when interviewed). The weighting factor used for an angler who had a fishing frequency of 1 would be 1/1, or 1 in the equation above. Also, we limited the maximum fishing frequency value to 28 times (1 time per day over the last 4 weeks). Thus, anglers who reported fishing 27 or more times in the last 4 weeks were recorded as having fishing frequencies of 28. The weighting factor used for an angler with a fishing frequency of 28 would be 1/28 in the equation above.

The avidity bias adjustment does not change an individual angler's consumption rate. The adjustment increases or decreases the weight given to anglers' responses in the aggregated sample based on their fishing frequency. For example, the adjustment reduces the contribution of avid angler's consumption to the total consumption rate to compensate for oversampling this group.

Adjusting for avidity bias may introduce additional error by using one random variate (fishing frequency) to adjust another (consumption). However, to the extent that higher consumers are actually oversampled in a survey (which cannot be determined from the data themselves), sampling theory tells us that reweighted estimates should be more accurate than unweighted ones (Snedecor and Cochran 1989). Note that, as with all sampling efforts, the true population averages remain unknown. The reported 95% confidence intervals reflect the magnitude of the uncertainty, and the true population values are expected to lie somewhere within those intervals.

Because not all variables could be adjusted, results that have been adjusted for avidity bias are described as "adjusted" in this report. However, the tables in Appendix K include both the adjusted and unadjusted data, where appropriate.

2. Calculation of Fish Consumption Rate

Consumption rate was determined by multiplying the respondent's reported portion size by meal frequency, and converting to grams per day. Portion size (in ounces) refers to the amount of fish eaten at one time. Respondents were shown a cast plastic model, representing an 8-ounce raw fish fillet. They were then asked if the model represented the amount they ate at one time, regardless of its source (SF Bay, outside SF Bay, store or restaurants). Respondents could report a portion size amount equal to the

8-ounce model, a fraction of the model (e.g., one half, one third, etc.), or a multiple of the model (e.g., two times, three times, etc.). Respondents were asked the portion size question only one time during the survey. This single response was used to estimate all fish consumption rates used in this study. Meal frequency refers to the number of times the respondent consumed fish over a specified time period. We asked about meal frequency of SF Bay fish for two different time periods to derive two different consumption rates. First, we asked respondents for the number of times they ate specific species of SF Bay fish in the four weeks prior to being interviewed; we then summed these answers for the specific species to give the total number of times the respondent ate SF Bay fish. Second, in a single question we asked respondents for the total number of times they consumed SF Bay fish in the last 12 months. Appendix J contains a more detailed discussion of how consumption rates were derived for this study.

Although we also asked respondents to report meal frequency for three types of shellfish, due to resource constraints, no portion size was obtained for shellfish. Therefore, we could not derive consumption rates for SF Bay shellfish.

Descriptive statistics for consumption rates are presented in Section IV.D, including arithmetic and geometric means, standard deviations, minimum and maximum values, and 50th (median), 90th, and 95th percentile values. Appendix K contains tables displaying more complete percentile distributions, from the 10th to 95th percentile.

3. Shape of the Consumption Rate Distribution

The procedures used to provide confidence intervals around estimates of population means, and to conduct statistical tests of consumption differences between subgroups, assume that the population distribution follows the so-called "normal," or Gaussian, distribution. Previous studies have reported that fish consumption rates tend to be lognormally distributed (Hill 1995, Hill and Lee 1995, Murray and Burmaster 1994, Ruffle *et al.* 1994). We examined the mean, median, standard deviation, skewness, kurtosis, histograms, and normal quantile plots of consumption rates derived for SF Bay anglers (recent consumers). As will be further discussed in Section IV.D.1, we found the unadjusted median and geometric means to be identical (about 16 grams/day), and the unadjusted arithmetic mean to be about 28 g/day. The extreme skewness of the distribution produced an arithmetic mean falling near the 72nd percentile, rather than near the median (50th percentile) as in a normal distribution. Citing an arithmetic mean from a non-normal sample not only conveys a misleading "mean" value, but attempting to estimate a population's arithmetic mean from a non-normal population produces confidence intervals that are far below their stated accuracy. As expected from this analysis and the previously cited experience of others, the logarithmic transformation, common in biological and medical applications (Armitage and Berry 1987), produced a more normal distribution. Thus, we primarily refer to geometric means and medians for describing measures of central tendency (USEPA 1996, Sokal and Rohlf, 1981). The geometric mean is obtained from the mean of the log transformed values, back transformed to their original units. Further discussion on the shape of the consumption rate distributions can be found in Appendix J. More detailed information about consumption rates is also presented in Section IV.D.1.

4. Statistical Methods

The type of statistical test used in the data analysis is dependent on the type of variable being examined. For categorical variables we performed chi-square tests to measure the associations of different angler characteristics such as fishing mode and ethnicity. We used the Mantel-Haenszel chi-square statistic to test for trends in demographic variables representing ordered categories, such as income, education, and

age. In all chi-square analyses, we excluded missing, don't know, and refused to answer responses. Chi-square tests could only be performed on data unadjusted for avidity bias. Thus, discussion of statistical significance of chi-square results applies only to the unadjusted data. Also, chi-square tests could not be performed on some categorical responses where the possible responses were not mutually exclusive.

Because consumption rates were lognormally distributed, we used geometric means and 95% confidence intervals to compare among different groups. We considered two groups with non-overlapping confidence intervals to be significantly different. Consumption rate differences were also tested non-parametrically by the Wilcoxon signed rank test as an alternative way of dealing with non-normally distributed consumption rate data.

Statistical analyses were performed with SAS software, version 7 (SAS 1998).

IV. Results

The information presented in this section of the report serves to address the goals and objectives defined for the overall study (Section I.D). We have attempted to keep tabular data to a minimum in this section, relying more on figures and graphs for illustration. More extensive tabular data are included in Appendix K. Figures and tables that appear in the text are numbered sequentially. Tables that appear in Appendix K are prefaced by an upper case K, for example, Table K1.

For clarity, the following terms, which we use in this report, are defined:

- *Mode* refers to the type of fishing site where anglers were interviewed. Modes included in the study were: 1) public piers, 2) beach and bank sites, 3) private boat launch sites, and 4) party boat sites. Shore-based sites refer to pier sites and beach and bank sites.
- *Decliners* refer to anglers who declined to be interviewed.
- *Respondents* refer to anglers who agreed to be interviewed. This group includes both consumers and non-consumers of SF Bay fish.
- *Consumers* are anglers who report consuming fish caught from SF Bay (no time period specified). This group also includes a small number of anglers who reported fishing for the first time in the Bay and who planned to consume their catch. Further description of how consumers are defined is included in Appendix J.
- *Recent consumers* are defined as anglers who reported consuming fish caught from SF Bay in the four weeks prior to the date they were interviewed. Recent consumers are a subset of consumers. Further description of how recent consumers are defined is included in Appendix J .
- For presenting information on ethnic groups, we refer to the following major ethnic groups: *Black/ African American, Latino/Hispanic, Caucasian, Asian, and Other* (which included Russians, Middle Easterners and individuals of unspecified mixed ethnicity). Included in the Asian group are anglers who are *Filipino, Chinese, Vietnamese, Pacific Islander, and Other Asian* (which included Japanese, Southeast Asian other than Vietnamese, Korean, and mixed Asian). Additional tables and figures are also provided which delineate the Asian subgroups separately.

A. Sampling Success

As shown in Table 2, we attempted 1,868 interviews, 5% more than we had originally targeted. Of the 1,868 attempted interviews, 130 anglers had previously been interviewed and were not reinterviewed.

Table 2. Sampling Success by Mode

	Total		Mode							
			Piers		Beach and Bank		Private Boats		Party Boats	
	N	%	n	%	n	%	n	%	n	%

	Total		Mode							
			Piers		Beach and Bank		Private Boats		Party Boats	
	n	%	n	%	n	%	n	%	n	%
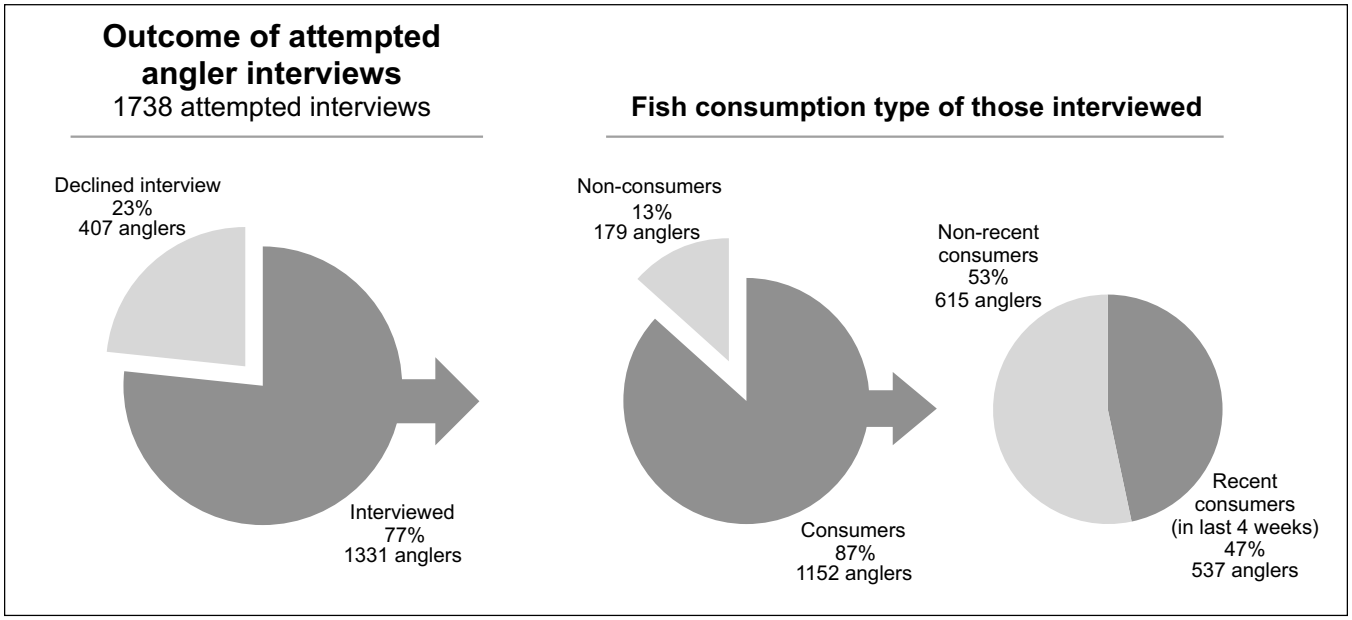
Recent Consumers of SF Bay Fish[8]	537	100	277	100	39	100	181	100	40	100
Recent Consumers with Defined Consumption Rate[10]	501	93	255	92	37	95	172	95	37	93

1 Target Attempts–as defined in the original sampling plan reflect the relative amount of fishing activity by mode within SF Bay.
2 Number refers to total target attempts for shore-based sites, which included pier and beach and bank sites.
3 Interviewed before includes anglers who initially agreed to be interviewed but were later identified to have been previously interviewed. Interviews with these individuals were subsequently terminated.
4 Net Attempt equals actual total attempts (1868) minus interviewed before (130).
5 Respondents refer to anglers who agreed to be interviewed and who had not been previously interviewed for this study.
6 Consumers are anglers who report consuming fish caught from SF Bay.
7 Non-consumers are defined as anglers who reported they do not consume fish caught from SF Bay.
8 Recent consumers are defined as anglers who report consuming fish caught from SF Bay in the four weeks prior to the date they were interviewed. Recent consumers are a subset of the overall consumer group.
9 Non-recent consumers are consumers of SF Bay fish who did not consume any in the four weeks prior to the interview.
10 Recent consumers with defined consumption rate indicated a portion size and a frequency of consumption within the last four weeks.

Figure 4



Anglers approached but found to be previously interviewed by this study not included (130 anglers). Not adjusted for avidity bias.

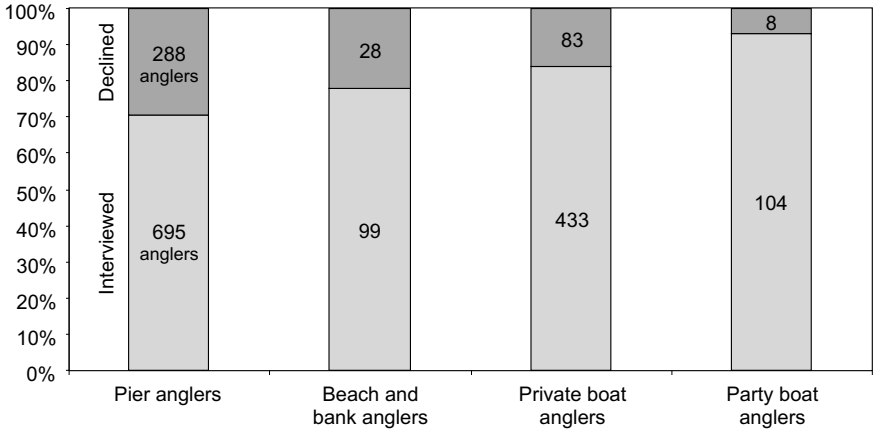
Figure 4 also shows that of those eligible to be interviewed (n = 1738), 77% agreed to be interviewed, a group we refer to as respondents. Consumers of SF Bay fish represented 87% of respondents.

An important indicator of sampling success was the total number of interviews achieved with recent consumers. As described in Section II.B., based mainly on data from the SMB study, we determined a sample size of 500 recent consumers would be needed to derive a reasonably precise mean consumption rate (i.e., 95% confidence interval of +/- 10% around the geometric mean consumption rate and 95% confidence interval of +/-15% around upper percentiles). We identified 537 recent consumers (see Figure 4 and Table 2). However, only 501 of these individuals provided adequate information for deriving a consumption rate based on a four week recall period, which still allowed us to meet our defined target.

Although consumption rate results will be discussed in later sections of this report, the precision of the geometric mean consumption rate in this study was +/-9% for the 501 recent consumers. This level of precision was within our target range. The confidence interval of +/-28% around the upper percentiles was wider than our target range (see Figure 2).

Figure 5

Proportion of interviews by fishing mode

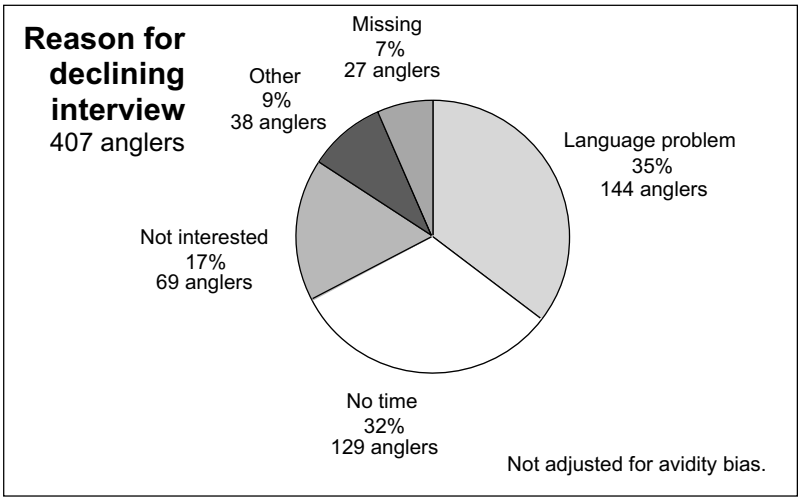


Not adjusted for avidity bias.

Our sampling plan (see Section II.B.) also identified target numbers of attempted interviews by mode, that were based on an estimate of the relative amount of fishing activity in SF Bay by mode. Table 2 and

Figure 5 show sampling results by four modes, pier, beach and bank, private boat, and party boat. (Separate codes assigned to (1) pier and, (2) beach and bank sites allowed for differentiation among the shore-based sites.) Proportionately, we had slightly less shore-based attempted interviews, more private boat attempts, and less party boat attempts than originally targeted. The resistance we encountered from party boat captains, which restricted our access to party boat anglers, accounted for our inability to reach our target for party boat interviews. As shown in Figure 5, we experienced greater cooperation among private and party boat anglers, as compared to pier and beach and bank anglers. Of pier and beach and bank anglers, 72% agreed to be interviewed, as compared to 84% of private boat anglers and 93% of party boat anglers.

Figure 6



B. Decliners

Twenty-three percent of anglers declined to be interviewed (see Table 2). Among the 407 individuals who declined to be interviewed, language problems and lack of time or interest were cited as the main reasons for declining (see Figure 6). Pier anglers were the most likely to decline an interview; they most commonly cited language problems as the reason (see Table K1). Among private boat anglers, no time was the main reason for declining to be interviewed.

Interviewers recorded observed ethnicity for 88% of anglers declining to participate. As shown in Figure 7, half of those declining were of Asian ethnicity (Chinese, Vietnamese, Filipino, Southeast Asian, Korean, and unknown Asian), whereas Asians represented one third of anglers who participated

Figure 7

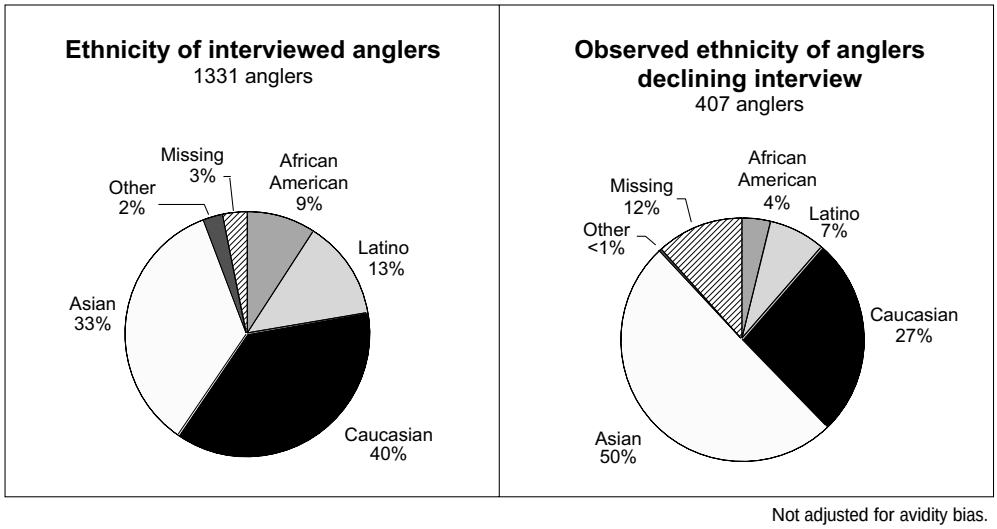


Figure 8

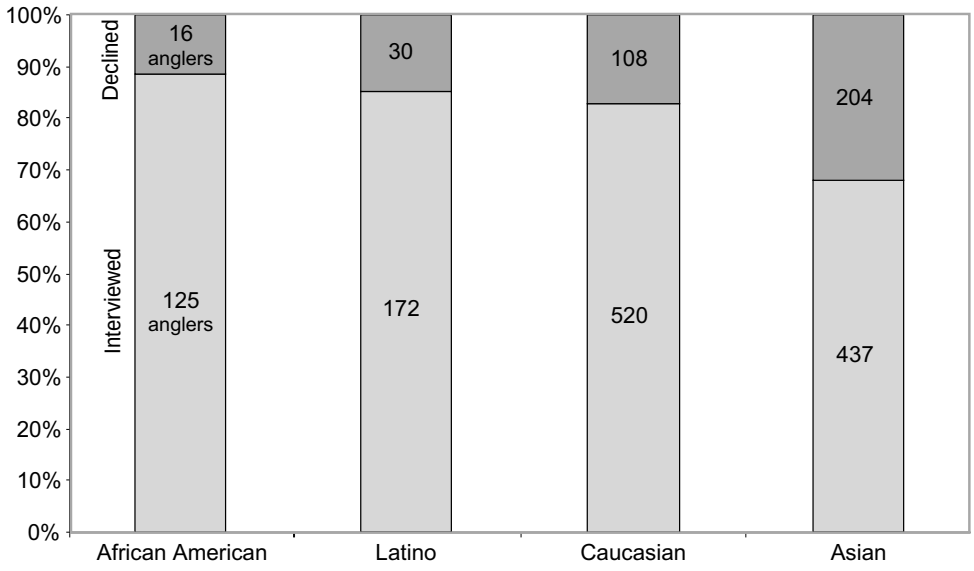
Proportion of interviews by ethnicity



Not adjusted for avidity bias.

in the survey. Figure 8 also shows that compared to other ethnic groups, a higher proportion of Asians declined to be interviewed. Generally, higher proportions of non-Caucasian ethnic groups were represented among pier and beach and bank anglers who declined to be interviewed than among private boat and party boat anglers who declined (see Table K1).

Interviewers were only able to note observed language spoken for 71% of decliners (see Table K1). Among those observed to be Vietnamese, Chinese, or Other Asian, language problems were noted as the most likely reason for declining (see Table K2). Interviewers generally encountered more languages other than English being spoken by pier and beach and bank anglers as compared to private and party boat anglers.

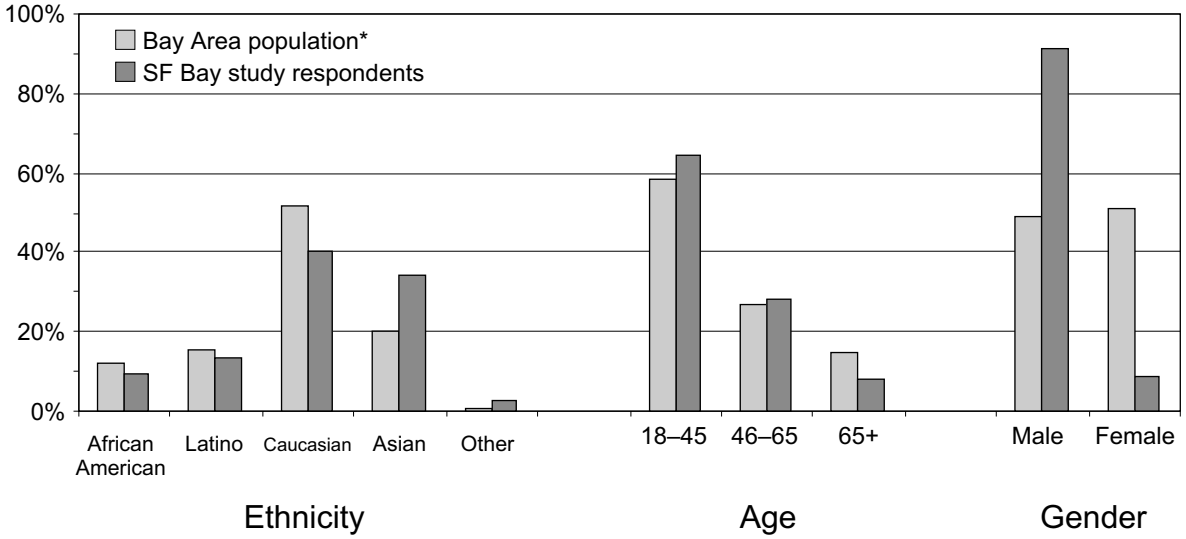
C. Angler Characteristics

One of the primary objectives of this study was to describe demographic characteristics of anglers who consume SF Bay fish. We present information regarding ethnicity, income, education, gender, and age for consumers of SF Bay fish by mode in this section. Information about the number of years consumers have been eating Bay fish, what they usually do with Bay fish, seasonal differences, household members consuming SF Bay fish, and household members who prepare or cook SF Bay fish is also included. Tables in Appendix K usually contain information for respondents, consumers, and recent consumers. The three groups are not mutually exclusive (e.g., 47% of consumers were recent consumers and 87% of respondents were consumers). The demographic characteristics of respondents, consumers, and recent consumers were largely similar. The tables in Appendix K also display data both unadjusted and adjusted for avidity bias. With respect to demographic characteristics, the overall proportions were largely unaffected by the avidity bias adjustment. The percentages given in the text below generally refer to adjusted values unless noted.

Figure 9 compares demographic variables for respondents and the aggregated population in the six Bay Area counties where the study was conducted. As shown, the study population was younger, had a

Figure 9

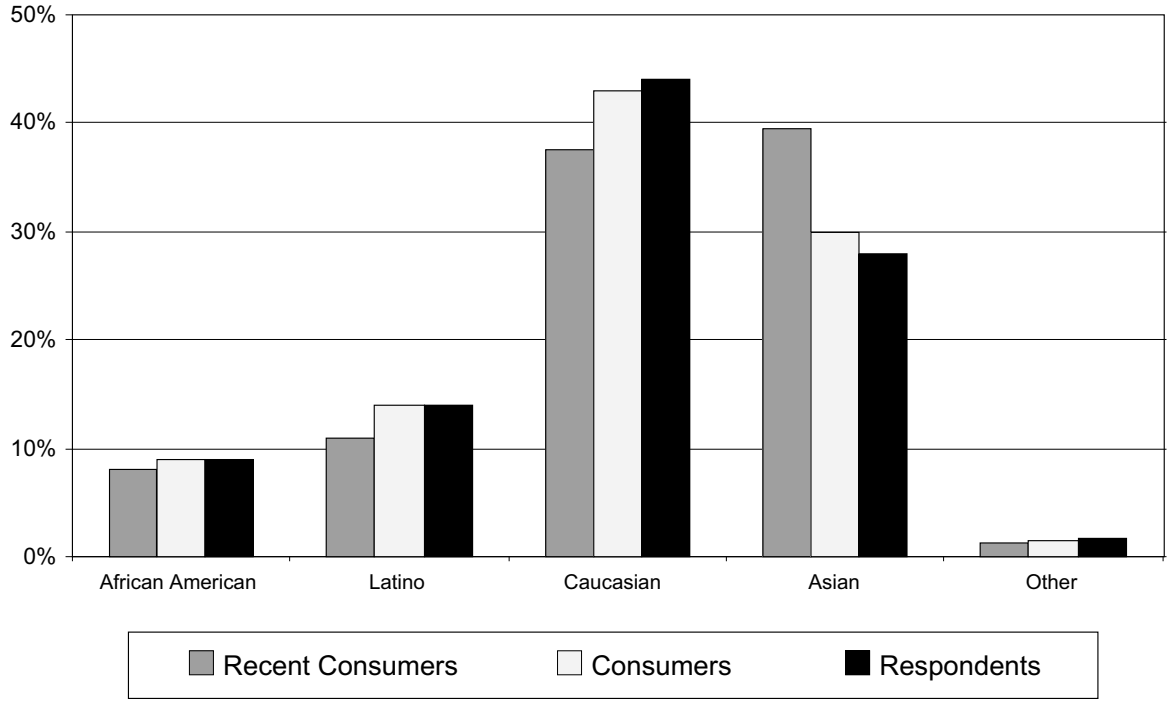
Demographic comparison of study respondents with Bay Area population



* Based on 1998 census data for the six Bay Area counties (Marin, Alameda, Contra Costa, San Francisco, Solano, and San Mateo) where the study was conducted. Not adjusted for avidity bias.

Figure 10

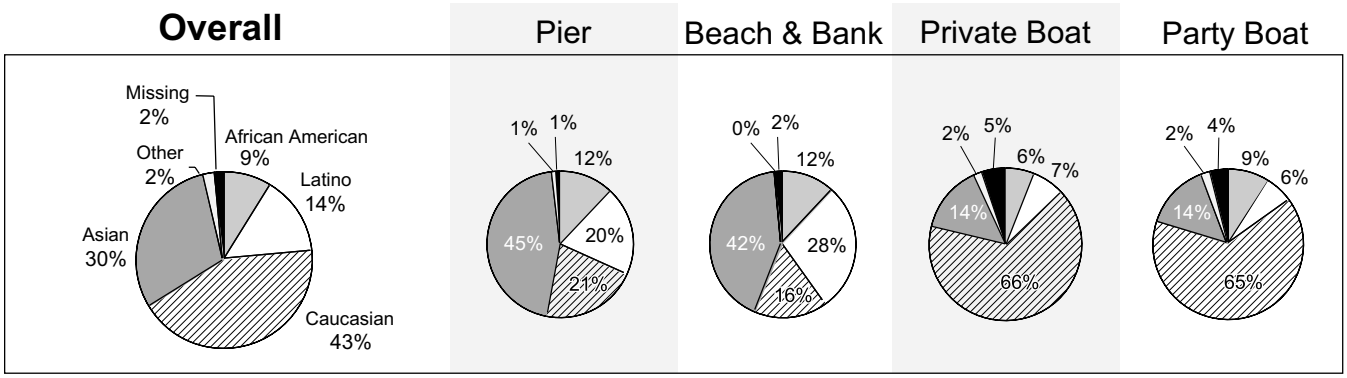
Comparison of ethnicity among recent consumers, consumers, and respondents



Adjusted for avidity bias.

Figure 11

Ethnicity of consumers by fishing mode



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

higher proportion of males and Asians, and a lower proportion of African Americans, Latinos, Caucasians, and females, as compared to overall Bay Area demographics.

Figures 10 through 20 present specific demographic information for consumers of SF Bay fish. Caucasians comprised the largest group of anglers who consumed Bay fish, followed by Asians, Latinos, and African Americans. Overall, more than half of the anglers consuming fish from SF Bay were non-Caucasian. Among recent consumers, Asians comprised the largest group, followed by Caucasians, Latinos, and African Americans. The overall fishing population was predominately male.

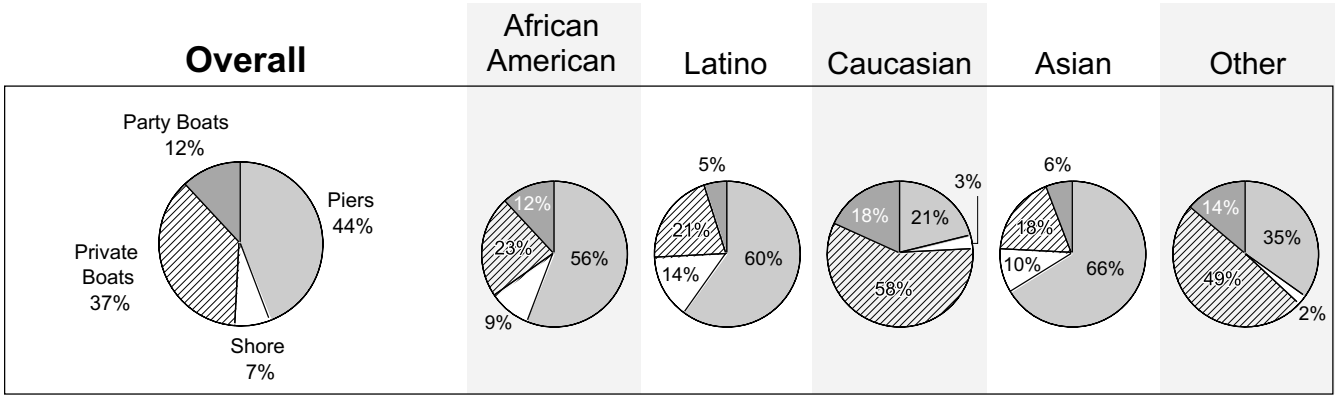
For all demographic characteristics except age and gender, we found differences by mode for consumers of SF Bay fish. Shore-based anglers tended to be non-Caucasian, whereas boat anglers were predominately Caucasian. Asians were the largest group fishing from piers and beach and bank sites, with Filipinos comprising the largest Asian group. A higher proportion of shore-based anglers reported household incomes less than $20,000/year, and also had lower education levels than boat anglers. Although the majority of interviews were conducted in English, 8% (106, unadjusted) were conducted in a language other than English and a much higher proportion of non-English interviews were conducted at piers and beach and bank modes compared to private and party boat modes.

Seasonal differences by mode were evident; the highest number of interviews for all modes was conducted during the summer months. Although 41% of consumers have been consuming SF Bay fish five years or less, about a fourth have been consuming Bay fish more than 20 years. A larger proportion of Caucasians and African Americans consumed Bay fish over the longest time period compared to other groups, while a majority of Latinos and Asians had consumed Bay fish five years or less. Ninety percent of consumers reported that they usually eat the fish they catch from SF Bay. Slightly less than half of all consumers reported they also give fish or shellfish they have caught to family or friends. Nearly one half (46%) of consumers reported that women of childbearing age (18-45 years) and 12% of consumers reported that children under six in their households ate SF Bay fish. About two thirds of consumers usually prepare or cook the fish they catch from the Bay themselves.

More specific information on angler characteristics is provided below and in tables found in Appendix K.

Figure 12

Fishing mode of consumers by ethnicity



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

1. Ethnicity

As shown in Figure 10 and Table K3, ethnic differences can be noted among respondents, consumers, and recent consumers. Overall, 55% of consumers were non-Caucasian, with Caucasians representing 43% of all consumers. For recent consumers, the proportion of non-Caucasians rises to 60%, with Asians surpassing Caucasians as the largest group.

Asian subgroups are also shown separately for consumers and recent consumers in Tables K4A and K4B. Caucasians represented the largest proportion of consumers, followed by Latinos, Filipinos, African Americans, Vietnamese, Other Asian, Chinese, Pacific Islander, and Other. Among recent consumers, Caucasians were followed by Vietnamese, Filipinos, Latinos, African Americans, Other Asians, Chinese, Pacific Islanders, and Other.

As shown in Figures 11 and 12 and Tables K3-K5, there were ethnic group differences by fishing mode. Among consumers, Caucasians were the dominant group fishing from private boats and party boats, whereas Asians comprised the largest group fishing from piers and beach and banks.

Table K6 shows ethnic differences by each site for respondents. For shore-based sites, Caucasians were the dominant group at Martinez Shoreline Park. Over 50% (unadjusted) of the respondents interviewed at Fort Point Pier, Point Pinole Shoreline Park, Alameda Rockwall, Candlestick Point Recreation Area, Coyote Point, and San Francisco Municipal Pier were Asian, with Filipinos representing the largest Asian subgroup (see Table K7). McNear's Beach had the highest number of Latinos; 35% (unadjusted) of interviews at this site were conducted with Latinos. African Americans were the dominant group at Port View Park. Caucasians were the largest ethnic group of all private boat and party boat sites. The proportion of Asians using Richmond Marina and Oyster Point Marina was higher compared to other private boat sites. Vallejo Marina and Oyster Point Marina had the highest proportion of Filipino private boat anglers while San Leandro Marina had the highest proportion of Vietnamese.

2. Language Spoken During Interview

The majority (87%) of all interviews with consumers were conducted in English (see Table K8). The proportion of non-English interviews conducted at piers and beach and bank sites was four times higher than at private boat sites. At McNear's Beach, Pt. Pinole Shoreline Park, San Francisco Muni Pier, and Coyote Point, over 20% of the interviews were conducted in a language other than English (see Table K9).

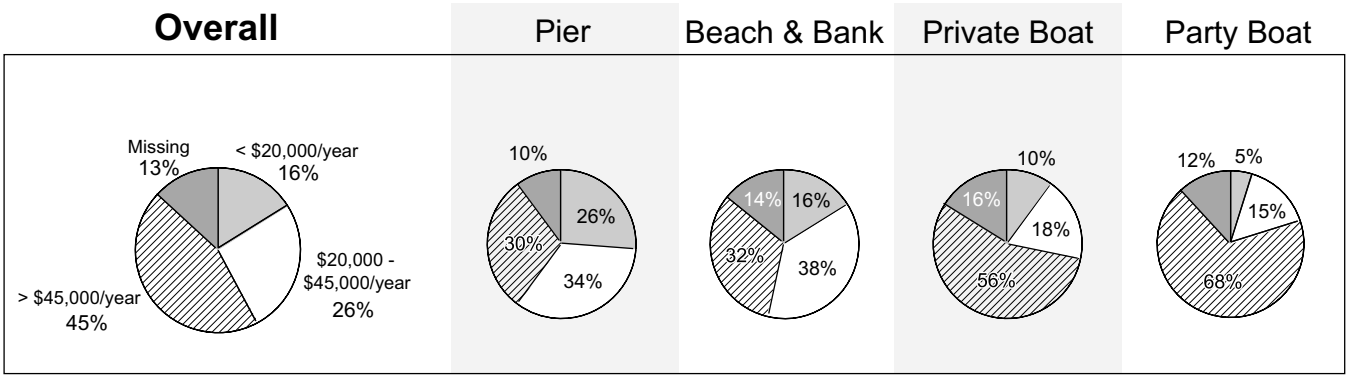
3. Income

To determine income, we asked respondents if their total household income was greater than $20,000/year. For those who indicated yes, we then asked if their household income exceeded $45,000/year.

Of all the demographic information gathered, we had the highest proportion of missing information for income (see Figure 13 and Table K10). Income information was missing for 13% of consumers as compared to 4% to 7% for the other demographic characteristics. Overall, 45% of consumers reported a total household income greater than $45,000/year (see Figure 13). The proportion of boat anglers reporting household incomes greater than $45,000/year was nearly two times the proportion of shore-based anglers.

Figure 13

Income of consumers by fishing mode

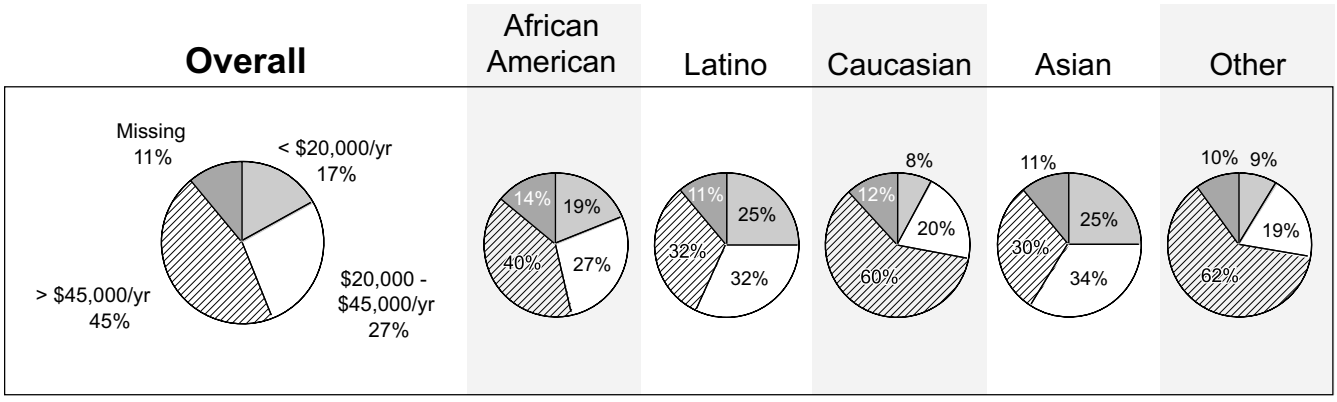


Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

Figure 14 and Table K11 show ethnicity by income for consumers. Within non-Caucasian groups a higher proportion reported annual household incomes less than $20,000 compared to Caucasians.

Figure 14

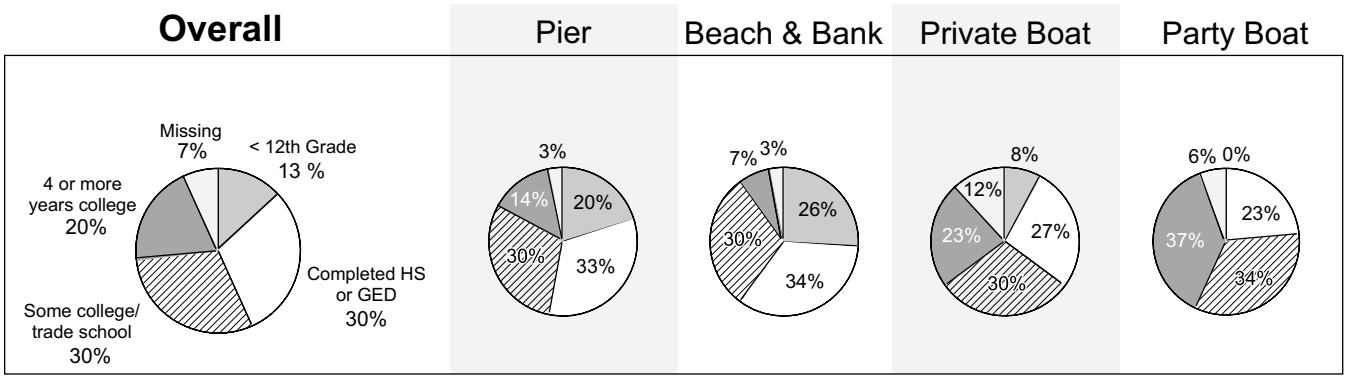
Income of consumers by ethnicity



"Overall" values differ from previous graphic due to exclusion of anglers missing ethnicity data.
Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

Figure 15

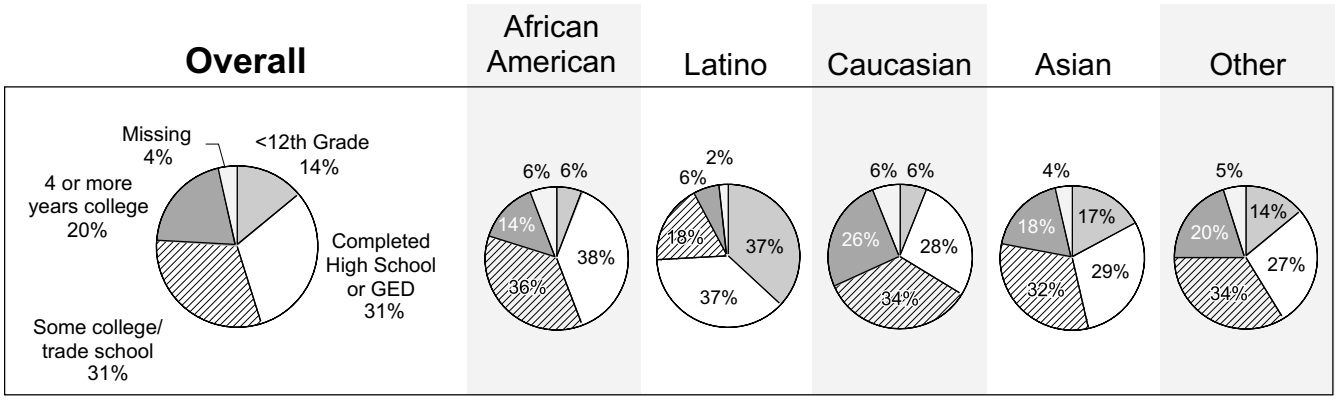
Education of consumers by fishing mode



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

Figure 16

Education of consumers by ethnicity



"Overall" values differ from previous graphic due to exclusion of anglers missing education data.
Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

4. Education

Education is usually highly correlated with income (Liberatos *et al.* 1988). Information on education was missing for only 7% of consumers. Among consumers, 50% reported some college level education or higher. Similar to income, there were differences in level of education by mode. A higher proportion of party boat and private boat consumers reported higher education levels than pier and beach and bank anglers (see Figure 15 and Table K12).

Education levels also varied by ethnicity, as shown in Figure 16 and Tables K13A and K13B. Among the different groups, 74% of Latino and 66% of Vietnamese consumers reported high school level or less. More than half of all the other groups reported some college level education or higher.

5. Gender

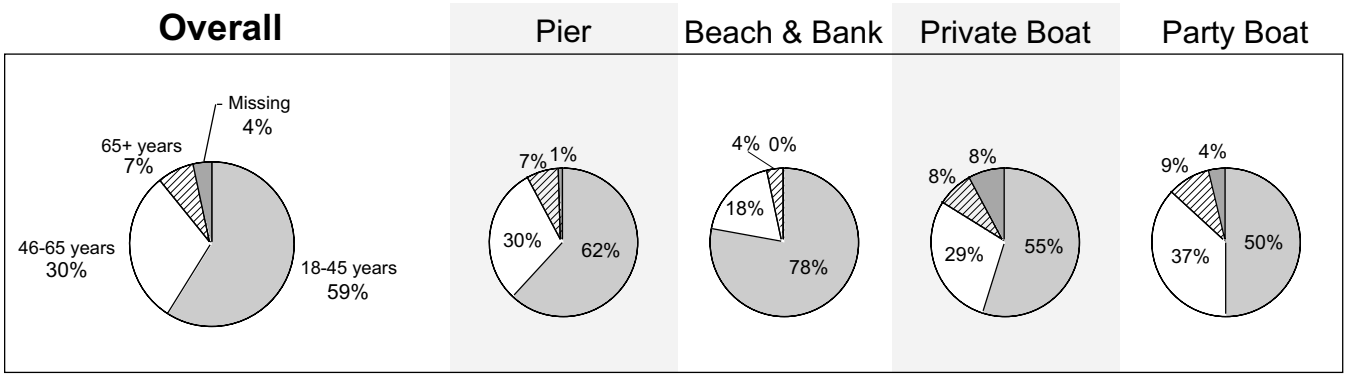
As shown in Table K14, 86% of all consumers were male. Differences by mode were not apparent.

6. Age Structure

Although interviewers recorded the number of anglers who appeared to be less than 18 years of age during the census at shore-based sites, these individuals were not included in the survey. About 20% of all anglers counted in the census at shore-based sites were observed to be younger than 18 years of age (see Appendix H).

Figure 17

Age of consumers by fishing mode



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

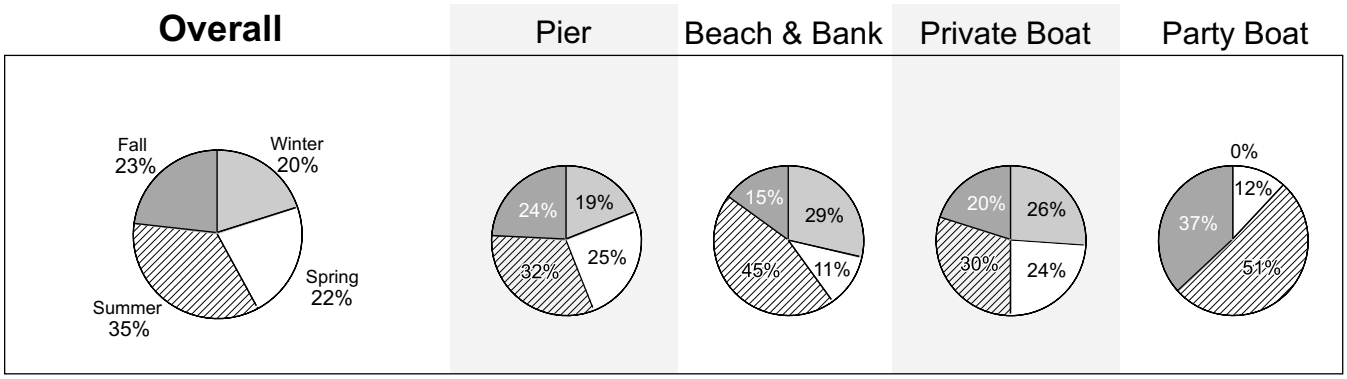
As shown in Figure 17 and Tables K15 and K16, 89% of all consumers fell within the 18 and 65 year range. Fifty-five percent of all female consumers were of child bearing age (18-45 years). A higher proportion of party boat anglers was in the age range above 46 years, as compared to anglers fishing from the other modes. More consumers over 65 years of age fished on weekdays than on weekends, in contrast to those less than 65 years of age (see Table K17).

7. Season of Interview

To define seasons, summer included all interviews conducted from July through September, fall included October through December, winter included January through March, and spring included April through June. Overall, the highest number of interviews was conducted during the summer due to the higher level of fishing activity (see Figure 18 and Table K18). Summer was also the dominant season within all

Figure 18

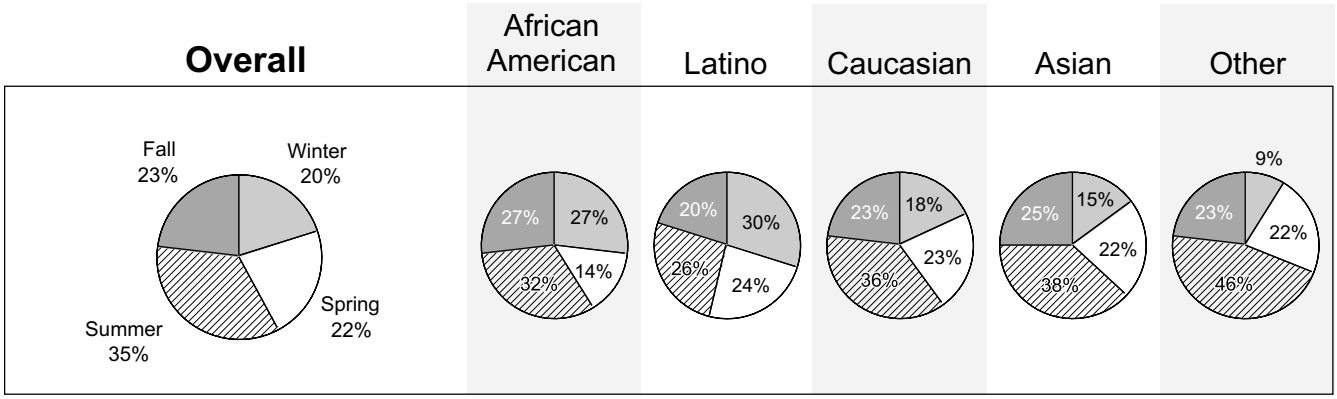
Season interviewed among consumers by fishing mode



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

Figure 19

Season interviewed among consumers by ethnicity



Anglers that reported no Bay fish consumption excluded. Adjusted for avidity bias.

modes and ethnic groups (see Figure 19), except for Latinos, Chinese and Pacific Islanders. More Latinos were interviewed during the winter, and more Chinese and Pacific Islanders were interviewed during the spring than other seasons (adjusted percentages, Table K19).

8. Years Eating Bay Fish

As shown in Table K20, 41% of all consumers have been consuming SF Bay fish 5 years or less and 27% have been consuming it for greater than 20 years. Among ethnic groups, Caucasians and African-American consumers reported eating Bay fish over a longer time period as compared to Latinos and Asians. Over 50% of Vietnamese, Chinese, Filipino, Pacific Islander, and Latino consumers reported consumption of Bay fish for five years or less compared to 25% of Caucasian consumers.

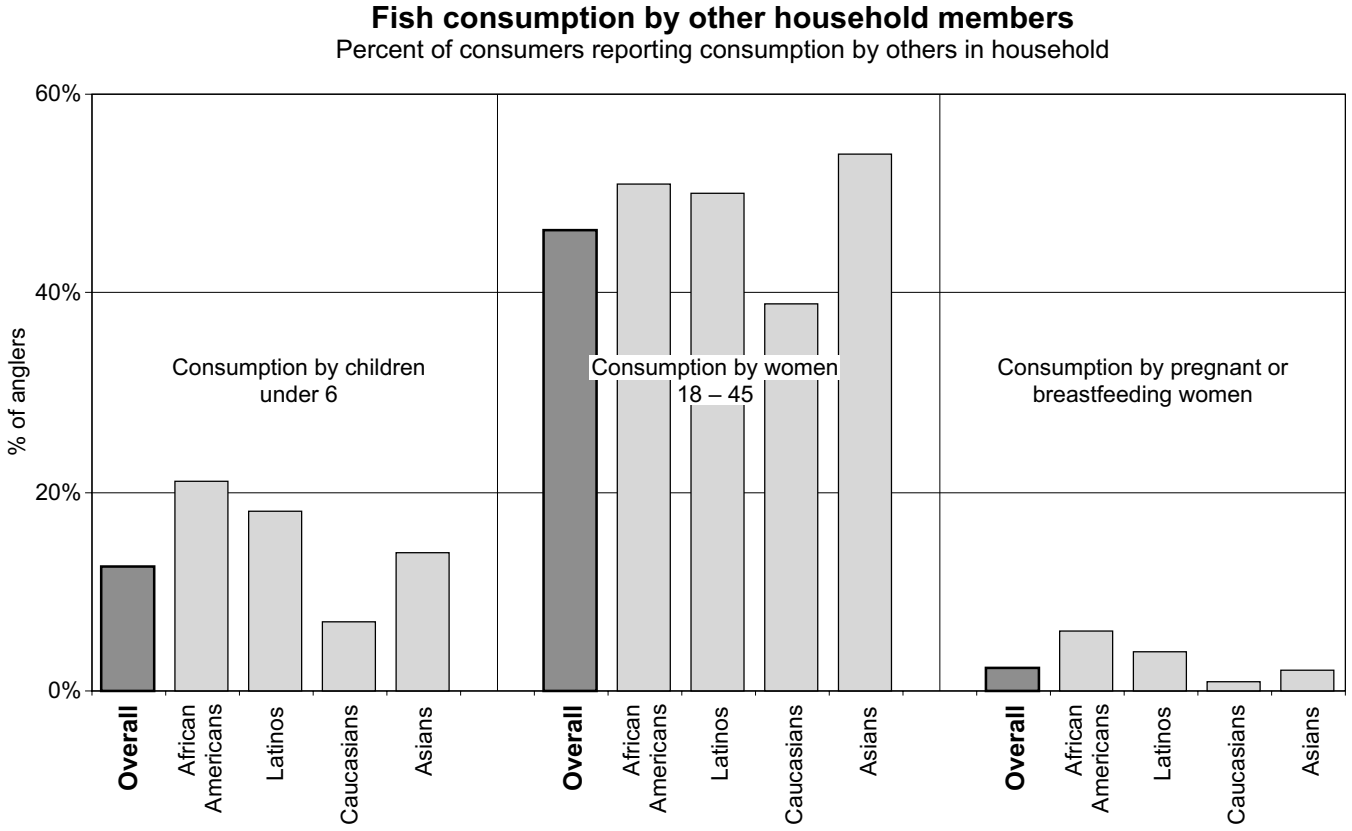
9. Fish Fate

Respondents were queried as to what they usually did with the fish or shellfish they caught from the Bay. The two most common responses were “eat it” or “give it to family or friend” (Table K21, unadjusted values). For consumers, most reported they usually ate the fish or shellfish they caught from SF Bay. A little less than half indicated they also give fish or shellfish to family or friends. As expected, non-consumers reported eating Bay fish much less frequently but gave it to family or friends. Responses to this question were not used to define whether the angler was a consumer or not (see Appendix J).

10. Household Members Who Eat Bay Fish

Because pregnant and breastfeeding women, women who are of childbearing age, and young children face increased risks from eating Bay fish, we asked respondents who else in their household eats Bay fish. As shown in Figure 20 and Table K22 (unadjusted values), only 2% of consumers reported pregnant or breastfeeding women in their household who ate SF Bay fish. However, 46% of consumers reported that women of childbearing age (18-45 years) in their household ate Bay fish, and 13% reported that children younger than six years of age ate Bay fish. By mode, consumers fishing at piers or beach and bank sites reported a higher proportion of pregnant women, women of childbearing age, and young children than consumers fishing from boats. Although non-consumers reported they do not consume SF Bay fish, many non-consumers reported women of childbearing age and young children in their households do consume Bay fish (see Table K22).

Figure 20



Anglers reporting no fish consumption not included. Not adjusted for avidity bias.

Comparing by ethnic group (see Table K23, unadjusted), about half of Asian, Latino, and African American consumers reported women of childbearing age in their household ate Bay fish. About a fifth of African Americans reported children under the age of six, compared to 7% of Caucasians.

11. Who Prepares or Cooks SF Bay Fish

We also asked respondents who in their household usually prepares or cooks the fish they catch and eat from the Bay. The majority of consumers (64%, unadjusted) reported they usually prepare or cook the fish they catch themselves and about one-fourth reported that their spouse usually prepares or cooks their catch (see Table K24). About a third of Latinos and Asians also reported spouse as the person who usually prepares or cooks Bay fish (see Table K25).

D. Fish Consumption Characteristics

As described in Section I.D., the primary goals of the study were to gather information for characterizing anglers' exposures to chemicals from eating Bay fish and to use that information to identify highly exposed subpopulations. In this section, we describe how much Bay fish anglers eat, and use consumption information to identify highly exposed groups. Next, we describe which species of SF Bay fish anglers consume, what parts are consumed, and how fish are prepared. In addition, consistent with the

specific study objectives, we quantified consumption of fish from sources other than SF Bay. We also quantified how frequently anglers ate three types of Bay shellfish (crabs, clams, mussels).

In general, the fish consumption data presented in the figures in this section have been adjusted for avidity bias, when this adjustment could be made (see Section III.D.1 for further discussion of avidity bias). The data tables in Appendix K, however, provide both unadjusted and adjusted data, as well as more detailed descriptions of anglers' responses.

1. Bay Fish Consumption Rates

To describe how much Bay fish anglers eat, we estimated fish consumption rates based on the amount of fish consumed over a given time period. As discussed in Section III.D.2, consumption rates were derived by multiplying two variables, portion size and meal frequency, and converting to grams per day (g/d). The portion size question was asked only once during the interview and was used to calculate all fish consumption rates in this study. However, we asked anglers to report meal frequency for two different time periods. The primary time period used was a four-week recall. We asked anglers how many times they ate Bay fish in the four weeks prior to being interviewed. When multiplied by portion size, we derived a consumption rate for the four-week recall period. Although less reliable than the four week recall, we also asked anglers to report the number of times they ate Bay fish in the past 12 months. When multiplied by portion size, a consumption rate over the 12-month recall period was derived.

In the following sections we describe portion size, meal frequency, and consumption rate responses. Consumption rates are described primarily for two populations, consumers and recent consumers. Consumers are anglers who eat Bay fish. Recent consumers are a subset of consumers who reported consuming Bay fish in the last four weeks. More detailed definitions of consumers and recent consumers can be found in Appendix J. We also derived "per angler" consumption rates, based on all respondents, to allow for comparisons with other studies.

a. Portion Size

Portion size responses characterize the amount of fish anglers reported consuming at one time. Figure 21 shows how consumers of Bay fish responded to the portion size question. In general, anglers gave portion size responses in multiples or fractions of the fish fillet model. Just over half (54%, adjusted) of consumers reported that the 8-ounce model was equal to the amount they eat at one time. Portion size responses of respondents and recent consumers were similar to consumers. Table K26 shows portion size responses for recent consumers, consumers, and respondents for common responses. Figure 22 shows the portion size responses among consumers as a distribution. Similar to Figure 21, responses are grouped around 8 ounces, (one model) 4 ounces (one half the model), 12 ounces and 16 ounces (one and a half and two times the model). The overall mean (adjusted) portion size for consumers was 7.7 ounces

Figure 21

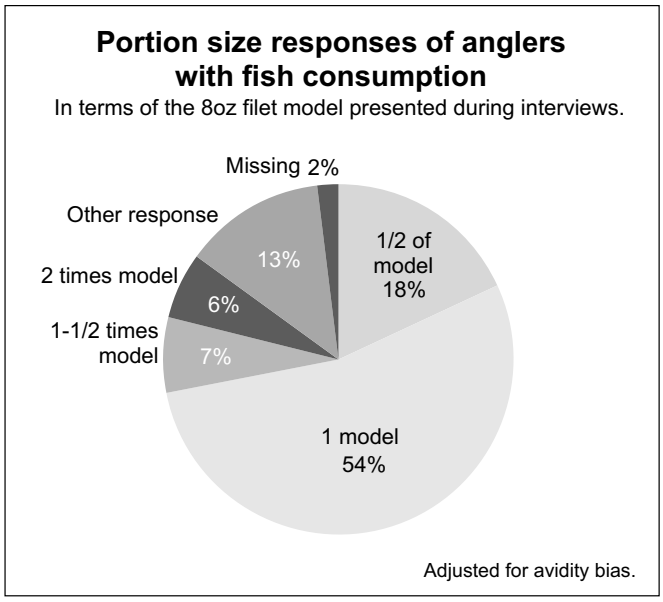


Figure 22

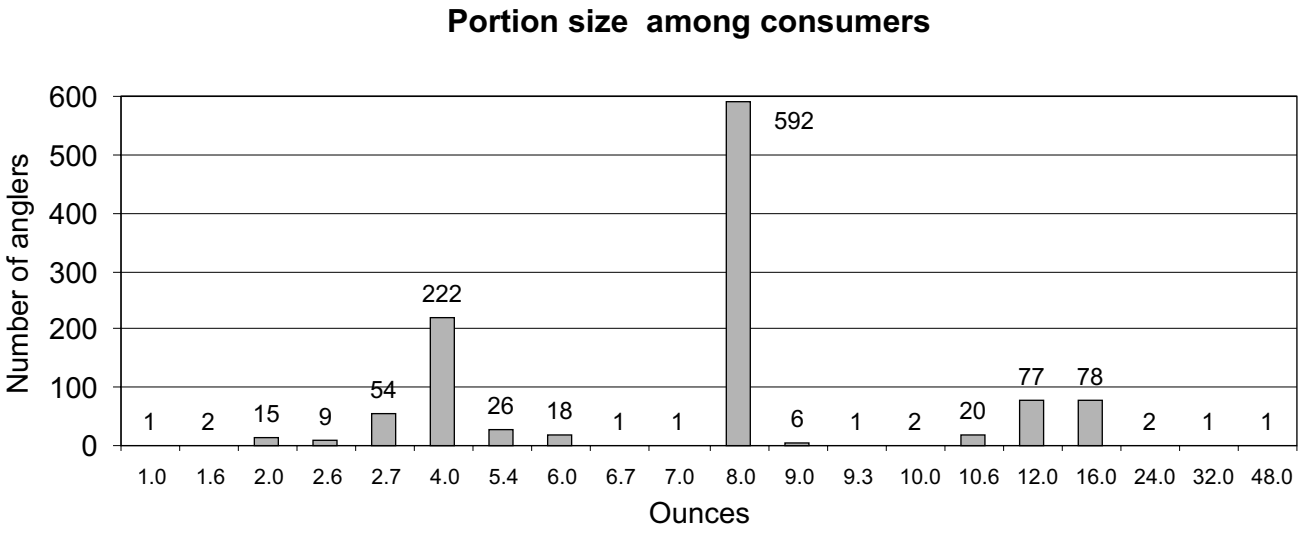


Not adjusted for avidity bias.

(217 grams), slightly less than the 8-ounce model. Tables K27a and K27b show the full distribution of portion size responses for consumers and recent consumers.

b. Meal Frequency among Recent Consumers

Meal frequency describes the number of times that anglers reported consuming Bay fish over a specified time period. In this section, we describe meal frequency responses for recent consumers based on a four-week recall. Table 3 summarizes meal frequency for recent consumers, both unadjusted and adjusted for avidity bias. The adjusted geometric mean meal frequency was slightly lower than the unadjusted meal frequency, although the medians were the same (two times in the last four weeks). Table K28 provides the complete meal frequency distribution (from the 10th to 95th percentile) for recent consumers.

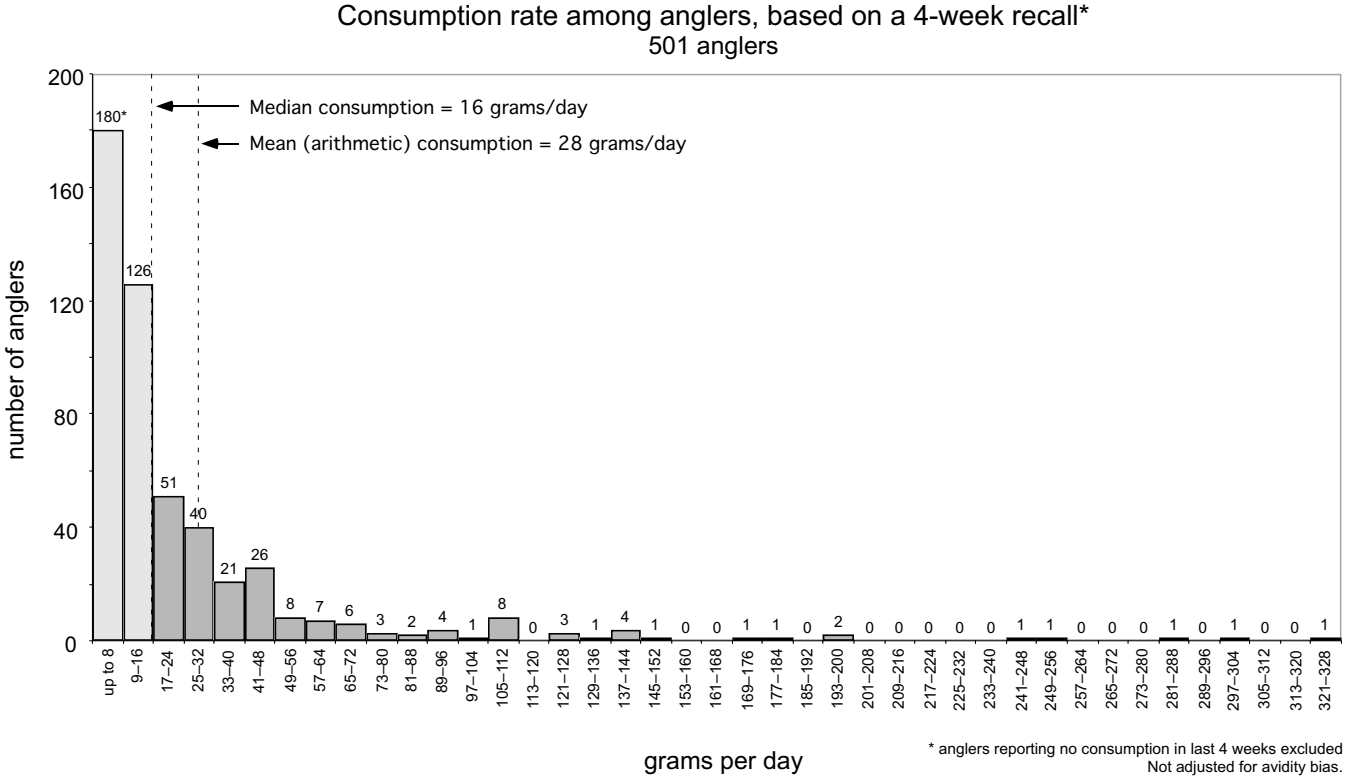
Table 3. Meal Frequency for Recent Consumers Based On Four Week Recall

Number of Times Bay Fish Was Consumed in the Last Four Weeks	Recent Consumers (Unadjusted for Avidity Bias) n=512[a]	Recent Consumers (Adjusted for Avidity Bias) n=473[a,b]
Mean (Standard Deviation)	3.5 (4.3)	2.9 (3.4)
Minimum Value	1	1
Maximum Value	32	32
Geometric Mean	2.4	2.0
Median (50th Percentile)	2	2
90th Percentile	7	6
95th Percentile	11	8

[a] For 25 recent consumers, meal frequency information was missing.

[b] For an additional 39 anglers, fishing frequency was not reported. Thus, meal frequency could not be adjusted for avidity bias. See Section III.D.1 for further discussion of avidity bias.

Figure 23



Although we identified 537 recent consumers in our sample, meal frequency information was missing for 25 recent consumers. Thus meal frequency could only be derived for a slightly smaller group of recent consumers (n = 512). In addition, not all recent consumers provided information on fishing frequency, which was needed to adjust for avidity bias. Thus, meal frequency (adjusted) was derived from 473 recent consumers (n = 473).

c. Consumption Rates among Recent Consumers

By multiplying portion size by meal frequency responses, we derived consumption rates for recent consumers. Figure 23 shows the consumption rate distribution for recent consumers using the raw (untransformed) data. The raw data show a skewed distribution that required a log transformation. (Further discussion of the shape of the consumption rate distribution can be found in Appendix J.)

In Table 4 we provide a summary of the consumption rate distribution for data unadjusted and adjusted for avidity bias. Table K29 displays the complete consumption rate distribution (from 10th to 95th percentile) for recent consumers. Similar to the meal frequency results in Table 3, consumption rate results could only be provided for a slightly smaller subset of recent consumers because information needed to estimate consumption rate or adjust for avidity bias was missing.

Tables 4 and K29 show the geometric mean to be much closer to the median value, whereas the arithmetic mean falls near the 70th percentile of the full distribution for both adjusted and unadjusted data. Median consumption rates for recent consumers were 16.0 g/d for both unadjusted and adjusted data. This amount is equal to consuming two eight-ounce meals over a four-week (28 day) period. Adjusting the data for avidity bias resulted in only a slight lowering of the arithmetic and geometric means.

The values reported in Table 4 represent overall consumption rates of recent consumers that apply across fishing modes. In the sampling plan, as discussed in Section II.B.3, we set sampling targets that were weighted by the relative amount of fishing activity in each mode. As discussed in Section IV.A, our estimate of the relative proportions by mode in the sample of anglers we interviewed was slightly different than our targets. However, re-weighting the sample proportions by mode to reflect these differences did not change the consumption rate estimates in Table 4 (see Appendix J for further discussion).

Table 4. Consumption Rates in Grams/Day (g/d) for Recent Consumers Based On Four Week Recall

Consumption Rate (g/d)	Recent Consumers (Unadjusted for Avidity Bias) N=501[a]	Recent Consumers (Adjusted for Avidity Bias) N=465[a,b]
Mean (Standard Deviation)	28.1 (39.6)	23.0 (32.0)
Minimum Value	2.0	2.0
Maximum Value	324.0	324.0
Geometric Mean	16.5	14.0
Median (50th Percentile)	16.0	16.0
90th Percentile	56.0	48.0
95th Percentile	108.0	80.0

[a] For 36 recent consumers, there was insufficient information for deriving a consumption rate
[b] For an additional 36 recent consumers, fishing frequency was not reported. Thus, their consumption rate could not be adjusted for avidity bias.

d. Consumption Rates among Consumers

In order to gain a better understanding of the larger population of anglers who consume Bay fish, we present in this section consumption rate results for all consumers of Bay fish. We estimated consumption rates for consumers based on both a four-week and a 12-month recall. Table 5 shows values that characterize consumption rates for consumers of Bay fish for these two recall periods.

Table 5. Consumption Rates in Grams/Day (g/d) for Consumers Based on Four Week and 12 Month Recall

Consumption Rate (g/d)	Four Week Recall (adjusted for avidity bias) N=1080[a]	12 Month Recall (unadjusted for avidity bias [b]) N=1019[c]
Mean (Standard Deviation)	6.3 (19.6)	11.0 (35.7)
Geometric Mean	0.0	1.2
Minimum Value	0.0	0.0
Maximum Value	324.0	638
Median (50th Percentile)	0.0	2.5
90th Percentile	16.0	22.1
95th Percentile	32.0	44.2

[a] For 36 anglers, there was insufficient information for deriving a consumption rate. For an additional 36 anglers, fishing frequency was not reported. Thus, their consumption rate could not be adjusted for avidity bias. See Section III.D.1 for further discussion of avidity bias.
[b] Twelve month recall data could not be adjusted for avidity bias.
[c]Consumption rate data for 133 respondents (12%) was missing.

Consumption rates based on a four-week recall have been adjusted for avidity bias (the full distribution and unadjusted data can be found in Table K30a). Because about half of consumers (53%) did not consume any fish in the four weeks prior to being interviewed (i.e., their consumption rate in the last four weeks was zero), the geometric mean and median are zero.

Most consumers reported some consumption of Bay fish in the last 12 months. However, as noted by USEPA (1998), the accuracy of a survey respondent's recall decreases as the time period over which the recall is made increases. Thus, the consumption rate results based on the 12-month recall may be less reliable than the responses based on a four-week recall. Among consumers who reported consumption of Bay fish in the last 12 months, 14% (n=142) said that the number of times they had eaten fish was zero. Because zero was a valid response, these zero values were included in the calculation of the consumption rate values in Table 5. Missing values, however, were excluded. The median consumption rate for consumers was 2.5 g/d. This amount is equal to consuming about one 8-ounce portion every three months. The consumption rate based on a 12-month recall period could not be adjusted for avidity bias because we did not ask anglers how frequently they fished in the past 12 months. The full distribution can be found in Table K30b.

e. Per Angler Consumption Rates

Some angler studies report per angler consumption rates that are based on all survey respondents including non-consumers (i.e., anglers who do not eat any fish). In Table 6 we present per angler consumption rates based on both four-week and 12-month recall periods so that comparisons to other studies can be made. These estimates include a significant number of anglers who reported consumption rates of zero. In fact, similar to results presented in the previous section, the majority of consumers and respondents based on a four-week recall had consumption rates of zero; thus the median is zero. Also, as noted in the previous section, consumption rates based on a 12-month recall may be less reliable than those based

Table 6. Consumption Rates in Grams/Day for Respondents Based on a Four Week and 12 Month Recall

Consumption Rate (g/d)	Four Week Recall (adjusted for avidity bias) N=1259[a]	12 Month Recall (unadjusted for avidity bias[b]) N=1198[c]
Mean (Standard Deviation)	5.3 (18.2)	9.3 (33.1)
Geometric Mean	0.0	0.4
Minimum Value	0.0	0.0
Maximum Value	324.0	638
Median (50th Percentile)	0.0	1.8
90th Percentile	16.0	18.4
95th Percentile	24.0	36.8

[a]For 36 anglers, there was insufficient information for deriving a consumption rate. For an additional 36 anglers, fishing frequency was not reported. Thus, their consumption rate could not be adjusted for avidity bias. See Section III.D.1 for further discussion of avidity bias.
[b] Twelve-month recall data could not be adjusted for avidity bias.
[c]Consumption rate data for 133 consumers (10%) was missing; non-consumers were assigned a consumption rate of zero.

on a four-week recall. The median consumption rate of 1.8 g/d based on a 12-month recall is equivalent to consuming about one eight-ounce portion every four months. The full distribution of these consumption rates for respondents can be found in Tables K31a and K31b.

2. Differences Among Demographic Subgroups

In addition to estimating overall fish consumption rates for anglers who consume SF Bay fish, another primary goal of the study was to identify highly exposed subpopulations. One way to identify a highly exposed subpopulation is to compare consumption rate variables (i.e., portion size, meal frequency, and consumption rates) within demographic subgroups and look for differences among these subgroups.

When we compared the arithmetic mean (adjusted) portion sizes among consumers of Bay fish, we found differences for ethnicity, season interviewed, and gender (see Table K32). Among ethnic groups, African Americans reported the largest portion size (9.0 ounces); their portion size was significantly larger than Caucasians and Asians. Asians reported the smallest portion size (6.7 ounces). Their portion size was significantly smaller than Latinos and Caucasians, as well as African Americans. Portion sizes differed by season of interview, with larger portion sizes reported during the fall (8.1 ounces) than the spring (6.6 ounces). Also, female anglers reported a smaller portion size (6.6 ounces) than male anglers (7.8 ounces).

For meal frequency and consumption rates in this study we compared the geometric means (adjusted). Comparisons of meal frequency based on a four-week recall for recent consumers showed no differences among demographic subgroups except among ethnic groups (see Table K33). Figure 24 shows adjusted geometric mean meal frequencies with 95% confidence intervals by major ethnic groups. Asians had a higher meal frequency (2.5 times in the last four weeks) than Caucasians (1.7 times). As shown by the non-overlapping confidence intervals, these differences were statistically significant. Among Asian subgroups, shown in Figure 25, Filipinos had the highest meal frequency (3.1 times). The

Figure 24

complete distribution of meal frequency responses by demographic factors can be found in Tables K34a and K34b.

Comparisons of consumption rates among subgroups of recent consumers showed differences for ethnicity but not for other demographic characteristics (see Table K35). Figure 26 shows adjusted geometric mean consumption rates by major ethnic groups. The geometric mean consumption rates for African Americans were roughly 50% higher than Caucasians, the ethnic group with the lowest consumption rate. Figure 27 includes Asian subgroups. Filipinos also had consumption rates approximately 50% higher than Caucasians. These differences were statistically significant. Pacific Islanders and anglers whose ethnicity was described as "Other" (Russian, Middle Easterners, and individuals of unspecified mixed ethnicity) had the highest consumption rates of all ethnic groups, approximately double the rate for Caucasians. However, anglers in these two groups were very small in number (Pacific Islanders, n=12 and Other, n=7), and differences in the geometric means between these two groups and Caucasians were not significant. Tables K36a and K36b describe the geometric mean and full distribution of consumption rates among recent consumers by demographic variables for unadjusted and adjusted data.

Because consumption rate data were not normally distributed, we also used a non-parametric test, the Wilcoxon signed rank test, to compare consumption rates within demographic variables. Using this test, ethnicity showed significant differences ($p<0.05$) between subgroups with consumption rate. No statistically significant differences with consumption rates existed based on mode, income, education, age, gender, or season of interview.

3. Highly Exposed Consumers

As discussed in the previous section, one way to identify highly exposed subpopulations is to compare consumption rate variables among subgroups and look for differences. In this section, we discuss another way to identify highly exposed anglers by describing the demographic characteristics of the group of anglers with the highest consumption rates. We characterize two highly exposed groups, those who eat

Figure 26

above health advisory levels, and those whose overall consumption rate is above the 95% percentile. These highly exposed groups are then compared to consumers of Bay fish who are below these levels.

a. "Above Advisory" Consumers

Anglers who consume Bay fish above levels recommended by the health advisory for SF Bay can be considered a highly exposed group. The health advisory recommends that anglers limit their consumption of most species of Bay fish to no more than two meals per month, with meal size adjusted for body weight. (See Appendix A for full text of the health advisory). We defined "above advisory" consumers as those who reported consuming greater than 16 ounces (two 8-ounce meals) of advisory species in the four weeks prior to being interviewed. (Sixteen ounces consumed within a four-week period is equal to 16 g/d.) Above advisory consumers differ from anglers whose overall consumption rate is greater than 16 g/d because some commonly consumed species, such as jacksmelt and salmon, are not included in the health advisory.

In order to see how the above advisory consumers are different from other consumers of Bay fish, we compared them to consumers who did not surpass the health advisory level. We call this group the "below advisory" group. We find in Figure 28 that 9% of consumers (adjusted; 15%, unadjusted, see Table K37a) reported consuming above advisory levels (greater than 16g/day) in the four weeks prior to being interviewed. Looking only at meal frequency, we also find that 9% (adjusted; 16%, unadjusted) of consumers reported consuming greater than 2 meals of advisory fish within a four week period. Based on consumption rates, for the 9% above advisory consumers, Figure 28 also shows how far above the advisory recommendations these anglers are consuming. For example, 41% of above advisory consumers are consuming between two to four times (32 g/day to 64 g/day) above the advisory level. Only 1% are consuming 16 times (256 g/day) or more above the advisory level.

We also examined the demographic differences between the above and below advisory groups in two ways. In Figure 29, we compare how the demographic profile of above advisory consumers differs from below advisory consumers. Among fishing modes, we found that private boat anglers represented a smaller proportion of the above advisory consumers when compared to the below advisory consumers. Among ethnic groups, Asians represented a larger proportion among the above advisory group when compared to the below advisory group, whereas Caucasians represented a smaller proportion among the above advisory consumers. Within income and education levels, differences between the above and

Figure 28

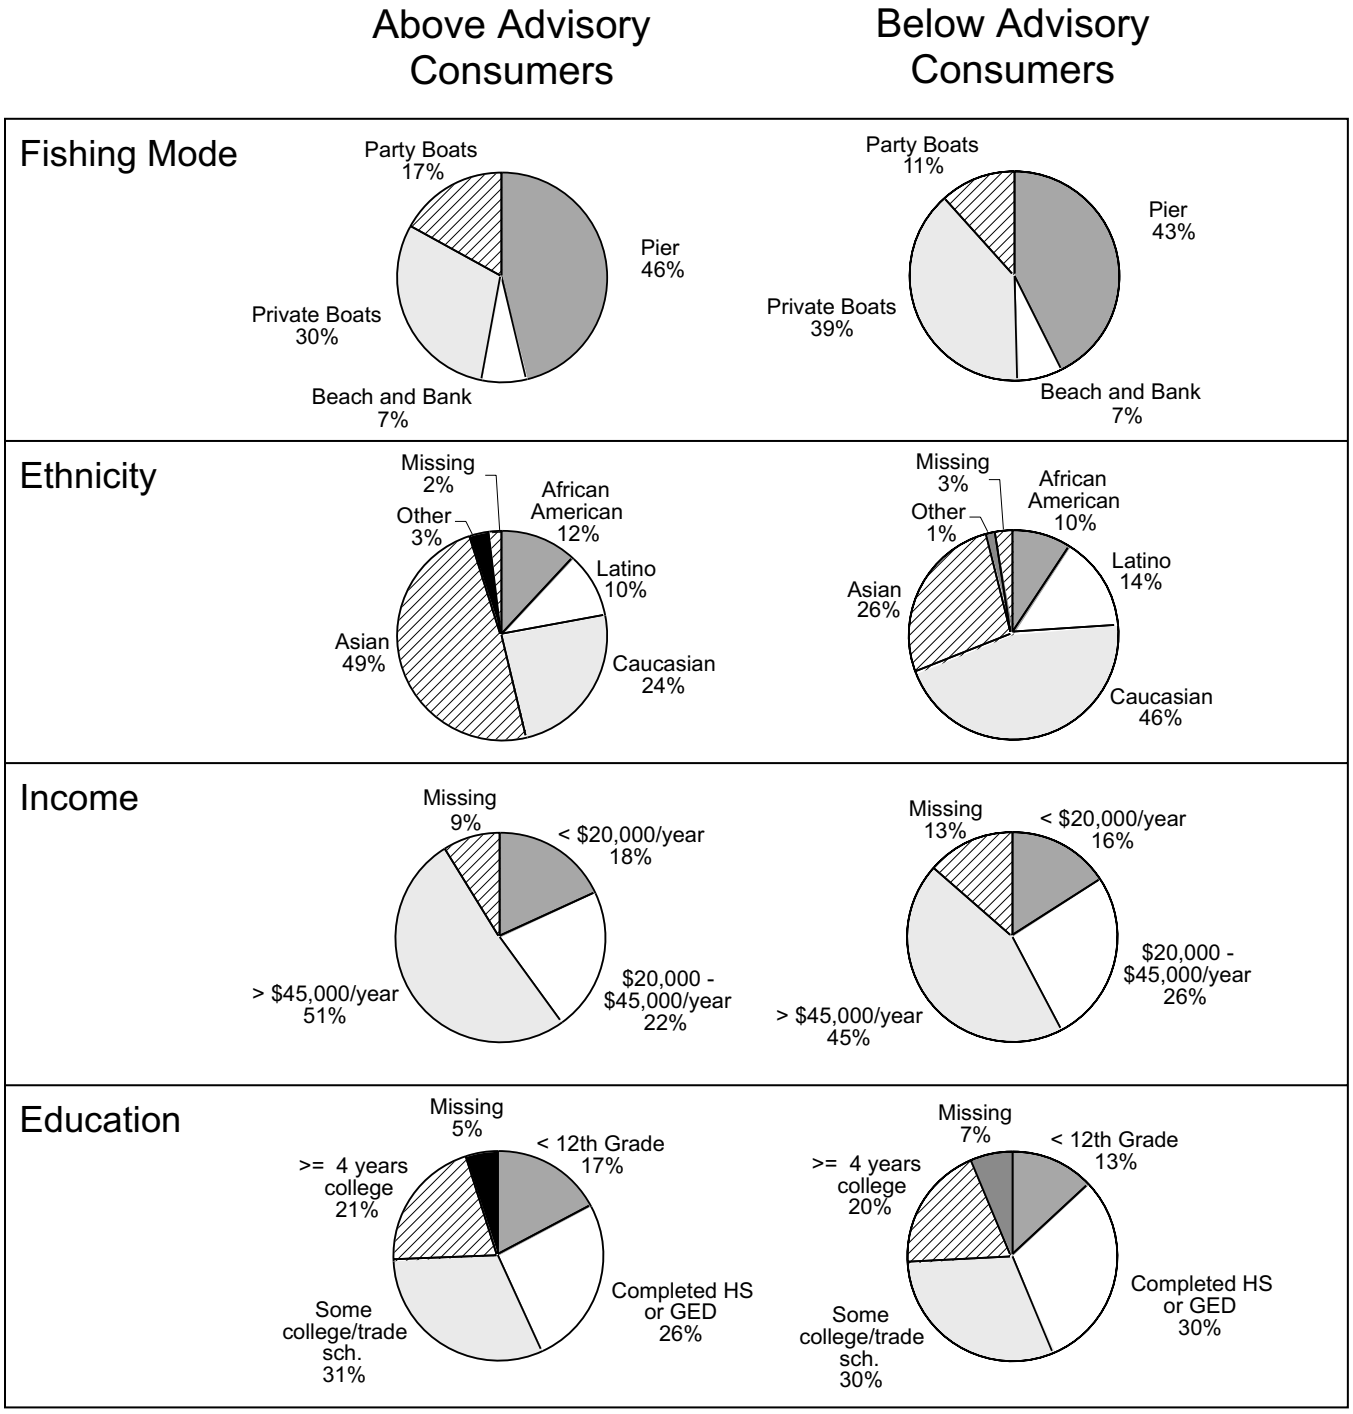
Demographic characteristics of anglers consuming above and below the advisory

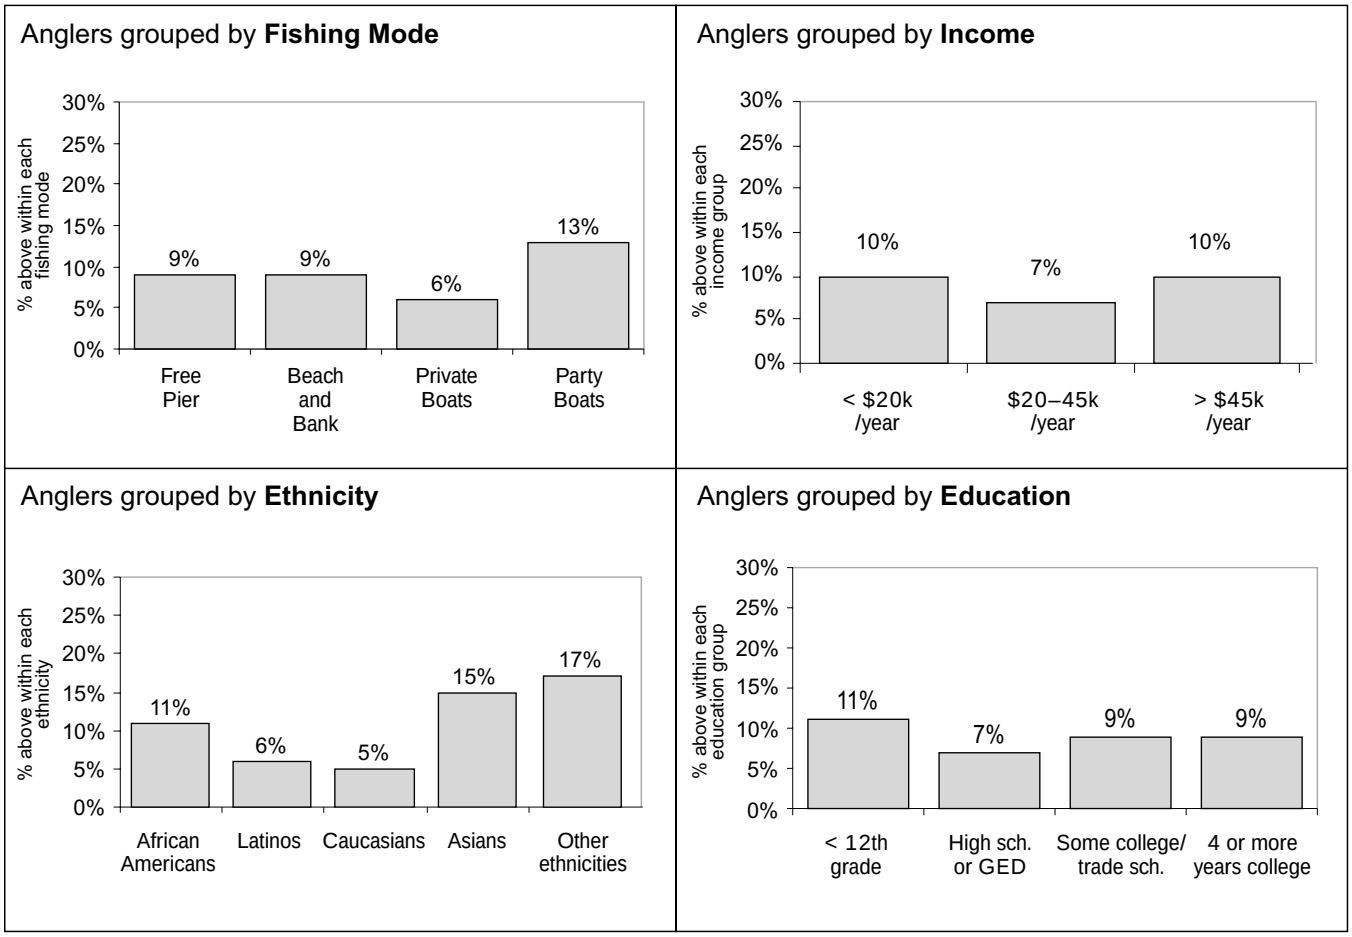


All percentages adjusted for avidity bias.

Figure 30

Percentage of anglers consuming above advisory recommendations

Anglers with Bay fish consumption



Anglers with no fish consumption excluded from percentage calculations. All percentages adjusted for avidity bias.

below advisory group were small. Tables K37a and K37b compare the above advisory groups to the below advisory group for these and other demographic variables. We also show these same data presented in a different way. Figure 30 compares the proportion of above advisory consumers within demographic subgroups. For example, within ethnic groups, Asians were three times more likely to be in the above advisory group than Caucasians (see Table K37b).

It is important to note that the health advisory is more restrictive for women who are pregnant, planning to become pregnant, or nursing, and for small children. For these groups, the health advisory recommends that consumption of Bay fish be limited to no more than one time per month. We did not interview any children, and we did not determine whether the women we interviewed were pregnant, planning to become pregnant or nursing. However, as discussed previously and shown in Table K35, consumption rates for female anglers did not differ from consumption rates for males. Thus, if consumption rates for pregnant women, women planning to become pregnant, and nursing women are similar to women we interviewed, then a much higher proportion of these women will exceed a more restrictive health advisory.

b. Consumers above the 95th Percentile

Because risk assessors often use upper percentiles of a distribution to characterize high end exposures, in Figure 31 we characterized the consumers of Bay fish whose consumption rate was among the top five percent of consumers (i.e, above the 95th percentile). We compared this group, who consumed greater than 32 g/day (adjusted), to consumers of Bay fish whose consumption rate was at or below the 95th percentile.

Figure 31 also compares these two groups by demographic variables. Similar to the above advisory consumers discussed in the previous section, we found that a larger proportion of the top five percent of consumers were Asian and a smaller proportion were Caucasian, when compared to the remaining 95% of consumers. However, unlike the above advisory consumers, a larger proportion of the top five percent group reported the highest income level (>$45,000 per year) than the comparison group. Differences by mode and education were small. Table K38 compares the top five percent to the remaining 95% of consumers for these and other demographic variables.

4. How Decliners May Affect Consumption Rates

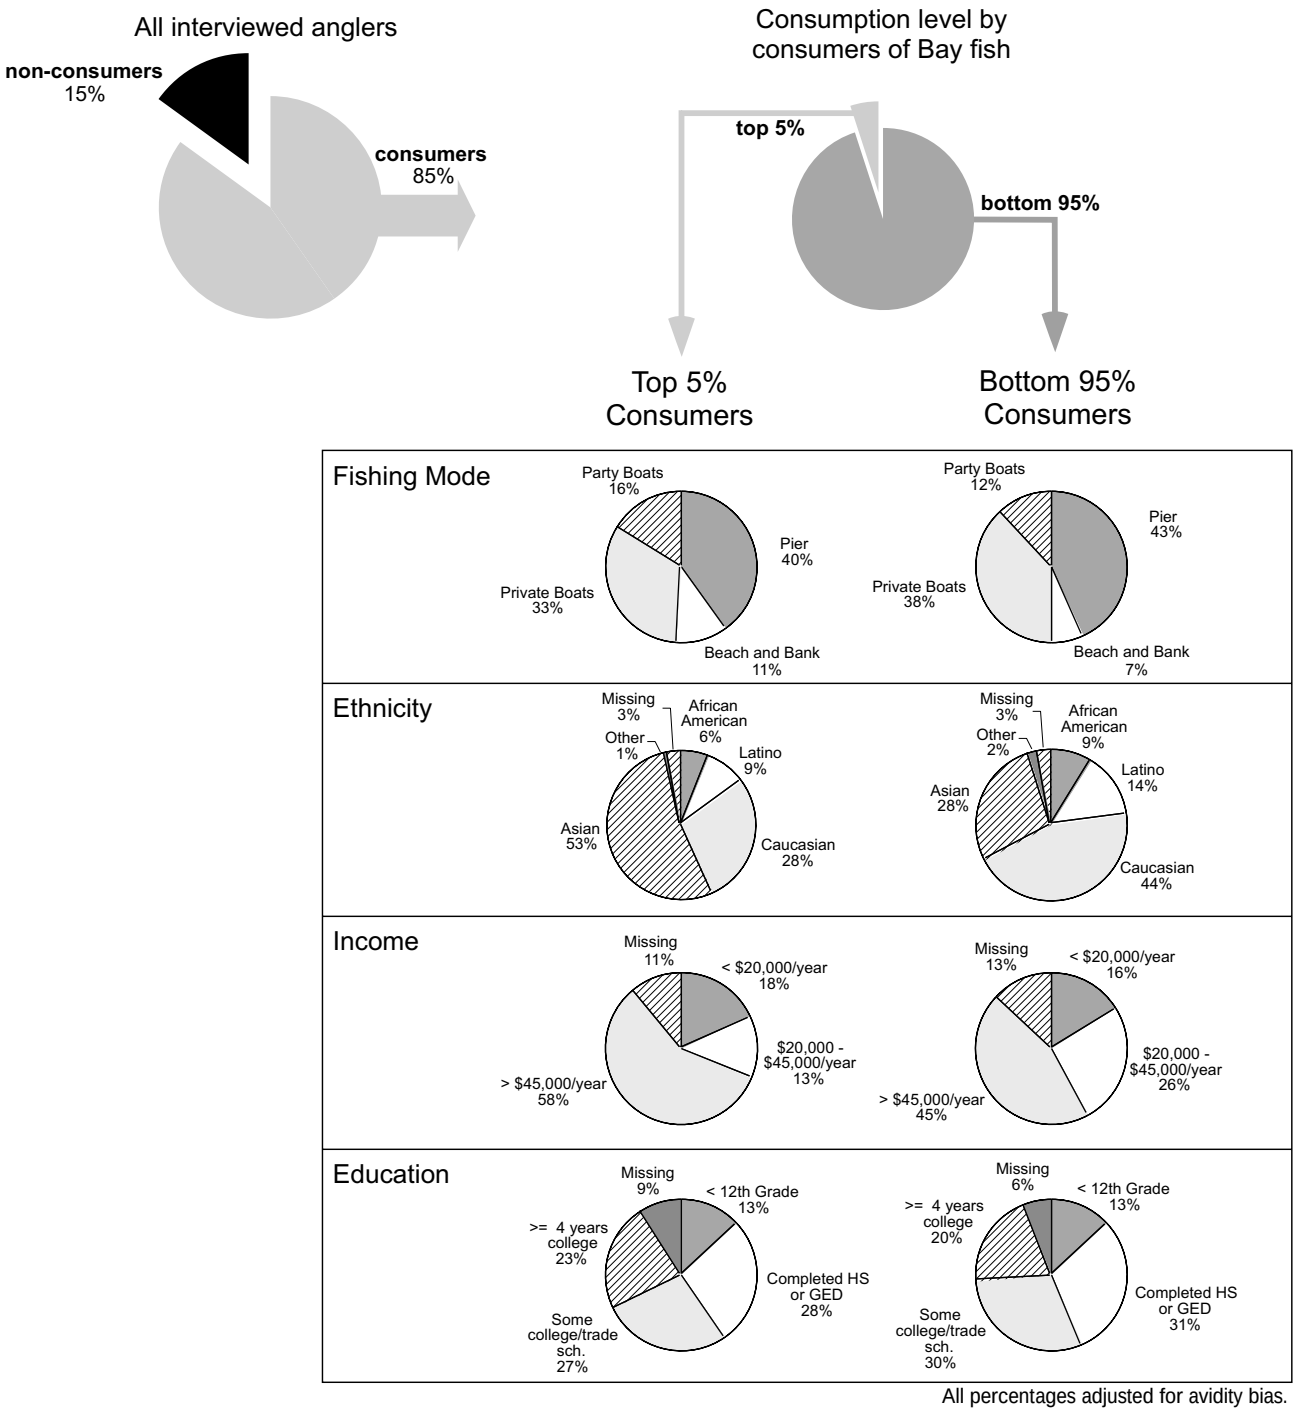
Anglers who declined to be interviewed for this study represented 23% (n=407) of net attempted interviews (see Section IV.B, Figure 4 and Table 2). Although the decline rate for this study was lower than similar studies (Wong *et al.*1997, SCCWRP/MBC 1994), lacking data on nearly one fourth of the sample may have introduced some bias. By recording observed ethnicity for anglers who declined to be interviewed, we were able to show that the ethnic profile of those who chose not to participate in the study (i.e., decliners) differed from anglers who agreed to be interviewed (Tables K1c and K3c). Decliners, for example, had a higher proportion of Asians than anglers who were interviewed. In addition, for about a third of decliners, we recorded language problems as the reason the angler declined to be interviewed. These anglers could be comprised of recent immigrants who may be less aware of health advisories and thus have higher consumption rates than the angler population as a whole.

We evaluated how consumption rates of recent consumers (based on a four-week recall) may have been influenced by the decliners. As a worst-case scenario, to ensure that we do not underestimate the influence decliners may have had on overall consumption rates, we assumed that all decliners had recent consumption (in the last four weeks) of Bay fish. (More likely, decliners included non-consumers or consumers who had not eaten Bay fish recently, as in the interviewed population). Furthermore, because ethnicity was the only demographic variable that showed a significant influence on consumption rate, we adjusted our sample to account for ethnic differences between the decliners and interviewed anglers. We did this by assuming that decliners of a certain ethnic group had the same consumption rate as recent consumers we interviewed in the same ethnic group. We found that consumption rates of recent consumers with decliners included were virtually identical to the consumption rates of recent consumers without decliners.

It is also plausible that decliners have consumption rates that are lower than anglers who were interviewed. For example, they may have declined to be interviewed because they consume very little Bay fish or do not eat Bay fish at all. If decliners have low consumption rates, the consumption rates presented in Section IV.D.1 may be biased upwards. Although any bias associated with anglers who declined to be interviewed is not quantifiable, our analysis using reasonable assumptions about this group revealed that the 23% of anglers from whom we could not directly obtain consumption data are not very likely to influence our overall derived consumption estimates.

Figure 31

Demographic characteristics of anglers with consumption rate in the top 5% (above 32 grams/day) and bottom 95%



All percentages adjusted for avidity bias.

5. Commonly Consumed Species

One of the study objectives was to determine which species of SF Bay fish were most commonly consumed by anglers. We determined the most commonly consumed species in two ways. First, for the three species of greatest health concern in SF Bay white croaker, leopard shark, and striped bass, we asked whether anglers, in general, consumed these species. Second, we asked anglers whether they had had recent consumption (in the last four weeks) of any SF Bay fish species, including these three species. Data reported in this section could not be adjusted for avidity bias, thus results are unadjusted.

a. Consumption of White Croaker, Leopard Shark, and Striped Bass

For three species of SF Bay fish—white croaker, leopard shark, and striped bass—interviewers asked respondents the general question, "Do you eat this fish?" When asking about these three species, the interviewer showed the respondent color photos of these fish (see Appendix F). Among consumers of Bay fish, about three fourths reported that, in general, they ate striped bass while much smaller proportions (28% and 20%, respectively) reported that they ate white croaker and leopard shark (see Figure 32).

We also looked at the demographic variables that describe consumers of these three species. For consumers who said they eat white croaker, there were statistically significant differences within mode, ethnicity, income, and education (see Figure 32 and Table K39). For example, a much higher proportion of consumers who fish from piers and beach and bank sites, reported that they eat white croaker, compared to boat anglers. Among ethnic groups, 46% of Asians eat white croaker compared to only 10% of Caucasians. The proportion of consumers who reported the lowest income level (<$20,000) were twice as likely to consume white croaker than consumers reporting the highest income level (>$45,000). A similar pattern was found for level of education.

For consumers of leopard shark, there were statistically significant differences within ethnicity (when Asian subgroups were included), income, and education (see Figure 32 and Table K39). A higher proportion of Vietnamese and Chinese reported consuming leopard shark compared to other ethnic groups. As with white croaker, consumers at the lowest income and educational levels had a higher proportion of leopard shark consumers than consumers at the highest income and educational levels.

Because such a high proportion of consumers eat striped bass, there were no statistically significant differences by mode, ethnicity, income and education, for consumers of this species (see Figure 32 and Table K39).

b. Commonly Consumed SF Bay Fish Species

In addition to asking respondents if they, in general, eat white croaker, leopard shark, or striped bass, respondents were also asked if they had consumed any SF Bay fish species in the last four weeks. The interviewers showed respondents color pictures of 16 fish species and three types of Bay shellfish. Shellfish consumption is described in a later section (Section IV.D.8). Interviewers then asked respondents about recent consumption of other fish species for which pictures were not available.

Figure 33 shows the 14 most commonly consumed fish species among recent consumers during the twelve-month survey period. Striped bass was the most commonly consumed fish species, with slightly over half of recent consumers reporting they consumed striped bass in the last four weeks. We excluded fish species reported by less than 1% of recent consumers. Interviewers showed anglers pictures of all species in Figure 33 except salmon.

In Figure 34, we compared the demographic variables that characterize the anglers who had recent consumption of two species, halibut and jacksmelt. These two species were the second and third most

commonly consumed species (in the last four weeks) after striped bass. We do not present demographic factors that characterize recent consumers of striped bass because there were no significant differences within these factors except for season of interview (Table K40). We found statistically significant differences within mode, ethnicity, and income for both halibut and jacksmelt (see Figure 34). For example, among fishing modes, a much higher proportion of party boat anglers had recent consumption of halibut compared to shore-based anglers. In contrast, a higher proportion of shore-based anglers (especially beach and bank anglers) had recent consumption of jacksmelt compared to boat anglers.

Caucasians were more than two times as likely to have consumed halibut than Asians, although Asians were almost ten times as likely to have consumed jacksmelt than Caucasians. For recent consumers of halibut, the proportion in the highest income level was nearly three times that in the lowest income level. For recent consumers of jacksmelt, the proportion in the lowest income levels was nearly twice the highest income level.

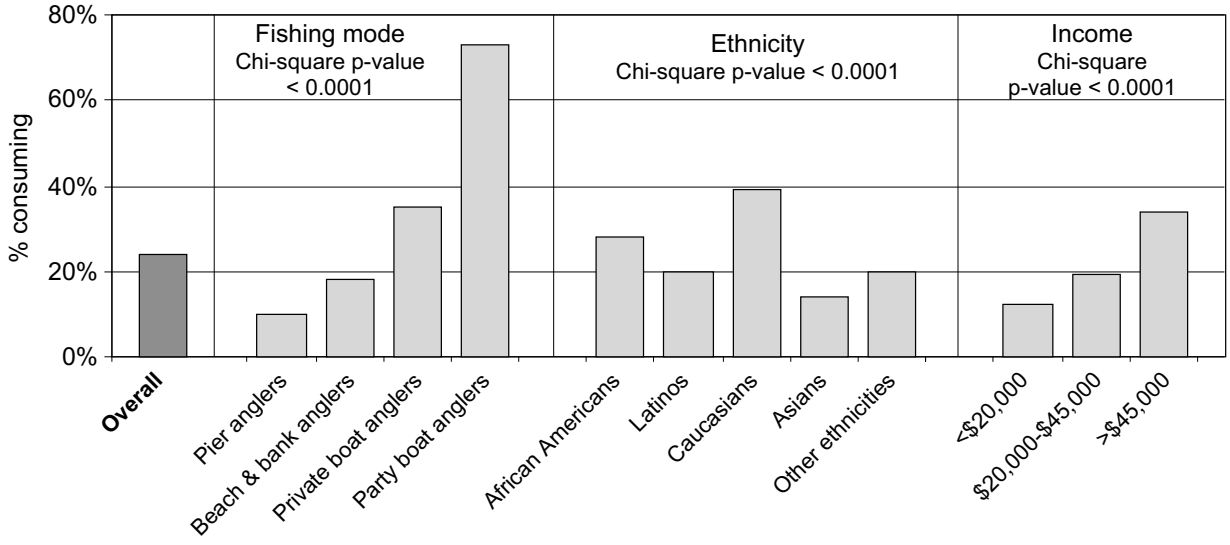
Comparison of demographic factors among recent consumers of the top seven fish species (striped bass, halibut, jacksmelt, sturgeon, white croaker, surfperch, and leopard shark) can be found in Table K40.

6. Fish Parts Consumed and Fish Preparation Practices

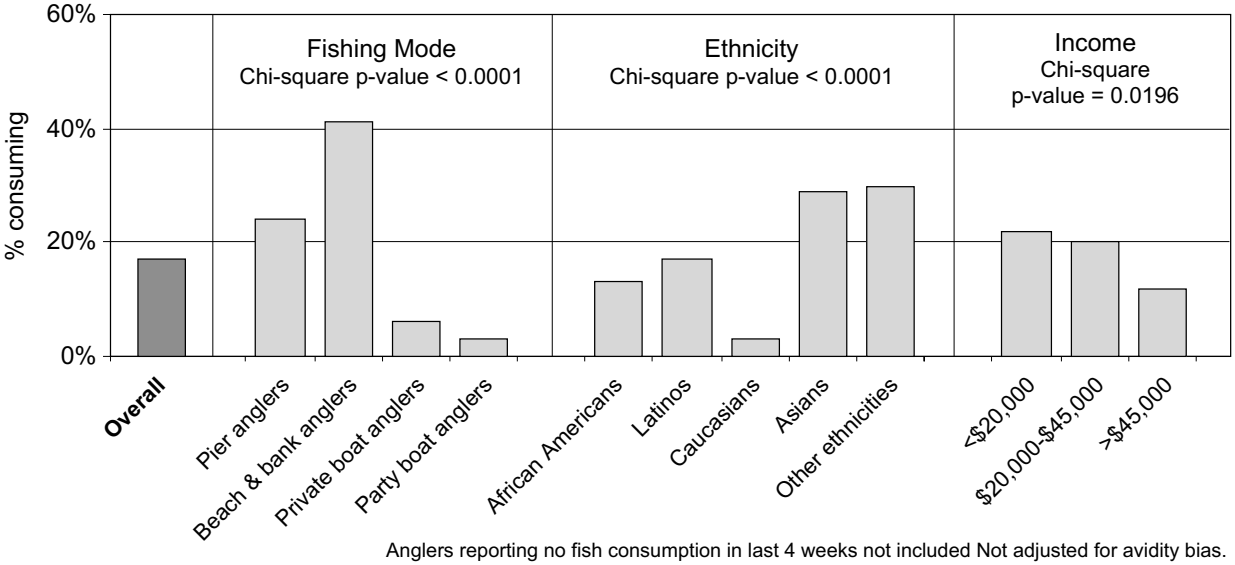
Because the parts of the fish consumed and the preparation and cooking methods used will influence an angler's exposure to chemicals in contaminated fish, another objective of the study was to characterize these consumption methods for three SF Bay species: white croaker, leopard shark, and striped bass. This information will help identify populations that are likely to be more exposed to chemical contaminants because of their consumption practices.

Figure 34

Percentage of recent consumers with halibut consumption



Percentage of recent consumers with jacksmelt consumption



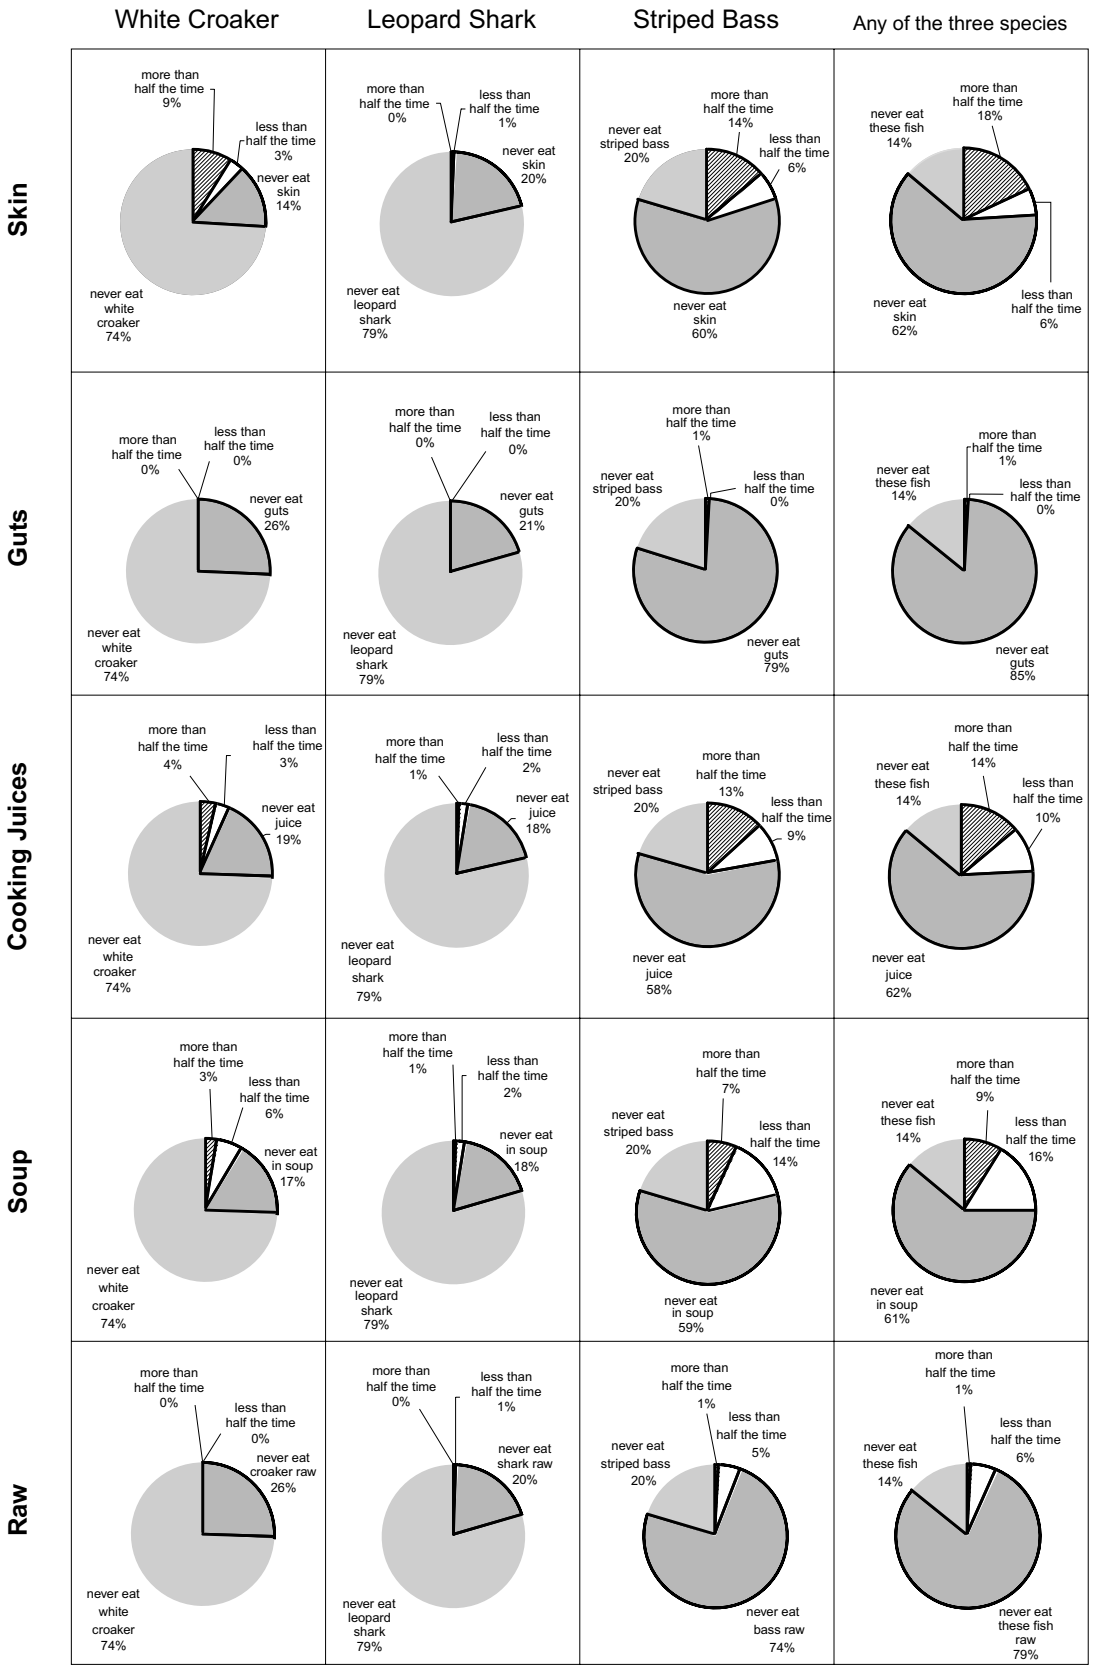
Anglers reporting no fish consumption in last 4 weeks not included Not adjusted for avidity bias.

Anglers were asked about each of the three species independently. Anglers first had to report that they, in general, ate one of the three species before they were asked about their consumption methods for that species. Specifically, interviewers asked anglers how often they ate: (1) the skin, (2) the guts, (3) the cooking juices or drippings, (4) the species in soup, (5) the species raw. In answering these questions, respondents indicated whether they followed the consumption practice more than half the time, less than half the time, or never.

The data on fish parts consumed and fish preparation methods used by anglers is summarized for the three species in Figure 35 and Table K41. Overall, we found that the majority of consumers of Bay fish never reported any of these five consumption practices for the three species. Only about one fourth

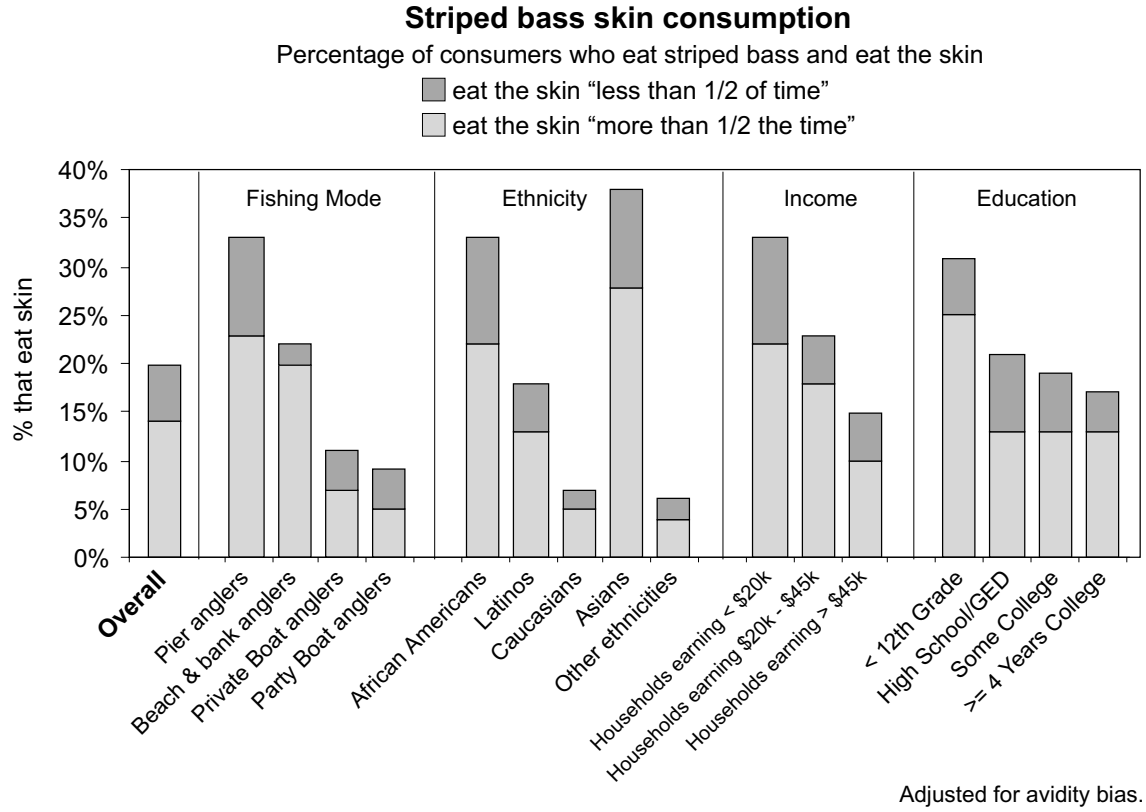
Figure 35

Fish parts consumed and fish preparation practices among consumers



Adjusted for avidity bias.

Figure 36a



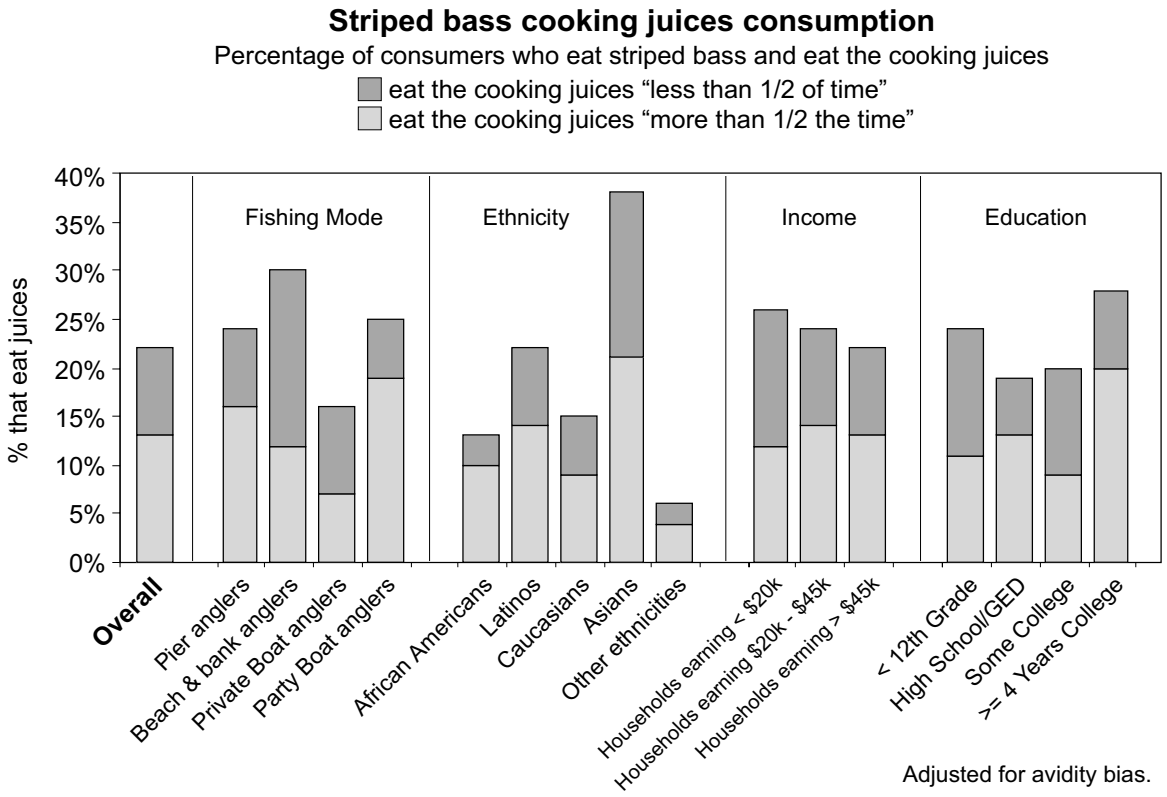
of consumers reported that they ever ate skin, cooking juices, or ate soup made from at least one of these species. Only 1% of consumers reported consumption of guts for any of the three species and only 7% reported raw consumption.

Consumers of Bay fish more frequently reported consumption of striped bass skin, guts, etc., compared to the other two species. This was due largely to the fact that a much higher percentage of consumers ate striped bass than other species (see Figure 35). However, when consumers who did not eat these species were excluded, the proportions changed. For example, among consumers of white croaker, nearly half ate white croaker skin whereas only one fourth of striped bass consumers ate striped bass skin. About one in three consumers of white croaker ate this species in soup. In comparison, only one in five striped bass consumers ate this species in soup. About one fourth of striped bass and white croaker consumers ate the cooking juices of these species at least some of the time. Raw consumption was still highest among striped bass consumers, compared to other species. These consumption methods among leopard shark consumers were uniformly lower than the other two species.

Further analysis of consumption of striped bass skin, cooking juices, and consumption of this species raw by demographic factors is presented in Figures 36a-36c. We chose to present more detailed analysis of consumption practices for striped bass because the majority of anglers in all demographic groups consumed this species, thus consumption methods were not skewed by who did or did not eat this species.

Among consumers who ate striped bass skin, shore-based anglers were twice as likely as boat anglers to eat skin of this species at least some of the time. African American and Asians were four to five times as likely as Caucasians to eat skin at least some of the time. Also, the proportion of anglers

Figure 36b



who ate striped bass skin was highest at low income and education levels. Among consumers who ate cooking juices of striped bass, private boat anglers were less likely to consume cooking juices of striped bass than anglers of other fishing modes. Asians were nearly three times as likely as Caucasians and African Americans to consume cooking juices at least some of the time. Differences by income and education were relatively small.

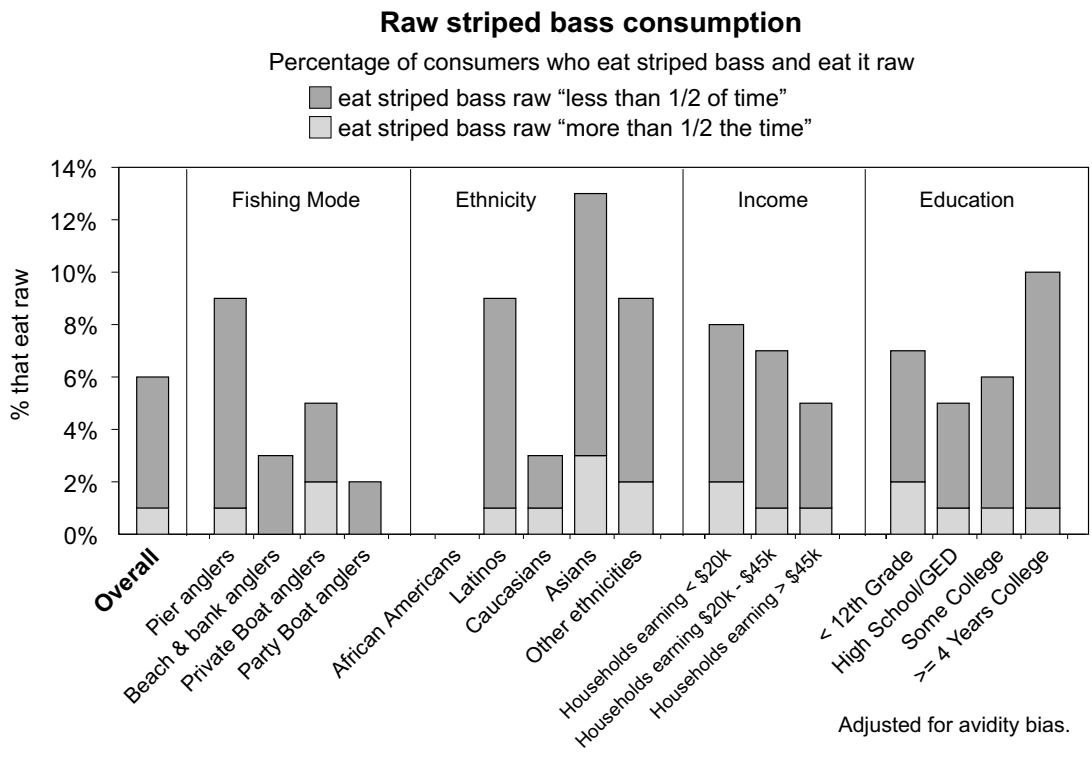
Although raw consumption of striped bass was relatively uncommon among consumers of this species (6%), pier anglers and Asians were more likely to report raw consumption than other modes and ethnic groups (see Table K42e). Tables K42a-K42e summarizes the five consumption methods for striped bass by mode, ethnicity, income, and education.

In contrast to the population that consumes striped bass, the population consuming white croaker differed markedly from the overall consumer group (see Figure 32 and Table K39). Consumption methods for consumers of white croaker for some demographic factors are presented in Tables K43a-K43e. No further analysis of leopard shark was conducted because few anglers reported any of these consumption patterns for this species.

7. Consumption of Fish Caught from Outside SF Bay and Commercial Sources

Although the primary purpose of this study was to characterize anglers' consumption of fish from SF Bay, we also characterized consumption of fish from two other sources: (1) fish caught from areas outside SF Bay, including the ocean and freshwater rivers and lakes, and (2) fish from commercial sources (i.e., fish purchased from stores or restaurants). We only asked respondents whether they had recent consumption (in the last four weeks) of fish from these sources. We found, in Figure 37, that one

Figure 36c

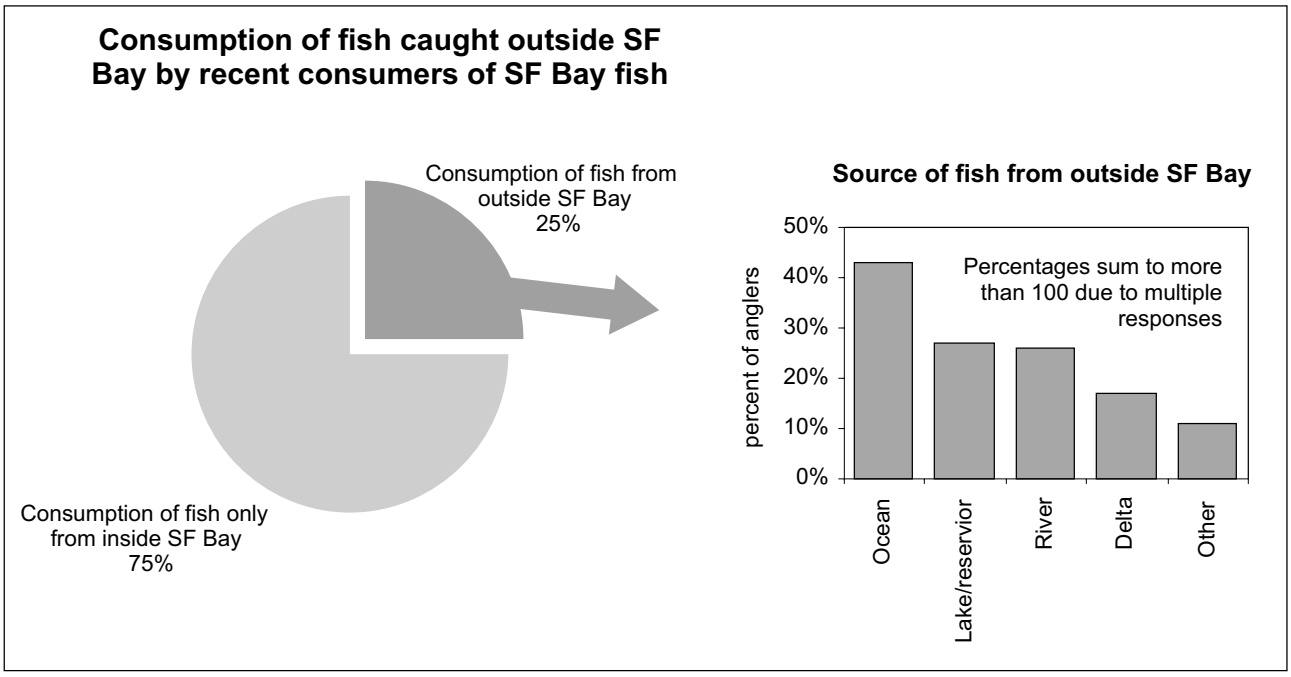


fourth of recent consumers of SF Bay fish also reported eating fish caught from areas outside of SF Bay in the four weeks prior to the interview, with the ocean being the area most often reported. In Figure 38, we show that half of recent consumers reported consumption of fish from a store or restaurant. The proportion of anglers reporting recent consumption from areas outside SF Bay and from commercial sources was very similar for two other groups, respondents and consumers (see Table K44).

In Table 7, we show how consumption rates for recent consumers of SF Bay fish increase when fish from other sources is included. The first column of Table 7 shows consumption rates of SF Bay fish only. The second column of Table 7 shows consumption rates that include all sport fish (fish from SF Bay plus fish from outside SF Bay). Consumption rates shown in the first two columns (SF Bay fish and all sport fish only) are very similar because relatively few recent consumers of SF Bay fish also had consumption of fish from outside SF Bay. The median consumption rates do not change when outside SF Bay fish is added; it remains at 16.0 g/d. The geometric mean value, however, rises slightly from 14.0 g/d to 17.1 g/d (adjusted).

The third column of Table 7 describes consumption rates that include all fish, which is the sum of fish from SF Bay, outside SF Bay, and from commercial sources. The median consumption rate that included all fish is 24.0 g/d (adjusted), equivalent to three eight-ounce meals per month. This amount is 50% higher than consumption rates for SF Bay fish only. The full distribution of consumption rates among respondents, consumers, and recent consumers, both unadjusted and adjusted, is shown in Tables K45a and K45b.

Figure 37



Adjusted for avidity bias.

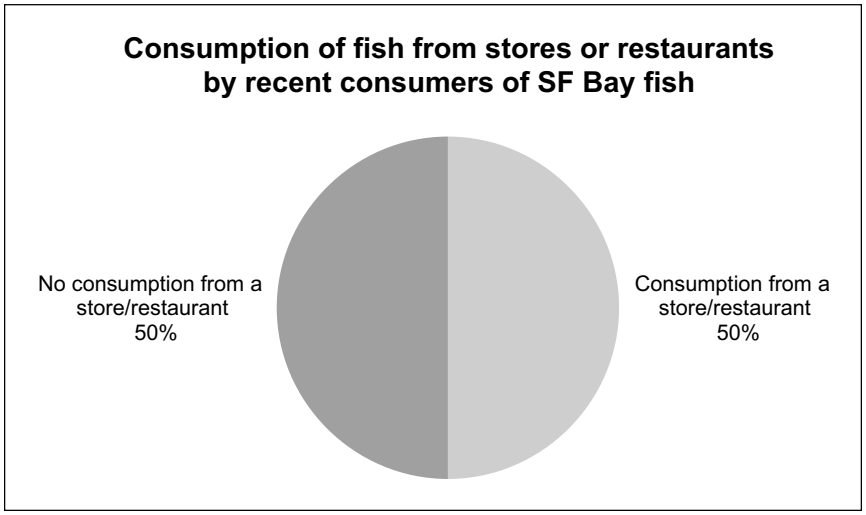
Table 7. Consumption of Fish From Outside SF Bay and Commercial Sources among Recent Consumers of SF Bay Fish (n=465, adjusted)

	Fish From SF Bay Only (g/d)	All Sport Fish (Fish From SF Bay and Outside SF Bay) (g/d)	All Fish (Fish from SF Bay, Outside SF Bay, and Commercial Sources) (g/d)
Mean (Standard Deviation)	23.0 (32.0)	27.9 (35.6)	43.4 (76.0)
Minimum Value	2.0	2.0	2.0
Maximum Value	324.0	324.0	848.0
Geometric Mean	14.0	17.1	26.0
Median (50th Percentile)	16.0	16.0	24.0
90th Percentile	48.0	56.0	80.0
95th Percentile	80.0	96.0	128.0

[a] For 36 recent consumers, there was insufficient information for deriving a consumption rate. For an additional 36 recent consumers, fishing frequently was not reported. Thus, their consumption rate could not be adjusted for avidity bias.

8. Shellfish Consumption

Figure 38



Adjusted for avidity bias.

Interviewers asked respondents about their consumption, in the last four weeks, of three types of shellfish from SF Bay: crabs, clams, and mussels. Consumption rates for shellfish could not be derived because no portion size question on shellfish was included in the survey. Only meal frequency, the number of times shellfish was eaten in the last four weeks, was recorded. In addition, these shellfish consumption data do not characterize the population of shellfish consumers in SF Bay. These data reflect the population of anglers who also had recent consumption of shellfish. Due to resource constraints, persons who were gathering shellfish but were not fishing were not interviewed. For example, many people deploy crab pots from piers in SF Bay. These persons were not interviewed unless they were also fishing at the time they were approached by the interviewer.

Overall, only a small percentage (6%) of consumers of Bay fish also had recent consumption of Bay shellfish. Among shellfish types, anglers reporting recent consumption of crab were far more numerous than those who consumed mussels or clams (see Table K46). The proportion of crab consumers differed among the respondents, consumers, recent consumers, and above advisory consumers. The proportion of crab consumers was twice as high (16%) among above advisory consumers than consumers of SF Bay fish (6%).

In Figure 39 and Table K47 we describe some of the demographic characteristics of consumers of Bay fish who also had recent consumption of crab. By mode, the highest proportion of crab consumers fished on piers. The proportion of crab consumers among Asians (especially Vietnamese) and African American was higher than other ethnic groups. Also, anglers with lower income and education levels were more likely to have consumed crab, and anglers interviewed during the summer or fall were more likely to have consumed crab than those interviewed during the winter or spring.

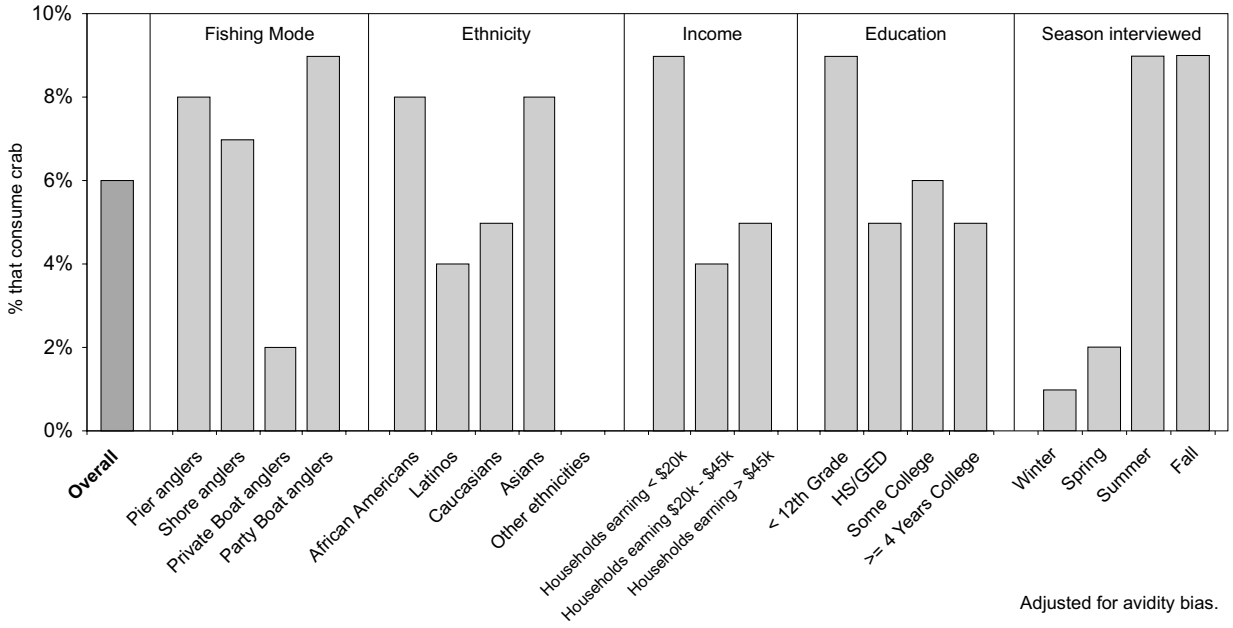
The median (adjusted) meal frequency for crab and all shellfish (sum of crab, clams, and mussels) was one time in the last four weeks for consumers of Bay fish (see Table K48).

E. Health Advisory Questions

In this section, we assess anglers' awareness and comprehension of the health advisory, and determine whether awareness and/or comprehension influenced anglers' fish consumption behavior. We also identify ways anglers preferred to receive health advisory information. Questions concerning the health advisory were not asked of party boat anglers, thus, the findings reflect only responses from shore-based and private boat anglers. Because the health advisory provides guidance that may have influenced an angler's decision to consume fish caught from the San Francisco Bay, we present information in this section for both consumers and non-consumers as noted. (The health advisory for SF Bay can be found in Appendix A.) Values adjusted for avidity bias are presented unless otherwise noted. Tables presenting

Figure 39

Percentage of consumers with recent crab consumption



data (adjusted and unadjusted for avidity bias) for respondents, consumers and non-consumers are provided in Appendix K.

1. Awareness of San Francisco Health Advisory

To determine anglers' awareness and comprehension of the health advisory we asked a two-part question. In the first part, we asked anglers "Have you heard or seen any information or health advisories about eating fish from the Bay?" For those who responded yes, we assessed the angler's comprehension of the advisory by asking them "What did the information say about fish from the Bay?" Verbal responses to the latter portion of the question were written down. These responses were later reviewed and manually coded (see Appendix I for coding categories for text responses). Responses to the first part of the question are reported in this section and responses to the second part are reported in the following section.

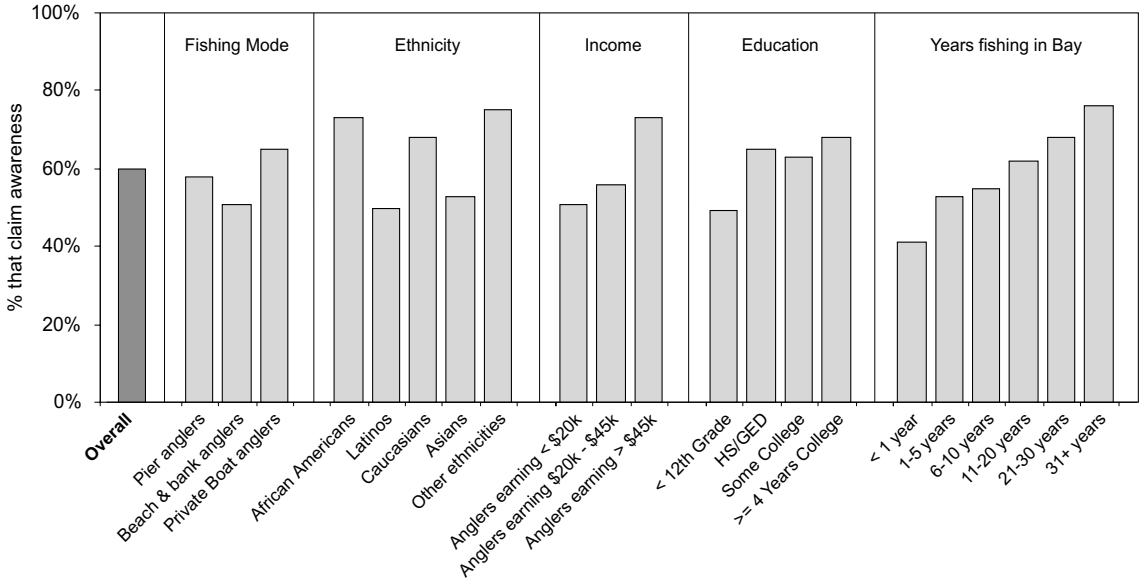
For the first part of the question, as shown in Figure 40, 60% of consumers reported awareness of an advisory. As shown in Table K49, 62% of non-consumers similarly reported awareness of an advisory. We found differences in reported awareness of a health advisory among consumers by demographic characteristics (Figure 40 and Table K49). For example, Latino and Asian consumers were less likely to report an awareness of the health advisory compared to African Americans and Caucasians. The proportion of consumers who were aware of health advisories also increased nearly 50% from the lowest income level (less than $20,000 per year) to the highest income level (greater than $45,000 per year). A similar trend was observed for education level.

The proportion of consumers reporting awareness of the advisory also increased with the length of time they had been fishing in the Bay (see Figure 40 and Table K49). Less than half of the consumers with less than a year's experience fishing in SF Bay reported awareness of the advisory, compared to over three fourths of consumers with 30+ years experience.

Figure 40

Awareness of health advisory by demographic characteristics

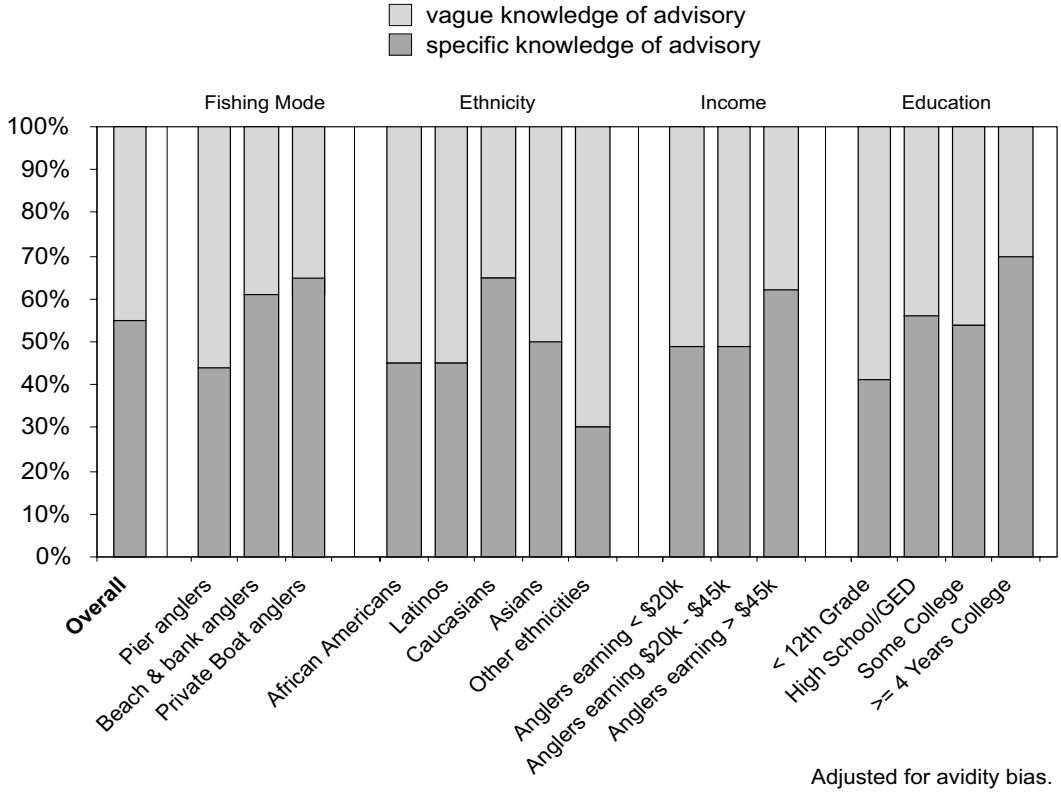
Percentage of consumers claiming awareness of advisory
Anglers reporting no consumption of Bay fish not included



Party boat anglers not asked health advisory questions Adjusted for avidity bias.

Figure 41

Comprehension of health advisory among consumers with awareness of advisory



Adjusted for avidity bias.

2. Comprehension of Health Advisory

We assessed comprehension or understanding of the health advisory only among respondents who indicated an awareness of the advisory (see Figure 41 and Table K50). We categorized their responses in one of two ways: (1) anglers who described a specific health protective measure, such as eating less fish or preparing and cooking fish in safer ways ("specific knowledge"), or (2) anglers who reported a general awareness about fish or water being contaminated ("vague knowledge"). Anglers who described specific health protective measures had better comprehension or understanding of the advisory than anglers who indicated only vague knowledge. Of consumers who reported awareness of an advisory, 55% reported a specific health protective measure.

Similar to our findings regarding awareness in the previous section, we found differences in comprehension by mode, ethnicity, income, and education (see Figure 41). Among consumers, a higher proportion of beach and bank and private boat anglers reported health protective recommendations compared to pier anglers (see Table K50). By ethnicity, a lower proportion of Filipinos, African Americans, and Latinos reported specific health protective measures compared to Caucasian and Chinese consumers (see Table K51). The proportion of consumers reporting specific health protective recommendations also increased with income and education levels (see Tables K52 and K53).

In addition to determining whether anglers understood specific health protective measures, we also looked at whether any anglers recalled the consumption recommendations from the SF Bay advisory to eat no more than two meals per month. We found that only 35 (6%) consumers who were aware of the health advisory reported the two meals per month recommendation. However, it should be noted that interviewers only recorded responses and did not prompt respondents or question their responses.

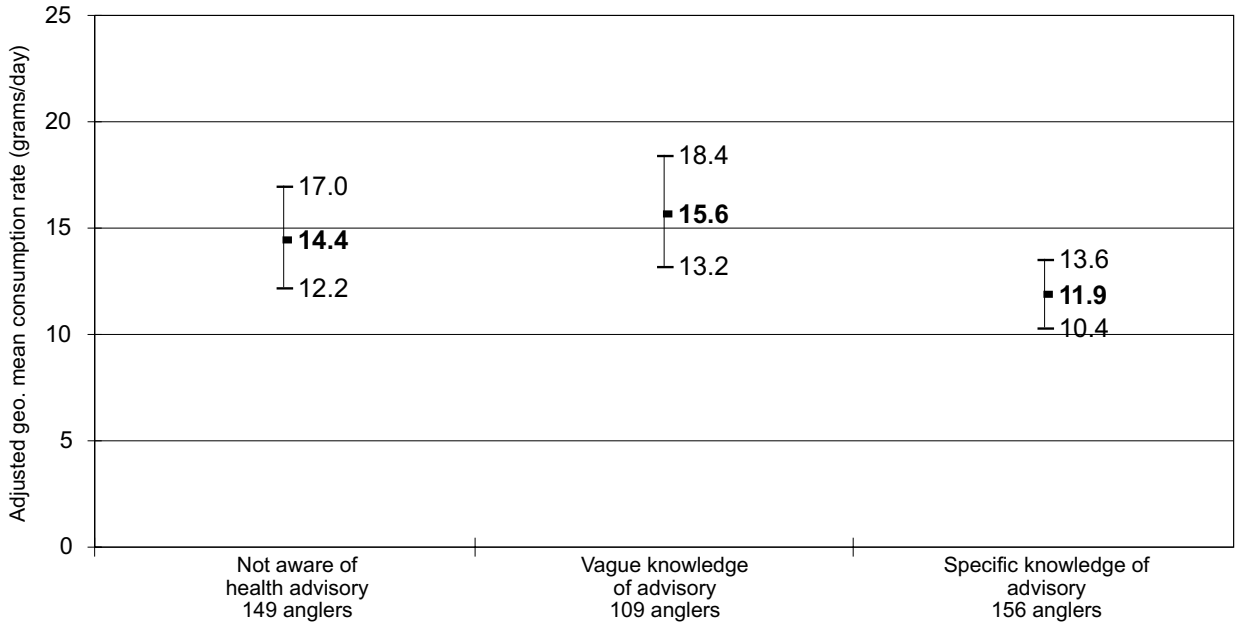
3. Awareness and Comprehension of Advisory and Consumption Rates

We also examined how awareness and comprehension of the health advisory were related to consumption rates among recent consumers (consumers who had consumed Bay fish in the four weeks prior to the interview). Firstly, we compared adjusted consumption rates for three groups of recent consumers: (1) recent consumers who indicated they were not aware of an advisory for the SF Bay, (2) recent consumers who reported awareness that fish or water is contaminated ("vague knowledge"), and (3) recent consumers who reported health protective measures. Although differences between these three groups were not statistically significant, anglers who showed specific knowledge of health protective measures had the lowest consumption rates (see Figure 42). Anglers who reported only vague knowledge had the highest consumption rate. The consumption rate for anglers who reported no awareness of health advisories fell between these two groups.

Secondly, we compared awareness and comprehension of the health advisory between two groups of consumers: (1) those who consumed above advisory levels (see Section IV.D.3.a), and (2) those who consumed below advisory levels (see Figure 43 and Table K54). We found the proportion unaware of the health advisory was similar for anglers consuming above and below the health advisory. However, above advisory consumers had a higher proportion of anglers with vague knowledge and the below advisory consumers had a higher proportion of anglers with specific knowledge. In other words, consumers who consumed above advisory limits demonstrated a poorer understanding of health advisories, and those who consumed below advisory limits showed a better understanding of advisories.

Figure 42

Geometric mean consumption rate of recent consumers* and their awareness of the health advisory



* Party boat anglers were excluded because they were not asked any health advisory questions.
Error bars indicate 95% confidence intervals.
Adjusted for avidity bias.

4. Behavioral Changes in Fish Eating Habits

We also assessed changes in fish consumption habits among anglers who reported that they were aware of an advisory. If anglers reported awareness of health advisories, they were asked if the information did or did not cause a change in their fish-eating habits. Next, if anglers reported changing their fish-eating habits, they were asked how they changed their habits. If they reported that they had not changed their fish eating habits, they were asked why not. The anglers' verbal responses were written down and later reviewed and manually coded (see Appendix I for coding categories for text responses). Anglers who adopted a behavioral change reported they either: (1) engaged in protective measures (i.e., prepared and cooked fish using safer methods); (2) stopped eating Bay fish entirely, or (3) ate only uncontaminated fish. Anglers who reported no change in behavior reported they either: (1) already consumed below the limit, (2) believed contamination did not pose a health problem, or (3) did not elaborate on why. (For the group reporting no behavior change, we did not attempt to verify whether their responses to this question matched their responses to other survey questions, for example, whether their consumption rate was actually below the advisory level.)

Of the consumers who indicated awareness of the advisory, 37% said they had changed their consumption habits (Figure 44). Out of this group, 71% reported to have engaged in health protective measures since hearing the advisory, and 16% reported they had stopped eating Bay fish entirely (see Figure 44 and Table K55). Consumers who said they had not changed their habits represented about one-third of all consumers who indicated being aware of a health advisory. Among this group, 60% said

Figure 43

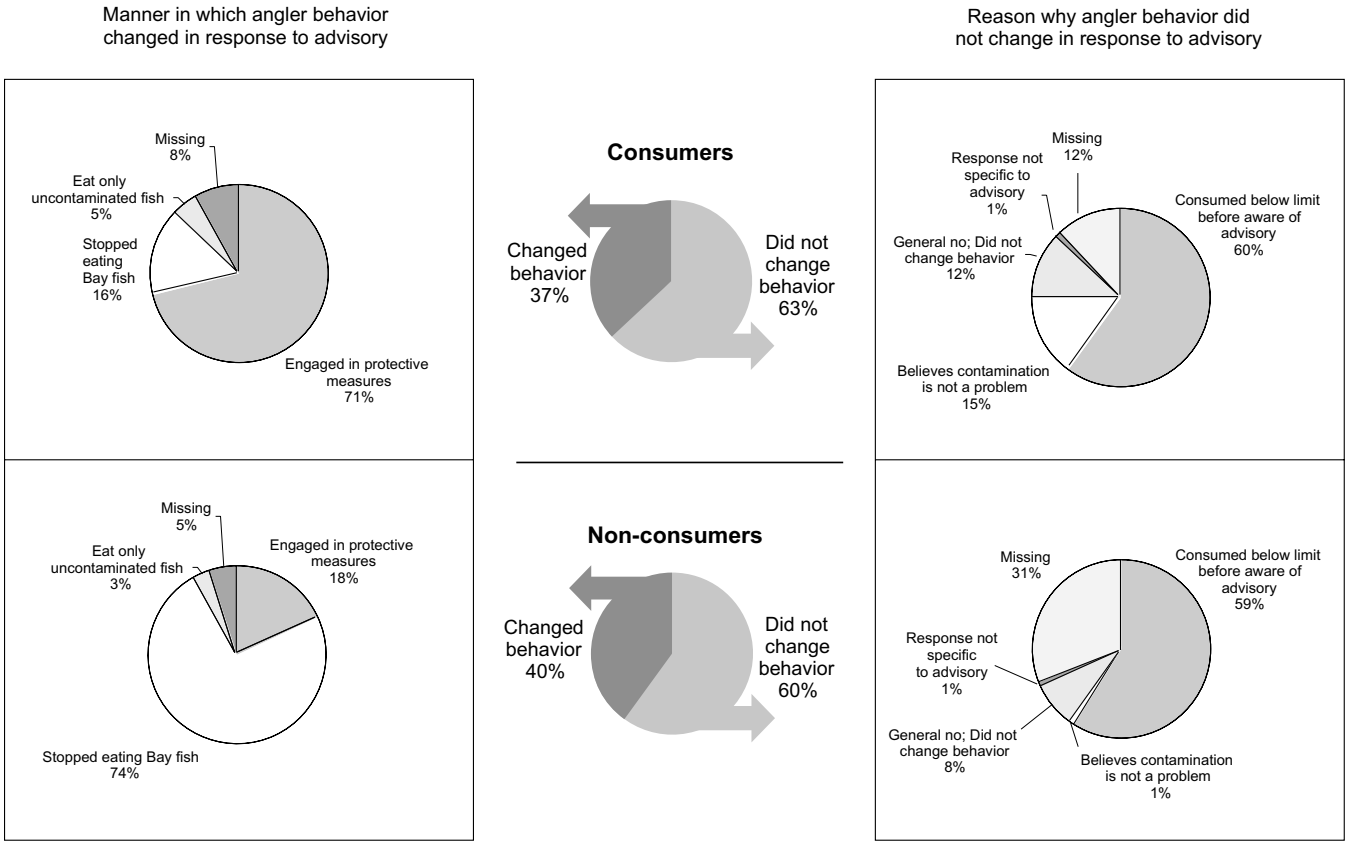
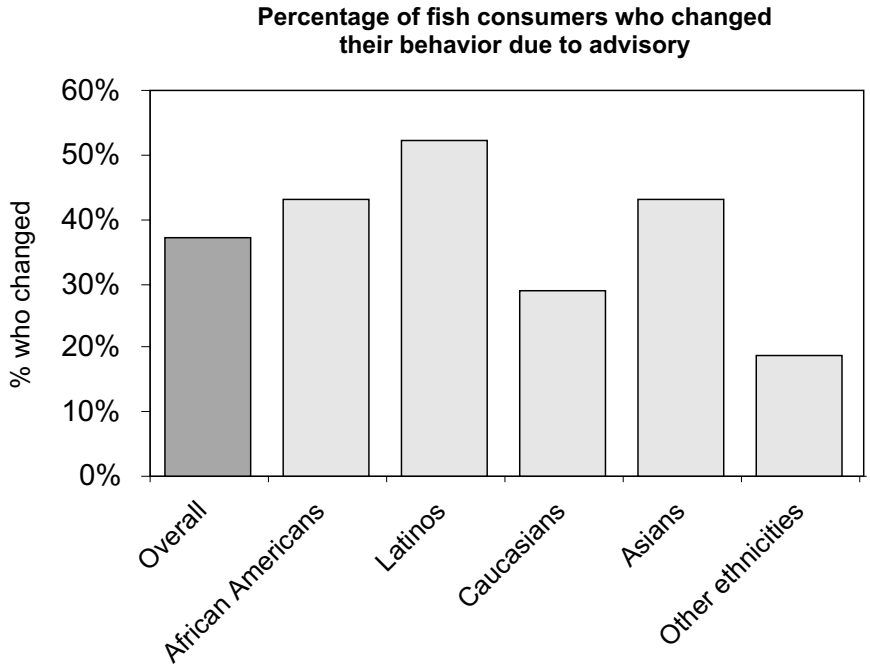
Figure 44

Anglers' behavior changes in response to health advisory



Adjusted for avidity bias.

Figure 45



Party boat anglers not asked health advisory questions.
Adjusted for avidity bias.

they already consumed below the advisory limits (as they understood it) prior to learning of the advisory, and 15% said that fish contamination was not a health problem.

For non-consumers who indicated they had changed their behavior, 74% indicated they stopped eating Bay fish (see Table K55). As expected for non-consumers, when asked why they had not changed their habits upon learning of the advisory, most indicated they already consumed below the limit before they were aware of the advisory.

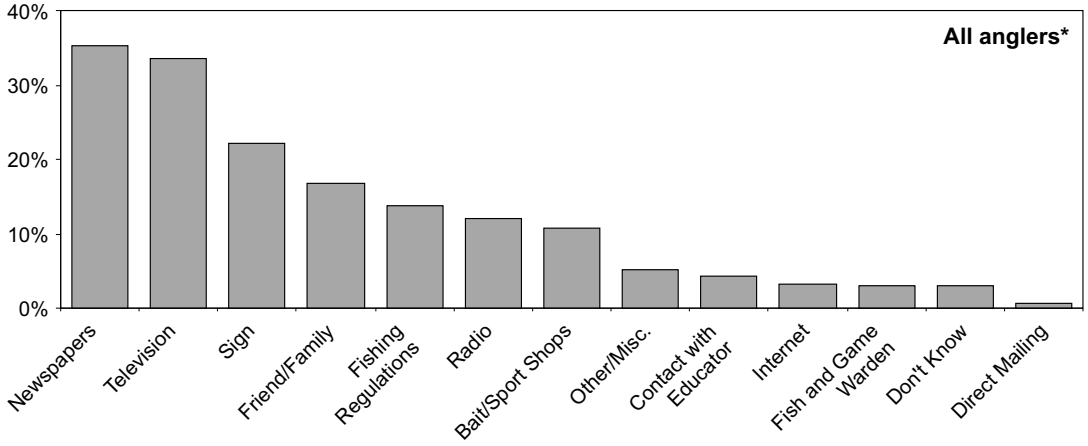
There were only slight differences between those who changed their behavior or not within demographic groups (see Tables K56 and K57). However, a larger proportion of African American, Latino, and Asian consumers reported changes in their fish consumption habits compared to Caucasians (see Figure 45 and Table K56). Responses for non-consumers by demographic characteristics are shown in Table K57.

5. How Anglers Prefer to Receive Information about Fish

One of the study objectives was to identify ways anglers preferred to receive information about health advisories. All respondents were asked: "What is the best way for you to get information about catching and eating fish from the Bay?" Figure 46 and Table K58 show that among respondents the three most frequently mentioned responses were newspapers, television, and signs. Private boat anglers preferred newspapers, but shore-based anglers mentioned television and newspapers, about equally. Among the different ethnic groups, Caucasians were the only group to prefer newspapers to television. Responses for consumers were similar (see Table K59).

Figure 46

Preferred methods for receiving fishing information
Percentage of anglers indicating each method



*except party boat anglers, who were not asked health advisory questions. Not adjusted for avidity bias.

6. Discussion Groups

We also conducted four discussion groups with anglers. The purpose of the discussion groups was to further our understanding of anglers' awareness of the health advisory and to explore ways to reach anglers with health information. After reviewing preliminary study results, the project staff identified three groups of shore-based anglers and one group of boat anglers to invite to participate in discussion groups. The shore-based angler groups were: (1) Filipino anglers (the largest group of Asian anglers), 2) anglers who were unaware of the advisory, and (3) anglers who were aware of the advisory but had not changed their consumption habits.

Although we carried out extensive efforts to contact and recruit eligible participants for these discussion groups, only 17 of the 217 anglers we contacted actually participated. Due to the small number of anglers who participated in the discussion groups, generalizations about the findings to the overall fishing population cannot be made. However, those participating in the groups raised pertinent concerns and questions regarding advisory messages and educational strategies that merit further consideration. For example, during discussion over terms used in the health advisory, participants indicated that they did not interpret the term "sport fish" to mean the fish they caught from the SF Bay. Additionally participants indicated preferences for graphics and wording to be used for health advisory recommendations and signs, such as specifying pounds and number of fish meals, rather than grams or ounces, that can be safely consumed. Appendix L contains a more detailed description of the efforts to organize and conduct the discussion groups and content of the discussion groups.

V. Discussion and Conclusions

Our study design, field survey methods and procedures, and data analyses and presentation contained in this report provide documentation that the study goals and objectives have been achieved. We have gathered quantitative data on anglers fishing in SF Bay. This information can be used to characterize anglers' exposure to chemical contaminants. Although we found that the majority of SF Bay anglers consume below health advisory limits, we found that some anglers are highly exposed, and we described

these highly exposed populations in several ways. Finally, we gathered information that can be used to develop educational messages to target specific groups of SF Bay anglers.

In order to gain a better understanding of the results of this study, we compared our findings to results from similar studies where valid comparisons could be made. In particular, we made most of our comparisons to the Santa Monica Bay study (Allen *et al.* 1996, SCCWRP/MBC 1994) and Save San Francisco Bay Association's Save the Bay study (Wong *et al.* 1997). Overall, our findings and methodology were consistent with these studies, who likewise were based on angler interviews at fishing locations. We compared our findings on consumption practices to two community-based studies, one conducted by the Asian Pacific Environmental Network (Chiang 1998) and the other by Sechena *et al.* (1999). These studies drew participants from specific Asian ethnic groups who were recruited through community-based organizations, although participants were not necessarily anglers. We also compared health advisory responses to an angler survey conducted at a single location by the Office of Environmental Health Hazard Assessment (Russell *et al.* 1997). A survey of pier anglers in SF Bay by Communities for a Better Environment (Karras 1998) could not be compared because adequate documentation on this study's methodology was not available.

In addition to comparing our results with other studies, we also describe some of the limitations of how these results should be interpreted. Despite our efforts, we were not able to address all possible sources of bias in this study. These limitations are discussed further at the end of this section.

A. Sampling Success and Angler Characteristics

Overall, we achieved a higher response rate when compared to the Santa Monica Bay and Save the Bay studies (see Table 8). Because Save the Bay's study included only pier anglers, we compared their response rate to pier anglers from our study. Although, in both studies the proportion of decliners, due to language barriers among total interview attempts was similar, we still found a lower rate of decliners among pier anglers in this study.

Table 8. Comparison of Decliners among San Francisco Bay Seafood Consumption Study, Santa Monica Bay Study, and Save the Bay Study

	SF Bay Seafood Consumption Study (unadjusted)		Santa Monica Bay Study (Allen *et al.* 1996, SCCWRP/MBC 1994)	Save the Bay Study (Wong *et al.* 1997)
	All Fishing Modes	Pier Only	All Fishing Modes	Pier Only
Total Attempts	1738[a]	983 [a]	1740	379[a]
Total Decliners	407 (23%)	288 (29%)	496 (29%)	145 (38%)[b]
Decliners due to language barrier	144 (8%)	125 (13%)	---[c]	53 (14%)

[a] based on net attempts, anglers interviewed before were excluded
[b] incomplete interviews excluded from declines but included in total attempts
[c] not recorded

We also compared the ethnic composition of respondents from this study with the Santa Monica Bay and Save the Bay studies in Table 9. This study and the Santa Monica Bay study found that Caucasians comprised the largest group of respondents. However, after Caucasians, Asians were the largest group in this study, while Latinos were the largest group in the Santa Monica Bay Study, which reflects the ethnic differences of anglers in the two regions.

Our finding of a high proportion of non-Caucasians among pier anglers in our study population was very similar to Save the Bay's results. Both studies found that Asians were the dominant group

Table 9. Comparison of Ethnic Groups among Respondents for San Francisco Bay Seafood Consumption Study, Santa Monica Bay Study, and Save the Bay Study

Ethnic Group	SF Bay Seafood Consumption Study (unadjusted)		Santa Monica Bay Study (Allen *et al*. 1996, SCCWRP/MBC 1994)	Save the Bay Study (Wong *et al.* 1997)

[a]includes Middle Easterners, Samoans, and Cambodians
[b]Pacific Islanders were included under the "Other" category
[c]includes Japanese and Koreans

fishing from piers in SF Bay, with Caucasians representing only about one-fourth of respondents. Filipinos were the largest Asian subgroup in both studies.

B. Fish Consumption Rates

Comparisons of consumption rates between studies are inherently difficult to make. Study methodologies are rarely identical and differences in methods can greatly affect the results. Consumption rates from different studies cannot be compared without a clear understanding of how the rates were derived. Most importantly, it is essential when comparing consumption rates to describe both the population to which the consumption rates applies, and the recall period over which the estimate was made.

1. Consumption Rates Among Recent Consumers

Table 10 summarizes consumption rates from this study, the Santa Monica Bay study (ATES/OEHHA 2000, Allen *et al.* 1996, SCCWRP/MBC 1994), and the Save the Bay study (Wong *et al.* 1997). The consumption rates for recent consumers (based on a four week recall) reported in this study were lower than consumption rates reported in the comparison studies, although these differences can probably be explained by differences in methodology.

The unadjusted geometric mean consumption rate from the Santa Monica Bay study is about 50% higher than the rate derived in this study, and this difference is statistically significant. Although consumption rates in both studies were derived from recent consumers based on a four-week recall, there were important differences in the way the studies calculated consumption rate that can explain the differences in their results. In the Santa Monica Bay study, when calculating the fish consumption rate of a consumer within the last four weeks, fish that an angler had caught—but not yet eaten—was observed by the interviewer and included in the fish consumption rate data. Interviewers attempted to identify

Table 10. Comparison of Consumption Rates (g/d) for San Francisco Bay Seafood Consumption Study, Santa Monica Bay Study, and Save the Bay Study

	SF Bay Seafood Consumption Study (unadjusted)	Santa Monica Bay Study (Allen *et al.* 1996, SCCWRP/MBC 1994) (Unadjusted)	SF Bay Seafood Consumption Study (adjusted)	Santa Monica Bay Study (adjusted) (ATES/OEHHA 2000)	Save the Bay (Wong *et al.* 1997)
Respondents	n=1331	n=1244	n=1152	[b]	n=222
Population used to derive consumption rate (% of respondents)	n=501 (38%)	n=555 (45%)	n=465[c] (40%)	[b]	n=62 (27%)
	Consumed fish in last 4 weeks	Consumed fish in last 4 weeks	Consumed fish in last 4 weeks	Consumed fish in last 4 weeks	Consumed fish in last 7 days
Mean (Standard Deviation)	28.0 (39.5)	49.6 (111.1)	23.0 (32.1)	30.5 (45.)	[b]
Geometric Mean	16.5	23.6 [a]	14.0	[b]	[b]
Median (50th Percentile)	16.0	21.4	16.0	15.0	32
Upper 95% Confidence Limit of the Geometric Mean	18.0	25.8 [a]	[b]	[b]	[b]

[a] Derived from Hill and Lee (1995b).
[b] Not reported
[c] For 36 anglers there was insufficient information for deriving a consumption rate. For an additional 36 anglers, fishing frequency was not reported, thus their consumption rate could not be adjusted for avidity bias.

and record all fish that the angler had caught at the time of the interview. For example, if the interviewer observed white croaker in the angler's bucket, the number of times the angler ate fish in the last four weeks was increased by one to account for future consumption of the white croaker. In this study, only fish that had already been consumed (in the past four weeks) was included. Fish that the angler caught on the day of the interview that had not yet been consumed when the interview took place was not included in any consumption rate calculation. This additional factor may explain why Santa Monica Bay estimates were higher than SF Bay estimates.

Furthermore, other differences between the two studies may have contributed to differences in the results, for example, the way sampling effort was allocated across modes in the two studies and the use of different portion size models. In this study, sampling effort was based on the relative amount of fishing activity in each mode (see Section II.B.3 for further discussion). In the Santa Monica Bay study, sampling effort was not explicitly allocated by fishing activity. How this difference would affect consumption rates is not known, because the relative amount of fishing activity by mode in the Santa Monica Bay study was never estimated. The Santa Monica Bay study also used a 150 gram (5.3 ounce) portion model while this study used an 8 ounce (227 gram) portion model. The model size appeared to influence the

responses in both studies. (This will be discussed further below.) Whether the different model sizes would widen or narrow the consumption rate difference between the two studies is not known.

It is likely that other factors unrelated to methodology contributed to the different findings of the two studies. These factors include (1) avidity differences due to climate which could result in anglers in Southern California spending more time fishing than the average angler in SF Bay (as discussed in Section III.D.1, avidity is generally correlated with consumption), (2) differences in how productive the two fisheries are, (3) the different years the studies were conducted, and (4) differences in demographic characteristics of anglers in the two populations.

Staff from the Air Toxics Epidemiology Section within OEHHA adjusted the data from the Santa Monica Bay study for avidity bias (ATES/OEHHA 2000) using methods similar to ours. This adjustment lowered their results significantly so that they are closer to the adjusted data from this study than comparisons of the unadjusted data. For example, the adjusted median is very similar to the one derived from this study.

We also compared the results of this study with Save the Bay's study of pier anglers in SF Bay (Wong *et al.*1997). Save the Bay found a median consumption rate of 32 g/d, which was two times the median consumption rate of 16.0 g/d found in this study (see Table 11). However, the target population and recall period used in the Save the Bay study differed from this study. This may explain the difference in results. Save the Bay derived a consumption rate from the subset of anglers who had reported consuming fish in the last seven days. In this study, a seven-day recall was never used. The primary consumption rate was derived from anglers who had reported consuming fish in the last four weeks. Anglers who consumed fish in the past seven days represent an even smaller subset of all anglers than those who consumed fish in the last four weeks. This smaller subset selectively includes anglers with the highest consumption rates. Thus, these two groups cannot be directly compared. In fact, the group that was used to derive a consumption rate in the Save the Bay study represented 27% of respondents. In this study, the group (recent consumers) used to derive a consumption rate represented 38% of respondents.

Other factors could also have contributed to the different results. Save the Bay used a 150 g (5.3 ounce) portion size model while this study used an 8-ounce (227 g) model. As noted earlier, while the model size is likely to influence consumption rate estimates, the direction and magnitude of this influence is not known. Save the Bay also conducted interviews only during the fall, while interviews in this study were conducted over a full year. We found that consumption rates of anglers in the fall were higher compared to other seasons, although differences among seasons were not statistically significant (see Tables K35 and K36). Finally, the two studies were conducted several years apart. Many factors during the years between the two studies could have influenced the consumption patterns of the population that fishes in the Bay. These factors include (1) changes in the fishery or variability in fish abundance over time (in fact, an El Niño occurred in 1998), (2) better knowledge of fish contamination issues among anglers (e.g., SFEI released a report on contaminants in fish in 1998 that was widely covered by the press), and (3) changes in the fishing population due to immigration, since many anglers report having fished in the Bay for a relatively short amount of time (See Table K20).

2. Consumption Rates Among Consumers

Although one of the study goals was to gather information for characterizing exposures to the population that consumes Bay fish, comparisons of consumption rates based on all consumers could not be made. Neither of the comparison studies reported consumption rates based on the whole population of consumers, rather than a subset comprised of recent consumers. Both studies only reported consumption rates for a subset of consumers (recent consumers based on a four-week or seven-day recall).

3. Per Angler Consumption Rates

We compared the per-angler consumption rate based on a 12-month recall in this study (see Table K31) to a consumption rate derived by the USEPA (1997) for marine recreational anglers. Both studies reported low consumption rates. USEPA estimated an average consumption rate of 2.0 g/d of marine fish for Northern California recreational anglers. This value is higher than both the geometric mean value of 0.4 g/d and median of 1.8 g/d reported in this study for respondents based on a 12-month recall. It should be noted, however, that the methodologies used in these two studies were very different. The USEPA value was derived using estimates of recreational catch from the National Marine Fisheries Service's Marine Recreational Fisheries Statistics Survey (NOAA/PSMFC 1997) and assumptions about the fraction of the catch that was consumed and the number of anglers who consumed the catch. In addition, the two consumption rates represent different types of fish; the USEPA estimate includes all marine fish and this study includes only SF Bay fish. Also, the USEPA value was adjusted for avidity bias while the value in this study (based on a 12-month recall) was not.

4. Influence of the Portion Size Model

This study used an eight-ounce portion size model to help respondents describe the amount of fish they consume at one time. Multiplying portion size by meal frequency, we derived a consumption rate. Most respondents reported that they ate an amount equal to the model, and many respondents reported that they ate an amount equal to a fraction (e.g., one half of the model) or multiple (e.g., two times) of the model. As a result, the consumption rate distribution did not follow a smooth and continuous shape, but was peaked around multiples of the model (see Figure 22). These results appear to confirm that the model influences consumption rate responses and introduce a degree of bias in the results.

Portion size responses were not reported in the comparison studies so they could not be compared to results from this study. Although not explicitly discussed in either study, the portion size model appears to have influenced results in both the Santa Monica Bay and Save the Bay studies. In the Santa Monica Bay study, the consumption of an amount of fish equal to their model of 150 grams over the 28-day recall period is equal to a consumption rate of 5.36 g/d. Their median consumption rate of 21 g/d was equal to four times the model. Other consumption rate results they report are multiples of their model. For example, consumption rates for individual species are typically 11 g/d (two times the model), 16 g/d (three times the model), etc. A similar pattern can be found in the Save the Bay study.

5. Avidity Bias Adjustment

One of our study findings (discussed in Section IV.D.1) was that the adjustment for avidity bias resulted in only a slight change in the results. For consumption rates of recent consumers, the geometric mean, 16.5 g/d, dropped to 14.0 g/d (adjusted) with the avidity bias adjustment, although the median value did not change. This difference is much smaller than has been observed in other studies such as Price *et al.* (1994). The small effect of an avidity bias adjustment in this study can be explained by the weak correlation between consumption rate and angler avidity ($r = 0.23$). This weak correlation might result from two related factors. Firstly, we limited this consumption rate calculation to only recent consumption (the last four weeks). If a longer recall period was used, the consumption rate responses would likely show greater variation. Secondly, we also limited the angler avidity (fishing frequency) response to the same relatively narrow time range (number of times fishing in the last four weeks). The minimum fishing frequency that could be recorded in our study was one-time fishing in the last four weeks (including the trip during which the interview occurred) and the maximum number of times was 28 (one time per day). The range from one to 28 times in the last four weeks is relatively narrow compared to a longer time

period such as one year. With a longer time period we would expect a wider range of consumption rates and fishing frequencies, a much stronger correlation between these variables, and a much stronger avidity bias effect. In fact, studies finding a strong avidity bias effect, such as Price *et al.* (1994), used a one-year recall to estimate consumption rate and fishing frequency.

C. Consumption Rate Differences Among Ethnic Groups

One important finding of this study was that we were able to show consumption rate differences between ethnic subgroups. In general, we did not find significant differences for other demographic characteristics. Although the planning of this study focussed on obtaining a sample of anglers that reflected the population by mode, ethnic differences appear to be far more important in influencing consumption rates among SF Bay anglers than mode.

Among the comparison studies, only the Santa Monica Bay study described consumption rates by ethnic groups, although the statistical significance of differences between these groups was not described. Table 11 compares geometric mean and median consumption rates for major ethnic groups from this study and the Santa Monica Bay study. Overall, there were only a few similarities between the two studies. For example, both studies found that African Americans had higher rates than other groups, although these differences were not large. In the SF Bay study, we found that Caucasians had the lowest geometric mean consumption rates of all groups and the Santa Monica Bay study found Latinos had lower rates than other groups. Geometric mean consumption rates for Asian subgroups were not available for the Santa Monica Bay study. Based on arithmetic means, the Santa Monica Bay study found Pacific Islanders to have consumption rates considerably higher than other groups, similar to findings from this study. However, these results were based on very small samples in both studies.

Table 11. Comparison of Geometric Mean Consumption Rates (g/d) by Ethnicity (unadjusted) for San Francisco Bay Seafood Consumption Study and Santa Monica Bay Study

Ethnic Groups	SF Bay Seafood Consumption Study (g/d)		Santa Monica Bay Study (g/d)[a]	
	Geometric Mean	Median	Geometric Mean	Median
African American	19.4	16	26.8	24
Latino	16.6	16	17.9	16
Caucasian	14.4	16	26.3	21
Asian	17.8	16	26.1	21

[a] Derived from Hill and Lee 1995a.

Other angler studies have also reported consumption rate differences among ethnic groups (Burger *et al.* 1999, Shatenstein *et al.* 1999, Shubat *et al.* 1996, West *et al.* 1992 and 1989). However, direct comparisons to this study could not be made due to differences in sampling and data analysis methods.

As discussed in Section II.B., this study was designed to obtain a highly representative sample of the population fishing in SF Bay. The study design best suited for obtaining a representative sample, however, is not the optimum study design for making comparisons between subgroups. In the absence of specific subgroup variance information, the optimal design for testing subgroup differences would have deliberately sampled equal numbers of persons in each subgroup to be compared (Levy and Lemeshow 1999). Nevertheless, we were able to show some statistically significant differences between subgroups.

In order to help assess whether consumption rate differences between subgroups could be replicated in other studies, we also considered the statistical power of these subgroup comparisons. We found that

the standard deviation of the log consumption rate for most demographic subgroups was about 1.0. This value can be useful in planning future studies, or for calculating the sample size needed to detect specific differences in consumption rate (Armitage and Berry 1987). In Table 12, we show the sample sizes needed to detect differences in consumption rates using a standard deviation of the log consumption rate of 1.0. We assumed 80% power to detect a statistically significant difference (a=0.05, two-sided) between a consumption rate of 16 g/d (the overall study unadjusted geometric mean) and alternatives 100% to 33% higher. Groups of 30 to 60 were sufficient to detect 1.5 to 2-fold increases in consumption rate with 80% power. Thus, the statistical power was adequate in many of the subgroups we compared to detect 1.5 to 2-fold differences in consumption rates had they been observed.

Table 12. Minimum Sample Sizes Needed for Detecting Consumption Rate Differences Between Two Groups of San Francisco Bay Anglers

Difference to be Detected	Minimum Sample Size per Group
16 g/d vs. 32 g/d	33
16 g/d vs. 24 g/d	60
16 g/d vs. 21 g/d	212

D. Interpretation of Above Advisory Consumers

Our conclusion that about one in ten consumers of SF Bay fish exceeded the health advisory limit should be considered approximate, as a precise determination of above advisory consumers was not possible. Several factors highlight the lack of precision in the above-advisory estimate. In general, these factors indicate that we may have underestimated the number of above-advisory consumers.

Firstly, the definition of an above-advisory consumer is very sensitive to how the consumption recall period is defined. The health advisory recommends that anglers limit their consumption of Bay fish to no more than two meals per month. If we assume that a month has 30 days, and each meal is equivalent to 8 ounces, the health advisory limit is equal to 15 g/d. However, this study used a 28-day recall period, to be comparable with the Santa Monica Bay study, not one month. Two 8-ounce meals per 28 days are equal to 16 g/d. Although a one-gram difference, between 15 g/d and 16 g/d, appears to be insignificant, it is not. Many SF Bay anglers reported consuming 16 ounces in the last four weeks. This amount is equal to 16 g/d, and thus these anglers are right at the health advisory limit. This lack of precision is also compounded by the use of a portion size model (see Section V.B.4). We define anglers as exceeding the health advisory limit if they consume greater than 16 g/d. If the 15 g/d day level were used to identify above-advisory consumers, the proportion of consumers exceeding the advisory would nearly double, from 9% to 16% (adjusted).

Secondly, the health advisory recommends using body weight to determine a person's meal or portion size. The 8-ounce portion size is based on an angler with a body weight of 154 pounds (70 kilograms). For anglers who weigh more or less than this amount, the portion size should be adjusted up or down. We did not attempt to ascertain body weights of the anglers we interviewed, so we do not know if the reported portion sizes are proportional to the anglers' body weights.

Thirdly, the health advisory recommends no consumption of large striped bass (greater than 35 inches). Although over three-fourths of consumers of Bay fish reported that they consume striped bass, no effort was made to determine if this advice for striped bass was being followed. Thus, we do not know whether this size restriction for striped bass is significant or not in determining who is above the health advisory.

Finally, the health advisory recommends more restrictive limits for women who are pregnant or breastfeeding, planning to become pregnant, and for young children. For these groups the health advi-

sory recommends that consumption of Bay fish be limited to no more than one meal per month. In this study, we did not interview any children and we did not determine whether the women we interviewed were pregnant, breastfeeding, or planning to become pregnant. If consumption rates for these groups of women are similar to the women we did interview, a higher proportion will exceed the more restrictive advisory.

E. Consumption Patterns

In addition to recommending limits on the amount and types of Bay fish that can be eaten, health advisories for SF Bay recommend that anglers consume only the skinned fillet and that the fish be cooked so that the juices drain away and are discarded (see Appendix A). These practices can reduce one's exposure to the contaminants in fish. We have shown that these practices are not always followed, particularly among Asians. This finding is generally consistent with other studies.

Similar to the findings in this study, Save the Bay found consumption of skin of two species—striped bass and white croaker—to be common among pier anglers in SF Bay (Wong *et al.* 1997). They found that 49% of consumers of striped bass ate the skin and 36% of white croaker consumers ate the skin in the previous 30 days. They did not report skin consumption by ethnic group, however. In this study, among pier anglers, we found that consumers of striped bass and white croaker ate skin 40% and 52% (unadjusted) of the time respectively. However, these rates were slightly higher, 49% and 56% (unadjusted), respectively, for Asians who consumed these species.

The Santa Monica Bay study did not report whether skin was eaten. However, a higher proportion of Asians in that study did report eating fish whole/gutted, compared to other ethnic groups.

APEN's community-based study of Laotians in West Contra Costa County, which borders SF Bay, found that among respondents who had ever eaten Bay fish, 76% eat the skin of the fish and 86% eat fish in soup or stews. We interviewed only a very small number of Laotians (<1% of respondents). APEN's findings are higher than the rates we reported for all Asians. This may be due to the fact that APEN asked respondents about consumption patterns for all fish, not by specific species. The higher rates in APEN's study could also be due to Laotians consuming skin and soup more frequently than other Asians groups. Sechena's (1999) community-based study of Asians and Pacific Islanders in King County, Washington, found that 55% of their respondents ate skin of fish; however, the primary source of fish in this study was the grocery store.

F. Consumption of Fish From Other Sources

Few studies of fishing populations have looked at total sport fish and commercial fish consumption. We are aware of no such studies for California populations. Using data collected by West *et al.* (1989), Murray and Burmaster (1994) estimated consumption rates of sport fish and total fish (including both sport and commercial sources) for Michigan anglers. West *et al.* collected the data over a six-month period through a mail survey sent to a sample of licensed Michigan angler. The consumption rate recall period was seven days and the data were not adjusted for avidity bias. Although there were many methodological differences between the Michigan study and our study, we compared the results in Table 13.

The Michigan study showed higher consumption rates for both sport fish and total fish. This may be explained in part by the shorter recall period (seven days) used in the Michigan study compared to our study that used a four week recall. Both studies showed that anglers augment their intake of sport fish with fish from commercial sources.

Table 13. Comparison of Sport Fish and Total Fish Consumption Rates (g/d, unadjusted) Between San Francisco Bay Recent Consumers and Michigan Anglers

	SF Bay Seafood Consumption Study (unadjusted)		Michigan Anglers (Murray and Burmaster 1994)	
	Sport Fish[a] n=501	Total Fish[b] n=501	Sport Fish n=191	Total Fish[b] n=191
Arithmetic Mean (Standard Deviation)	33.0 (42.8)	46.5 (62.5)	45.0 (23.7)	55.1 (33.1)
Median	16.0	32.0	32.7	40.8
95th Percentile	112.0	324.0	98.0	114.3

[a] Sport fish includes fish from SF Bay and other areas (see Table K45a).
[b] Total Fish includes sport fish and commercial fish.

G. Health Advisory

We compared our findings on angler's awareness of health advisories to findings from other angler studies that included the Save the Bay and Santa Monica Bay studies (see Table 14). The comparison studies also included an angler survey at Berkeley Pier in SF Bay by the Office of Environmental Health Hazard Assessment (Russel *et al.* 1997) that focused on angler awareness of advisories on posted signs. Awareness to health advisories among the subset of anglers who consume Bay fish (consumers) could not be derived for the comparison studies so only awareness among all survey respondents is compared. Because some of these studies only included pier anglers, we also compared pier anglers from this study to the other studies. We found awareness to health advisories in this study to be very similar to the two other angler studies from SF Bay.

Table 14. Comparison of Awareness to Health Advisories among Respondents of the San Francisco Bay Seafood Consumption Study, Save the Bay Study and OEHHA Study

	SF Bay Seafood Consumption Study (unadjusted)	SF Bay Seafood Consumption Study (unadjusted)	Save the Bay (Wong *et al.* 1997)	OEHHA (Russell *et al.* 1995)	Santa Monica Bay (Allen *et al.* 1996, SCCWRP/MBC 1994)
Population	Shore-based and Private Boat Anglers	Pier Anglers	Pier Anglers	Anglers at Berkeley Pier	All Respondents (Shore-based Anglers and Party and Private Boat Anglers)
No. of Survey Respondents	n=1227[a]	N=695[a]	n=212[b]	n=520	n=1244
No. Aware of Health Advisory	722	392	124	278	942
%	59%	56%	58%	53%	76%

[a] missing, don't know, and declined to answer responses are not included in total
[b] responses for 16 anglers appear to be missing and are excluded from the total; inclusion of these anglers would lower the rate slightly

Awareness of health advisories among respondents in the Santa Monica Bay study was higher overall than among SF Bay anglers. This difference could be due to health advisory awareness actually being higher in the Los Angeles area. It could also be due in part to a higher proportion of boat anglers—57% compared to 35% in this study (excluding party boat anglers). Although not reported in the Santa Monica Bay study, this study found that boat anglers are more likely to be aware of health advisories than anglers at shore-based modes.

None of the comparison studies attempted to assess angler's knowledge or understanding of health advisories so comparisons with this study could not be made, although OEHHA assessed respondent's knowledge of posted signs.

We also compared findings on what anglers thought was the best way for them to get information on health advisories (see Table 15). The results from this study and the Save the Bay study were similar, with anglers reporting television and newspapers most often. In the OEHHA study, anglers reported the posting of signs more often than other methods. This may have been due to the recently posted signs at Berkeley Pier for the previously issued striped bass advisory when OEHHA administered their survey in 1995. In addition, because the main goal of the OEHHA study was to determine the effectiveness of signs, anglers were asked many questions specifically about signs, which may have influenced their responses relative to the other studies.

Table 15. Comparison of Sources of Health Advisories Information among Respondents of San Francisco Bay Seafood Consumption Study, Save the Bay Study, and OEHHA Study

	SF Bay Seafood Consumption Study (unadjusted)	SF Bay Seafood Consumption Study (unadjusted)	Save the Bay (Wong *et al.* 1997)	OEHHA (Russell *et al.* 1997)
Population	Shore-based and Private Boat Anglers	Pier Anglers	Pier Anglers	Anglers at Berkeley Pier
No. of Survey Respondents	n=1227	n=695	n=212[a]	n=520
Newspaper	35%	34%	30%	13%
Television	33%	35%	29%	17%
Sign	22%	25%	14%	27%
Family/Friend or word of mouth	20%	20%	20%	10%/3%[b]

[a] responses for 16 anglers appear to be missing

[b] 10% reported "friend" and 3% reported “family”

H. Highly Exposed Populations

A primary goal of this study was to identify populations that may be highly exposed to chemicals from eating Bay fish. We used several different criteria to identify highly exposed populations including consumption rates, the proportion consuming above health advisory levels, species consumed, and consumption methods. We also looked at whether an angler's higher level of exposure was related to lack of access to health advisory information.

Overall, differences among ethnic groups were more distinct than for other demographic locators. Among ethnic groups we found that Asians (particularly Filipinos) were consistently the most highly exposed group. Filipinos and African Americans had the highest overall consumption rates of SF Bay fish. (Pacific Islanders also had high rates but this was based on a small sample.) Vietnamese, Chinese, and Filipinos were more highly represented among anglers who consumed above advisory levels.

Of the three species of Bay fish of greatest health concern (white croaker, striped bass, leopard shark), most anglers in all ethnic groups ate striped bass. However, Asians more frequently ate white croaker compared to other groups and Vietnamese and Chinese more frequently ate leopard shark. In general, Asians were more likely to follow consumption methods (i.e., eating skin, cooking juices, etc.) that increased their exposure to chemicals.

One reason Filipinos may be highly exposed is because of their lack of access to health advisory information. Filipino consumers had the lowest overall awareness and lowest understanding of health advisories compared to other groups.

Some criteria showed shore-based anglers to be more highly exposed than boat anglers. For example, shore-based anglers more frequently consumed white croaker and were more likely to follow consumption methods that increased their exposure to chemicals. This may be due in part to the fact that Asians dominated shore-based fishing modes, although we did not find higher consumption rates among shore-based anglers.

We expected to find a correlation between high consumption of Bay fish and a low level of income and/or education, but we did not. In fact, at the highest levels of consumption (above the 95th percentile), it appeared that anglers with incomes greater than $45,000 are more highly represented than those with lower incomes. Anglers with low income/education levels are still an important concern, however, for several reasons. Firstly, low income and education are related to consumption of two highly contaminated species, white croaker and leopard shark. Secondly, low income and education were often correlated with consumption methods that increase exposure to chemicals, such as eating skin. Finally, low income and education are related to low awareness and understanding of health advisories.

The health advisory for SF Bay recommends stricter consumption limits for women who are pregnant, breastfeeding, planning to become pregnant, and for young children (under the age of six), because these populations are at greater risk than others. Although consumption rate information on household members was not obtained, anglers reported that these high-risk groups consume the fish the anglers catch from SF Bay.

I. Study Strengths and Limitations

To improve upon previously conducted studies, we included several unique elements in our sampling plan and data analyses procedures. Specifically, we determined a target sample size needed to estimate consumption rates with a defined level of precision. The study was designed to obtain a representative sample of the fishing population in SF Bay, thus the results could be extrapolated to the overall angler population. Moreover, efforts were taken to characterize the group of anglers who declined to participate. We describe consumption rates of SF Bay fish for consumers, recent consumers, and per angler. We also presented data on consumption of sport fish from sources other than SF Bay and commercial fish.

The study greatly benefited by having all phases of the study design, field implementation, data analyses, and report generation undergo rigorous review by members of the Seafood Consumption Task Force and selected outside reviewers (see Appendix C). The data and information contained in this report can reliably be used to estimate demographic characteristics and seafood consumption practices of anglers fishing in San Francisco Bay.

Although we designed and conducted this study to minimize sources of measurement error or other biases, it was not possible to eliminate all sources of bias. To help the reader understand the limitations of the data and to assist in the design of future studies, we have summarized some of these limitations below:

1) We experienced higher decline-to-participate rates among shore-based anglers. Since higher proportions of non-Caucasian ethnic groups were represented among shore-based anglers who declined, especially those of Asian ethnicity, our sample may have underrepresented these ethnic groups. We can never truly know consumption rates of anglers who declined to participate. However, we have extrapolated consumption rates for these anglers based on consumption rates derived for anglers who did participate and found no change in overall consumption rates.

2) In general, the sampling plan excluded low activity sites and focused on high activity sites for shore-based and private boat modes. (In some cases, low activity beach and bank sites, if adjacent to a high activity pier site, were included). An ideal sampling plan would have begun with a sampling frame that included all known sites. However, such plans would have resulted either in a much lower sample size (since interviewers would be spending time in lightly-used area) or much higher cost. Since the study costs were fixed, our only options were to have lower sample size (with a less precise consumption rate estimate) or a higher sample size with a less representative sample. We opted for a more precise consumption rate estimate.

3) Consistent with our sampling plan, interviewers at private boat sites attempted to interview all boat anglers using the site during the scheduled sampling period. Most of the time, the interview staff assigned to a site could attempt to interview all anglers using that site. The field coordinator also made an effort to ensure that sufficient interview staff was assigned to sample these sites. However, on a few sampling days, for example, when we had not anticipated a higher level of fishing activity, not all anglers in a group or an entire group of anglers could be interviewed. We did not attempt to quantify the number of anglers that were not interviewed. These anglers who were missed resulted in a slight under sampling of private boat anglers. Additionally, although interviewers attempted to find anglers who had been fishing on berthed boats, no berthed boat anglers could be found to be interviewed.

4) The sample of party boat anglers was about 50% lower than our target. This was due to the lack of cooperation by party boat captains. Furthermore, the sample we did obtain may not be representative of party boat anglers in SF Bay for a number of reasons. For example, the port of origin of the party boat and the sampling days were not randomly selected, and the actual sampling days were not allocated by activity over the 12-month sampling period. In addition, we did not attempt to stratify the party boat sample by day, thus most interviews occurred on weekend days. Also, during exit interviews that we initiated in May 1999, we could not interview all anglers who had been on a boat.

5) Party boat anglers were not asked any health advisory questions to avoid discouraging their participation in the survey. As a result, health advisory results only apply to other fishing modes.

6) As discussed in our sampling plan (see Appendix D), we over-sampled weekend days and under-sampled weekdays relative to the amount of fishing activity by day type (weekend or weekday) in SF Bay at shore-based modes. We over-sampled weekend days to obtain sufficient sample size. Anglers who fish on weekends may differ in their demographic characteristics and consumption patterns than those who fish on weekdays. Since we did not analyze our data for differences by day, the magnitude and direction of any possible bias due to day type differences are not known.

7) Interviewers used a model of an 8-ounce raw fish fillet to help estimate the amount of fish the respondents ate at one time. Most respondents said their portion size was equal to the model. The degree to which the 8-ounce model influenced anglers' responses to this question is not known.

8) Consumption rate estimates based on a 12-month recall may be unreliable. Survey questions that use long recall periods are difficult for respondents to answer accurately.

9) We made no adjustment for the length of the angler's fishing trip at shore-based sites, a type of bias called length-of-stay bias. This bias is similar to avidity bias in that the probability of being sampled may be greater for anglers whose fishing trip is longer than average, compared to those whose trip is shorter than average (Pollock 1994, Otis 1993, Thomson 1991). Length-of-stay bias will not affect anglers such as boat anglers who are interviewed after their fishing trip is completed. Anglers who tend to fish for longer periods of time may also catch and consume more fish than anglers who fish for shorter periods of time. Unless corrected, as with avidity bias, this bias may result in consumption rates that are biased upwards.

10) In our sampling design, interviewers asked anglers if they had been interviewed for this study before. If they had, they were not interviewed again (sampling without replacement). In adjusting our data for avidity bias, we assumed that the probability of being sampled is proportional to an angler's avidity. However, for anglers sampled without replacement, the probability of being sampled is less than proportional to an angler's avidity (USEPA 1997). This occurs because anglers who are not resampled tend to be more avid, on average, than anglers in the sample. The effect of sampling without replacement is that the magnitude of the avidity bias is lessened, thus our adjusted consumption rate results may be biased upward.

11) Interviewers' contact with anglers may have influenced anglers' responses to the health advisory questions. Interviewers read respondents a paragraph describing the health advisory and provided written information for those who requested it at the end of the interview. It is likely that information we provided over the 12-month data collection period was shared with other anglers.

VI. Recommendations

This study was undertaken to fill gaps in our understanding of anglers' exposures to Bay fish, to identify highly exposed populations, and to gather information needed for developing educational messages and outreach activities for these populations. Much of the information presented in this report describes parameters for characterizing anglers' exposures, including highly exposed groups. Findings from this study can also be used to help develop educational messages and activities aimed at reducing anglers' exposures to chemical contaminants. Our recommendations focus primarily on how educational messages should be developed, and how outreach and educational activities should be conducted. We also identify areas where additional research is needed.

A. Recommendations for Outreach and Education Activities

- Conduct outreach and education activities to reach highly exposed groups

  One of the central goals of the study was to identify highly exposed groups and gather information needed for developing educational messages for these groups. As discussed in Section V.H, we identified Asians, particularly Filipinos, as the group most consistently among the highly exposed. In addition, African Americans had high overall rates of Bay fish consumption. The highest priority should be given to developing messages specifically targeted to these groups.

- Develop educational messages that are culturally appropriate

  Given the ethnic diversity of SF Bay anglers, we recommend that culturally appropriate educational messages be developed. To be culturally appropriate, these messages need to be multilingual, sensitive to ethnic differences, and be at an appropriate literacy level.

- Develop educational messages that address the consumption practices of the target groups

  We found clear demographic differences among groups in the species that they eat, the parts of the fish they eat, and the ways in which they cook or prepare the fish. For example, Asians were much more likely to eat white croaker than other groups and, in general, Asians ate parts of the fish or prepared fish in ways that increased their exposure. We recommend that educational messages for target groups address these specific consumption practices. Thus, educational messages for Asians should focus on limiting white croaker consumption and emphasize safe consumption practices that would decrease their exposure.

- Develop educational messages that reflect the current advisory (see Appendix A)

  Until the current advisory is updated, we recommend that all educational messages convey the content of this advisory.

- Develop educational programs using a variety of approaches

  Because we found that none of the methods of delivering educational information to anglers received overwhelming support by all anglers, education activities will likely require a diversity of approaches. Both the survey results and the fish discussion groups indicated the need for educational material with a range of complexity and depth to meet the needs of the highly diverse SF angler population. We recommend that different methods, including newspaper, television, radio, and written materials, be explored.

- Post warning signs in all areas of SF Bay

  Although we found signage to be the third most popular method of communicating to anglers on fish contamination issues, signs seem to be the most direct way to reach anglers. We recommend comprehensive sign posting and maintenance in SF Bay at piers, beaches and banks, and at marinas to warn anglers about contaminants in Bay fish.

- Direct the Education and Outreach Task Force on Fish Consumption and Fish Contamination Issues to carry out the outreach and education activities recommended above

  The goals of the Task Force are consistent with the outreach and educational activities we recommended above. However, the Task Force has been constrained by lack of resources. We recommend that additional resources be obtained to enable the Task Force to implement the outreach and education activities recommended above.

- Direct the Task Force to take a leadership role

  A major barrier to conducting educational activities, particularly posting of warning signs, in the SF Bay area has been uncertainty over which organizations have jurisdiction to undertake these activities. For example, it is often unclear who has authority to post and maintain a warning sign at a pier. We recommend that the Task Force take a leadership role in developing and overseeing the implementation of an integrated strategy to communicate health advisories on fish in a more effective manner. This would include coordinating input from the different agencies and organizations when conducting educational activities.

B. Recommendations for Community Involvement

- Expand the membership of the Task Force to have broader community representation

  For outreach and educational activities to be successful, the Task Force membership must more closely reflect the interests of the highly diverse angler population. We recommend that the Task Force seek broader representation from community-based organizations that represent health care, environmental, fishing, and other pertinent interests in the SF Bay area and that commensurate resources be made available for this purpose.

- Conduct activities that enhance participation from community-based organizations

  In addition to seeking broader membership on the Task Force, we recommend that the Task Force specifically undertake activities that will enhance participation and support from community-based organizations. CDHS is piloting a community-based approach to outreach and education on fish issues in the Los Angeles area. We recommend using this approach as a model for SF Bay activities.

C. Recommendations for Further Study

- Investigate the influence of the portion-size model on consumption rates

  The use of a single physical model to estimate the amount of fish anglers eat influences the angler's response. In this study, the model produced a consumption rate distribution that was peaked around common multiples or fractions of the model, and introduced an unquantifiable degree of uncertainty in the consumption rate results. Further study should focus on ways to estimate consumption rates that minimize this effect. For example, models of different portion sizes could have elicited a broader range of responses and may have produced more accurate consumption rate responses.

- Gather additional data on shellfish consumers in SF Bay

  Due to resource constraints, the data we gathered in this study on shellfish consumers was limited. Although we asked anglers (i.e., people who fish) if they consumed shellfish, we did not conduct any interviews with persons who collected only shellfish but did not fish. We also know little about the quantity of shellfish people eat from the Bay, the types of shellfish eaten, and the parts of the shellfish that are consumed. Because Bay shellfish may pose health risks to people who consume it, we recommend that more information be gathered about shellfish consumers in the Bay.

- Gather additional data on party boat anglers in SF Bay

  The sample of party boat anglers we collected in this study fell short of our target, thus our findings may not accurately reflect this population. In addition, party boat anglers were not asked any questions about health advisories. We recommend that additional data be gathered on party boat anglers to better characterize their consumption rates and practices and their awareness to health advisories.

- Gather additional data on high risk groups

  We know that some groups, i.e., pregnant and breastfeeding women, women planning to become pregnant, and young children, are at higher risk because they may be more sensitive to the harmful effects of chemicals found is Bay fish. Although we interviewed only people who fish in this study, we did find that many anglers have women of child bearing age and young children in their

households who consume Bay fish. The limited data on female anglers of child bearing age in this study indicate that consumption rates are similar to male anglers. Thus, if these women are pregnant, nursing, or planning to become pregnant, they may be exceeding the more restrictive advisory for these groups. However, we know very little about exposures to these groups and how to develop educational message to reach them. We recommend that additional data be gathered on these groups.

- Test the effectiveness of educational messages and activities

  Data on the actual effectiveness of alternative messages and how these messages are communicated to target audiences are lacking. We recommend that further research examine how alternative messages are understood and how effective different activities are at reaching target audiences.

1994 Interim Health Advisory for the San Francisco Bay

San Francisco Bay Seafood Consumption Study

Health Advisory on Catching and Eating Fish
Interim Sport Fish Advisory for San Francisco Bay

The California Environmental Agency's Office of Environmental Health Hazard Assessment (OEHHA) has performed a preliminary review of the data from the 1994 San Francisco Bay pilot study, "Contaminant Levels in Fish Tissue from San Franciso Bay." The results of the study showed elevated levels of chemical contaminants in the fish tissues. Based on these results, OEHHA is issuing an interim consumption advisory covering certain fish species from the bay.

- Adults should limit their consumption of San Francisco Bay sport fish to, at most, two meals per month.*
- Adults should not eat any striped bass over 35 inches.
- Women who are pregnant or may become pregnant, or who are breast-feeding, and children under 6, should not eat more than one meal per month and, in addition, should not eat any meals of large shark (over 24 inches) or large striped bass (over 27 inches).
- This advisory does not apply to salmon, anchovies, herring, and smelt caught in the bay; other ocean caught sport fish; or commercial fish.
- This advisory supersedes the existing advisory on striped bass in the bay, but does not revoke the recent advisory issued for the Richmond Harbor Channel Area.

Individuals who follow these interim guidelines will protect themselves from potential adverse effects caused by the levels of the chemicals found in fish by the study. OEHHA scientists also have the following simple suggestions for catching and eating fish from San Francisco Bay: (1) fish in a variety of locations, (2) eat smaller amounts of several species of fish rather than large amounts of a single species that may have a higher level of contamination, (3) clean and gut fish, eat only the fillet portion, (4) skin and trim fat from fish, (5) bake, broil or steam fish on a rack, (6) discard the juices from cooked fish.

This interim consumption advice is being issued due to health concerns based on exposure to sport fish form the bay contaminated with methylmercury, polychlorinated bipheyls (PCBs), dioxins, and pesticides like DDT. The principal effects of concern (from long-term consumption of fish) are possible neurotoxicity to developing fetuses, infants, and small children (e.g., impaired mental and motor development), mainly associated with excessive methylmercury or PCBs exposure, and potential increased risks for cancer due to exposure to PCBs, dioxins, and the pesticides. There is some indication of greater sensitivity of the nervous system in fetuses, infants, and young children. Because of this sensitivity, more restrictive consumption advice is given for young children and pregnant or breast-feeding women who may pass the contamination on to their fetus or child.

Although this advisory is based only on a preliminary review of the data form the study, OEHHA felt it would be prudent to issue interim guidelines at this time. More specific advisories and recommendations will be issued when a thorough evaluation of the study data is completed by OEHHA in conjunction with other public agencies.

More information can be obtained by calling OEHHA at (916) 324-7572.

---

* A fish meal for a 154-poound (70 kilogram) person is considerd to be an 8 oz. portion of fish prior to cooking. Meal size should be adjusted according to body weight, with roughly 1 ounce of fish per 20 pound body weight. for a 40-pound child, for example, a fish meal would be 2 ounces of fish.

San Francisco Bay Seafood Consumption Study
Advisory Task Force and Reviewers

San Francisco Bay Seafood Consumption Study

The following individuals served as Task Force Members:

Ray Arnold, Exxon Biomedical Sciences, representing Western States Petroleum Association (WSPA)
Marcia Brockbank, San Francisco Estuary Project
Carlyle Johnston, Save San Francisco Bay Association
Bridgette DeShield, Harding Lawson, representing WSPA (replacing Paul Krause)
Margy Gassel, Pesticide and Epidemiology Section, Office of Environmental Health Hazard Assessment, California Environmental Protection Agency
Martin Golden, National Marine Fisheries Service
Paul Gregory, California Dept. of Fish and Game
Kay Johnson, Tetra Tech
Paul Krause, Harding Lawson, representing WSPA (replacing Ray Arnold)
Carrie Pomeroy, Institute of Marine Sciences, University of California, Santa Cruz
Brian Sak, Bureau of Public Works, City and County of San Francisco
Karen Taberski, San Francisco Regional Water Quality Control Board, Region II
Carol Thornton, San Francisco Estuary Project

The following individuals served as special consultants and outside reviewers:

Jeff Bigler, USEPA, Office of Water
Robert Brodberg, PETS/OEHHA, CA EPA
Jordan Gold, Applied Marine Sciences
Tom Grieb, Tetra Tech
Barbara Knuth, Dept. of Natural Resources, Cornell University
John Ong, Office of Water, USEPA, Region IX
Cassandra Roberts, Moss Landing Marine Laboratories
Gail Roper, CA Dept. Fish and Game
Hanafi Russell, PETS/OEHHA, CA EPA
Bob Smith, EcoAnalysis

Task Force members and outside reviewers performed the following tasks:

A. Proposal Review and Contractor Selection

Ray Arnold
Jay Davis – SFEI
Margy Gassel,
Rainer Hoenicke (SFEI Project Manager)
Brian Sak
Karen Taberski

B. Phase I – Survey Design

Project Staff: Diana Lee, Alyce Ujihara, Dan Smith, Martha Harnly, Bob McLaughlin, Christine Arnesen, Ian Walker, Gloria Cardona – Environmental Health Investigations Branch (EHIB), California Dept. of Health Services

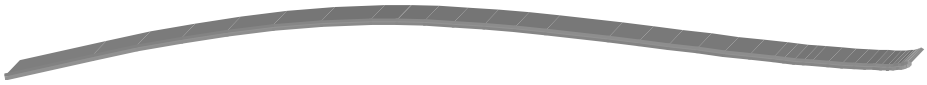
Appendix D

Sample Design, Site Selection, and Sampling Schedule

San Francisco Bay Seafood Consumption Study



Appendix D - Sampling Plan for the San Francisco (SF) Bay Seafood Consumption Study

In Section II.B, we provided an overview of the study's sampling plan. This appendix describes the sampling plan in further detail.

A. Survey Approaches

There are many different survey approaches that can be used to gather fish consumption information about anglers. These approaches include off-site methods such as mail and phone surveys as well as on-site methods such as personal interviews at fishing locations. We determined that the best way to gather fish consumption information from SF Bay anglers was to use personal interviews at fishing sites.

Off-site methods could not be used for this study because, in California, no comprehensive list of anglers, from fishing licenses or other sources, was available when this study was planned. A list of fishing license holders, even if available, may not be complete for SF Bay anglers because fishing licenses are not required at public piers in California (CDFG 2000). A significant amount of fishing activity occurs on these public piers in SF Bay and the proportion of pier anglers who hold licenses is not known. Additionally, on-site personal interviews conducted by bilingual interviewers would enhance participation of respondents who may have difficulty understanding written questionnaires due to cultural or language barriers, or low literacy. Finally, because of the importance of estimating consumption rates, we opted to use a physical model of a fish fillet to elicit information about the quantity of fish typically eaten by the angler. The use of the fillet model required us to use personal interviews.

B. Sampling Frame

The sampling frame is a complete list of the populations units that will be sampled (Pollock et al 1994). For example, the population units can be the individual members of a population, if all the members can be identified. With on-site surveys, the sampling frame is a complete list of all time-place combinations where anglers are present. In other words, it includes all possible fishing sites or access points in the study area and all possible sampling days and times during the study period.

The study area included the San Francisco Bay within the Golden Gate Bridge, including San Pablo Bay in the north (see Figure 1 in the report). To the east, the study area includes the Carquinez Straits and Suisun Bay to Chipps Island (near the city of Pittsburg). The list of fishing sites used in this study was drawn from the Marine Recreational Fisheries Statistics Survey (MRFSS) site list (Roper 1997). The site list from the MRFSS for SF Bay identified 47 sites with shore-based fishing[1], 24 with private boat access, and 8 with party boat access.

[1] Although the MRFSS identifies two shore-based modes, (1) man-made (e.g. piers) and (2) beach and bank, we combined these modes into a single "shore-based" mode.

To ensure that the MRFSS site list included all possible fishing locations in our study area, we consulted task force members, California Department of Fish and Game staff, and other sources. In addition, we identified sites in the Carquinez Straits and Suisun Bay areas of SF Bay where the MRFSS is not conducted. Some areas of SF Bay where we could not gain access, such as military bases, were not included in the study.

In addition to a comprehensive list of sites in the study area, the sampling frame includes all days and times when anglers are present at the sites. The possible sampling days included the one-year period, from July 1, 1998 to June 30, 1999.

C. Sample Size Estimate

1. Sample Size of Recent Consumers

We set a target sample size based on an estimate of the minimum number of interviews needed to meet the objectives of the study. Because of the emphasis placed on defining exposure assessment parameters such as consumption rate, the sample size was based on the minimum number of interviews needed to estimate a reasonably precise mean consumption rate. The consumption rate was derived from the subset of anglers who consumed fish caught from SF Bay in the four weeks prior to the interview, a group we refer to as recent consumers. In choosing the four week time period, we sought to maximize the time period over which a consumption rate estimate could be made while minimizing recall bias. In addition, the Santa Monica Bay Seafood Consumption Study (Allen 1996, SCCWRP/MBC 1994) has to date provided the best estimates of fish consumption rates from a California population. This study also used a four week recall to estimate consumption rate. By using a similar method to define consumption rate, we could compare rates derived from both studies.

We used consumption rate data from the Santa Monica Bay study to estimate the target sample size for this study. Using the mean and standard deviation from the Santa Monica Bay study, we calculated confidence limits around a geometric mean and upper percentiles (90th and 95th) for different sample sizes (Hahn and Meeker 1991). Figure 2 (in the report) shows that for a sample size of n=480, the 95% confidence limits are +/-10% around a geometric mean. At n=480, the 95% confidence limits around the 90th and 95th percentiles are slightly larger (+/-13-15%). As can be expected, the width of the confidence limits increases as the sample size decreases. Figure 2 also shows that as the sample size increases beyond n=480, little increase in precision of the consumption rate estimate is gained. We consider a 95% confidence limit of +/-10-15% to be reasonable and thus select n=480, or n~500, as our target sample size for the group of recent consumers.

2. Target Interview Attempts

The sample size estimate described above showed that we needed to conduct interviews of about 500 recent consumers in order to calculate a reasonably precise consumption rate. We then estimated the number of anglers we would need to approach to obtain

completed interviews of 500 recent consumers. The last row in Table D1 shows that in three past angler surveys, 23% to 32% of attempted interviews yielded a completed interview of a recent consumer.

Table D1. Comparison of Response Rates in Three Angler Surveys in California

Angler Survey	**Santa Monica Bay[a]**	**SF Bay Pier Anglers[b]**	**SF Bay Pier Anglers[c]**
Interviews attempted	1740	388	111
Refusal	496 (29%)	160 (41%)	28 (25%)
Persons interviewed	1244 (71%)	228 (59%)	83 (75%)
Respondents without recent consumption	689 (40%)	137 (35%)	54 (49%)
Respondents with recent consumption	555 (32%)	91 (23%)	29 (26%)

[a] Allen et al. (1996) and SCCWRP/MBC (1994).
[b] Wong et al. (1997).
[c] Ujihara (1997).

The highest percentage (32%) of respondents providing recent consumption information comes from the Santa Monica Bay Seafood Consumption Study. Although this study had a much larger sample size than the other studies, over half of the interviews were of private or party boat anglers, where the proportion of recent consumers was higher than shore-based fishing modes (Table D2).

Table D2. Proportion of Recent Consumers by Fishing Mode for Santa Monica Bay Seafood Consumption Study

Fishing Mode	Attempted Interviews	Recent Consumers
Pier/Beach Intertidal	806	216 (27%)
Private Boat	630	233 (37%)
Party Boat	304	106 (35%)

Source: SCCWRP/MBC (1994) and Allen et al. (1996).

Only shore-based anglers were interviewed in the SSFBA and EHIB studies. The proportion of total attempted interviews where anglers reported recent consumption from these two studies was only 23% and 26%. As discussed further in subsequent sections, SF Bay fishing activity is dominated by shore-based fishing, leading us to estimate that approximately 25% of our interview attempts of anglers will yield interviews of recent consumers. Thus, we concluded that 2000 (500/0.25) interviews must be attempted to reach our target of 500 recent consumers.

D. Sampling Plan Elements

In addition to meeting our sample size goals, there were a number of elements included in the sampling plan that guided our selection of sampling sites and determined how frequently we sampled at the selected sites. These elements include stratification of the sample by mode, season, and day type. In addition, we describe how our budgetary resources shaped the sampling plan.

1. Sample Stratification by Mode

Stratification of a sample into homogenous, non-overlapping groups called strata can improve the overall precision, facilitate administration, and reduce costs of the survey (Pollock et al. 1994, Scheaffer et al. 1996). To determine how much to sample in each strata, Pollock et al. (1994) recommends distributing sampling effort in proportion to fishing effort or the variable of interest such as catch. We stratified our sample by the three fishing modes based on the relative amount of fishing activity in each mode. We used fishing activity (the relative number of anglers using a site) rather than fishing effort (relative amount of time anglers spend at a site) because of our primary interest in angler characteristics (e.g., consumption rate, demographic factors) rather than factors that describe fishing effort (e.g., catch per effort, catch).

For estimates of fishing activity we relied on fishing pressure data developed for the MRFSS. Fishing pressure, as defined by MRFSS, is an estimate the average number of anglers that are present at a site over an eight-hour day. For boat modes, the fishing pressure is an estimate of the number of anglers using a launch ramp or departing from a marina. The number of anglers present at a site is provided as a range, i.e., a site can be assigned a fishing pressure of zero, 1-4 anglers, 5-8 anglers, 9-12 anglers, 13-19 anglers, or 20-29 anglers, etc. A separate fishing pressure estimate is made for weekend days and the weekdays for each of the 12 months of the year at each site.

In order to estimate the relative amount of fishing activity for each mode, we summed MRFSS fishing pressure estimates for 1997, using the mid-points of the ranges, for all sites in SF Bay. We then averaged this value over the 12 months in a year, and weighted the weekend and weekday estimates by the proportion of weekend days and weekdays in a year. The resulting value provided an estimate of the relative number of anglers fishing in each mode for an average eight hour day. These values are shown in column 2 of Table D3.

Table D3. Fishing Activity in SF Bay and Original Target Survey Attempts by Mode

1	2	3	4	5	6
Mode	Fishing Activity in SF Bay (uncorrected)*	Proportion Outside SF Bay	Fishing Activity in SF Bay (corrected)*	% of total	Target number of attempted surveys
Shore-based	263.0	0%	263.0	62.5%	$n_{shore\text{-}based} = 1250$
Private boat	131.9	11.8%	116.3	27.6%	$n_{private} = 553$
Party boat	93.4	55.6%	41.5	9.9%	$n_{party} = 197$
Total	488.3	---	420.7	100%	$n_{total} = 2000$

*The average number of anglers fishing on typical day by mode.

Some anglers on private and party boats depart from sites within SF Bay but they fish primarily outside the Bay. Because the focus of our study is fishing within SF Bay, we sought a correction to eliminate fishing activity originating in the Bay but occurring outside the Bay from our estimates of fishing activity by boat modes. Using data collected by MRFSS interviewers for 1994-1996, we found that a significant amount of the fishing activity, particularly among party boats, originated within SF Bay but was primarily conducted outside the Bay. Of fishing trips originating within the Bay, Table D4 shows the proportion of boat trips that were primarily conducted outside the Bay.

Table D4. Boat Anglers Fishing Outside and Inside SF Bay from MRFSS 1994-1996

	FISHING MODE			
	Private Boat		Party Boat	
	No.	%	No.	%
Outside SF Bay	471	12	421	56
Inside SF Bay	3512	88	336	44
Total	3983	100	757	100

Source: Van Buskirk (1997).

Table D4 shows that 12% of private boat anglers and 56% of party boat anglers originated their trip in the Bay but fished primarily outside the Bay. We then corrected our fishing activity estimates in Table D3 by reducing fishing activity for out of Bay trips among boat modes. Column 3 of Table D3 shows the proportion of fishing activity outside the Bay and column 4 shows the revised fishing activity estimate. We concluded in column 5 that about 62% of the total fishing activity in SF Bay is attributed to anglers fishing at shore-based sites (n_{shore}), 28% to anglers fishing within SF Bay on private boats ($n_{private}$), and 10% to anglers fishing within SF Bay on party boats (n_{party}).

Column 6 of Table D3 provides an initial target number of interviews we should attempt in each mode, derived by multiplying the percent of total activity for each mode by our targeted of 2000 interview attempts. For example, we estimated that 0.625 x 2000 = 1250 interview attempts for shore-based anglers.

2. Seasonal Variation

One of the study's objectives was to characterize seasonal variation in fish consumption patterns and angler characteristics. In order to observe seasonal variations that occurred over the one year study period, we planned to visit the same group of sites each month. Thus, observed differences could be attributed to changes over time rather than differences among the sites sampled. Visiting the same group of sites on a monthly basis also facilitated administration of the survey.

3. Day Type Differences

Overall, there is more fishing activity in SF Bay on a typical weekend day than on a typical weekday. However, in number, there are more weekdays than weekend days. (The ratio of weekdays to weekend days is 5:2). In Table 5 we calculated the relative amount of fishing activity for 1997 by shore-based and private boat modes, based on MRFSS fishing pressure data. For shore-based modes, there is more fishing activity on a typical weekend day, but this is offset by the greater number of weekdays. Thus, the amount of fishing activity by day type over a year is roughly equal. For private boat modes, fishing activity is far greater on a typical weekend day than a weekday. Even after adjusting for the greater number of weekdays, the ratio of fishing activity on weekends to weekdays at private boat sites is approximately two to one.

In making this estimate, we could not exclude fishing activity that originated in the Bay but was primarily conducted outside the Bay. For private boats, the proportion is relatively small (12%) and thus, we ignored it. Because this proportion is large for party boats (56%), we did not make an estimate of fishing activity by day type for this fishing mode.

Table D5. Fishing Activity by Day Type at Shore-based and Private Boat Sites in SF Bay

Fishing Mode	Day Type		
	Weekday	Weekend	Total
Shore-based	51%	49%	100%
Private Boat	38%	62%	100%

In an ideal sampling plan, we would allocate sampling effort by day type according to the percentages in Table D5. Because fishing activity is much lower on weekdays, it is more costly to sample weekdays and the higher the proportion of weekend days, the greater the expected sample size. To reach our sample size goals, we considered oversampling weekend days. But, in order to address concerns that the population fishing on weekdays could be significantly different from the population fishing on weekends, we sought to include some sampling on both day types.

4. Resources

Ultimately, our field data collection efforts were restricted by the resources available in our budget. After taking into account the resources needed for training the interviewers, we calculated that we had about 1700 person-hours available for field data collection activities. We allocated those person-hours by the relative amount of fishing activity in each of the 3 modes (Table D6).

Table D6. Person-Hour Allocation for Data Collection by Mode

Mode	Fishing Activity inside SF Bay	% of total	Person Hours Available for Data Collection
Shore-based	263	62.5%	1063
Private boat	116.3	27.6%	469
Party boat	41.5	9.9%	168
Total	420.7	100%	1700

5. Exclusion of Low Activity Sites

In an ideal study, the sampling frame would include all sites for shore-based and private boat anglers at all fishing locations where anglers fish and all points where anglers depart from. However, according to MRFSS data, many fishing sites in SF Bay have low activity and require more resources per interview to sample.[2] In selecting sites, we attempted to maximize the number of sites that could be included. But, in order to reach our sample size goal, most sites with low activity were excluded from the sampling plan. In general, low activity areas were included only if adjacent to a high activity site. For example, we included beach or bank areas next to a busy fishing pier.

We did consider the trade-off between the possible introduction of a bias by excluding low activity sites and the loss in precision from a reduced sample size if low activity sites were included. An outside consultant was hired to model these factors for shore-based sites (Smith 1998). This analysis found that any bias introduced by focusing on only high activity sites would be small in comparison to the loss in precision from a smaller sample size that would result by including low activity sites.

6. Geographic Distribution

Because the study addresses fishing throughout SF Bay, we considered the overall geographic distribution of sampling sties. We sought to include sites from all areas of the Bay.

[2] We defined low activity as sites where the MRFSS has assigned zero or the lowest fishing pressure estimate, a range of 1-4 anglers over an 8-hour day.

E. Sampling Plan for Shore-Based Sites

To derive an optimal sampling plan for shore-based sites we considered several sampling alternatives. For comparison, one alternative included sampling at all 46 MRFSS sites. The other alternatives included fewer numbers of sites but focused on the sites with the highest fishing pressure.

1. Fishing Activity Differences Among Sites

In order for the sampling plan to capture fishing activity differences between sites, the amount of time we conducted interviews at each site was not predetermined. Interviewers were instructed to interview all anglers present at a site. If no anglers were present, they remained for a minimum of one hour before going to the next site or ending the sampling day. By using this method, site differences in activity would be reflected in the relative number of anglers interviewed at a site.

2. Projecting Interview Attempts

For each sampling alternative, we projected the number of interviews we could expect to attempt during the study using MRFSS fishing pressure data. MRFSS data reflect the number of anglers at a site over an eight hour day, while we planned to interview all anglers present at a site and then leave. We did not expect to remain at a site for eight hours, even at the busiest locations. Thus we had to adjust the MRFSS fishing pressure estimates in order to project the number of interviews we could expect at a site. Based on a census of anglers during site visits we made in 1997, we estimated conservatively that we could expect to find 75% of the MRFSS fishing pressure estimate during our site visits where we remained at a site long enough to interview all anglers present. In other words, if MRFSS data estimate that 13-19 anglers will be present at a site over an 8-hour day, we took the midpoint of the range, 16, and multiply by 75%. Thus we estimated that we expected to find 16*.75=12 anglers on average during a site visit.

3. Projecting Person-Hours

In addition to projecting the number of interviews we could attempt for each sampling alternative, we also projected the number of person-hours needed to sample these alternatives. The person-hour estimates included the time needed to conduct the interview, including interviews in languages other than English, the time needed for conducting a census of anglers, travel between sites, and reviewing the completed surveys at the end of the day.

Because of the difficulty in keeping the study within our resources while still maintaining a reasonable a number of sampling sites, several changes were made to the sampling design to reduce costs. We grouped sites into pairs based on geographic proximity and site pairs were sampled together. Interview team size, originally set at three persons to cover all the target languages, was reduced to two persons.

4. Shore-based Sampling Plan Selected

As could be expected, we found that the greater the number of sites included in the sampling plan, the lower the expected sample size. To sample at all 46 sites and stay within our budget, we estimated that the number of interview attempts would be about 40% below our target of 1250.

The final site combination selected included 14 sites (7 site pairs). Two sites were specifically included in the selected sites to improve geographic coverage. One site (Martinez) was added in the Carquinez Straits area which is outside the area of the MRFSS. Also, one site (Dumbarton Bridge) was added to replace the San Mateo Bridge site. The San Mateo Bridge site is one of the most heavily used sites in the Bay but was closed during the duration of survey. The 14 selected sites are listed in Table D7 and shown in Figure D1.

Table D7. MRFSS Fishing Pressure at 14 Selected Shore-based Sites

			MRFSS Fishing Pressure	
Rank	County	Site Name	Weekday	Weekend
1	San Francisco	Fort Point Pier	13.9	19.4
2	Marin	Fort Baker Pier	12.9	20.5
3	Marin	McNear's Pier	9.2	16.7
4	San Francisco	Municipal Pier	8.2	12.8
5	Alameda	Berkeley Pier	5.5	16.5
6	Alameda	Alameda Rockwall	6.6	11.3
7	San Francisco	Candlestick Point	4.3	16.3
8	San Mateo	Oyster Point	4.8	9.5
9	Contra Costa	Point Pinole	2.8	12.0
10	San Mateo	Coyote Point	3.4	10.7
11	Alameda	Port View Park	2.0	13.0
12	Solano	Vallejo shoreline	4.8	9.2
13	Alameda	Dumbarton Pier	1.0	6.5
14	Contra Costa	Martinez Pier*	1.0	1.0
		Total	80.3	175.4

*Martinez Pier is outside the area of the MRFSS. We estimated the fishing pressure based on our own observations.

In Table D5, we estimated that shore-based fishing activity was 51% weekdays and 49% weekends. Thus, we allocated equal sampling days to weekends and weekdays by

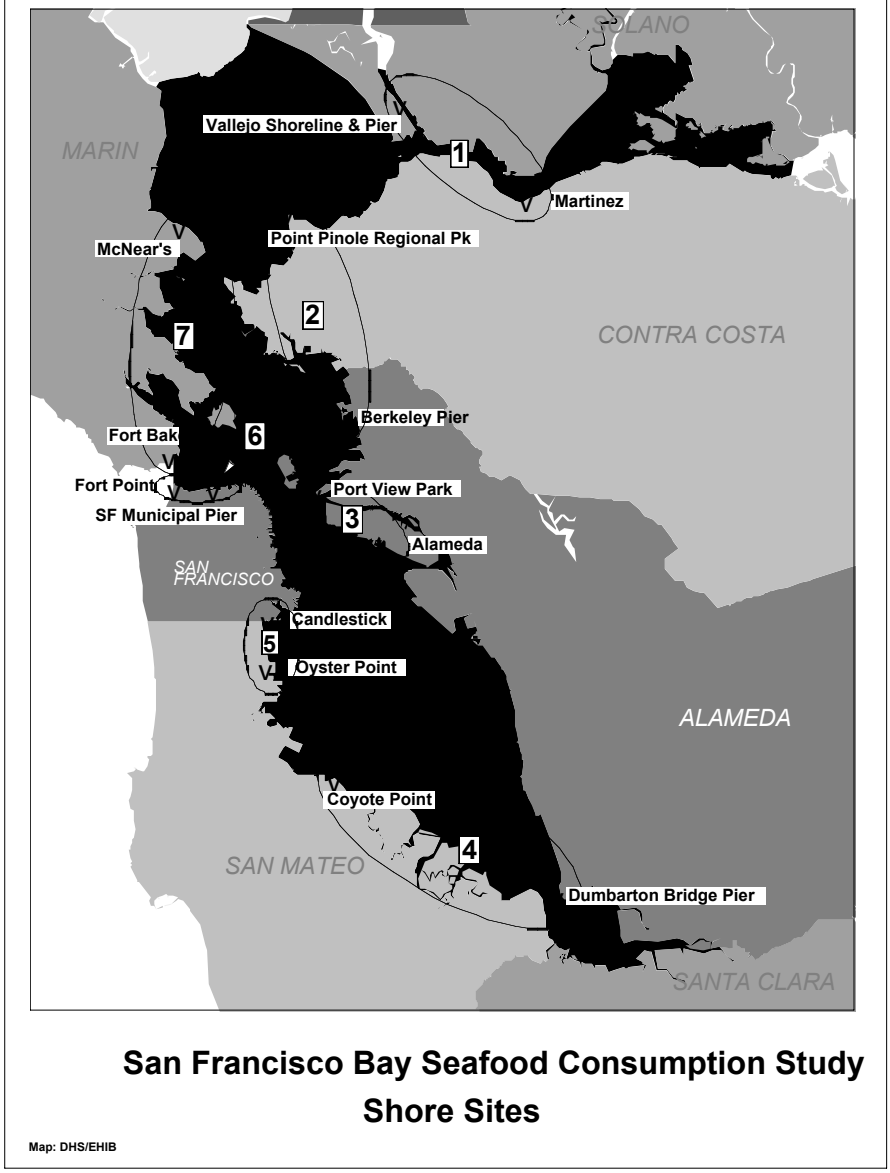


Figure D1. Shore-based Sites

alternating day types at a site each month. However, because activity at all sites was generally higher on weekends, our sampling effort was approximately 2/3 weekend and 1/3 weekday. This resulted in an oversampling of weekend days relative to our estimate of fishing activity but allowed us to maintain an adequate sample size.

Table D7 also shows the average fishing pressure at the 14 sites. We used these averages to estimate the projected number of interview attempts shown in Table D8. By visiting each site one time per month, half on weekdays and half on weekends, we estimated attempting 1150 interviews, below our original target of 1250 but within our resources (Table D9).

Table D8. Estimating Interview Attempts for 14 Shore-based Sites

	Weekday	Weekend	Total
MRFSS Fishing Pressure (average number angler per 8 hour day)	80.3	175.4	256
Estimated Interview Attempts per Visit (75% of fishing pressure)	60.2	131.6	192
Sum Over 12 months (6 weekday and 6 weekend visits per site)	361	789	1151

Table D9. Comparison of Original Target Sampling With Revised Target at Shore-Based Sites

	Interview Attempts	Person-Hours
Original Target	1250	1063
Revised Target Chosen Sampling Plan	1151	1042

F. Sampling Plan for Private Boat Sites

As with the shore-based sites, we considered several sampling alternatives for private boat sites. One alternative included all 24 identified private boat sites in SF Bay. Other alternatives included the top 5 and top 10 sites with the highest fishing pressure. Our primary goal for sampling private boat anglers was to interview anglers at access points as they left on a fishing trip or returned from a fishing trip. The primary access point was a boat launch, where anglers launch boats from trailers. We also screened anglers to ensure that their fishing trip that day was in SF Bay; we did not interview anglers fishing predominately outside SF Bay.

There were concerns that interviewers stationed at launch ramps would miss private boat anglers who used berthed boats. To include anglers using berthed boats, interviewers were instructed to visit marina areas adjacent to launch ramps sites and look for berthed boats about to depart or returning from a fishing trip and interview these anglers.

1. Fishing Activity Differences at Sites

Unlike the shore-based sampling plan, the length of time interviewers were stationed at a launch ramp was precisely determined based on fishing activity differences at the sites. Following Pollock, we assigned a shift length that was proportional to the relative amount of fishing activity at the site, using MRFSS fishing pressure data. Thus, these private boat sampling shifts varied by site, by month and day type (weekend or weekday). In other words, sites with the most activity were assigned longer shifts than sites with less activity. In general, shifts were longer during weekends and during warm weather months because these times generally had more activity.

2. Projecting Interview Attempts

In order to evaluate the sampling alternatives, we projected the number of interview attempt we could expect for each alternative using MRFSS estimates. For example, if MRFSS data estimated a range of 13-19 anglers at a site for an eight hour weekend day in July, we took the range midpoint (16) and estimated that we could encounter two anglers per hour (16 anglers/eight hour day =two angler/hour) at that site for a weekend day in July. The interview rate (interview attempts per hour) was multiplied by the assigned shift length (hours) to derive an estimate of the number of interview attempts for a sampling shift. We then summed the interview attempts for all sites, day types, and months to give an estimate of the total interview attempts for the one year study period.

3. Projecting Person-Hours

We also projected the total person-hours by summing all shift lengths for all sampling alternatives. The total was multiplied by two because we planned to assign two interviewers to all shifts. We also assigned additional person-hours to allow interviewers to review their completed surveys at the end of the day.

4. Private Boat Sampling Plan Selected

As with the shore-based sampling plan, the greater the overall number of sites, the lower the projected sample size. The sampling alternative selected included five sites. This was the minimum number of sites that gave reasonable geographic distribution of the Bay (Table D10 and Figure D2).

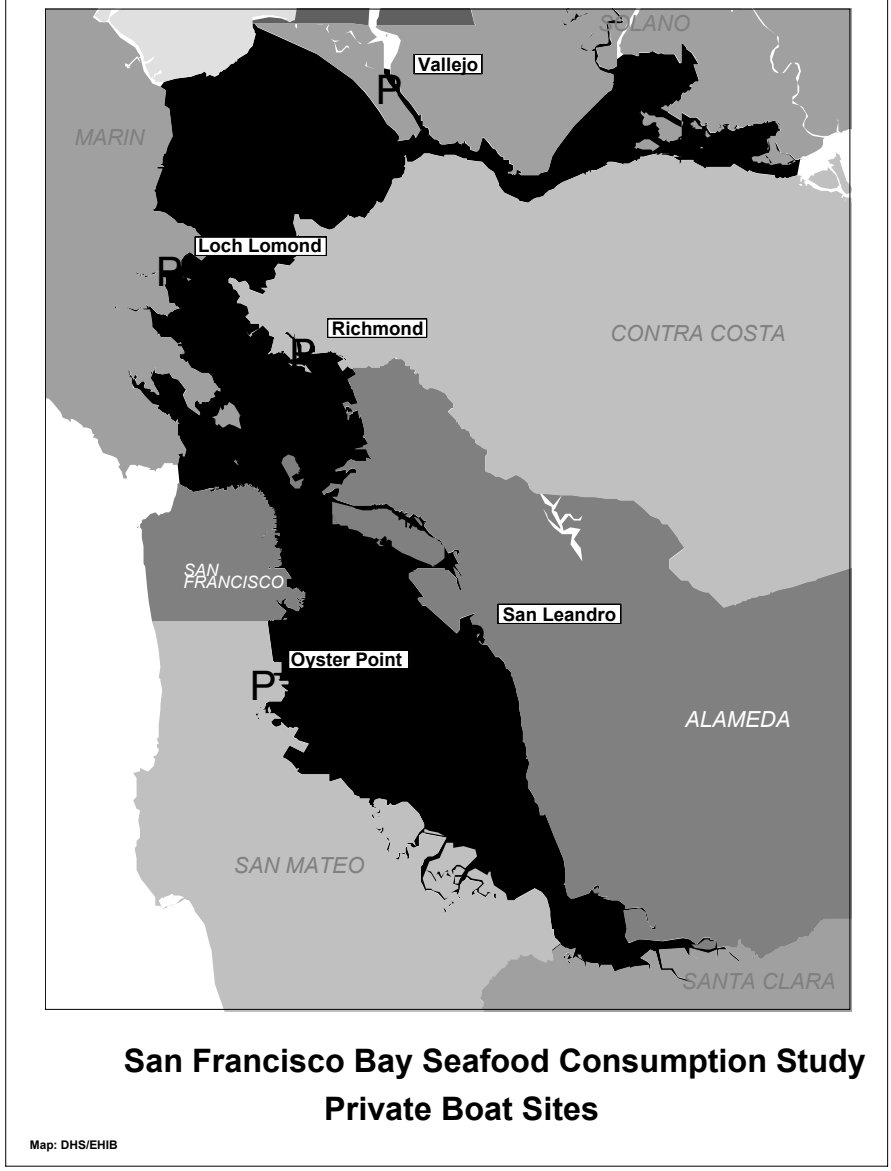

Figure D2. Private Boat Sites

Table D10. MRFSS Fishing Pressure at 5 Selected Private Boat Sites

			MRFSS Fishing Pressure	
Rank	County	Site Name	Weekday	Weekend
1	Contra Costa	Richmond	10.5	22.4
2	Solano	Vallejo	9.2	20.3
3	San Mateo	Oyster Point	8.2	19.5
4	Alameda	San Leandro	1.0	21
5	Marin	Loch Lomond	6.5	14.6
		TOTAL	35.4	97.8

The number of interview attempts we projected was 27% below our original target (Table D11). We opted to accept this lower sample size rather than make other modifications to the sampling plan. Based on the SMB study results (Table D2), we anticipated that we would have greater sampling success with private boat anglers than for shore-based fishing. Thus, we anticipated that the number of private boat anglers who were recent consumers would be adequate.

Table D11. Comparison of Original Target Sampling With Revised Target at Private Boat Sites

	Interview Attempts	Person-Hours
Original Target	553	469
Projection for Chosen Sampling Plan	406	510

In order to reduce the total number of person-hours needed to sample at the five selected sites, we chose not to sample at one of the sites, San Leandro, on weekdays. This site had very low weekday activity. We projected that we would interview only about one angler after six weekday visits. Our person-hour estimate still exceeded our target by about 10%.

G. Selection of Sampling Days and Times for Shore-based and Private Boat Sites

Selection of sampling days and times for shore-based and private boat sites was similar and is discussed in this section.

1. Sampling Days

We randomly selected the sampling days at shore-based and private boat sites. All days in a month were divided into two pools, one for weekdays and one for weekend days. Sampling days were then randomly selected from each pool. A few holidays were

excluded as possible sampling days[3] and some weekday holidays were counted as weekend days.[4]

Because of the difficulty in scheduling more than one interview team per day, sampling days for both shore-based sites and private boat sites were selected from the same pool, without replacement. Thus, only one site, either shore-based or private boat, could be sampled on a given day. The starting point for allocating sampling days was rotated among the sites each month, but the order in which days were assigned to sites followed the same order.

To ensure equal coverage of weekend and weekdays, day type was assigned, with half the sites designated as weekday sampling and the remaining sites designated as weekend sampling. For example, for shore-based sites, four site pairs were assigned as weekend days and the remaining three sites were assigned as weekdays for the first month. The weekday/weekend day designations alternated every month.

2. Sampling Times

To ensure coverage of the sampling day, shore-based sites were assigned morning or afternoon shifts. For example, site pair 1 (shore-based sites Vallejo and Martinez) followed the pattern in Table D12 for the first four months of sampling. For safety reasons, we assigned sampling times only during daylight hours for both shore-based and private boat sites. In order to maximize coverage of daylight hours, shifts at shore-based sites began earlier and ended later during the longer summer months.

Table D12. Sampling Schedule for Site Pair 1 for July 1998-October 1998

Month	Date	Day Type	Shift time during day
1	July 1998	Weekend	AM
2	August 1998	Weekday	PM
3	September 1998	Weekend	PM
4	October 1989	Weekday	AM

Private boat anglers generally leave in the morning and return in the afternoon. Because we anticipated that anglers may have more time for an interview when returning from a trip than when departing, all sampling shifts were conducted in the afternoon. However, interviewers attempted to interview all private boat anglers they encountered at a site regardless of whether they were beginning or ending a fishing trip.

For shore-based sites, the individual site of each site pair that was sampled first was also alternated each month.

[3] New Years Day, Thanksgiving, Christmas Eve and Christmas Day

[4] Martin Luther King, Jr. Day, Presidents Day, Memorial Day, July 3rd (a Friday), Labor Day, and the day after Thanksgiving

H. Sampling Plan for Party Boat Sites

Because the MRFSS fishing pressure data for party boat sites predominately reflect fishing trips outside of SF Bay, which was not the objective of this study, these data were not used to develop a sampling plan for party boats. In order to focus only on party boat fishing within SF Bay, we examined data collected by the California Department of Fish and Game (CDFG 1998) on party boat activities. CDFG requires all commercial passenger fishing vessels (also called party or charter boats) owners or operators to file detailed reports on their trips. Using data from the PMASTER database provided by CDFG for 1996 (CDFG 1998), we calculated the total number of party boat trips within SF Bay and determined how there trips were distributed by month. We also looked at the average number of anglers on these trips, and weekend and weekday differences

CDFG data showed that party boat activities within SF Bay were heaviest between May and August, and were lightest in January and December. These data also showed that the average number of anglers per trip was 13 and the amount of fishing activity by day type was about 50% weekends and 50% weekdays. We estimated conservatively that we could attempt 12 interviews per fishing trip and that a typical trip was nine hours. Based on our budget and our estimate of available person-hours, we estimated that we could meet our sampling target in 18 party boat sampling trips. We then allocated these 18 sampling trips by the relative amount of fishing activity for each month (Table D13).

Table D13. Party Boat Sampling Schedule

Month and Year	Number of Sampling Trips	Projected Interview Attempts	Projected Person-Hours
July 1998	2	24	18
August 1998	3	36	27
Sept. 1998	1	12	9
Oct. 1998	1	12	9
Nov. 1998	1	12	9
Dec. 1998/ Jan. 1999	1	12	9
Feb. 1999	1	12	9
March 1999	1	12	9
April 1999	1	12	9
May 1999	3	36	27
June 1999	3	36	27
TOTAL	18	216	162

Because our party boat sampling effort was relatively small and because few party boats usually remained within SF Bay, we did not attempt to stratify our sample by site. Furthermore, because we had to rely on the party boat captains to agree to allow us to send an interviewer, we did not attempt to randomly select sampling days. Finally, the

primary interviewer we selected to conduct party boat interviews was only available on weekdays, we did not attempt to stratify the sampling days by day type.

Appendix E

Questionnaire (English and Spanish)

San Francisco Bay Seafood Consumption Study

Date ☐☐ / ☐☐ / ☐☐ Site Code ☐☐ Mode ☐ Time Begin ☐☐☐☐ Interviewer: ☐☐

Person is: ☐ Fishing (has poles only) ☐ Both fishing and crabbing

Hello, my name is _____. I am doing a survey for the San Francisco Estuary Institute **(SHOW IDENTIFICATION)** We are gathering information about what types of fish or shellfish people catch and eat from the San Francisco Bay. I am not checking fishing licenses or checking your catch. Your answers will be kept confidential and you don't have to answer all the questions. You will also receive a small gift at the end of the survey **(CAN SHOW ITEM)**. May I talk to you for a few minutes?

Q1a. ☐ Yes (SKIP TO Q2a) ☐ No (END SURVEY, FILL OUT Q1b-Q1e)

Q1b. Reason

- ☐ No time
- ☐ Language problem
- ☐ Appeared threatening
- ☐ Other
- ☐ DK

Q1c. Observed Ethnicity

- ☐ Caucasian
- ☐ Native American
- ☐ African American
- ☐ Filipino
- ☐ Latino/Hispanic
- ☐ Chinese
- ☐ Asian (unknown)
- ☐ Vietnamese
- ☐ DK
- ☐ Other

Q1d. Language

- ☐ English
- ☐ Spanish
- ☐ Vietnamese
- ☐ Cantonese
- ☐ Mandarin
- ☐ Tagalog
- ☐ Other
- ☐ DK

Q1e. Gender

- ☐ Male
- ☐ Female

Q2a. Our study is called the San Francisco Bay Seafood Consumption Study. Have you been interviewed before for this study? (talked to someone with same vest/hat on?)

- ☐ Yes Q2b. When (m/y): ☐☐ / ☐☐ ☐ DK
- ☐ No (CONTINUE)
- ☐ DK (CONTINUE)
- ☐ Refuse

(STOP, END INTERVIEW)

15147

When I talk about the San Francisco Bay, I mean this area here: (SHOW MAP). I will mainly be referring to fish and shellfish from the Bay. When I say shellfish, I am referring to crab, mussels, or clams.

Q3a. Is this the first time you have ever fished in the SF Bay?

☐ Yes (SKIP TO Q5) ☐ DK ☐ Refuse

☐ No **Q3b.** When was the last time you fished in the Bay? (m/y) ☐☐ / ☐☐ ☐ DK

Q4. Not including today, **in** the **last 4 weeks,** what is the total number of times you have gone fishing in the San Francisco Bay? ☐☐☐ ☐ DK ☐ Refuse

Q5. What do you usually do (plan to do -**FOR FIRST TIME FISHERS**) with the fish or shellfish you catch from the SF Bay? (CHECK ALL THAT APPLY)

☐ Eat it ☐ Give it to family or friends ☐ Trade or sell it ☐ Use for bait ☐ Catch and release it ☐ DK ☐ Refuse

☐ Other (specify)

For the next few questions, I am asking about eating fish that you or someone you know has caught from San Francisco Bay. This can be fish that's fresh, or fish from the Bay that you have frozen, dried, canned, or smoked after being caught to eat at a later time.

Q6a. Do you eat fish that you or someone you know catches from the SF Bay?

☐ Yes ☐ DK ☐ Refuse

☐ Used to, but don't anymore **Q6b.** stopped when:m/y ☐☐ / ☐☐ ☐ DK

☐ No (SKIP TO Q10)

Q7. How many years have you been eating fish that you or someone you know has caught from the SF Bay?

☐ Less than 1 year ☐ 6-10 years ☐ 21-30 years ☐ DK

☐ 1-5 years ☐ 11-20 years ☐ more than 30 years ☐ Refuse

15147

Q8a. In the **last 4 weeks,** did you eat fish that you caught or someone you know caught from the SF Bay?

☐ Yes ☐ DK

☐ No (SKIP TO Q9) ☐ Refuse

Q8b. In the **last 4 weeks,** how many times did you eat fish that you or someone you know caught from the Bay?

times per day ☐☐ times per week ☐☐ total times in last 4 weeks ☐☐☐

☐ DK

☐ Refuse

Q9. Over the last 12 months (__/97-8 to _/98-9) how many times overall did you eat fish that you or someone you know caught from the SF Bay?

times per day ☐☐ times per week ☐☐ times per month ☐☐☐ times in last 12 mos. ☐☐☐

☐ DK

☐ Refuse

Q10a. This is a model of 8 ounces (half pound) of raw fish fillet. When you eat fish from anywhere (the Bay, other places, stores, restaurants), is the amount that you eat: **(SHOW PERSON FISH PORTION BUT DO NOT LET THEM HOLD IT.)**

☐ About this size (SKIP TO Q11) ☐ DK ☐ Refuse

☐ More ⇓ **Q10b.** About how much more? ⇓⇓ ☐ Half more ☐ Two time (double) more ☐ DK ☐ Refuse

☐ Other ☐

☐ Less ⇓ **Q10c**. About how much less? ⇓⇓ ☐ Half this amount ☐ One third this amount ☐ DK ☐ Refuse

☐ Other ☐

15147

Now I'm going to show you pictures of 3 specific fish that can be caught from the SF Bay and ask you whether you eat them or not. Again this can be fresh fish, or fish that is frozen, dried, canned or smoked after being caught.

11a. Do you eat this fish **(KINGFISH)** that you or someone you know catches from SF Bay? (POINT TO PIX)

☐ Yes
☐ No (SKIP TO Q12)
☐ DK ☐ Refuse

What do you call it?

11b. Have you eaten any **(kingfish)** from the Bay in the last 4 weeks? (fresh, frozen, dried, canned, smoked)

☐ Yes No. times ☐☐ DK ☐
☐ No
☐ DK
☐ Refuse

11c. When you eat **(kingfish)**, how often do you eat the _____?

11c1. Skin

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

11c2. Guts

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

11d. When you eat **(kingfish)**, how often do you ___?

11d1. eat cooking juices/drippings

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

11d2. eat it in soup

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

11d3. eat it raw

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

12a. Do you eat this fish **(LEOPARD SHARK)** that you or someone you know catches from SF Bay? (POINT TO PIX)

☐ Yes
☐ No (SKIP TO Q13)
☐ DK ☐ Refuse

What do you call it?

12b. Have you eaten any **(leopard shark)** from the Bay in the last 4 weeks? (fresh, frozen, dried, canned, smoked)

☐ Yes No. times ☐☐ DK ☐
☐ No
☐ DK
☐ Refuse

12c. When you eat **(leopard shark)**, how often do you eat the _____

12c1. Skin

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

12c2. Guts

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

12d. When you eat **(leopard shark)**, how often do you ___?

12d1. eat cooking juices/drippings

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

12d2. eat it in soup

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

12d3. eat it raw

☐ more than half the time
☐ less than half the time
☐ never
☐ DK ☐ Refuse

13a. Do you eat this fish **(STRIPED BASS)** that you or someone you know catches from SF Bay? (POINT TO PIX)

- ☐ Yes
- ☐ No (SKIP TO Q14)
- ☐ DK ☐ Refuse

What do you call it?

13b. Have you eaten any **(striped bass)** from the Bay in the last 4 weeks? (fresh, frozen, dried, canned, smoked)

- ☐ Yes No. times ☐☐ DK ☐
- ☐ No
- ☐ DK
- ☐ Refuse

13c. When you eat **(striped bass)**, how often do you eat the_____?

13c1. Skin

- ☐ more than half the time
- ☐ less than half the time
- ☐ never
- ☐ DK ☐ Refuse

13c2. Guts

- ☐ more than half the time
- ☐ less than half the time
- ☐ never
- ☐ DK ☐ Refuse

13d. When you eat **(striped bass)**, how often do you ___?

13d1. eat cooking juices/drippings

- ☐ more than half the time
- ☐ less than half the time
- ☐ never
- ☐ DK ☐ Refuse

13d2. eat it in soup

- ☐ more than half the time
- ☐ less than half the time
- ☐ never
- ☐ DK ☐ Refuse

13d3. eat it raw

- ☐ more than half the time
- ☐ less than half the time
- ☐ never
- ☐ DK ☐ Refuse

Q14a Now I have some pictures of other fish that can be caught from SF Bay. Looking at these pictures, please show me which fish you have eaten in the last 4 weeks. Again, these are the fish you ate in the last 4 weeks which you caught or someone you know caught from SF Bay. The fish could have been fresh, frozen, dried, canned or smoked.

Q14b. How many times have you eaten this fish in the last 4 weeks? **(ASK AS RESPONDENT POINTS TO PICTURE, RECORD RESPONSE IN COLUMN 14B.)**

Q14c. What do you call this? **(ASK AS RESPONDENT POINTS TO PICTURE, RECORD RESPONSE IN COLUMN 14c.)**

15147

(SHOW PICTURES AND HAVE RESPONDENT POINT OR TELL YOU WITH PROBING AS NEEDED: "ANY OTHER FISH YOU HAVE EATEN IN THE LAST 4 WEEKS THAT YOU CAUGHT OR SOMEONE YOU KNOW CAUGHT FROM SF BAY?")

	Q14a. Eaten in last 4 weeks?	**Q14b.** No.of times		**Q14c.** What do you call this?

Q14d. Are there any other fish from the Bay that you or someone you know catches that you ate in the last 4 weeks for which I don't have pictures? **(IF RESPONDENT NAMES ONE OF THE FOLLOWING LISTED FISH, CHECK THE BOX AND INDICATE NUMBER OF TIMES EATEN. IF RESPONDENT NAMES A FISH THAT IS NOT LISTED, SPECIFY TYPE OF FISH AND NUMBER OF TIMES EATEN IN LAST 4 WEEKS IN THE BLANK BOXES BELOW.)**

Perch	☐ Yes	☐☐	☐ DK	Pacific Tomcod	☐ Yes ☐☐ ☐ DK
Anchovy	☐ Yes	☐☐	☐ DK	Goby	☐ Yes ☐☐ ☐ DK
Starry Flounder	☐ Yes	☐☐	☐ DK	Bat Ray	☐ Yes ☐☐ ☐ DK
Shark (OTHER THAN Brown Smoothhound or Leopard shark)	☐ Yes	☐☐	☐ DK		

	☐☐ ☐ DK		☐☐ ☐ DK
	☐☐ ☐ DK		☐☐ ☐ DK

Q15. Who in your household eats the fish that you or someone you know catches from the SF Bay? **(CHECK ALL THAT APPLY)**

☐ Yourself ☐ Women between ages 18-45 years ☐ Women who are currently pregnant or breastfeeding

☐ Children under age of 6 ☐ Children between 6 and 17 years ☐ People 65 or older ☐ DK ☐ Refuse

Q16. How many people altogether, including yourself, are in your household? ☐☐ ☐ DK ☐ Refuse

Q17. Who usually cooks or prepares the fish you catch and eat from the Bay? **(CHECK ALL RESPONDENT INDICATES)**

☐ Self ☐ Family member (specify)

☐ Friend ☐ Other (specify)

☐ DK

☐ Refuse

Now I want to ask you some questions about fish from OTHER places, rather than fish from the SF Bay. Again we ask you to think about fresh fish as well as fish that has been, frozen, dried, canned, or smoked after being caught.

Q18. In the last 4 weeks, did you eat fish that you caught or someone you know caught from places other than the SF Bay (like a lake or river)? **SHOW MAP AS NEEDED TO REMIND RESPONDENT ABOUT AREA COVERED BY SF BAY)**

☐ Yes ☐ No (SKIP TO Q21) ☐ DK ☐ Refuse

Q19. From what places, other than the San Francisco Bay, did you or someone you know catch fish that **you** ate in the **last 4 weeks**? (check all that Respondent indicates)

☐ Lake/Reservoir

☐ River ☐ DK ☐ Other (specify)

☐ Delta ☐ Refuse

☐ Ocean (outside SF Bay/other Bays)

Q20. In the last 4 weeks, how many times did you eat fish that you or someone you know caught from places other than SF Bay?

times per day ☐☐ times per week ☐☐ total times in last 4 weeks ☐☐☐

☐ DK

☐ Refuse

Q21. In the last 4 weeks, have you eaten any fish from a store or restaurant? This includes any fish fillet burgers or canned tuna also.

☐ Yes ☐ No (SKIP TO Q23) ☐ DK ☐ Refuse

Q22. How many times **in the last 4 weeks** did you eat fish from a store or restaurant, including any fish fillet burgers or canned tuna ?

times per day ☐☐ times per week ☐☐ total times in last 4 weeks ☐☐☐

☐ DK

☐ Refuse

15147

Now I am going to ask you a few questions about information you may have heard about eating fish from the Bay.

Q23. Have you heard or seen any information or health advisories about eating fish from the Bay?

☐ Yes ☐ No (SKIP TO Q25) ☐ DK ☐ Refuse

Q24. What did the information say about fish from the Bay? ☐ DK ☐ Refuse

Q24a. Has the information you have heard or seen about eating fish from the Bay caused you to change your fish eating habits?

☐ Yes ☐ No ☐ DK ☐ Refuse

Q24b. If yes, how have you changed your fish eating habits? If no, why not?

Q25. What is the best way for you to get information about catching and eating fish from the Bay? (CHECK ALL THAT RESPONDENT INDICATES)

☐ Friend/Family ☐ Sign ☐ Fishing regs ☐ Newspaper ☐ Radio ☐ TV ☐ Other (specify) ☐ DK ☐ Refuse

These next few questions will help us describe the people who fish from the SF Bay. We find this information helpful when we are developing information and materials for people who fish. Please remember the information is kept confidential and you don't have to answer if you don't want to.

Q26. How would you describe your racial or ethnic background?

- ☐ Black/African American
- ☐ Latino/Hispanic
- ☐ Caucasian
- ☐ Native American
- ☐ Chinese
- ☐ Filipino
- ☐ Vietnamese
- ☐ DK
- ☐ Refuse
- ☐ Pacific Islander (specify) _____
- ☐ Other Asian (specify) _____
- ☐ Other (specify) _____

Q27. What category best describes your age?

- ☐ Under 18
- ☐ 18-45
- ☐ 46-65
- ☐ 65+
- ☐ DK
- ☐ Refuse

Q28. What is the highest grade in school you have completed?

- ☐ Less than 12th grade
- ☐ Completed HS or GED
- ☐ Some college or trade school
- ☐ Completed at least 4 years college
- ☐ DK
- ☐ Refuse

Q29a. Is your total yearly household income greater than $20,000 per year?

- ☐ Yes (ASK Q29b)
- ☐ No (DO NOT ASK Q29b)
- ☐ DK
- ☐ Refuse

Q29b. greater than $45,000?

- ☐ Yes
- ☐ No
- ☐ DK
- ☐ Refuse

Q30. Gender of Respondent:

- ☐ Male
- ☐ Female

15147

That's about all the questions I have. In order to thank you for your participation, we would like to give you a small gift. (OFFER GIFT). We'd also like to enter your name into a monthly drawing. You will be eligible to win a $20 gift certificate to either Sportmart or Target. If you would like your name entered, we will take down your name, address, and phone number. We can also send you information about the results of this survey when they become available. My supervisor may also contact you to check my work or for some further follow-up.

Q31. Would you like to have your name entered into the drawing? ☐ Yes (FILL OUT NAME,ETC. BELOW) ☐ No

Q32. Would you like us to send you information about the results of our survey when they become available?

☐ Yes (FILL OUT NAME,ETC. BELOW) ☐ No

Q33. May my supervisor contact you ? ☐ Yes (FILL OUT NAME,ETC. BELOW) ☐ No

Name

Address

City State Zip

Phone - -

I'd also like to give you some information about the current advisory for the SF Bay **(OFFER COPY OF ADVISORY; READ TO RESPONDENT):** The current health advisory for fish caught from the San Francisco Bay recommends that adults limit their consumption of most types of fish caught from the San Francisco Bay to no more than 2 eight ounce meals/month (one pound total per month). Women who are pregnant, planning to become pregnant, or breastfeeding, and children under 6 years of age should not eat more than one meal per month. There is more detailed information in the handout. If you'd like more information about the advisory or about the survey, you can contact the agencies listed here.

Thanks again. You've really helped us out a lot!

15147

Me gustaria darle alguna informacion sobre las actuales recomendaciones de la Bahia de San Francisco. (OFREZCA UNA COPIA DE LAS RECOMENDACIONES; LEASELA): Las recomendaciones de salud para la pesca en la Bahia de San Francisco, indica que los adultos deben limitar el consumo de la mayoria de pescados de la Bahia, a no mas de dos comidas de 8 onzas por mes (en total, una libra por mes), Las mujeres embarazadas, que planean quedar embarazadas o que esten lactando, asi como los ninos menores de 6 anos, no deben comer mas de una comida por mes. En los folletos encontrara mas informacion. Si desea mas informacion sobre las recomendaciones o sobre los resultados, puede llamar a las agencia que estan en el folleto.

Muchisimas gracias. Realmente su ayuda ha sido muy valiosa!

1. INTRODUCTION

Welcome to the San Francisco Bay Seafood Consumption Study! This manual contains some tips and pointers to help make your job easier, and to ensure that the data you will collect are of the highest quality possible. This manual contains materials for the following topics:

- an overview of the study and its goals and objectives
- the importance of accurate data collection
- your desired state of mind for conducting good interviews
- approach and greeting guidelines, methods of dealing with refusals
- data collection tools and props
- angler census methods, and detailed coding instructions for each question
- weekly debrief and administrative duties
- health and safety issues
- travel to and access to sites

1.1. Study Overview, Goals and Objectives

Levels of certain chemical contaminants in fish commonly caught from the San Francisco Bay have raised public concern regarding health risks related to consuming fish and shellfish from the Bay. In response to this concern, the San Francisco Estuary Institute has contracted with the Environmental Health Investigations Branch of the California Department of Health Services and Impact Assessment, Inc. to conduct a comprehensive seafood consumption study of people who catch and consume fish and shellfish from the Bay. Information gathered through the study will be used to develop recommendations and methods for improving outreach and education efforts to different segments of the fishing population and to refine assessments of health risks to people who consume fish caught from the San Francisco Bay.

The goals of the study are as follows:

- To gather quantitative data that can be used to characterize exposures of the general fishing population of San Francisco Bay to chemical contaminants from consumption of Bay-caught fish and shellfish.

- To identify highly exposed fish and shellfish consuming sub-populations

- To gather information needed to develop educational messages for targeted sub-populations

Specific objectives of the study include the following:

1. Develop estimates of exposure assessment parameters (fish and shellfish consumption frequency, duration of exposure, and portion size) for San Francisco fishers. Characterize distributions for these parameters.

2. Characterize pier, boat, and shoreline fishing populations by age, sex, income, ethnic composition, education, mode of fishing, and consumption rates.

3. Characterize consumption of fish tissues other than muscle, such as skin and organs, and preparation/cooking methods.

4. Determine which species are consumed most commonly. Assess the frequency of consumption of white croaker, striped bass, and leopard shark.

5. Characterize what people do with the fish and shellfish they catch or harvest (i.e., release it, eat it themselves, share it with family or friends).

6. Characterize seasonal variation in consumption and demographics.

7. Characterize the frequency of consumption of fish and shellfish obtained from stores and markets, and of fish and shellfish obtained from fishing outside the SF Bay, including freshwater and marine locations.

8. Assess awareness of current health advisories and changes in behavior as a result of awareness (e.g., decreased consumption).

9. Identify how people are informed about advisories and preferred mechanisms for getting information.

10. Identify fishers' reasons for catching and consuming fish and shellfish.

11. Determine whether fishers think the term "sportfish" refers to fish they catch from SF Bay.

1.2. Importance of accurate data collection

As stated above, a crucial task for this study is to estimate consumption of seafood for various subgroups that compose the study population, and the population as a whole. Having the ability to do this relies heavily on an assumption that people have accurately and truthfully reported their seafood consumption. Your role in this task is to facilitate accurate and complete responses, to the extent possible. There is a subtle difference between helping study participants enhance their recall, as opposed to the interviewers providing the answers for them. We DO NOT want the latter situation to develop. You will have to monitor each person who participates in the survey and determine if he or she understands each question asked. You may rephrase the question if a participant is having difficulty giving a response, but DO NOT try to answer the question for them. If it appears that the respondent can't answer the question, give her or him a few minutes to ponder it. In this situation, it is much better to record a 'don't know' response, instead of having the participants guess at their true response.

There will most likely be tremendous variation as to how study participants respond to the survey. Some study participants will have questions about the study, others will not. Participants will vary in how long it takes them to complete the survey, how much they mull over a particular question, how often they change their minds, how many questions they ask you the interviewer, and how often they will digress or otherwise get "off track." The bottom line is

some interviews will be easy to administer, others will not. As a result, some days the surveys you administer will be done easily and you will have a very high completion rate. Other days, things may go very slow. This is to be expected! Do not try to rush things. If you are uncertain of participants' response, don't be reluctant to ask them the same question twice. You will be asking people to recall behaviors that may have occurred a year ago. Do you remember what you had for dinner two weeks ago? Put yourself in the position of the study participant for a few minutes, and you will gain some appreciation of the mental effort they may need to go through in order to accurately answer the questions. Be patient when administering interviews, and remember it is much more important to conduct a few high quality interviews each day, instead of conducting many interviews in a sloppy, incomplete manner. Having high quality data is crucial to the success of this study.

1.3. Adopting the right frame of mind

Your frame of mind will have a great influence on the quality of the data collected. Ideally, you should be in a good mood when you arrive on-site to begin your assignment. If you are not, you should take a few minutes to clear your head of whatever negative things may be occupying your thoughts. This may sound silly, but having the right frame of mind really does influence your ability to conduct a good interview. You should be thinking about what a great study this is, a great day to be outdoors, and what a great opportunity this is for the study participants to provide you information about seafood consumption behaviors that could impact their health. You need to believe in the value of this study, and the potential public benefits associated with it. Finally, you need to believe that you are doing the potential study participants a favor. This, too, may sound funny, but I'm being serious. You are asking potential participants for their invaluable opinions, you are offering an incentive, and if they agree to give their name and address, you will be offering them a chance to win something big. This is a good deal for study participants!

When first approached, anglers may not want to talk to you. They may try to avoid eye contact with you or in some other nonverbal way, ignore you. Don't be deterred! The best way to deal with this is to start the conversation off with an 'icebreaker', such as "How is the fishing today?" It is important to be patient at this point, and simply initiate a conversation. If you get a cold response to the initial question, try asking another non-threatening type question. However, if you are still having problems establishing a connection at this point, you still need to begin the interview protocol.

Dealing with refusals

The respondent may initially refuse to participate but may change his or her mind, as you read through the introduction. Sometimes if you can overcome a potential participant's objections by answering Frequently Asked Questions (study and know your FAQ and their answers! see Section 9) you may get his or her cooperation. However, in the event that you don't, record the nature of the refusal and the other observational type variables (i.e., gender, ethnic group) and move on to the next participant. Don't be discouraged by refusals! It is just part of the screening process that some people will not participate regardless of what you tell them, and regardless of how good you are at establishing rapport. Another possibility is that participants will discontinue the interview before you have completed asking all the questions. This will occur with some participants. In this situation, do not try forcing the respondent to continue. But after the interview has ended, make a note that the respondent did not complete all the questions.

Dealing with belligerent anglers

Some people that you approach won't want to talk to you. That's okay. However, some people won't want to talk to you and they will want to make sure that you know this. They may become hostile. Please bear in mind this is an extremely small minority of the people you will encounter. Everyone has a different tolerance point regarding verbal abuse, and you do not need to tolerate abuse from a potential study participant. During my first job as a field interviewer, I discontinued an interview because I felt the respondent was paranoid and abusive. I interviewed about 300 people for that particular project, and the above mentioned person was the only belligerent one I encountered.

Language barriers

It is likely that most of your interviews will be conducted in English. But an important component of this study is to conduct surveys in: Spanish, Cantonese, Mandarin, and Vietnamese, as needed. Ideally, your interview team will have capability in two languages in order to minimize language barriers for most respondents you will encounter. If you are able to switch to the potential participant's language, this may help put him or her at ease, and increase interview participation rates. If you encounter someone who is speaking a foreign language that you don't speak but your partner does, you should make a note of this, and let your partner know. Some people will pretend they don't speak English in order to avoid participating in the study. If the potential participant does not appear hostile, try asking him or her 2-3 questions in English to see if you can "get the ball rolling."

Frequently Asked Questions

Some individuals will ask questions of you during the interview. Having an answer for them is important. The types of questions you may be asked probably will pertain to:
1) credibility and qualifications of the organization sponsoring this study, 2) who is paying for the study, 3) the ecological health of the SF Bay, and 4) the personal health risks to the study participant from eating SF Bay caught fish.

To enable you to deal with questions in a brief and consistent manner, we have prepared a list of the most Frequently Asked Questions and their answers. We will amend this list after pretesting the survey.

Dealing with Multiple Participants

Sometimes two respondents will try and give you answers to the same survey. To conduct statistical analyses of these survey data, every respondent must complete their own survey independent of the opinions and behaviors of other members of their fishing party. In other words, we want one completed interview for each respondent. If two people try answering the questionnaire at the same time, tactfully tell them that you can only interview one of them at a time. If they don't get the idea that we only want one person to complete an interview at a time, just continue and complete the interview with them and record separate answers for each individual in the margins. At the end of the sampling session, fill out two separate surveys, one for each person.

2. DATA COLLECTION INSTRUMENTS AND OTHER IMPORTANT ITEMS

There are a number of items you will need with you for each interviewing day. The basic items that you will have with you for each interview day include:

- Interviewer identification, including a name badge, and vest and hat with a study logo
- Logo for car
- Clipboard
- Sharpie pens
- Census forms
- Survey forms
- Binder with SF Bay map, fish and shellfish pictures, and staff phone list
- Health advisories (in six languages)
- Referral info sheet
- Answers to frequently asked questions
- Fish fillet model
- Site Map book
- Gifts (tape measures with logo)
- Cellular phone (One per interviewer team)
- Watch or other timepiece

For your personal comfort and convenience:

- Dress in layers and be prepared for windy, cool weather
- Sunscreen
- Food and beverages for yourself
- Backpack or other carryall to hold your items
- Sunglasses

Please be careful with the survey forms! They need to be maintained in good shape to allow for optimal scanning.

3. DATA RECORDING

All data recording should be done with your Sharpie pens. This will allow for optimal scanning of all data collection forms.

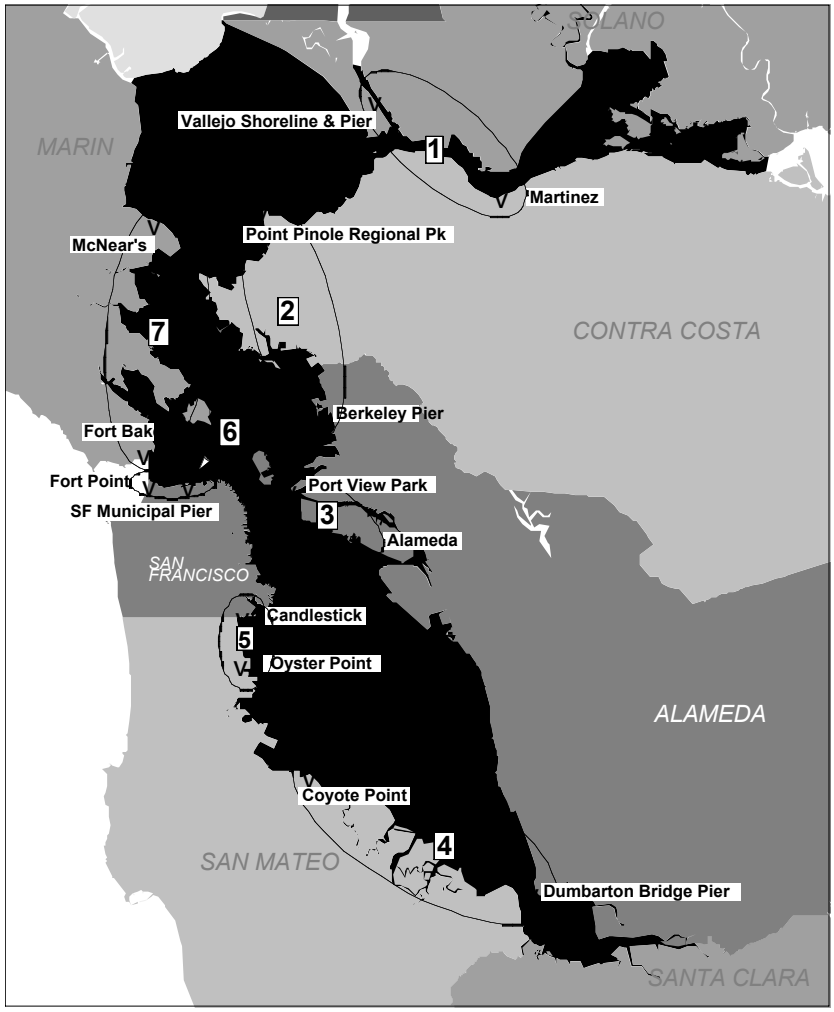
3.1 Shore Sites

3.1.1 Recording Site and Mode

The 14 shore sites are grouped into 7 pairs. Each site has been assigned a site code. The site codes, the site name and the county of the site are listed below. A map showing the sites can be found in Diagram 1. Detailed maps of the sites, including directions to the sites can be found in the Site Map Book.

Shore Sites

Site Code	Site Name	County
1A	Vallejo Shoreline	Solano
1B	Martinez Regional Shoreline Park	Contra Costa
2A	Point Pinole Regional Shoreline Park	Contra Costa
2B	Berkeley Pier	Alameda
3A	Port View Park	Alameda
3B	Alameda Rockwall	Alameda
4A	Dumbarton Bridge Pier	Alameda
4B	Coyote Point	San Mateo
5A	Oyster Point	San Mateo
5B	Candlestick Point State Recreation Area	San Francisco
6A	San Francisco Municipal Pier	San Francisco
6B	Fort Point	San Francisco
7A	Fort Baker Pier	Marin
7B	McNears County Park/China Camp	Marin



San Francisco Bay Seafood Consumption Study
Shore Sites

Map: DHS/EHIB

All the shore sites (except 4A. Dumbarton Bridge Pier) can be further divided into 2 or more areas. These areas are classified into fishing modes. The modes for the shore sites are:

Shore Site Modes

Mode Code	Description
1	"Free" piers. These are areas, primarily municipal piers, where a fishing license is NOT require to fish. Free piers include areas that are not technically piers: the Vallejo Waterfront, Alameda Rockwall, and the jetty at Coyote Point.
2	All other shore based areas that are not free piers. These areas are primarily rip-rap banks. These areas may include man-made structures such as the small pier adjacent to the Vallejo Launch Ramp and the rock jetty at Fort Baker.

3.1.2. Conducting the Census

Upon arrival at all shore sites, a census, or count of all anglers present, will need to be conducted. The purpose of the census is to estimate the number of persons fishing at a site at a single point in time. Because interviewing at a site may be conducted over one or more hours (depending on the number present), the number of anglers recorded from the census is likely to differ from the number of interviews completed at the site. Only one person should conduct the census. The other interviewer may begin interviewing.

As indicated on the census form (see next page) record the site code, mode code, date, start time and your initials. We recommend that you break the site up by mode and only census the part of the site you are planning to conduct interviews at next. In other words, census and interview at the pier first then census and interview at the shoreline/bank areas second (see example). The census is taken by walking the site and counting all persons who are fishing, i.e., have poles. It may be easiest to focus on one side of a pier first and then count the other side on the return trip. Only count those anglers who are "in front of you." This means that if you have already initiated the count and a new anglers arrives but you have already passed the point where he or she is standing, do not include him or her in the census.

You will also need to determine the number of anglers who are adults (18 years of age or older) and the number of anglers who are 17 years and younger. At times, it may be difficult to determine who is actually fishing and who is not, and who is an adult. Some anglers may not be stationed near their poles. Use your best judgement to determine who is fishing and the anglers' ages without actually stopping to talk with the anglers. Remember the census is only an estimate and should take no longer than the time to walk the site.

Also included on the Census Form is a Site Summary Chart. For each site you and your partner visit on an assigned shift, note the time you and your partner started your shift at the site, the time you left the site, and the total number of interviews attempted at the site. This number should equal the number of interview forms filled out by both you and your partner.

Boat Site Codes

11. Vallejo Marina
12. Richmond Marina
13. San Leandro Marina
14. Oyster Point Marina
15. Loch Lomond Marina

3.1.3. What To Do If There are No Anglers

Sometimes, particularly on weekdays and during the winter months, there may not be any anglers present at a site. You must remain at the site for a minimum of one hour. You may conduct the census at this time and record a zero for the number of anglers. You will also have recorded the start time on the census form and will know when an hour is up. You do not need to revise the census if anglers appear later. If anglers appear, you must attempt to interview them. If you finish interviewing all anglers and one hour has not passed, please make sure you stay the entire 60 minutes. This is important so that we adhere to a consistent approach to counting and interviewing anglers. You should repeat this same procedure at the next site if there are not any anglers there when you arrive. If you have already conducted interviews that day, this would be a good time to review your surveys for completeness. This will save time at the end of your interview day.

3.1.4. How to Cover the Site

Our goal at shore sites is to interview all anglers present at a site. The order in which anglers are interviewed at a site should be similar to the way the census is conducted. We recommend that you break up the site by mode, and census and interview at one area before moving on the next area. This makes sense because some areas within a site are far apart. For example, you may want to start with the pier area first and then move to the shoreline/bank areas next. We also recommend that you interview anglers in a sequential fashion, for example, going up one side of a pier and doing the second side on the return trip.

Because you may be at a site for several hours, there may be many anglers coming and going during the time you are interviewing. We would like to interview new anglers who have arrived after you have begun interviews at an area if possible, <u>but only if you can keep track of the new arrivals.</u> This will require some judgement on your part. If you can't keep track of new anglers, it is best to stick to only those anglers "in front of you." We believe it will be possible to keep track of new arrivals in relatively contained areas (e.g., the pier at Portview Park) or when the number of anglers present is small. With long piers (such as Dumbarton and Berkeley Pier) it will be impossible to keep track of new anglers arriving.

We want to avoid the situation where certain types of anglers always get selected to be interviewed and certain other types of anglers always get overlooked. Keeping track of new arrivals is much harder to do than it sounds. At a site with 20, 30 or more anglers, the anglers really do begin to look alike. We have found that in these situations you may be able to remember <u>not</u> interviewing some anglers, but for many you will not be sure. Again, unless you can keep track of all new anglers arriving at a site you should stick to interviewing only the anglers "in front of you" and not attempt to interview new anglers that have arrived to a point past where you have already interviewed.

3.1.5. Before You Begin the Interview

Before beginning to interview, you can code some information in advance. These include:

- Date
- Site (use the appropriate site codes)
- Mode (use the appropriate mode codes)
- Time (use military time, such that 1300 refers to 1:00 p.m., etc.)
- Your initials
- Whether the angler is fishing only, or is fishing and crabbing

Before beginning an interview you need to make sure each potential study participant meets several screening criteria.

- The person must be fishing, i.e., has one or more poles (doing both crabbing and fishing is ok!)
- The person should not be a child (we want interviews from people 18 years or older) If you are uncertain if a person is at least 18 years old, ask them before beginning the interview
- The person should not have been interviewed previously for ***this seafood consumption study***

3.1.6. Reviewing Your Work

After you have completed interviewing at the sites, it is important to review all of your surveys for completeness. This should not take long, but you must flip through all pages to ensure all areas have been filled out properly. For example, there may be areas where you could not fill in a box but wrote in the margins instead. Now is the time to fill in the box. If you made a mistake filling in a box and had to correct the answer, be sure to mark or record the correct answer and circle the correct answer so that we can manually correct it when the form is being scanned. Make notes in the margins if necessary. Also, there may be clarifications that need to be made in the "Other observations or notes" section. We prefer that the review be done before you leave the last site but if it is getting dark, you may review them at home. Be sure the review is done on the same day the interviews were conducted. You may also have time to review some of your surveys while waiting for the other interviewer to finish an interview.

3.1.7. If You Are Unable to Complete Your Assigned Sites

We would like to keep the maximum number of hours worked in a day to no more than 8 hours (excluding a minimum of 30 minutes for a lunch or dinner break if you work 6 or more hours in a day). In some cases, you may not be able to complete the sites assigned to you for the day. This may happen because there are many more anglers than anticipated. We will try to anticipate the number of anglers at a site and add a third interviewer if the expected number is high. However, in some cases a sampling day may take longer than anticipated, and you simply will not be able to finish before dark or before an 8 hour work day has passed. You should also allow time within your shift for reviewing your completed surveys. In these cases it is important to notify the field coordinator as soon as possible (she may be able to find additional interviewers who are available before the day is over). You must notify the field coordinator even if it is near the end of the day when you realize you will not finish your assigned sites. Try to find a clear

ending point, for example, finish the pier or shoreline/bank area if you can. When sites are incomplete they will be finished the next day or as soon as possible.

3.2 Private Boat Sites

3.2.1 Recording Site and Mode

The 5 private boat sites are marinas where boats on trailers are launched at a launch ramp. These marinas also have privately-owned boats that are kept berthed. The site codes, site names, and county are listed below. A map showing the sites can be found in Diagram 2. Detailed maps of the sites, including directions to the sites can be found in the Site Map Book.

Private Boat Sites

Site Code	Site Name	County
11	Vallejo Marina	Solano
12	Richmond Marina	Contra Costa
13	San Leandro Marina	Alameda
14	Oyster Point Marina	San Mateo
15	Loch Lomond Marina	Marin

Anglers interviewed at private boat sites can be classified into two fishing modes. These modes are:

Private Boat Site Modes

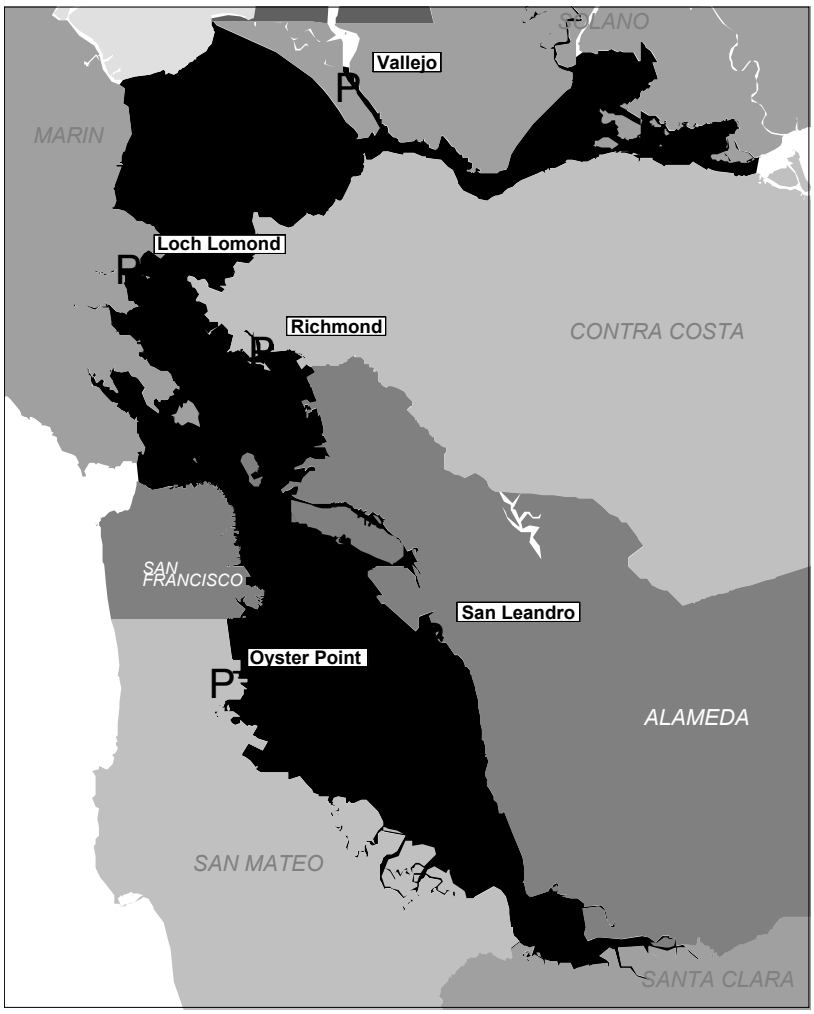
Mode Code	Description
3	Private boat anglers intercepted when using a boat launch facility
4	Private boat anglers from berthed boats

3.2.2 Shift Length

Unlike the shore sites, the number of hours you will attempt to conduct interviews at private boat sites has been preset. The private boat site shifts range from 2 to 5 hours. The length of the shift was set based on the amount of fishing activity at the site. The number of hours in a shift varies by site, season, and whether interviewing is on a weekend day or a weekday. If both interviewers cannot remain at the site for the entire shift, you must notify the field coordinator as soon possible.

3.2.3 Determining Whom to Interview

Our primary goal at the private boat sites is to interview all anglers who: (1) are beginning or ending a fishing trip and (2) are using a private boat launched at the launch ramp, and (3) plan to do (or have just completed) the majority of their fishing ithin San Francisco Bay. You should station yourself near the boat launching area and look for boats both coming in and going out.



San Francisco Bay Seafood Consumption Study
Private Boat Sites

Map: DHS/EHIB

The interview shifts for private boat sites are all in the afternoon so that you are more likely to encounter anglers returning from a fishing trip. Not all persons using the launch ramp are angler and not all persons on a fishing trip are anglers. When you encounter a boat, you must first determine whether any of the persons on the boat plan to fish that day (for outgoing boats) or have just finished fishing (for incoming boats). We want to talk to people before or after their fishing trip; we **do not want** to interview persons who do fish at times but are **not** going out on or coming back from a fishing trip.

You must also determine where they plan to fish (for outgoing boats), or where they went fishing (for incoming boats). **We want to include only people who are fishing within San Francisco Bay**. Some boat anglers leave from one of the 5 sites in the Bay but then travel to the open ocean (past the Golden Gate Bridge),or up the Delta (past Antioch/Pittsburg) to fish. Persons fishing exclusively in areas outside the Bay are to be excluded from the survey. Some anglers may fish in both the Bay and areas outside the Bay. If they do, try to determine whether half or more of their fishing activity was in the San Francisco Bay (regardless of how many fish they caught). If half or more of their fishing activity was in the Bay, you must interview them. In some cases, in outgoing boats, the anglers may not have decided where they are going to fish; where they fish may depend on where the fish are biting that day. In these situations, try to get the anglers' best guess as to where they will be fishing that day. If half or more of their anticipated fishing activity is going to be in the Bay, include them.

Our secondary goal at the private boat sites is to interview anglers on berthed boats who are: (1) beginning or ending a fishing trip and (2) plan to do (or have just completed) the majority of their fishing within San Francisco Bay. Although you should focus on the boats using the launch ramp, we expect there will be times when there is little or no activity at the launch ramp. When this happens, one of the interviewer should walk over to the marina area where berthed boats are docked and look for anglers who may be coming in from or about to depart on a fishing trip. You may also want to check the area where boaters can fuel their boats. As with anglers at the launch area, you want to interview persons who plan to fish that day on a private boat or have just returned from a fishing trip on a private boat. **Do not include** persons who have just fished on a party boat.

Once you encounter a launched or berthed boat with anglers, both interviewers should attempt to interview all anglers on that boat before moving on to a new boat. Sometimes it will not be possible to interview all anglers on a boat because the anglers are anxious to begin their trip or go home. Do the best you can to finish interviewing anglers on that boat. The reason we want to focus on one boat at a time is that we want to avoid selecting only one or two persons who are most vocal from each boat. These selected people as a group may not be representative of all private boat anglers.

As with the interviews conducted at shore sites, you can code some information in advance of beginning your interview. These include:

- Date
- Site (use the appropriate site codes)
- Mode (use the appropriate mode codes)

- Time (use military time, such that 1300 refers to 1:00 pm, etc.)
- Your initials

Before beginning an interview, you need to make sure that each potential study participant meets several screening criteria:

- The person must be planning to fish that day or have just finished fishing
- The person must have been fishing on a private boat, not a party boat
- The person must have conducted (or plans to conduct) the majority of his/her fishing activity in SF Bay
- The person should not be a child (we want to interview only people 18 years or older). If you are uncertain if a person is at least 18 years old, ask them before beginning the interview
- The person should not have been interviewed previously for ***this seafood consumption study***

3.2.4 Before you Begin the Interview

As with the interviews conducted at shore sites, you can code some information in advance of beginning your interview. These include:

- Date
- Site (use the appropriate site codes)
- Mode (use the appropriate mode codes)
- Time (use military time, such that 1300 refers to 1:00 p.m., etc.)
- Your initials

Before beginning an interview you need to make sure each potential study participant meets several screening criteria.

- The person must be planning to fish that day or have just finished fishing
- The person must have been fishing on a private boat, not a party boat
- The person should not be a child (we want interviews from people 18 years or older) If you are uncertain if a person is at least 18 years old, ask them before beginning the interview
- The person should not have been interviewed previously for ***this seafood consumption study***

Additional suggestions for approaching boat anglers include:

1. Read the survey introduction.

2. Determine whether anyone has been fishing (incoming boats) or plans to fish (outgoing boats). You can ask, for example, “Have you been fishing today?” or “Do you plan to fish today?”

3. Determine whether they are planning to fish or whether they have completed their fishing. For an incoming boat, ask the person “Can you tell me where you fished today?” If they are on an outgoing boat, you can ask “Can you tell me where you plan to fish today?” If they

want to know why you are asking them, tell them they must have fished in SF Bay to be interviewed for this survey. Show them your map of the SF Bay if necessary.

4. If they fished exclusively in the Bay, include them. If they fished exclusively outside the Bay, thank them for their time and go on to the next boat.

5. If they fished in both the Bay and other areas, try to determine whether at least half of their fishing activity was in the Bay. You can ask them: "Did you spend at least half your time fishing in the Bay?" If so, include them. For outgoing boats, if they plan to fish in both the Bay and other areas, ask them: "Do you plan to spend at least half your time fishing in the Bay?" If so, include them.

3.2.5 Reviewing Your Work

As with the shore interviews, it is important to review all of your surveys for completeness. This review can be done while you are waiting for boat anglers to arrive. We prefer that the review be done before you leave the site. At the latest, the review should be done before the day is over.

3.3 General Interviewing Guidelines

Once you have completed the screening questions, and have started the interview, be focused and brief. External factors, such as bad weather, another member of the group wanting to leave, or the study participant suddenly getting a fish on the line can break the tempo of the interview. The longer the interview takes, the greater the likelihood that external factors will prevent you from completing it. This perhaps sounds contradictory to the "be patient" advice discussed earlier, but there is a fine line between being patient and taking too long to complete an interview. After completing a few interviews you'll get the idea. One of the best things you can do to facilitate a good interview is to practice, and we will provide several practice opportunities during the training sessions. Feel free to practice on family and/or friends too!

Below are some guidelines you should be aware of when making the initial contact and conducting the interview.

- **Speak clearly.** You may also need to speak loudly due to weather conditions.

- **Don't say more than necessary.** Keep the initial contact and the interview as uncomplicated as possible. The more you talk about matters you are not asking questions about, the more reasons some people can think of not to be interviewed.

- **Please read the questions clearly and as written in order for the survey tool to be consistently administered to all respondents.** If a respondent does not understand the question, you may repeat it, but do not alter the wording. I know this can become tedious, but you must adhere to a consistent way of reading the questions. During the practice and field test sessions, if questions appear awkwardly worded, please make note of what suggested changes are needed.

- **You should be familiar enough with the questions that you can read them naturally and know what is coming next.** This is why we have scheduled several practice sessions. By the time actual data collection begins, you should sound coherent and relaxed.

- **Throughout the interview form, instructions to interviews are written in capital letters.** Do not read these aloud. Also, become familiar with the different skip patterns in the survey.

- **Be aware of the possible responses for each question, and how to the code them.** The attached coding instructions (Section 8) are intended as reference material, but you should read through them at least once before you begin practicing administering the interview.

4. WEEKLY DATA TRANSFER AND DEBRIEFING

Every week that you conduct interviewing you will be required to:
- Turn in completed survey forms to the research coordinator
- Fill out a timesheet
- Fill out a mileage reimbursement form
- Pick up additional survey forms as needed
- Briefly meet with the Field Coordinator to discuss the week's events

If your week of data collection has been uneventful this will be a very short meeting, probably 10 or 15 minutes. If there were problems such as high refusal rates, low numbers of anglers to interview, or health and safety issues, our meetings will take more time. Ideally, the Field Coordinator will review your completed interview forms within 1-2 days after receiving them, so any problems with data quality can be resolved in a timely manner. Your availability for work the upcoming week will also be reviewed.

5. HEALTH AND SAFETY

Your health and safety are more important than the data we are collecting. Please be aware of several potential safety hazards that may be present en route to or at some of the sites that you are visiting.

Bad weather can make docks, piers, rocks, and boat ramps slippery. It can also make you wet, cold, and miserable. Please wear shoes with good traction, and always bring warm clothing with you. Even during the Summer months standing immobile next to the Bay for several hours can make you feel pretty uncomfortable.

Do NOT board private boats. When you are trying to interview people in this fishing mode, do not board any private boats, even if someone invites you on board. For those of you who will be interviewing people on party boats, please do not board or disembark from the boat until the captain or the deck hand has given you an okay.

Beware of bad traffic situations. You all know how bad the Bay Area traffic can be. Some days you may encounter serious delays in getting to your assignment. Do not start driving carelessly or recklessly if you find yourself late for work.

Avoid heavy lifting. There isn't anything you need to lift for this job that weighs more than 10-15 pounds. Please do not try moving heavy furniture or boxes during your visits to the office. We have other staff that do that type of work; it is not worth injuring your back doing a job you are NOT paid to do. For those of you who are interviewing on party boats, do not volunteer your services for heavy lifting.

Beware of people conducting illegal activities. Some of the people that use these sites may be doing illegal activities. We are trying to avoid times when illegal activities occur by only conducting interviews during daylight hours. Please do not remain at these sites after dark. If you observe illegal activities taking place, do not get involved in these situations! Also, beware of people that may threaten your own safety. If you have any doubts about whether a site is unsafe, leave immediately.

6. TRAVEL AND ACCESS TO THE SITES

There are 14 shore sites, 5 sites for sampling individuals on private boats, and 4 sites where some of you will be boarding and riding party boats. Please plan accordingly to try and be on time to your interviewing assignments. Some of the sites may require more than 45 minutes travel one way to reach them, assuming no traffic problems. As part of our training session, we will be visiting each site so you can familiarize yourself with them. Also provided in the Site Map Book are maps and directions to help you locate the sites, and a local point of contact.

Two of the sites, Pt. Pinole, and Dumbarton Bridge require traveling at least 1.5 miles from the parking lots to the piers. At Pt. Pinole, a shuttle bus departs every 30 minutes except on Tuesdays and Wednesdays. At Dumbarton Bridge, vehicular access is restricted for five months, from April through August. Access to this pier is 3 miles from the parking lot on a flat road. If you must interview at Dumbarton during this limited access time, you must go to the ranger station and obtain a key to unlock the gate to allow you to drive to the pier. Many of the sites require public users to pay an entrance fee. YOU SHOULD NOT HAVE TO PAY A FEE for access to any of these sites. We have made arrangements to have entrance fees waived for all of our interviewers. During your first visit to a site requiring a fee, please take a few minutes to introduce yourself to rangers/managers that are present and show your identification. However, if you are required to pay a fee, you will be reimbursed by claiming it on your travel reimbursement.

7. COMPENSATION

In order to be compensated for your time and reimbursed for project related expenses, there are two forms you must complete. Every week that you work you need to turn in a timesheet and a reimbursable expense record. Impact Assessment, Inc. issues paychecks twice a month. At a minimum you will be paid 4 hours per shift, even if there are no anglers to interview. The other form you must complete pertains to reimbursable expenses. For the most part these expenses will be limited to tolls, parking, and private vehicle mileage. For mileage you will be reimbursed

at the State of California rate of $0.24/mile for travel between sites and for travel from your home to the site and from the site back to your home. For expenses less than $6.00 each, you do NOT need to turn in receipts, but for expenses more than this amount, receipts are required. If you are using your own cellular phone to make emergency telephone calls, you will be reimbursed for the number of minutes the call(s) take. A copy of your phone bill itemizing the calls made must be submitted with your reimbursement claim. In general, guidelines for reimbursement for travel related expenses follow those established for state employees.

You are allowed to take one 15 minute break for every 4 hours worked. You will be paid for the break. If you work at least 6 hours, you must take a break of at least 30 minutes (up to one hour) for lunch or dinner. You will not be paid for this lunch/dinner break. We want to limit your workday to no more than 8 hours; for most days you will only work 4 to 6 hours. If it looks like you will not finish your assigned sites within 8 hours, you must notify the Field Coordinator as soon as possible.

8. DETAILED CODING INSTRUCTIONS

- **Use Sharpie pens**
- **Avoid making stray marks on the survey forms, especially in marked boxes.**
- **If you must make notes as the Respondent is trying to answer a question, write in the margins or where there are no boxes.**
- **Write clearly and mark boxes within the boundaries of the box.**
- **When you print letters and numbers, use block letters. Print only one character per box, keeping the character's lines completely inside the box. Do not cross zeros, sevens, or the letter "Z".**
- **If you must correct an answer, circle the corrected answer.**
- **Fill in text in the "other" boxes; please write legibly and neatly.**
- **Mark all appropriate boxes!**
- **In asking the questions, you will read the response categories, unless otherwise noted for specific questions. For all questions, DO NOT READ DK (don't know) or Refuse. The latter two responses are available to be recorded if needed, but do not need to be read.**
- **For people who initially respond DK, try some gentle probing first to see if their memory can be "enhanced" (a true art!)**
- **If there are confusing marks or answers on the survey form, or you used a "translated" form to ask the questions, transcribe the responses to another form and make note of doing so on the original form. Clip both forms together and turn both forms in, indicating to the Field Coordinator that both forms reflect the responses from one Respondent.**

Introducing yourself and the survey: Before reciting the formal introduction, ask a casual question, such as "How's the fishing?", or "What are you catching?", or "Been out here awhile?", etc. Take a minute to engage the person in conversation if they will talk to you, then start the formal introduction. Try to adopt a conversational tone and approach. The end of the interview must include the question asking for permission to interview.

Q1a. Permission to conduct interview: You must obtain the person's consent before beginning the interview. Check one of the boxes 'yes', or 'no'.

Q1b, Q1c, Q1d, and Q1e. Fill out only for individuals refusing to participate. Do not fill these out if Respondent agrees to participate (yes to Q1a). If you have recorded a 'no' to **Q1a**, then you must record only one response for **Q1b** ("reason for refusal"). It may take you a few minutes to gauge the reason for refusal; the person may tell you why he or she will not participate in the study, or you may have to use your judgment and record a reason. DON'T PROBE THE PERSON FOR REASONS! IF THE POTENTIAL RESPONDENT (R) DOES NOT APPEAR HOSTILE THANK HIM OR HER FOR THEIR TIME, AND THEN MOVE ON TO THE NEXT POTENTIAL RESPONDENT.

Q1c, Q1e. Check observed ethnic group and gender. (your best guess).

Q1d. Language (if Non-English Speaking): You have several response categories here. Again, choose and mark only one choice. DO NOT GUESS! If the person is speaking a language that you do not understand, simply record 'undetermined.'

Q2. Has the person already been interviewed for our seafood consumption study? A response to this question may be given during a refusal following the interview introduction. A person may tell you that she or he has already been interviewed. You should be aware of the other fishery/creel survey type studies that are occurring in the SF Bay area. If a person tells you that she or he has been previously interviewed, try to determine whether it was for this study or some other one. For instance, ask if they have talked to someone wearing the same hat and vest as you have on, with the SF Bay Seafood Consumption Study logo. If the person was interviewed for our study, then check the 'yes' box, and ask if she or he remembers the month and year they were interviewed (Q2b). Mark the noted month and year in the designated boxes. If the person does not remember when, mark the DK box next to the date box. {Note there are two DK boxes, mark the appropriate one!) Thank and end the interview with all individuals who answered YES to Q2, indicating that you can only interview individuals once for this study.

When you have received permission to conduct the survey, and have determined the person has NOT been previously interviewed you are ready to move on to the next portion of the survey instrument.

Show the Respondent (**R**) the map of San Francisco Bay, and identify the boundaries of the area with which we are concerned. You may want to point out a few landmarks (e.g., Antioch, Dumbarton Bridge, etc.) You can also say that you may be referring to the San Francisco Bay as "the Bay". You will need to clarify what you mean by fish and shellfish.

Q3a. "Is this the first time you have ever fished in the San Francisco Bay?" There are four response categories, check one only. If R says No, ask **Q3b**. when was the last time, noting month (if known) and year. If R indicates not remembering or not knowing the last time he or she fished in the Bay, mark the DK box next to the date field and continue to Q4.

For "first time anglers", or those responding yes, skip to Q5.

Q4. **Not including today, i**n **the last 4 weeks, what is the total number of times you have gone fishing?**

People will probably need a little time to think about their answer. They may give you a total number or they might say something like 3 to 4 times each week. You would then have to say to them: "so like 12 to 16 times total for the last four weeks? Is it closer to 12 or 16 or some number inbetween?" Try to get a specific number and record that number in the noted box.

Q5. "What do you usually do (plan to do for FIRST TIME FISHERS) with the fish or shellfish you catch from the SF Bay?" THIS IS A MULTIPLE RESPONSE QUESTION, SO YOU MAY CHECK AS MANY CATEGORIES THAT APPLY.

TRANSITION: YOU WILL NOW BE ASKING A DIFFERENT SET OF QUESTIONS. TO GET THE RESPONDENT IN THE PROPER FRAME OF MIND, YOU NEED TO READ THE TRANSITION PARAGRAPH TO HIM/HER. TRY TO MAKE SURE HE/SHE UNDERSTANDS WHAT YOU ARE SAYING!

Q6a. "Do you eat fish that you or someone you know catches from the SF Bay?" Read off Yes; Used to, but don't anymore; or No. If R answered Used to, ask Q6b. and mark month/yr in the noted box. If R indicates he/she doesn't know when they stopped eating fish from the Bay, mark the DK box next to the date box. If R indicates a 'no', then skip to Q10. If R indicates DK to the overall question (not the date as to when he/she stopped eating fish from the Bay), or doesn't wish to answer the question, mark the appropriate box.

Q7. "How many years have you been eating fish that you or someone you know caught from the Bay?" You have eight possible response categories, record only one response. **You do not need to read** the categories to R, but make sure his/her answer fits one of the eight categories. NOTE: This may be the first question where you encounter a 'don't know' response, since some people may not be able to accurately recall how long they have been fishing. If someone is vague in the time frame they give you, or gives a couple of conflicting answers, record a 'don't know' response.

Q8a. "In the last four weeks, did you eat fish that you caught, or someone you know caught from the Bay?" Make sure R understands you are asking for about the last 4 weeks. For this question there are four response categories, record only one response.

Q8b. In the last four weeks, how many times did you eat fish that you caught or someone you know caught from the Bay? Again, make sure the time frame is understood. Let the Respondent think a bit. Answer can be stated in times per day, times per week, or total times in last 4 weeks. **Record only one response**.
You can prompt: "how many times per day or times per week did you eat fish from the Bay in the last 4 weeks?" or "how many times all together?" The Respondent may give you a total number of times, or give you different frequencies such as "ate it every day a week ago, but not so much last week." You would have to probe more specifically, such as "So you only ate fish from the Bay every day for a week over the last 4 weeks? You didn't eat fish the first two

weeks? So you ate fish seven times over the last 4 weeks?, etc. **Make notes and tally later if needed**. Record the number of times corresponding to the specified time period.
If Respondent gives a range, such as 2-3 times/week, ask "was it more likely 2 times or 3 times?

Q9. **"In the last 12 months (specify time period, using the current date and then asking for the previous 12 months) how many times overall, did you eat fish that you caught or someone caught from the SF Bay**. Make sure the R knows you are talking about the last 12 months! Answer can be stated in times per day, times per week, times per month, or total times in last 12 months. You can prompt: "About how many times per day or times per week?" (especially for frequent consumers). You may have to prompt about seasons or months they fish and eat more often, etc. **You may have to make notes and count up the total times separately.**
Someone who doesn't eat it a lot may be able to tell you easily the total number of times in the last 12 months.
Record only one response. Record the number of times corresponding to the specified time period.

Q10a. This is a model of 8 ounces (half pound) of raw fish fillet. When you eat fish from anywhere (the Bay, other places, stores, restaurant), is the amount that you eat about this size, more or less? " SHOW PARTICIPANT THE FISH MODEL BUT DO NOT LET THEM HOLD IT; ALLOW THEM TO LOOK AT IT FOR SEVERAL MINUTES. NOTE: YOU SHOULD KEEP THE 3D MODEL IN YOUR VEST UNTIL YOU REACH THIS QUESTION. ALSO, THIS QUESTION REFERS TO FISH CAUGHT/EATEN FROM ANYWHERE, INCLUDING RESTAURANTS, STORES, AND NOT RESTRICTED TO THE SF BAY. Make sure the participant is aware of this distinction, because in the previous questions we have been talking about Bay caught fish.

If the person responds "about this size", then skip to **Q11**.
If the person indicates the amount of fish eaten is more than that shown in the 3D model, then ask **Q10b**.
If the person indicates the amount of fish eaten is less than that shown in the 3D model, then skip to question **Q10c**.

Be aware that cooking generally reduces the size by about 25% (one fourth); in other words, 8 ounces of raw fish will generally result in 6 ounces cooked fish.

It is likely that some respondents will not relate to the model, and will not be able to confidently determine their consumption. DON'T TRY TO FORCE AN ANSWER but probe gently. For instance, repeat that this is a model of 8 oz. (half a pound). Do you think you eat half more, a fourth more, etc. Try showing what half or one fourth would like, using either paper or your hands to cover up part of the fillet model. If the respondent really seems unsure, check the 'don't know' category.

TRANSITION TO THE NEXT SECTION BY READING THE STATEMENT "Now I'm going to show you pictures of 3 specific fish that can be caught from the SF Bay and ask you whether you eat them or not. YOU WILL NEED TO FOCUS THE RESPONDENT'S ATTENTION TO

THE THREE SPECIES MENTIONED IN Q11-14. TO DO THIS, READ THE ENTIRE PARAGRAPH BEFORE BEGINNING QUESTIONS 11-14.

Q11a. "Do you eat this fish that you or someone you know catches from San Francisco Bay?" (POINT TO Kingfisher/Croaker picture)

Starting with Kingfish, you will record a 'yes', 'no', or 'don't know'. Ask them what he/she calls it and write the response in the noted space. For those responding affirmatively you will continue asking questions Q11b-Q11d3. For those responding with a 'no' or 'don't know', you will then ask the same question for the next species (Leopard shark). You will repeat this procedure for all three fish species.

Q11b. "Have you eaten any _____ from the Bay in the last 4 weeks?" (use the name given by the R) For each species the R reports eating, you will ask if he/she has eaten any in the last 4 weeks. It is important to emphasize the last four weeks AND the fish may be freshly caught or frozen, dried, canned or smoked after being caught. If the respondent answers 'yes', you will need to record the number of times that he or she has eaten the specific fish. If the R can't recall the no. of times eaten in the last 4 weeks, mark the DK box next to the No. of times box.

Q11c1 – skin and 11c2- guts. **When you eat kingfish (or whatever the respondent indicates calling the pictured fish), how often do you eat the skin of the fish?** …., (how often do you eat the guts or organs of the kingfish?) Read: "more than half the time, less than half the time or never?" Mark the appropriate box.

Q11d1, d2, d3. When you eat kingfish, how often do you eat the cooking juices or drippings (make soup with it?; eat it raw?) Read: "more than half the time, less than half the time, or never?" Mark the appropriate box.

Q12a to Q12d3 – ask similar questions for **leopard shark**.

Q13a to Q13d3 – ask similar questions for **striped bass**.

Q14a. **Now I have some picture of other fish that can be caught from SF Bay. Looking at these pictures, please show me which fish you have eaten in the last 4 weeks**. **Again these are the fish you ate in the last 4 weeks which you caught or someone you know caught fromSF Bay. The fish could have been fresh, frozen, dried, canned, or smoked.**
SHOW PICTURES AND HAVE RESPONDENTS POINT OR TELL YOU WHICH ONES THEY HAVE EATEN IN THE LAST 4 WEEKS. Some probing may be necessary and you may have to show the pictures more than once. Mark the Yes box only for those the R indicates.

Q14b. As Respondent identifies fish he/she has eaten in the last 4 weeks, ask **"How many times have you eaten this fish in the last 4 weeks?"**

Q14c. "What do you call this?". (ASK RESPONDENT AS HE OR SHE POINTS TO THE PICTURES, AND THEN RECORD THE RESPONSE IN COLUMN 14C.) NOTE: For those interviews conducted in Spanish, please record the exact word given by the Respondent; ask them to spell it for you if you are unsure. For interviews conducted in Chinese, Mandarin, or Vietnamese, write the characters or the equivalent.

Q14d. Are there any other fish from the Bay that you eat most often for which I don't have pictures? If R names one of the listed fish, check box and indicate number of times eaten. If R names a fish that is not listed, specify the type of fish and the number of times eaten in the last 4 weeks in the blank box(es).

Q15. "Who in your household eats the fish that you catch from the SF Bay?"
Please read the 6 main response categories and check all that apply.

Q16. "How many total people, including yourself, are in your household?" You have three choices for this question, record only one response: the number of total people, a don't know, or a refuse to answer response.

Q17. "Who usually cooks or prepares the fish you catch and eat from the Bay?" This a multiple response type question, so you may check more than one response. Please record the noted family member or other individuals in the appropriate boxes.

TRANSITION: THE NEXT SET OF QUESTIONS DEALS WITH FISH FROM PLACES OTHER THAN THE SF BAY. YOU WILL NEED TO READ THIS PARAGRAPH TO RESPONDENTS BEFORE ASKING THE NEXT FEW QUESTIONS.

Q18a. "In the last four weeks, did you eat fish that you or someone you know caught from places other than the SF Bay (like a lake or river) in the last four weeks?" (SHOW MAP AS NEEDED TO REMIND RESPONDENT ABOUT THE AREA COVERED BY THE SF BAY)
Mark the given response in the appropriate box. If no, DK, or refuse skip to Q21a. If yes, continue to Q19.

Q19. "From what places, other than the San Francisco Bay, did you or someone you know catch the fish that you ate in the last four weeks?" This is a multiple response type question, so you may check all responses that apply. Fill in text box if Other is marked.

Q20. "In the last four weeks, how many times did you eat fish that you or someone you know caught from places other than SF Bay?" Answer can be stated in times per day, times per week or total times in last 4 weeks. **Record only one response**. If other is marked, please record in the indicated box what the Respondent indicates.

Q21. In the last 4 weeks, have you eaten any fish that you got from a store or restaurant, including any fish fillet burgers or canned tuna?" Check only one response. If the respondent gives a yes response go to Q22. If the respondent gives a 'no', 'don't know', or 'refuse' response, go to Q23.

Q22. "How many times in the last four weeks did you eat fish that comes from a store or a restaurant, including any fish fillet burgers or canned tuna?" Answer can be stated in times per day, times per week or total times in last 4 weeks. **Record only one response**.

TRANSITION: READ OR SAY: "Now I am going to ask you a few questions about information you may have heard about eating fish from the Bay."

Q23. "Have you heard or seen any information or health advisories about eating fish from the Bay?" Record only one response. If the respondent answers 'yes', go to **Q24**. For all other responses, go to **Q25**.

Q24. "What did the information say about fish from the Bay? This is an open-ended question. Listen to what the Respondent says and then repeat back in a summary form to make sure you have heard him/her correctly and then record the noted response.

Q24a. Has the information you have heard or seen about eating fish from the Bay caused you to change your fish eating habits? Record only one response.

Q24b. If yes, how have you changed your fish eating habits? If no, why not? Listen to what the Respondent says and then repeat back in a summary form to make sure you have heard him/her correctly and then record the noted response.

Q25. "What is the best way for you to get information about catching and eating fish from the Bay?" This is a multiple response type question; check all that apply. If the other box is checked, record the Respondent's answer in the text box.

TRANSITION: (The last series of questions deals with personal information, and respondents may be uncomfortable answering these questions.) Read the transition paragraph: **These next few questions will help us describe people fishing or collecting shellfish from the SF Bay. We find this information helpful when we are developing information and materials for people who fish or collect fish. Please remember the information is kept confidential and you don't have to answer if you don't want to.**

Q26. "How would you describe your racial or ethnic background?" You do not need to read the response categories. Code the response as the Respondent answers, checking only one box. Note that several of the the response categories require you to record a specific description in the text box. Pacific Islander groups include Samoan, Tongan, Guamanians. Other Asian can include Koreans, Japanese, Cambodians, Thailanders, Laotians, etc. If Respondent indicates a mixture of ethnic backgrounds or some group not listed, check Other and note the response in the text box.

Q27. "What category best describes your age?" Read "under 18, 18-45, 45-65, over 65?" You have six response categories, check only one.

Q28. "What is the highest grade in school you have completed?" Read "less than 12^{th} grade,

etc." (not DK or Refuse!) You have six response categories, check only one.

Q29a. "Is your total yearly household income greater than $20,000?" You have four response categories, check only one. If the respondent answers 'yes', then ask Q-29b.

Q29b. "Greater than $45,000?" you have four response categories, check only one.

Q30. Gender DON'T ASK THIS- JUST RECORD THE APPROPRIATE CATEGORY based on your observation.

TRANSITION: You are getting ready to end the interview. Offer R the tape measure key chain as our gift for participating. Read the noted paragraph and ask the following questions.

Q31. "Would you like to have your name entered into the drawing?" Mark the noted box. If yes, fill out name, address, etc. in designated boxes.

Q32. "Would you like us to send you information about the results of our survey when they become available?" Mark the noted box. If yes, fill out name, address, etc. in designated boxes.

Q33. "May my supervisor contact you?" Mark the noted box. If yes, fill out name, address, etc. in designated boxes.

Read paragraph regarding the advisory and offer copy of advisory in the appropriate language. You can point out more specific recommendations as given in the handout. If the R wants more information, refer them the agencies listed on the sheet.

Be sure to thank the Respondent for participating!

Enter time the interview was completed in the noted boxes. Use military time.

The **final page** of the interview form is for you to note your impressions of the quality of the interview, additional observations you may want to note, and language in which the interview was conducted. Also if the Respondent refused to answer Q26 (ethnicity), note your observation of the Respondent's ethnicity.

9.0 FREQUENTLY ASKED QUESTIONS

1. Who is paying for this study?
The San Francisco Estuary Institute (SFEI), located in Richmond, is paying for this study. SFEI is a nonprofit research organization that conducts studies to assess and monitor the ecological health of the San Francisco Bay.

2. Who do you work for?
I work for a private company, Impact Assessment Inc. Impact Assessment Inc. is under contract with SFEI and is working in close collaboration with the California Department of Health Services to carry out this study.

3. How much are you paid to do this job?
You can answer this question honestly if you wish although you can also politely tell the respondent that this isn't something you want to share with him or her.

4. How much did SFEI get to do this study?
I am not sure. My supervisor, Gloria Cardona, can provide you with an answer to this question. Her number is (510) 450-3818 (or give them a copy of the referral sheet).

5. Who is in charge of this study?
Gloria Cardona is my immediate supervisor and there are two other people at the Department of Health Services who work with Gloria, Diana Lee and Alyce Ujihara. The phone number for Gloria, Diana, and Alyce is (510) 450-3818 (of give them a copy of the referral sheet).

6. Can I get a copy of the study results?
Yes. We will send you a copy of the final study results when we have completed this project in June 2000. Record "yes" on question 32 in the survey. If he or she is not a survey participant, take down his or her name and address and give to Gloria.

7. Is San Francisco Bay badly polluted?
Nearly all water bodies near urbanized areas show some degree of contamination in the sediments, water, and/or biota. Chemical contaminants measured by SFEI's Regional Monitoring Program show that most contaminants are considerably higher inside the Bay than outside the Golden Gate. However, overtime, the level of contamination is slowly decreasing.

8. Which SF Bay fish are safe to eat?
Most species of Bay fish are included in the health advisory for San Francisco Bay. There are some species that are not included in the health advisory. These are salmon, anchovies, herring and smelt. Although these species have not been tested, they are expected to have lower contamination levels because they spend most of their lives in the sea or because their diets differ from the species included in the health advisory.

9. What about Striped Bass and Sturgeon Caught in the Delta?

Striped bass and sturgeon live in both the Bay and Delta thus the Health Advisory applies to these species in both areas.

10. I have never become sick eating fish from the Bay, why should I worry about the amount of fish I consume? What will happen if I eat contaminated fish?

At the levels found in Bay fish, the chemicals should not make you sick from eating just occasional meals or from eating a large amount of fish at one time. Even regularly eating large amounts of contaminated fish is not certain to cause health effects. But the link between eating contaminated fish and potential health effects is not well understood. Some health effects like cancer may develop only after many years of regularly eating large amounts of fish. To be safe, we recommend that you follow the limits in the health advisory. These limits should protect you from any adverse health effects.

11. Should my children and breastfeeding wife eat Bay fish?

Children under 6 and women who are pregnant, may be come pregnant, or who are breastfeeding should not eat more than one meal per month of most Bay fish. In addition, they should not eat any meals of large shark (greater than 24 inches) or large striped bass (over 27 inches). A fish meal for a 120 pound female is about 6 ounces. For a 40 pound child a fish meal is about 2 ounces.

12. Don't contaminated fish look sick? Should I just avoid fish that look sick?

Fish that contain chemicals do not look sick and they do not look any different from fish that do not contain chemicals. You should follow the health advisory for all fish caught in SF Bay.

13. Are there better places to fish?

Chemicals at levels of health concern were found in fish throughout the Bay so the health advisory applies to all areas of the San Francisco Bay west of the Pittsburg/Antioch area. For striped bass and sturgeon, the health advisory should be followed in the Delta as well. There are not any health advisories for fish in the ocean (outside the Golden Gate Bridge) except for Southern California. There are also many freshwater rivers, lakes and reservoirs in the area. Be sure to consult the Department of Fish and Game Sport Fishing Regulations for a listing of other health advisories in freshwater areas.

14. Are store bought fish any better?

The fish you buy in a store or restaurant may also contain chemicals but in most cases they are probably safe. The federal Food and Drug Administration (FDA) monitors levels of chemicals in fish from commercial sources and has set limits on the amount of chemicals these fish can contain. However, because of the many different sources and species, not all fish and shellfish are tested. The FDA has issued advice for consumers of shark and swordfish because these species have higher levels of mercury than other kinds of fish. FDA recommends that pregnant women and women who may become pregnant limit their consumption of shark and swordfish to no more than once a month. For all other persons, shark and swordfish consumption should be limited to no more than once per week. A typical adult serving is about 7 ounces.

15. Would you eat fish from the Bay?

We can't answer this question for you. But, you should expect to be asked this question in the field and have thought of a response before you begin interviewing in the field. In thinking about a response, it is helpful to be familiar with the materials on the health advisory.

Appendix H

Field Activities Summary

San Francisco Bay Seafood Consumption Study

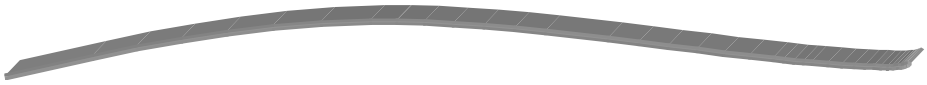
Appendix I

Coding for Text Entries

San Francisco Bay Seafood Consumption Study



Appendix I -Text Coding Key
Revised 12/5/00

Q1b Reason for declining interview
Coding of text box responses for "other"
5 = not interested; didn't want to
6 = said information would be same as another respondent
7 = just leaving
8 = first time fisher
9 = doesn't eat fish
10 = other (out of state, etc.)

Q1c Observed ethnicity of decliners
Coding of text box responses for "other"
(recode according to Q1c categories as appropriate)
8 = other Asian (other than Korean, SE Asian, e.g., Japanese)
10 = SE Asian other than Vietnamese
11 = Russian
12 = Korean

Q1d Language of decliners
Coding of text box responses for "other"
8 = other Asian other than Korean, SE Asian
10 = SE Asian other than Vietnamese
11 = Russian
12 = Korean

Q5 Disposition of catch
Coding of text box responses for "other (specify)"
1 = feed to animals, birds, etc.
2 = give to restaurants
3 = eat occasionally, eat only some fish (recode Q5 as "eat it" for angler's response)

Q11-Q13 Consumption Practices of White Croaker, Leopard Shark, and Striped Bass
Anglers who reported that they followed consumption practices (skin, cooking juices, guts, soup, raw) half the time were recorded as "more than half the time."

Q14 Species of fish not listed and for which picture were not available
1 = salmon (included in SF Bay fish consumption)
2 = SF Bay advisory species (included in SF Bay fish consumption)
3 = other fish not from SF Bay (e.g., red snapper, any freshwater fish)
4 = commercial fish
5 = SF Bay shellfish (crab, mussels, clams) (included in SF Bay shellfish consumption)
6 = non-SF Bay shellfish (squid, shrimp, oysters)

Q17 Who cooks or prepares Bay fish
Coding of text box responses for "family member (specify)"
1 = mother/parent/grandparent
2 = wife/partner/spouse/husband
3 = other (daughter, child, nephew, brother, roommate, sister, girlfriend, etc.)

Coding of text box responses for "other (specify)"
1 = roommate, girlfriend, boyfriend
2 = other (anybody, whoever catches)

Q19 Fish consumption from areas outside SF Bay

Coding of text box responses for "other" (recode to Q19 categories as appropriate)
1 = out of state
2 = not specific CA location
3 = unknown

Q23-Q24 Awareness and comprension of health advisory

To determine whether anglers were aware of the health advisory and their understanding of the advisory, we asked a two-part question. In the first part (Q23), we asked anglers if they had heard or seen health advisory information about eating Bay fish. We then recorded whether the respondent said Yes, No, Don't Know, or refused to answer. In the second part (Q24), we assessed the anglers' comprehension of the health advisory by asking "What did the information say about fish from the Bay?" (We excluded respondents who answered no to the first part). Responses were categorized in the following ways:

Q24 What did information say?

Coding of text responses
1 = Did not express an awareness of current Bay fish advisory
2 = Expressed some knowledge of contaminated fish or waters respondents may have implied awareness of health protective measures, but did not actively state any. (i.e. make you sick, possible kill)
3 = Expressed some knowledge of health protective recommendations
4 = Answered regarding shellfish, not current fish advisory

Respondents who showed no awareness of the current advisory in the second part of the question (Q24) were re-categorized as having no awareness in the first part (Q23). This recategorization of awareness resulted in a 4% drop in awareness across respondent groups, as shown in Table I.1 below. The recategorized response was used for the analysis presented in Section IV.E.

Table I.1. Comparison of Claimed and Actual Awareness of Health Advisory

	RESPONDENTS N=1227*		CONSUMERS N=1054*		NON-CONSUMERS N=173*	
	No.	%	No.	%	No.	%
Claimed to be Aware of Health Advisory in First Part of Questions	771	63	657	62	325	66
Actually Aware of Health Advisory Based on Recategorization in Second Part of Question	722	59	616	58	106	61

*Party boat anglers were excluded because they were not asked health advisory questions.

Q24b Changes in fish eating habits

Coding of text responses for "other (specify)"
1= Claimed to have stopped eating Bay-caught fish entirely after hearing of advisory
2 = Claimed to have engaged in a health protective measures after hearing of advisory. Health protective measures include eating less, preparing or cooking food in a protective manner, and eating different species of fish.
3 = Claimed to eat only uncontaminated fish after hearing of advisory
4 = Claimed not to have consumed above the limit before hearing of advisory. Respondents replied either that they didn't eat much before, or didn't eat any before learning of the advisory.
5 = Does not believe contamination poses a significant problem
6 = Generally no, have not changed behaviors after hearing of advisory
7 = Not specific to current Bay fish advisory

Q25 Best way for angler to get information

Coding of text responses for "other (specify)"
1 = one-on-one contact from educator, includes Department of Fish and Game, interviewers, others
2 = Direct mailings to fishers
3 = Information in bait & sports shops
4 = Internet
5 = Fish and Game
6 = other/miscellaneous

Q26 Ethnicity

Coding of text responses for "Pacific Islander (specify)"
1 = Guamanian
2 = Samoan
3 = Hawaiian

Coding of text responses for "Other Asian (specify)"
1= South East Asian (other than Vietnamese)
2 = other mixed Asian
3 = Japanese
4 = Korean

Coding of text responses for "Other (specify)"
1 = mixed ethnicity (unspecified)
2 = Russian
3 = Middle Eastern

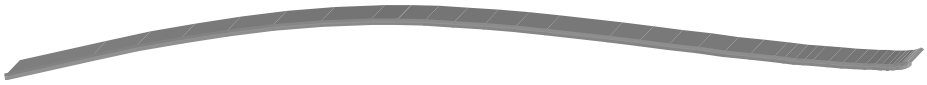
If an angler reported mixed ethnicity, for example African American and Chinese, he was coded using the first listed ethnicity (African American).

If respondent refused to answer Q26 (ethnicity), interviewers recorded observed ethnicity. Where possible, Q26 responses were recoded.

Appendix J

Defining Consumers and Derivation of Consumption Rates

San Francisco Bay Seafood Consumption Study



Appendix J - Defining Consumers and Deriving Consumption Rates

In this appendix we provide a more detailed discussion of how two groups, consumers and recent consumers, were defined and how consumption rates were calculated in this study. We also describe the shape of the consumption rate distribution and discuss why the consumption rate data were log transformed. Finally, we discuss how consumption rates were weighted across modes.

A. Definition of Consumers

One of the study's central goals was to characterize the population that is exposed to chemicals from consumption of Bay fish. Thus, we have focused much of our analysis and discussion on the subset of the angler population called consumers. Consumers are anglers who reported that they eat Bay fish. Anglers who reported that they do not eat Bay fish (i.e., non-consumers) were excluded from the consumer group.

To define a consumer, we looked at responses to several questions. Respondents were first asked a single, general question (Appendix E, Question 6a): "Do you eat fish that you or someone you know catches from the SF Bay?" They were then asked a series of question about whether they ate specific species of Bay fish (Questions 11-14). We attempted to define consumers as inclusively as possible. Anglers who reported they ate Bay fish in any of the above questions were defined as consumers. Some anglers, however, provided inconsistent responses to these questions. For example, they answered no to the general question, but when asked about specific species of fish, they answered yes to at least once species. Anglers with inconsistent responses were defined as consumers if any of their responses indicated that they ate SF Bay fish.

The one exception to this definition was the angler's responses to the survey question (Question 5) that asked what the angler usually did with the fish he or she caught from SF Bay. Respondents could indicate that they usually ate the fish, gave it to family or friends, traded or sold it, etc. This question was never used to determine whether an angler was a consumer or not because this questions was less reliable than subsequent questions. In other words, if an angler answered this question by indicating he or she usually ate the fish he caught, but later in the survey did not report eating Bay fish or did not identify that he or she ate specific species of Bay fish, he was defined as a non-consumer of Bay fish.

The shaded area of Table J1 describes the survey questions and possible responses that were used to categorize respondents as consumers. Out of 1331 respondents, 179 anglers were categorized as non-consumers. The remaining 1152 anglers we defined as consumers. Most consumers (961 or 83%) provided consistent responses to questions on whether they ate Bay fish. Some consumers (153 or 13%) who answered inconsistently but were still categorized as consumers. In addition, a small number of anglers who were fishing for the first time and (38 or 3%) reported that they planned to consume their catch were also included as consumers even though they had no past consumption of Bay fish.

Table J1. Definition of Consumers (Shaded Areas) N=1152

		Eats specific species of Bay fish (Questions 11-14)		
		Yes	No[a]	
Eats Bay fish (Question 6a)	Yes	961	96	
	No[a]	57	Non-consumers= 179	
			First-time fishers=38[b]	
				1331 Respondents

[a] respondent could also have answered don't know, refused to answer, or the response could have been missing

[b] Anglers who were fishing for the first time and also planned to consume their catch.

B. Definition of Recent Consumer

Recent consumers are defined as: 1) a subset of consumers, and 2) anglers who reported eating Bay fish in the last four weeks. Consumers were first asked a single, general question (Question 8a): "In the last four weeks, did you eat fish that you caught or someone you know caught from the SF Bay?" Then they were asked a series of question on whether they had eaten specific species of fish from SF Bay in the last four weeks. (Questions about whether the angler reported recent consumption of specific species of Bay fish were asked in Questions 11-14). The definition of recent consumers was not analogous to the definition of consumers. If anglers reported recent consumption of any specific species of Bay fish in the last four weeks they were defined as recent consumers; the general question (Q8a) was never used to define recent consumers (Table J2). Out of 1152 consumers, 537 were defined as recent consumers.

It should be noted that consumption rates (based on a four week recall) could not be derived for all 537 anglers who were defined as recent consumers. This occurred because some recent consumers provided incomplete information on their consumption rates. For example, some anglers reported that they had recent consumption of specific species of Bay fish yet they did not report the number of time they consumed that species in the previous four weeks (meal frequency). Also some recent consumers did not provide information on their portion size. Both meal frequency and portion size were needed to calculate a consumption rate. As a result, consumption rate estimates could only be derived for a subset of recent consumers (n=501). In addition, some anglers failed to report information on their fishing frequency, which was used to adjust data for avidity bias. Thus, avidity bias adjusted consumption rate data could only be estimated for an even smaller subset (n=465).

Table J2. Definition of Recent Consumers (Shaded Areas) N=537

		Ate specific species of Bay fish in the last four weeks (Questions 11-14)		
		Yes	No[a]	
Ate Bay fish in the last four weeks (Question 8a)	Yes	445	43	
	No[a]	92	572	
				1152 Consumers

[a] respondent could also have answered don't know, refused to answer, or the response could have been missing

C. Deriving Consumption Rates Based on a 4 Week Recall

As discussed in the previous section, anglers could be defined as recent consumers in two ways: 1) based on a single general question or 2) based on a series of questions about specific fish species. Similarly, consumption rates (based on a 4 week recall) could be derived in two ways. The questionnaire allowed for consumption rates to be derived in two ways, from the single general question (Q8a), or consumption rates could be derived by summing the total number of times the anglers ate specific species of Bay fish in the last four weeks. When we compared the distributions for these two consumption rates, we found them to be very similar. The correlation between the two consumption rates was high (n=424, r=0.78).

Rather than present two similar consumption rate results based on a four-week recall in the report, we chose to limit our analyses to the consumption rate derived by summing individual species. We selected this rate for two reasons. First by asking respondents about specific species with the aid of color pictures, we may have helped the respondent to remember all species that had been eaten. In fact, more respondents reported a consumption rate based on the sum of individual species (n=501) compared to the consumption rate based on a single question (n=435). Second, we wanted to calculate consumption rates based on only advisory species. This consumption rate could only be derived using species specific consumption rates.

D. Shape of the Consumption Rate Distribution

Estimation of population means and statistical tests of consumption rate differences between groups assume normal distributions in each group being compared. Statistical tests are generally reliable as long as the normality assumption is not badly violated (Kleinbaum, Kupper, and Muller 1988, Armitage and Berry 1987). We used a number of approaches to assess how the consumption rate data reported in Section IV.D.1 were distributed and whether they required transformation. Following Hill's (1995)

methodology, we found that the standard deviations were larger than the mean, which indicates a high degree of variability in the distribution. The standard deviation is usually a fraction of the mean in a normal distribution (Table J3). The skewness and kurtosis, which are indicators of normality, were positive. Both are zero in a normal distribution. A positive skewness indicates a distribution with a tail to the right. A positive kurtosis indicates heaviness of the tails. The geometric mean is much closer to the median than is the arithmetic mean, indicative of a log normal distribution.

Table J3. Descriptive Statistics of SF Bay Fish Consumption Rate (g/d) (Unadjusted)

	4 week Recall	12 Month Recall
	N=501	N=1019
Mean (Standard Deviation)	28.0 (39.5)	11.0 (35.7)
Geometric Mean	16.5	1.2
Median	16.0	2.5
Skewness	3.9	7.4
Kurtosis	19.9	70.9

Figures J1a and J1b show histograms of the distribution of consumption rate for recent consumers of SF Bay fish based on a four week recall. Above each histogram is a normal quantile plot (SAS JMP 2000), in which points derived from a normal distribution will lie along the diagonal line, or at least within the dotted-line confidence bounds. In Figure J1a, the distribution of consumption rate is grossly non-normal, and has the long upper tail characteristic of a lognormal distribution. In Figure J2b, applying a log transformation to the data markedly improves the fit to the normal distribution, as nearly all points lie within the confidence bounds of the normal quantile plot.

Because the SF Bay angler population is comprised of different ethnic groups whose consumption rate distributions may be distinct, the distribution of the total combined data may not be lognormally distributed, even if the subgroups are. We therefore examined these distributions for the major ethnic groups in Figures J2 to J5. Similar to the overall consumption rate distribution of recent consumers, the major ethnic groups show grossly non-normal consumption rate distributions and applying the log transformation greatly improves the fit to the normal distribution. As would be expected, the log transformed data for the individual ethnic groups fit the normal distribution better than the data for the overall population of recent consumers.

More complicated transformations (such as the negative reciprocal of the 10^{th} root) were found to improve the normal distribution fit slightly for some of the ethnic groups. But for ease of presentation, consistency across groups, familiarity, and comparison to other

studies, the natural log transformation was used for the overall population of recent consumers and all of the ethnic groups.

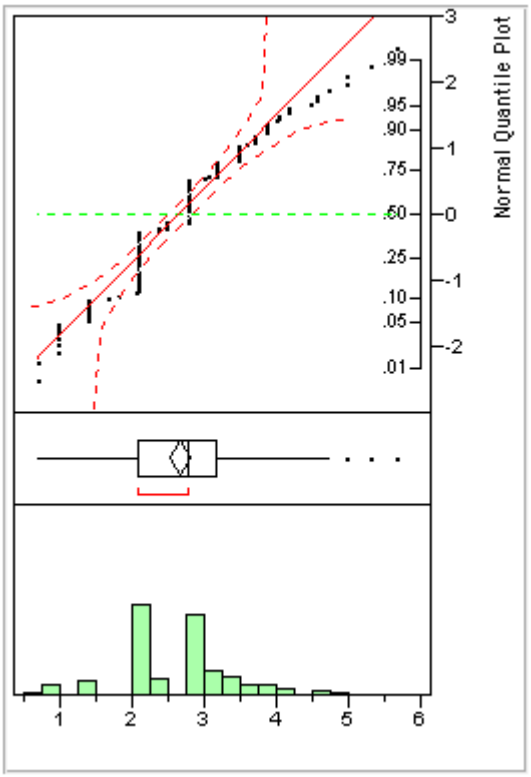

Figure J5b. Log Latino Consumption Rate (n=56)

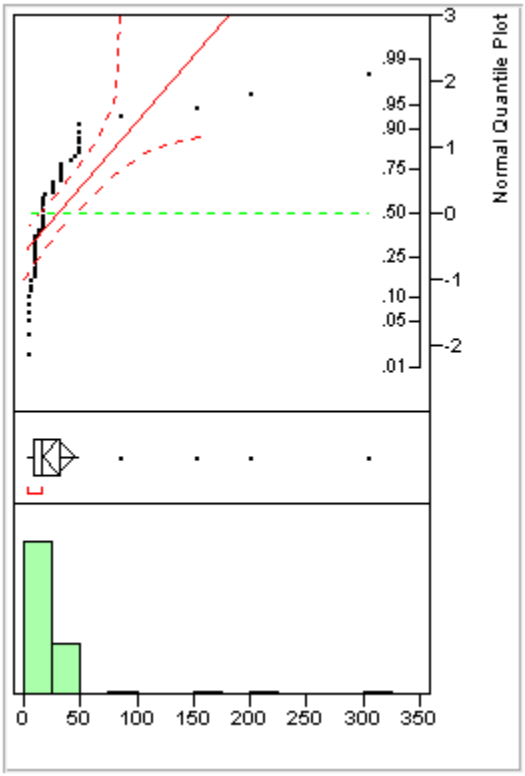

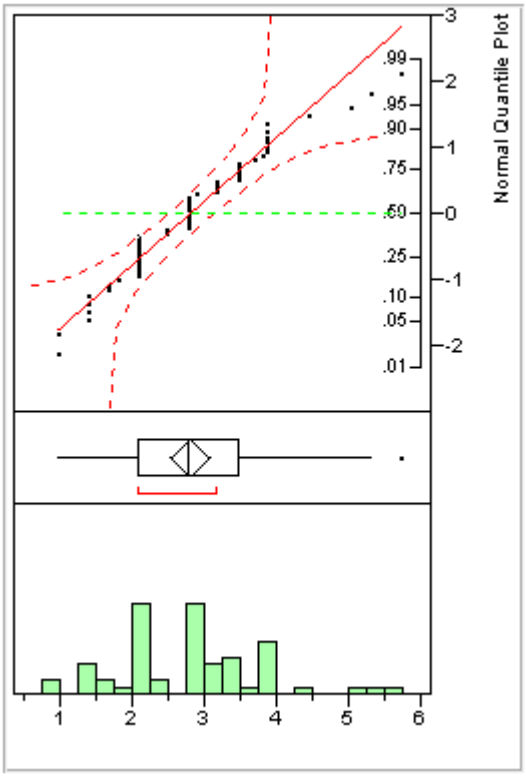

E. Consumption Rate Estimate Weighted by Mode

In the sampling plan, we sought to derive consumption rates that could be applied across all fishing modes. To do this, we set sampling targets for the fishing modes that were based on estimates of the relative amount of fishing activity in those modes, shown in Table J4. (This was also discussed in Section II.B.3 and Appendix D). Consumption rate estimates for recent consumers reported in Table 4 (of the report) were based on a sample of recent consumers that was slightly different than the original sampling targets. As shown in Table J4, we planned to interview more shore-based and party boat anglers, and fewer private boat anglers, than we actually did.

Table J4. Sample Target Interviews by Mode Compared to Actual Sample

Mode	Sampling Target Interviews Based on Fishing Activity	Actual Sample of Recent Consumers	
	N=500	Unadjusted N=501	Adjusted N=465
Shore-Based	62%	58.3%	57.0%
Private Boat	28%	34.3%	35.0%
Party Boat	10%	7.4%	8.0%
Total	100%	100%	100%

To determine if differences by mode between the sampling targets and the actual sample could have caused any bias in consumption rate, we recalculated consumption rates by weighting the geometric means for each mode by the sample targets (Table J5).

Table J5. Consumption Rate Weighted by Sample Targets for Fishing Mode

Mode	Unadjusted Geometric Mean Consumption Rate (g/d)	Avidity Bias Adjusted Geometric Mean Consumption Rate (g/d)
Unweighted by Mode	16.5	14.0
Weighted by Sample Targets Based on the Relative Fishing Activity for Each Mode	16.5	14.1

We found that the consumption rates weighted by the sample targets are nearly identical to the original, unweighted values. We conclude that there is no bias in consumption rate due to differences between the sampling targets and the actual sample.

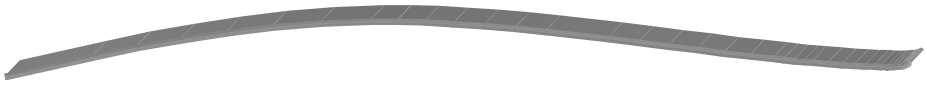
Appendix L

Health Advisory Discussion Groups

San Francisco Bay Seafood Consumption Study



Appendix L - Health Advisory Discussion Groups

The California Department of Health Services (CDHS) conducted four discussion groups with anglers in order to better assess anglers' actual awareness of the advisory, the effectiveness of the advisory language, and the best messages and modes of delivery for reaching anglers with information. We originally planned to conduct four discussion groups, each consisting of 8-12 participants. Participants would attend a two and one half-hour discussion facilitated by a community relations coordinator.

Discussion group participants were recruited from the survey population. At the conclusion of the interview, respondents were asked for their name, address, and telephone number for the purposes of quality control and follow-up. Of the 1331 respondents, 581 (44%) provided contact information. After reviewing preliminary study results, the project staff identified four target groups to participate in discussion groups. The four groups were categorized as: (1) Filipino anglers, who made up the largest group of Asian anglers; (2) anglers who were unaware of the advisory; (3) anglers who were aware of the advisory but had not changed their consumption habits; and (4) boat anglers. Out of the 581 anglers who provided contact information, 216 were eligible to participate in the discussions because they met the criteria for at least one of the four groups. The field coordinator attempted to contact all eligible participants. She explained the purpose of the focus groups and provided them with several scheduling options by which they could participate, including weekday evenings and weekend mornings. Those who indicated a willingness, received a confirmation letter with the date, time, and place of the discussion, and directions to the site. They also received a reminder call 24 hours before the meeting.

Out of 216 of eligible participants, 35 agreed to participate in the groups, and 17 actually participated. In response to the low attendance of the early meetings, we increased the compensation from $50 to $75, and offered meeting times during the workday as well as weekend and evening. We also re-contacted anglers who either declined to participate or failed to show, and offered them the increased compensation and meeting options. Participation by shore-based anglers, however, did not improve. We conducted all four of the proposed groups, and an additional group consisting of anglers from all three of the shore groups (aware, unaware, and Filipino anglers) in order to maximize participation. Information on discussion group contact and participation is presented in Table L1.

Table L1. Discussion Group Dates, Location, Contacts and Participants

Date Location	Target Group	Number Contacted	Number Confirmed	Number Participated
9/21/99 San Francisco	Filipino Consumers	21	5	2
9/23/99 Oakland	Filipino Consumers	55	5	2
10/30/99 Oakland	Unaware of Advisory	117	7	0
11/15/99 Oakland	Unaware of Advisory	117	5	3
11/20/99 Oakland	Unaware, Aware but haven't changed habits	117	5	3*
12/8/99 Martinez	Boat anglers	23	8	7

*One of these anglers was also Filipino.

One group was held in San Francisco, three were held in Oakland, and one was held in the Martinez Yacht Club (boat anglers). The group participants consisted of five Filipino anglers, three anglers who were unaware of the advisory, three anglers who were aware of the advisory but had not changed their behaviors, and seven boat anglers. One Filipino angler was also unaware of the advisory. For the purpose of discussion, we categorized respondents as either boat or shore-based anglers. Among participants, the length of time fishing ranged from 2 to 20 years.

To enhance objectivity in the interpretation of the discussion, three CDHS facilitators were present at each meeting. The groups were led by Ian Walker, Community Relations Coordinator, along with Gloria Cordona, and Diana Lee or Alyce Ujihara. Group participants were guided through a discussion outline (Attachment L-1) which contained specific questions. Responses were qualitative in nature, and recorded both on audio tape and by a note-taker.

Due to the small number of anglers who participated in the discussion groups, generalization to the overall fishing population was not possible. However, discussion group participants raised pertinent questions and concerns regarding the advisory messages and educational strategies. They also provided some insight into the efficacy of the language used in the advisory.

A. Discussion of Health Advisory

Even though anglers in the discussion groups had been read a summary and were offered written materials about the advisory during their field interview, their knowledge of the SF Bay advisory ranged from none whatsoever to two boat anglers who had a firm understanding of all the major recommendations. In general, the majority of participants

had fragmented or incorrect information regarding the health advisory. Anglers often had awareness of one element of the advisory (such as fish in different locations, limit size of fish, or eat less fish) but they were not knowledgeable about more than one aspect of the advisory. Overall, the boat anglers had the most accurate knowledge. Six out of seven expressed an awareness of the advisory and were able to correctly recite some element of it.

Anglers were then shown the health advisory for SF Bay fish (Appendix A). After reading the advisory, overall, the participants indicated that the information was important. Boat anglers and participants who were aware of the advisory but had not changed their habits, attached the least importance to the advisory.

B. **Discussion of Terms used in the Health Advisory**

In the discussion groups, we tried to assess whether anglers understood the term "sport fish." In the health advisory, "sport fish" refers to all species of fish from the Bay that an angler may catch and eat. All of the participants claimed to know what the term sport fish meant; however, none of the groups were able to agree on its definition. Despite some awareness of the advisory guidelines, no one from the three shore-based groups believed the term applied to all fish from the Bay. The most common assertion was that it applied to fish one did not eat (e.g. caught and released). Two anglers felt the term referred to fish one could not sell. Some believed it applied to specific kinds of fish, such as bass and shark, or fish from the ocean, that were caught for recreation and not for food. Boat anglers were closest to describing the health advisory's definition of "sport fish." Two anglers initially felt that it applied to all fish from the Bay; however this definition was not supported in the discussion, which continued to propose alternate definitions. Some of the boat anglers felt that white croaker, shark, string ray, and other fish were definitely <u>not</u> "sport fish"; two people in this group felt that subsistence fishing was different than sport fishing, and that anglers who needed the fish for food were not catching "sport" fish.

Overall, anglers appeared at a loss for a better term to describe all fish that they may catch and eat. Some anglers felt the term "fish" didn't need to be qualified if used on a waterfront sign. Others felt that "Bay fish" was a better term, or that a definition (such as "fish caught from the SF Bay") would help clarify text in which sport fish was used. A couple of anglers felt that the current wording suggested that all fish, including river and ocean fish, were implicated in the advisory. They felt it was important that the wording state very clearly that the advisory was for SF Bay fish only.

In general, terms referring to the fish itself, like fillet, and juices were well understood by the participants. In referring to amounts of fish that can be safely eaten, most anglers felt that indicating "grams" was not helpful. While the majority of participants understood "ounces," they also felt that people do not think in those terms.

Almost all of the shore-based anglers preferred "pounds" as the best way to express amount. They felt it took into consideration different meal sizes, and gave them more

freedom of choice. In contrast, almost everyone in the boat anglers group preferred that the amounts be expressed as "two meals." They felt it was simple and sufficient. However, several anglers in this group clearly stated that they would not be following any advice to limit their consumption.

Filipino anglers who participated in the groups felt strongly that they did not think in terms of meal or portion sizes. They indicated that rather than an individual "meal" or portion on a plate, fish is generally put on the table whole, and family members then take what they want throughout the meal.

During the discussions, we noted that the Filipino anglers (4) all reported eating the skin and parts other than the fillet (e.g. head, cheeks). Boat anglers, on the other hand, indicated that they almost always ate only the skinned fillet. Other anglers varied in their response to eating the skin.

C. Discussion of Methods to Conduct Educational Outreach

We asked participants who they thought would be the most believable agency for conveying information about fish. Given a choice between the state health department or a federal health agency, almost everyone from shore-based and boat groups believed that the state was a more believable messenger for advisory information. The majority of people also preferred the state to city or county health departments. On whether the state was a more believable messenger than non-governmental environmental agencies such as Save San Francisco Bay, the response was divided. While the majority of participants felt that the state should be responsible for this type of information, and would be less biased, several participants believed that non-governmental agencies would be more protective and more believable messengers. Many of the anglers felt that the Department of Fish and Game was a very credible messenger; however, a couple of participants felt that they were more interested in enforcing regulations, and considered their presence threatening.

We asked participants whom they would go to if they had a question regarding their health. Everyone stated their doctor as the first person they would ask about their health. Most of the doctors were identified as being connected to a health maintenance organization. Other people mentioned relatives and one individual mentioned his wife. We also asked if there were leaders in their communities who would be effective messengers for fish-related concerns. No one could identify a "leader" in their community. If the question was specifically about fish, other anglers were frequently mentioned as sources of information. Several individuals said they had already spoken to fishing friends about participating in this discussion group, and that they would be sharing with them information from this group.

Almost unanimously people did not participate in community centers, cultural centers, or other cultural/community activities. The local bar was the only "place" identified as a center for shore-based anglers. Boat anglers also indicated the yacht club as a social center for themselves.

Although we did not ask questions about in which languages fish messages should be provided, all four of the Filipino anglers who participated in the discussion group indicated that written materials in Tagalog were unnecessary. These anglers shared that given the many dialects of Tagalog, written communication is difficult, and the majority of individuals who could read Tagalog could also read English. Considering the small number of Filipino anglers who particpated in the discussion groups, clarification of this issue is merited.

D. **Sign Building Activity and Discussion**

We asked participants to assist us in the development of a fish health advisory sign, using their knowledge from our discussion. As a group, participants were shown three fish images, and asked which image they were most drawn to. The images were designed to be prototypes that could be simplified for logos, or elaborated upon for brochures and other educational materials. Each image contained two fish to visually support the advisory of two meals, or two half-pound portions, a month. Each of the three images were presented in three different color choices, making a total of nine possible images to choose from. After selecting their first choice, participants were asked to select a second choice. The most common choice for an image was of two colored fish on a line. The same image in black and white was the second most frequent choice with other images being mentioned with less frequency.

We then asked participants to assist us in the development of an advisory sign to be posted on fishing piers. Each of the signs were to contain three elements: a title, the general advisory consumption guidelines, and a the choice of additional health recommendations or information on how to obtain these recommendations. Participants in the two smallest discussion groups were allowed to create individual signs; the three larger groups developed signs as a group. A total of five signs were created. Participants were asked to choose between two word choices for the title of the sign: "Caution" or "Eat Bay Fish Safely." Three signs chose "CAUTION" as their title, two signs "EAT BAY FISH SAFELY."

Next we asked participants to choose between two grids showing consumption guidelines. The first presented the guidelines for the general population and pregnant women with size of fish; the second presented the guidelines with different consumption rates based upon individual species for men and pregnant women with size of fish. Four signs chose the simpler consumption rate, one chose the more complex.

Finally we asked participants to choose between providing information on where to write for additional recommendations and information, and one that provided information on how to prepare fish in healthier ways. Four signs chose additional information on where to write, one chose information on how to prepare fish.

The participant's choices regarding wording and content often appeared contrary to the views expressed during the earlier discussions. Individuals who had expressed

skepticism regarding the advisory sometimes chose the stronger (Caution) title for their sign. Likewise, people who wanted more information and greater freedom of choice sometimes selected the simpler consumption chart. The importance of access to more information may well have been a result of the lengthy discussion we were able to have with participants, which may have underscored the complexity of the issue.

Despite the small number of anglers who participated in the discussion groups, there were several notable observation:

- Almost none of the anglers who participated in our focus groups understood the term "sport fish."
- Use of "pounds" to indicate meal size is more acceptable than "ounces" or "grams".
- Anglers want to maintain some control over how they implement the advisory guidelines.
- None of the participants identified a "community leader" or local social or health center that could be utilized as a vehicle for delivering education.
- No single choice of words or content was preferred by the anglers in our discussion groups.

Attachment L-1

DISCUSSION GROUP -QUESTION GUIDELINES

Introductions **15 minutes**

Who we are	Presentation
Why we're having the group / **goals** / **Agenda**	Presentation
Confidentiality & recording the session	Presentation
Importance of individual answers (it's okay to disagree)	Presentation
Questions and Concerns	Q&A

Ice Breaker **10 Minutes**

Who's been out fishing in the last week?
In your opinion, has the water in the bay gotten worse? Better? Same?

Recognition / Meaning of the term "Sport Fish" **15 Minutes**

1. Have you ever heard of the term "Sport Fish" before? Show of Hands
2. What does it mean? Group Discussion
3. Where have you heard this term? Group Discussion
4. If you were to refer to <u>all</u> fish from the bay, what term would you use? Group Discussion
   - 4a. Would the term: "Fish from the Bay" be better?
   - 4b. Would the term: "Fish you catch yourself?"

Health Advisory Knowledge **20 Minutes**

1. Have you heard of a health advisory for the SF Bay? Show of Hands
2. What does it say? Discussion
3. How many fish does it say one can safely eat? Discussion
4. What types of fish does the advisory include? Discussion
5. How important do you feel this advisory is? Discussion

Understanding Lack of Behavior Change **20 Minutes**

(these questions will only be asked of the group which has indicated an awareness of the advisory, yet hasn't changed its behavior)

1. Have you changed how much you eat since hearing the advisory? Discussion
2. Do you feel the following statements are true? Show of Hands
   - 2a: The advisory isn't correct
   - 2b: The advice will change in a few years
   - 2c: I don't eat enough to hurt my health
   - 2d: I eat only healthy fish from the Bay
   - 2e: I don't plan to eat the fish forever
3. Why do you feel this/these statements are true? Group Discussion

The best way to deliver info **20 Minutes**

1. Who would you go to, trust, for advice on your health? Group Discussion
2. Who do you see as leaders, people you trust? Group Discussion
3. What groups, or agencies, do you regularly visit? Group Discussion
    3a. Where do you receive health care? Group Discussion
4. What is the best way to get this type of information to fishers? Discussion

BREAK **10 Minutes**

Educational Materials Evaluation **30 Minutes**

1. Which card would you pick up first? Group Activity
    1a. Which card would you pick up second?
2. (After reading the card) What did the card say? Group Discussion
3. Do you believe the info on this card? Group Discussion
    3a. Do think it comes from a reliable source?
    3b. What sources would be more reliable?
    3c. What would make the card/info more believable?
4. Should "one meal" be phrased in grams, pounds, or as "a meal" Group Discussion
5. What is meant by cooking juices Group Discussion
6. What part of the fish is the fillet or muscle? Group Discussion
7. How may types of fish/consumption rates can be included? Group Discussion

Build your own Sign Activity **15 Minutes**

Thanks/Closing **5 Minutes**

California Tribes Fish-Use

Final Report

California tribes have used fish for ceremony, diet, and as a part of culture for far longer than California has existed. Because of concern expressed by members of California tribes, the State Water Resources Control Board and the US Environmental Protection Agency supported the collection of information about the current and traditional use of fish by members of tribes across the state, to inform draft water regulations. We found that tribes use fish in similar patterns (fish types and source-waters) as they did traditionally, but not in terms of amounts. Tribes used 29 freshwater/anadromous fin-fish species, 23 marine fin-fish species, and 18 other invertebrate, and plant species and groups of species. Current 95th percentile rates of consumption of caught-fish varied by tribe and ranged between 30 g/day (Chumash) and 240 g/day (Pit River). The rate of fish use (frequency and consumption rate) was suppressed for many tribes, compared to traditional rates, which most tribes attributed primarily to water quantity and quality issues. This report describes the surveying approach and findings about tribes' use of fish.

Summary

Tribes have been concerned that water quality and other water-related decisions tend to lack consideration of tribes' use of water and fish. The State Water Resources Control Board and the USEPA provided funding to collaborate with tribes in discovering what the patterns of fish use were historically and are currently. UC Davis researchers worked with partner tribes to establish an appropriate approach to interviewing tribe members about fish use. Members of 40 CA tribes and tribe groups were surveyed directly at 24 locations and staff from 10 tribes were surveyed online using standard questionnaires. Traditional uses of fish were assessed using literature review and surveying of tribe members and staff. Contemporary uses were assessed using tribe member interviews. We found that tribes use fish in similar patterns (fish types and source-waters) as they did traditionally, but not in terms of amounts. Tribes used 26 freshwater/anadromous fin-fish species, 23 marine fin-fish species, and 18 other invertebrate, and plant species and groups of species. The single most commonly caught and/or eaten fish species group among all tribes was "salmon", which could include chinook or coho salmon. 95th percentile rates of consumption of caught-fish varied by tribe and ranged between 30 g/day (Chumash) and 240 g/day (Pit River). The rate of fish use (frequency and consumption rate) was suppressed for many tribes, compared to traditional rates, which most tribes attributed primarily to water quantity and quality issues.

Background

California Tribes have been fishing and eating fish for far longer than California has existed. Although practices, fishing areas, fished species, and amounts of fish eaten may have changed over time, the cultural and dietary importance of fish has not. Anglo-American anthropologists have estimated that for certain California tribes, fish consumption was at least one pound per day, which for certain coastal tribes may have been mostly salmon (Hewes, 1973; Hewes, 1942 and Hewes 1947, cited in Swezey and Heizer, 1977). This rate is similar to other reported rates in Northern California, for example, Harper and Harris (2008) report that a review of the literature reveals that Columbia River Tribes consumed about a pound of fish per day (620 gpd) before contact with Europeans led to suppression of fish populations and fish consumption.

The Karuk tribe and academic collaborators have studied their own fish use practices and health consequences of fish use (Karuk Tribe, 2004; Reed and Norgaard, 2005). They have demonstrated that the loss of salmon led to a decline in fish consumption by tribe members, and this was linked to health declines, including an increase in an incidence in diabetes, heart disease and hypertension. Because of the direct linkage between dam construction blocking salmon runs, which led to cultural, diet, and health problems for the Karuk, a case could be established that the dams should be removed.

Suppression of fish use and consumption is an important concept in the regulation of water management and problems related to development and extraction activities. Because many of these activities are permitted by state and federal agencies, there is an opportunity to reverse

the harm being caused to a use of aquatic systems, once it has been identified. Harper and Harris (2008) make the case that although fish consumption by Columbia River Tribes has been suppressed, a subset of the Tribes' members still practice original subsistence rates and that the subsistence practice should form the basis for regulatory and other means of protecting a recovered use of fish.

Aquatic organism use by California Tribes has been previously studied primarily by analyzing shell and bone fragments in middens associated with traditionally-settled areas, both before and after European colonization. Studies by Gobalet et al. (1990a, 1990b, 1992, 2004) demonstrated that tribes used at least 76 species and groups of species of marine and freshwater fish throughout California. Since colonization and displacement of tribes from most of their traditionally-fished areas, the pattern (fish targeted), geographic distribution, and rate of fish use may have changed.

Policy Framework

Water and aquatic ecosystems are protected by a number of different state and federal laws, such as the state and federal Clean Water Acts. Fish populations are further protected from endangerment and extinction by the state and federal Endangered Species Acts. Fish use by members of the public is protected as a beneficial use (when applicable) under the Clean Water Act, as a recreational use by the Fish and Game code and administratively protected on most public lands. Fish use by tribes is further protected for certain tribes with treaty rights, but not for most tribes. There is an increasingly-recognized gap between the traditional practices of many tribes to use fish for various reasons and the protection of these practices in state and federal law.

Previous studies of fish use by specific California tribes (e.g., Reed and Norgaard, 2005) and the current study suggest that new, or reformation of existing policies are needed that protect the various ways that fish use is important to tribes. These ways include health, sovereignty, culture, environment, economy, and moral/legal. Responsive policies from state and federal agencies will explicitly take these ways of use into account. Being responsive could mean developing new policies, such as SWRCB's proposed beneficial use designation for cultural and traditional use. It could also mean articulating the various ways that fish use is important in new state and federal statutes. Finally, it could mean identifying and protecting these uses in re-negotiated or new treaties between the US and tribes, or in new agreements between California and tribes.

A key component of water policy in California is the development of water quality criteria based upon standard fish consumption rates. These criteria are usually related to fish contamination (e.g., by mercury) and vary inversely with fish consumption rates. The USEPA recommends using a 90th percentile rate of consumption to protect the general population and a 99th percentile rate to protect anglers who consume their catch (USEPA, 2000). In California, both the San Francisco Bay Regional Water Quality Control Board (SFRWQCB, 2006) and the Central Valley Water Quality Control Board (CVRWQCB, 2010) have used the 95th percentile rate of consumption from regional studies to protect fish consumers. Subsistence fishing was considered in one alternative (Alternative 5) of the Delta methylmercury TMDL (CVRWQCB, 2010) as follows: "*Some people are subsistence consumers; because of tradition or need, these people have high consumption rates of locally caught fish, represented by a rate of 142.4 g/day (four to five fish meals per week). This rate is the 99th percentile consumption rate identified in a national food intake survey and recommended by USEPA for subsistence anglers and their families… Therefore, Alternative 5 is protective of (a) people who eat a very high amount of TL4 fish species*." (CVRWQCB, 2010). These various sources of guidance and policy findings support the use of a 95th or 99th percentile rate of consumption by tribes as the basis for local and regional water quality criteria, fish tissue criteria, and other water policies promulgated by the state to protect tribes' use of fish.

Methods

The sections below describe how partnerships were developed with tribes, how interviews were conducted, literature retrieval and analysis, and methods of statistical analysis.

Project Locations and Times

There were two primary types of locations where interviews were conducted: 1) tribal offices and 2) tribal or inter-tribal events. The tribes and event locations were distributed widely across California (Figure 1). Interviews were conducted between 1 and 3 times for each tribe between May/2013 and June/2014 (Table 1).

Figure 1. **Tribe and interview locations in California.**

Table 1 **Tribe locations and identities (in parentheses) and month when interviewing was carried out.**

Partner Tribes/Locations	Interview Months
Upper Lake Rancheria (Habematolel Band Pomo)	5,7/2013
North Coast Campout (Inter-Tribal)	6/2013
Bridgeport Indian Colony (Paiute)	6/2013
Big Valley Rancheria (Big Valley Band Pomo)	7/2013
Sugar Bowl Rancheria (Scotts Valley Band Pomo)	7,11,12/2013
Stewarts Point Rancheria (Kashia Band Pomo)	8/2013
Buena Vista Rancheria (Me-Wuk)	8/2013

Blue Lake Rancheria (Wiyot & Yurok)	8/2013
Round Valley Rancheria (Yuki, Pit, Pomo, Nomlacki, Concow, Wailaki)	9/2013
Bear River Rancheria (Mattole & Wiyot)	9/2013
Fort Bidwell Reservation (Northern Paiute)	9/2013
Big Pine Indian Reservation (Paiute)	10/2013
Wiyot Tribe Reservation (Wiyot)	11/2013
Bishop Reservation (Paiute)	12/2013
Death Valley (Timbisha Shoshone)	12/2013
Mechoopda Indian Tribe of Chico Rancheria (Maidu)	3/2014
North Fork Rancheria (Mono)	4/2014
Big Sandy Rancheria (Mono/Monache)	4/2014
Grindstone Indian Rancheria (Wintun-Wailaki)	4/2014
Manchester/Pt. Arena (Pomo)	4/2014
Santa Ynez Rancheria (Chumash)	5/2014
Chemehuevi Reservation (Chemehuevi)	5/2014
Fort Mojave (Mohave)	5/2014
Pit River (Achomawi & Atsugewi)	6/2014

Collaboration with Tribes

The project was inspired by tribes expressing the need for the state and federal agencies to use information about tribes' use of fish in setting water quality standards and thresholds. Tribes were also consulted about appropriate techniques to use to approach tribes and individual tribe members, appropriate questions to ask individuals, and the types of information that would be important to collect. This consultation led to the development and refinement of the questionnaires and the methods used in the field. Tribes suggested collecting information about historical uses of fish, traditional and customary uses of fish, contemporary uses of fish, and threats and causes of fish use reduction (if any).

Contact with Tribes

All 146 federally-recognized and state-recognized tribes and one tribe that has neither recognition (Winnemem-Wintu) were contacted twice by email and letter-mail to solicit their participation in the project. About two-dozen tribes responded by email, phone, or in-person at meetings that they would be interested in further discussion and possible participation. Of these, 12 participated and the remainder changed their position about participating. After

learning about the project in various ways (e.g., word-of-mouth), another 12 tribes wanted to participate.

Various reasons were given for not wanting to participate in the project. One major concern was that the federal and state governments and the University of California had all violated trust in various ways in the past and that regulatory, trust, and land management agencies were inconsistent in their consideration of tribes' needs, interests, and indigenous rights and uses of land and water. It is important to consider non-participation in this project NOT as lack of interest in fish use, but rather some combination of lack of time/resources to participate, political resistance to governmental intrusion, and knowledge of past failure of government to act to protect tribal interests.

Interview instruments

Two questionnaires were used to interview tribe members in the field, one focused on traditional uses and threats to uses (Appendix 1) and the other focused on contemporary uses and threats to use (Appendix 2). The traditional use questionnaire included questions about tribe's traditional fishing dependence, fishing areas, and traditionally-used fish. The questionnaire also included questions about past rates of consumption of traditionally-used fish and whether and why current fish use might have been impaired compared to traditional patterns. The contemporary use questionnaire included questions based on 30-day recall about the frequency of fishing and consumption of particular locally-caught and store-bought fish species. It also included questions about reasons that fish use may be less than desired or anticipated, as well as basic household and demographic information.

Tribes were also surveyed using an online instrument focused on tribes' traditional and customary use of fish (Appendix 3). The questionnaire contained questions focused on whether tribes used and still use fish, the types of fish used, the frequency tribes traditionally ate fish, and the barriers to fish use. Tribe staff were contacted via email and provided a link to the survey. This online questionnaire was used to reach additional tribes that were not involved in the two field surveys.

Field interviews

Field interviews were carried out in two primary ways: 1) working with tribes to organize tribe members on certain days when UC Davis staff could come and interview them and 2) working with tribes to find out how to engage in specific tribe events where interviewing tribe members was feasible. This approach is different from the method that an epidemiological study might use of randomly sampling a population, based on tribe rolls, and conducting in-person or phone interviews. The demographic mix (income, age, and gender) that resulted from our approach led us to believe that we had incidentally interviewed a random subset of each tribe. To encourage tribe members to come on certain days to be interviewed, staff would announce to the tribe members via email list-serves, newsletter announcements, and posted fliers (on notice boards) that interviews were going to take place. All tribe members were invited and no attempt was made to target anglers and users of fish specifically. Tribe cultural and community events were assumed to attract a cross-section of each tribe. People were approached opportunistically at these events, or sometimes people approached the interviewers at the UC Davis project booth.

Literature review

Available literature about tribes' fish use was searched from tribal and academic library resources. Several kinds of information were retrieved from these sources: 1) narrative descriptions of traditionally-fished areas, 2) narrative or quantitative description of rates of fish use and consumption, 3) narrative description of fish species used, and 4) descriptions of and threats to and changes in fish use. This information was important in understanding what fish tribes had traditionally relied upon and is important context for reports of current fish use.

Data management

Data from the questionnaires were entered into Excel spreadsheets by the field interview staff and the project lead. Photocopies of the questionnaires were kept by the field staff until safe delivery of the originals to UC Davis, then destroyed. Original questionnaire forms were kept in a locked file cabinet inside a locked office at UC Davis. Data entered into Excel spreadsheets were kept in password-protected computers. Incomplete questionnaire responses were retained as blanks in the spreadsheet. Any questions about individual responses were resolved

by discussions between the field staff and the project lead. All tribes were informed that they had the right to refuse sharing of the data after it had been collected. No tribe used this right.

Coding of interview responses

Narrative responses to questions were recorded as either one of the existing possible answers to questions, or as a new type of answer to the question. One of the questions referred to why a certain fish that had been eaten in the past was not consumed in the last 30 days. Answers were grouped by type of response, for example many respondents to this example questions said that they had not been fishing for the fish, or it was out of season. These types of answers were grouped as response types. If too few people responded with particular answer-types, then these more individual responses were retained, but not coded and therefore lumped together.

Mapping waterways for fishing

Tribe members were asked to list waterways where they had traditionally/historically caught fish and waterways where fish originated that they had consumed in the last 30 days. This list of waterway names was used to select hydrologic unit code-10 (HUC-10) watersheds from a standard USGS HUC map using ArcGIS 10. The HUC-10 scale was chosen because it was the smallest HUC scale that captured full waterways, such as specific creeks. For each tribe, 2 maps were created: 1) core traditionally-fished watersheds (identified by 2 or more respondents), and 3) watersheds where currently-consumed fish were obtained.

Statistical Analyses

State regulatory processes typically use the 95th percentile rate of fish consumption to calculate target contaminant concentrations that will protect most users (CVRWQCB, 2008). In order to represent as many native fish-users as possible, we calculated 95th and 99th percentile fish use rates. The mean use rate was not calculated or reported, because it has no meaning in policies intended to be protective of most or all users. The measures examined included frequency of fish consumption, fish portion sizes and fish consumption rates.

Frequency of traditional fish consumption was reported in one of 6 categories (>1 meal/day, 1/day, 2-3/week, 1/week, 1/month, <1/month). Frequency of contemporary consumption was reported as # meals in last 30 days and for comparison with traditional frequencies was converted to the frequency categories used for the traditional interviews. Traditional and contemporary frequency distributions among all tribe respondents were tested for significant differences using a Chi-test R (a statistical package; R Core Team, 2013) for two independent sample frequency distributions.

Traditional fish consumption rates were calculated by multiplying individually-reported frequencies of consumption by an estimated portion size of fin-fish. Meal portion sizes were estimated using the average and 95^{th} % portion size from the contemporary survey. The assumption of a similar portion size in the past and current consumption could be questionable, it was a conservative approach considering the lack of data on fish meal portion size from the past. The average consumption rate obtained was then multiplied by the traditional frequency numbers to get estimates of traditional consumption rates (grams per day).The comparison of traditional and contemporary fish consumption rates was carried out using the Wilcoxon-Mann-Whitney test, which is a suitable non-parametric test for two independent samples for which the dependent variable is not normally-distributed.

Fish consumption rate comparisons were also tested at more specific levels: at the tribe level and the regional level. For tribe comparisons, only those with samples sizes of 10 or more respondents were used. The regional level comparisons have been based on the Water Board region classification for California.

Results

Traditionally Fished Watersheds

Tribes traditionally used most or all streams in their national territories. This traditional use has been reduced in most cases to a set of streams and watersheds that are still used, or were used by recent generations (Figure 3). When present, ancillary areas were often at least as large as the core areas. In some cases, nearby tribes fished the same watersheds.

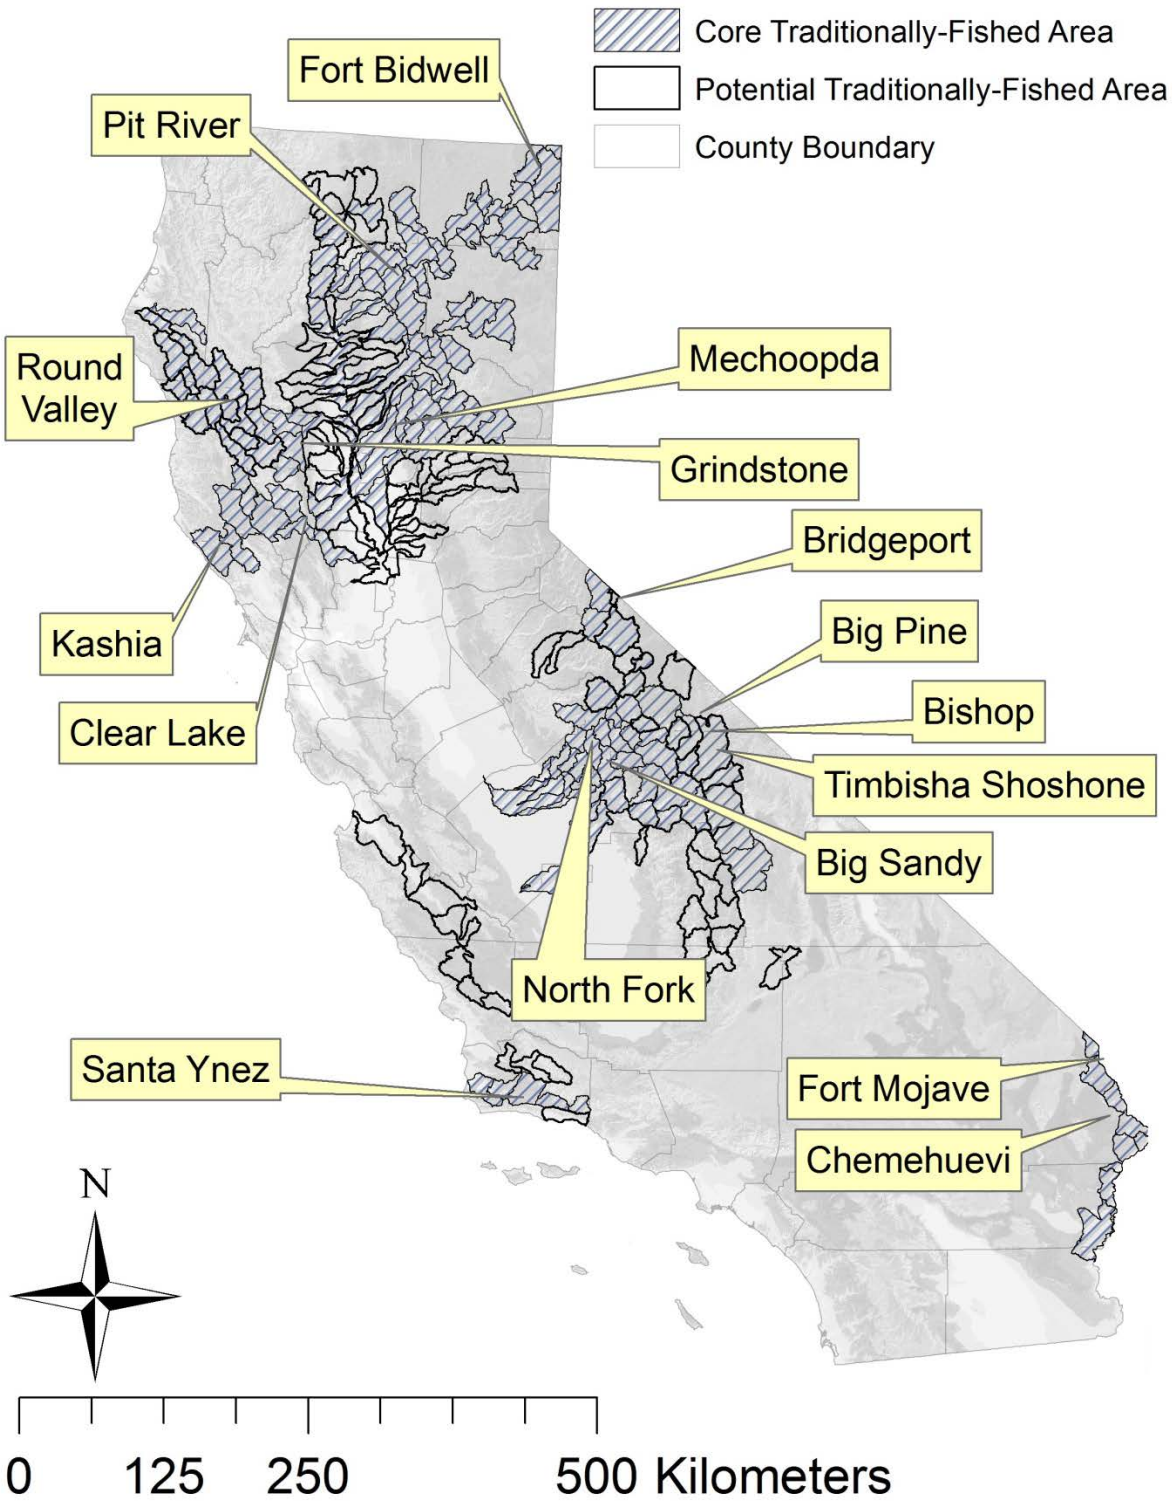

Figure 3. Traditionally-fished watersheds (hydrologic unit code HUC-10). Areas with darker color represent areas where fishing areas of more than one tribe overlapped.

Traditional Reliance of California Tribes on marine, estuarine, and freshwater aquatic organisms

California tribes have longed relied on bony and cartilaginous (e.g., sharks) fish. Much of this reliance has been recorded by the tribes by themselves and by archaeologists who have investigated midden piles at pre- and post-contact village sites (Table 2).

Table 2. Fish species relied upon historically/traditionally by California tribes.

Region	Tribe(s)	Marine, estuarine, freshwater	Fish Species/Groups	Top 5 (Marine, estuarine, freshwater)
North Coast (Karuk Tribe, 2009)	Karuk	All	Salmon, steelhead, sturgeon, trout, lamprey, suckers	*(list not prioritized) Salmon, steelhead, lamprey, sturgeon, trout, suckers
San Pablo Bay (Gobalet, 1990a)	Ohlone	Marine	Shark, rays, skates, herring, sardine, anchovy, midshipman, smelt, white seabass, surfperch, shiner perch, seaperch, pile perch, monkeyface prickleback, rockfish, sanddab	Sturgeon, sardine/herring, salmon, bat ray, topsmelt/jacksmelt
		Estuarine	Sturgeon, threadfin shad, salmon, striped bass, surfperch, gobies, longjaw mudsucker, sculpin, flounder	
		Freshwater	Minnows, splittail, hitch, hardhead, Sacramento sucker	
Delta, Cache Ck (Gobalet, 1990b)	Ohlone, Pomo, Patwin	Estuarine	Sturgeon, salmon, delta smelt,	
		Freshwater	Carp/minnow, thicktail chub, hitch, California roach, hardhead, Sacramento blackfish, splittail, Sacramento pikeminnow, speckled dace, Sacramento sucker, threespine stickleback, prickly sculpin, perch	Carp/minnow, perch, Sacramento sucker, salmon/steelhead, thicktail chub
South Bay, Central Coast (Gobalet, 1992)	Coastanoan	Marine	Shark, ray, longjaw mudsucker, anchovy, rockfish, pile perch, cabezon, rock prickleback, silverside, topsmelt, jacksmelt, herring/shad/sardine	Silverside, carp/minnow, Sacramento perch, Sacramento sucker, sturgeon
		Estuarine	Sturgeon, steelhead, salmon	

		Freshwater	Sacramento perch, Sacramento sucker, carp/minnow, thicktail chub, hitch, hardhead, Sacramento blackfish, splittail, Sacramento pike minnow	
	Chumash	Marine	Shark, ray, skate, herring/sardine, anchovy, jacksmelt, white sea bass, white croaker, corbina, black croaker, drum/hardheads, senorita, sheephead, kelp bass, sea bass/grouper, skipjack tuna, bonito, mackerel, albacore, yellowtail, barracuda, shiner perch, rubberlip seaperch, pile perch, surfperch, opaleye, lingcod, rockfish, halibut, flatfish	herring/sardine, shark, anchovy, ray, senorita
		Estuarine	Steelhead	
		Freshwater	Arroyo chub	
Sacramento Valley watershed (Gobalet et al., 2004)	Maidu, Wintu, Nomlacki, Wailaki, Pomo, Me-Wuk		Sturgeon, thicktail chub, hitch, California roach, hardhead, Sacramento blackfish, splittail, Sacramento pike minnow, speckled dace, Sacramento sucker, steelhead, chinook salmon, delta smelt, longfin smelt, threespine stickleback, sculpin, Sacramento perch, tule perch	Sacramento perch, Sacramento sucker, thicktail chub, Oncorynchus spp., Sacamento blackfish
San Joaquin Valley watershed	Mono, Yokuts	Freshwater	Sturgeon, thicktail chub, hitch, hardhead, Sacramento blackfish, splittail, Sacramento pikeminnow, Sacramento sucker, Chinook salmon, Sacramento perch, tule perch	Sacramento perch, Sacramento sucker, Sacramento blackfish, hitch, tule perch
		Marine	Shark, ray, yellowtail, barracuda	
Central Coast (near SB)	Chumash	Marine	Shark, smoothhound, skate, guitarfish, ray, herring/shad/sardine, anchovy, midshipmen, northern clingfish, silverside, rockfish, lingcod, sculpin, sea bass, yellowtail, jack mackerel, drum/croaker/hardhead, white sea bass, white croaker, queenfish, opaleye, shiner perch, perches, pile perch, barracuda, senorita, sheephead, kelpfish, longjaw mudsucker, bonito, chub mackerel, swordfish, flatfish, ocean sunfish	
		Freshwater	Steelhead, threespine stickleback	

Fish Historically Present in Traditionally-Fished Watersheds

Freshwater fish historically present in waterways fished traditionally by tribes were derived from the PISCES database (http://pisces.ucdavis.edu). According to this database, the number of species historically available in traditionally-fished areas varied between 2 (Fort Bidwell Paiute) and 12 (Mechoopda) species. This range is likely a function of the size of the area, the fish species diversity of the bioregion within which the tribe fishes, and the thoroughness of surveys of fish presence.

Tribe/Region	Fish Species
Bishop Paiute	Owens sucker, Owens speckled dace, Long Valley speckled dace, Kern River rainbow trout, Central California roach, Sacramento pikeminnow,
Bridgeport Paiute	Mountain sucker, Lahontan redside, Lahontan speckled dace, Lahontan cutthroat trout, mountain whitefish
Big Pine Paiute	Owens sucker, Owens speckled dace, Long Valley speckled dace
North Fork	Central California roach, hardhead, Sacramento pikeminnow, Sacramento hitch, Sacramento perch, Sacramento tule perch
Grindstone	Sacramento hitch, hardhead, Sacramento pikeminnow, Pacific lamprey, Chinook salmon, Central California roach, Central Coast coho salmon
Mechoopda	Hardhead, Sacramento pikeminnow, Pacific lamprey, Chinook salmon, Central California roach, Sacramento perch, Sacramento tule perch, Sacramento hitch, riffle sculpin, Lahontan redside, Lahontan speckled dace, mountain sucker
Fort Bidwell Paiute	Pacific lamprey, Northern (Pit) roach,
Clear Lake Pomo	Sacramento perch, Sacramento hitch, hardhead, Sacramento pikeminnow, Sacramento tule perch, Pacific lamprey, Chinook salmon, Central California roach, Central Coast coho salmon, coastal cutthroat trout
Kashia Pomo	Pacific lamprey, coastal cutthroat trout, Central Coast coho salmon, Sacramento pikeminnow, hardhead

Traditional Pattern of Fish Use

Traditional fish use among tribes varies geographically, based on a combination of local fish availability and trade with other tribes. We found that tribes used a wide range of aquatic species and organism types (Table 3). Salmon was reported as traditionally-used by all tribes except Timbisha Shoshone (Table 3). There was a tendency for the number of types of aquatic organism to increase based on the number of people interviewed (Figure 2), suggesting that it would be useful in the future to interview at least 20 to 30 people per tribe about traditionally-used organisms.

Table 3. Aquatic species and species groups historically used by tribe-members interviewed.

Tribe	Aquatic spp. (#)	Aquatic species (types)
Me-Wuk (1)	5	Striped bass, catfish, clams, mussels, salmon
Nomlacki (12)	20	Catfish, sucker, pike, salmon, steelhead, Sacramento pike minnow, hitch, surf-fish, black bass, trout, perch, carp, bluegill, crayfish, mussels, clams, abalone, seaweed, kelp, tule
Maidu (10)	17	Bluegill, bass, carp, catfish, trout, eel, salmon, perch, rainbow trout, pike, sturgeon, steelhead, crayfish, clams, mussels, tule, seaweed
Paiute (35)	17	Tui chub, speckled dace, sucker, pupfish, rainbow trout, salmon, catfish, Lahontan cutthroat, brook trout, brown trout, perch, brine fly larvae, freshwater clams, snails, watercress, tule
Timbisha Shoshone (9)	8	Brook trout, golden trout, rainbow trout, brown trout, carp, bass, catfish, pupfish
Mojave (4)	14	Trout, striped bass, catfish, humpback catfish, carp, bullhead, steelhead, rainbow trout, bluegill, sturgeon, black bass, bonytail chub, minnows, crayfish
Washoe (2)	3	Trout, salmon, catfish
Mono (13)	16	Rainbow trout, brown trout, salmon, steelhead, black bass, perch, sucker, bluegill, eel, carp, minnows, crayfish, mussels, clams, water cress, cattails
Chemehuevi (24)	15	Black bass, catfish, striped bass, bonytail chub, razorback sucker, humpback chub, bluegill, red-ear sunfish, Colorado humpback chub, Sacramento pike minnow, trout, carp, crappie, crayfish, clams
Pit River (13)	17	Salmon, trout, sucker, red-band trout, steelhead, catfish, sturgeon, eel, black bass, bluegill, perch, crab, crayfish, mussels, clams, water cress, water lily
Wiyot (1)	2	Salmon, sturgeon
Wailaki (2)	6	Salmon, trout, surf fish, crab, mussel, seaweed
Pomo (56)	27	Catfish, carp, bluegill, crappie, blackfish, perch, sucker, cod, shark, tuna, surf fish, salmon, trout, cabezon, rockfish, bullhead, crab, crayfish, barnacles, mussels, abalone, snails, sea urchins, sea anemone, kelp, seaweed, tule

Pomo/Wailaki (5)	16	Catfish, surf fish, salmon, blackfish, night fish, cod, abalone, hitch, bass, carp, bluegill, perch, eel, crab, mussels, seaweed
Chumash (7)	30	Salmon, trout, black bass, catfish, rockfish, steelhead, swordfish, sailfish, shark, sardine, tuna, halibut, perch, sea bass, surf-fish, mackerel, smelt, eel, crayfish, lobster/crab, abalone, snails, oyster, mussels, clams, urchin, cattails, seaweed, kelp

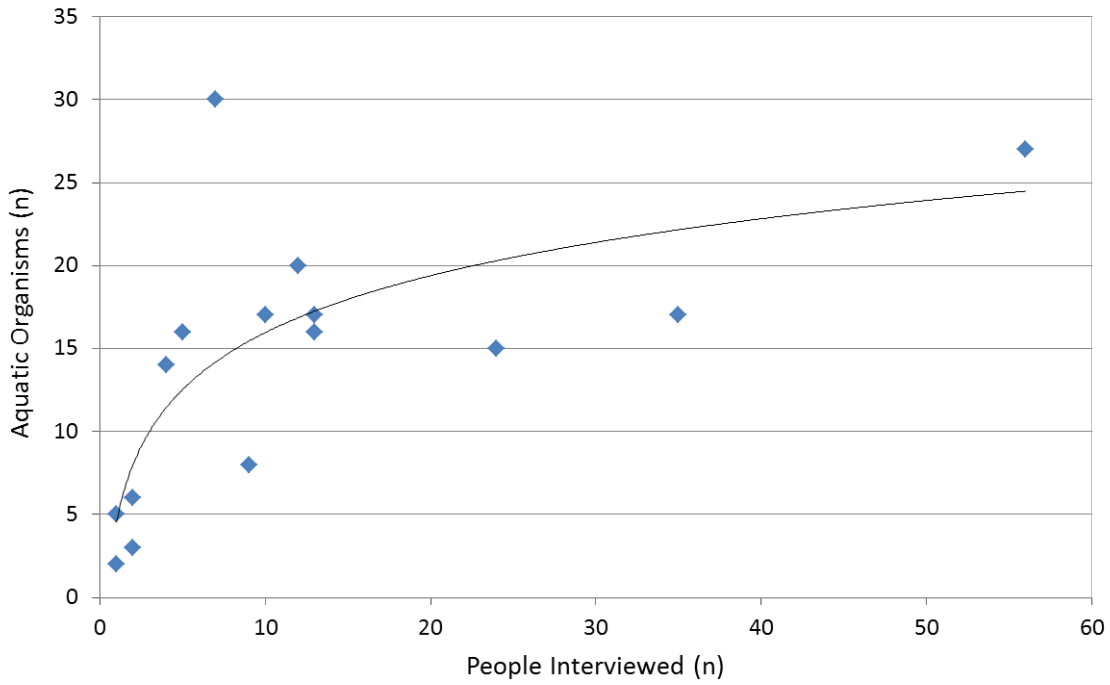

Figure 2. Comparison of number of aquatic organisms reported used by a tribe and the number of people interviewed. The log curve fit better than a linear regression (based on R).

The patterns of traditional fish use by tribes in different regions varied considerably (Table 4). Fish species used in certain regions were not used in others, most likely because of lack of availability. For commonly-used species and species groups (e.g., trout and black bass), the proportions varied among regions. The overall effect was that patterns varied among tribes and among regions.

Table 4. Fish species and groups historically used by tribe-members within each Region. Black bass includes both largemouth and smallmouth bass.

	Water Board Region				
Species	**Central Coast**	**Central Valley**	**Lahontan**	**North Coast**	**Total**

Traditional Rates of Fish Use

Most respondents to traditional-practices surveying (64%) reported eating fish every day, or more than once a day when they were young (Figure 4). About 90% of respondents ate fish more frequently than once per week.

Rates of fish consumption (of any fish species) were calculated for each respondent to the traditional survey (rate = meal size X frequency). For an average meal size of 7.9 oz, 95th % rates were up to 222.9 g/day for Maidu, Paiute, Pomo, Wailaki, and Yurok tribe members. For a 95th % meal size of 17.5 oz, rates were up to 496.1 g/day for Maidu, Paiute, Pomo, Wailaki, and Yurok tribe members.

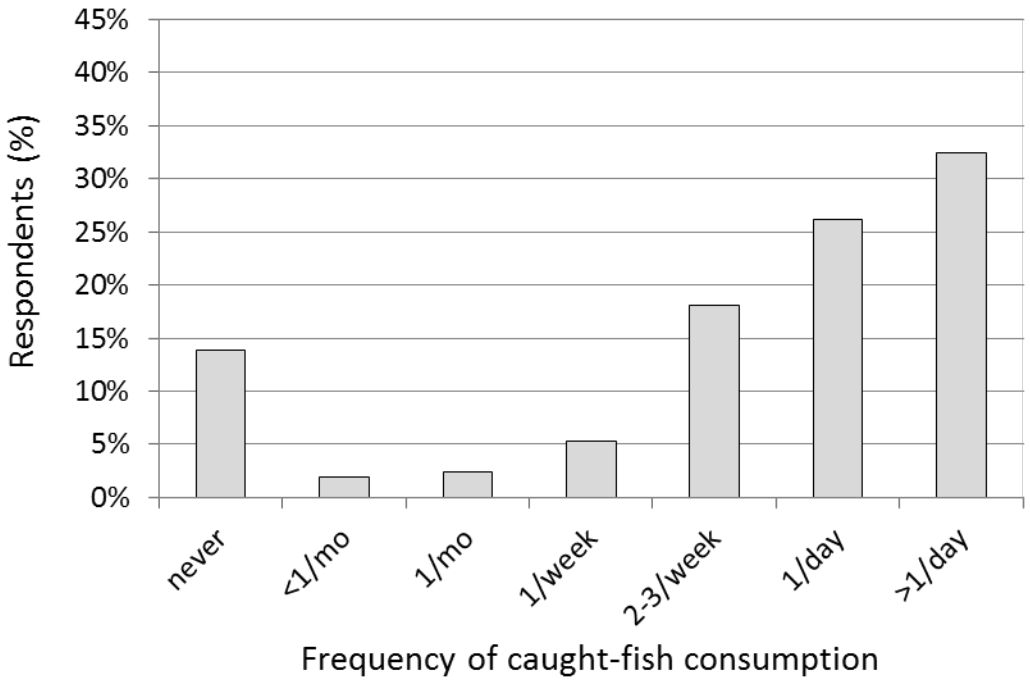

Figure 4. **Traditional frequencies of fish consumption.**

The vast majority of respondents reported that fishing and eating fish was culturally and traditionally important to tribes and an important part of tribe members' diet (Figure 5). Conversely, the majority reported that these traditional practices were not maintained now.

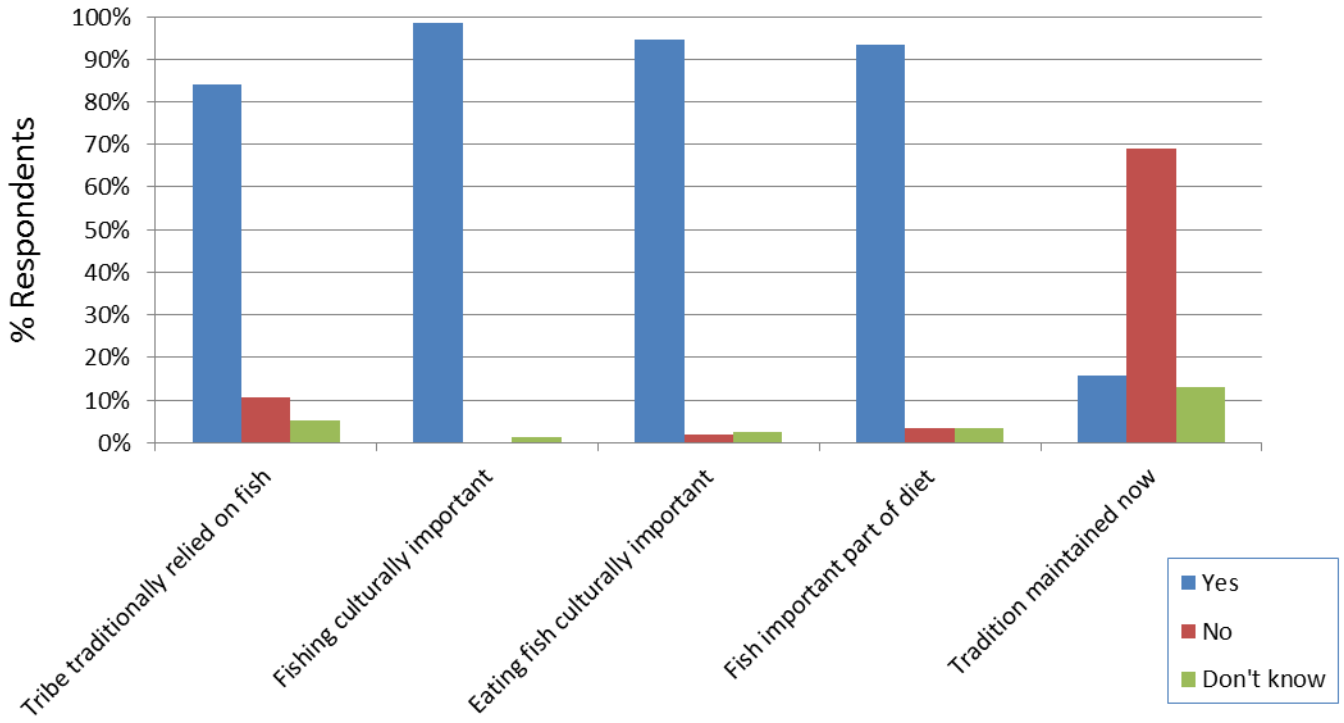

Figure 5. Fish use traditions and maintenance of traditions today.

Contemporary Places for Catching Fish

Where there were sufficient respondents, watersheds were identified from which tribe members had obtained fish in the last 30 days (Figure 6). In most cases, fished areas were adjacent to the tribes' Rancherias or Reservations. Most tribes had received salmon from the lower Klamath River watershed and many had caught fish from the ocean and coastal areas.

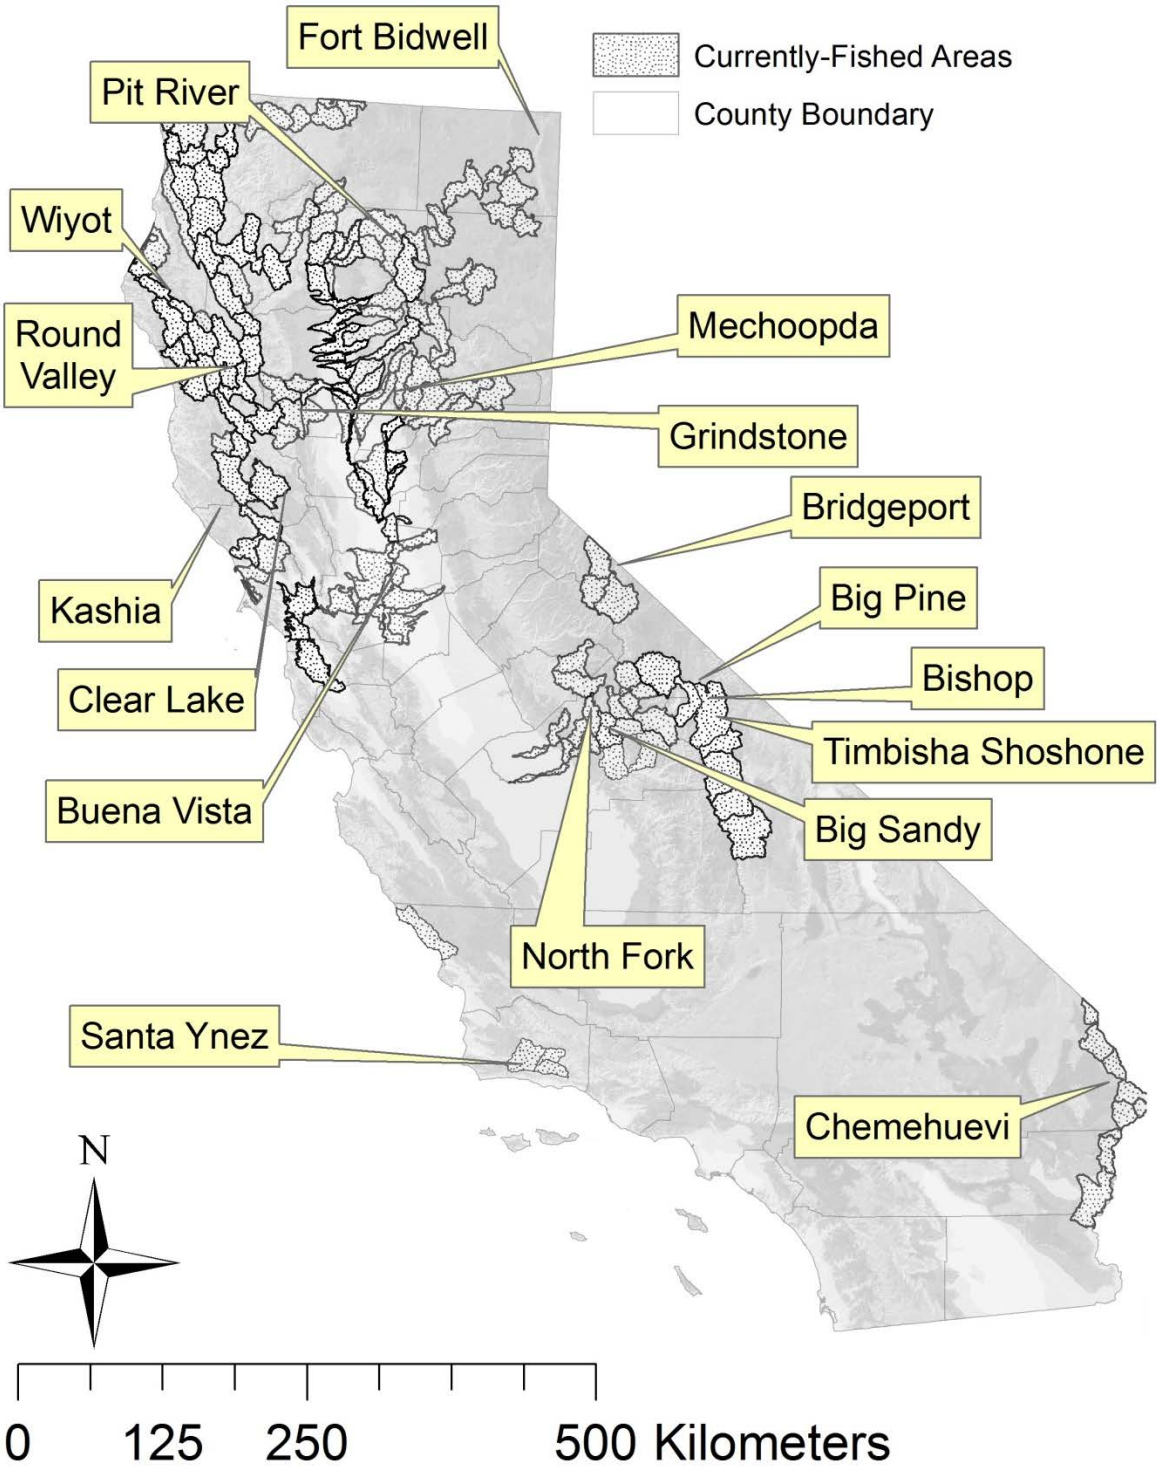

Figure 6. Currently-fished watersheds (hydrologic unit code HUC-10). Areas with darker color outlines represent areas where fishing areas of more than one tribe overlapped.

As was the case with the use of different types of aquatic organism, the number of places reported as being sources of fish increased based on the number of people interviewed (Figure 7), suggesting that it would be useful in the future to interview at least 30 people per tribe about places fished.

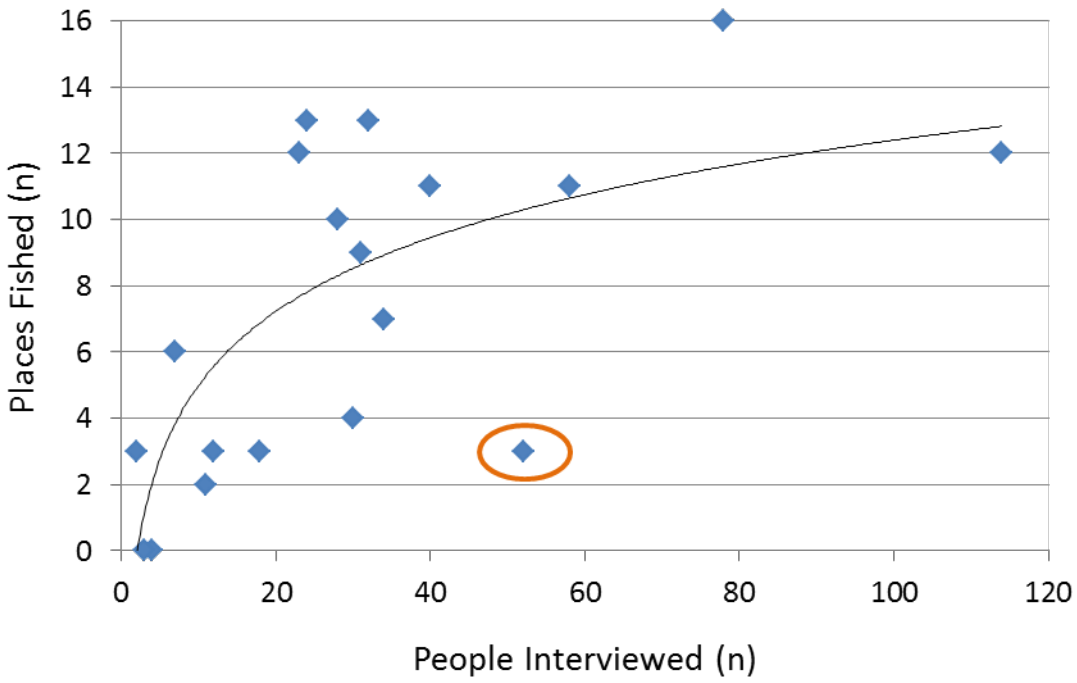

Figure 7. Relationship between # of people interviewed and number of places from which fish was caught and eaten. The log curve fit better than a linear regression (based on R). The circled point represents a desert tribe where 3 large places were cited as sources of fish.

Contemporary Pattern of Fish Use

Contemporary fish use among tribes varies geographically, based upon local native and non-native fish availability. We found that tribes used a wide range of aquatic species and organism types (Table 5). Salmon was reported as currently-used by all tribes and for most tribes was among the top 3 fish species/groups used (Table 5). For most tribes, current fish use was similar to historical use by the same tribe, where similarity was indicated by dividing the number of fish that are currently used that were used historically, divided by the total number historically used. As was the case with traditional use, there was a tendency for the number of types of

aquatic organism to increase based on the number of people interviewed (Figure 8), suggesting that it would be useful in the future to interview at least 30 people per tribe about currently-used organisms.

Table 5. Aquatic species and species groups used by each tribe interviewed. The number of people from each tribe is indicated in parentheses following the tribe name. Similarity was calculated as the number of currently-fished species/groups divided by the number traditionally-fished (underlined, cf. Table 3).

Tribe/Location	Aquatic species /species groups	Similarity (%)
Me-Wuk (37)	Salmon, trout, sturgeon, catfish, striped bass, bivalves, lobster/crab, crayfish, halibut, abalone, carp, sunfish/bluegill, perch, largemouth bass, snapper, cod, rockfish, lamprey/ eel, crappie, smelt, shrimp, squid, steelhead, American shad	100
Nomlacki (31)	Catfish, salmon, trout, abalone, lobster/crab, seaweed, bivalves, striped bass, largemouth bass, shrimp, sunfish/bluegill, carp, surf-fish, perch, sturgeon, kelp, Sacramento pikeminnow, lamprey/ eel, shark, sucker, crappie, hitch, steelhead, halibut, squid	80
Mono (6)	Salmon, trout, striped bass, largemouth bass, catfish, bivalves, smallmouth bass, sunfish/bluegill, sucker, lobster/crab, watercress	47
Maidu (32)	Salmon, trout, catfish, lobster/crab, largemouth bass, striped bass, crayfish, abalone, shrimp, bivalves, seaweed, sunfish/bluegill, sturgeon, carp, halibut, cod, tuna, perch, lamprey/ eel, rockfish, Sacramento pikeminnow, crappie, surf-fish, smallmouth bass, hitch, snapper, lingcod, tilapia, seabass, shark	47
Paiute (Bishop, 17)	Trout, salmon, catfish, crayfish, bivalves, largemouth bass, water cress, sunfish/bluegill, lobster/crab, brine fly larvae, carp, tule, striped bass, codfish, abalone, tuna, rockfish, perch, frog, sturgeon, lingcod, tilapia, haddock, algae, cattails	50
Paiute (Big Pine, 24)	Salmon, trout, crayfish, catfish, lobster/crab, bivalves, shrimp, largemouth bass, carp, sunfish/bluegill, striped bass, triggerfish, swordfish, mahi mahi,	29
Paiute (Bridgeport, 18)	Salmon, trout, catfish, crayfish, striped bass, largemouth bass, sunfish/bluegill, cui cui, tui chub, bivalves, sturgeon, smallmouth bass, perch, carp, pupfish, mountain whitefish, sucker, lobster/crab, abalone	57
Northern Paiute (Fort Bidwell, 11)	Salmon, trout, catfish, crayfish, lobster/crab, bivalves, abalone, largemouth bass, sturgeon, shrimp, cutthroat trout, striped bass, walleye, snapper, squid, scallop	36
Timbisha	Trout, catfish, salmon, crayfish, largemouth bass, lobster/crab, bivalves,	80

Shoshone (14)	sunfish/bluegill, striped bass, carp, watercress, shrimp, tuna, halibut, squid, shark, perch, crappie, rooster fish, cod, abalone, brine shrimp larvae, snail	
Washoe (6)	Salmon, trout, catfish, smelt, abalone, striped bass, largemouth bass, smallmouth bass, perch, sunfish/bluegill, sturgeon, steelhead, bivalves, crayfish	100
Chemehuevi (46)	Striped bass, catfish, largemouth bass, salmon, trout, sunfish/bluegill, crayfish, bivalves, lobster/crab, carp, abalone, tuna, smallmouth bass, sturgeon, shark, swordfish, tilapia, perch, halibut, sea bass, cod, orange roughy, squid, seaweed	60

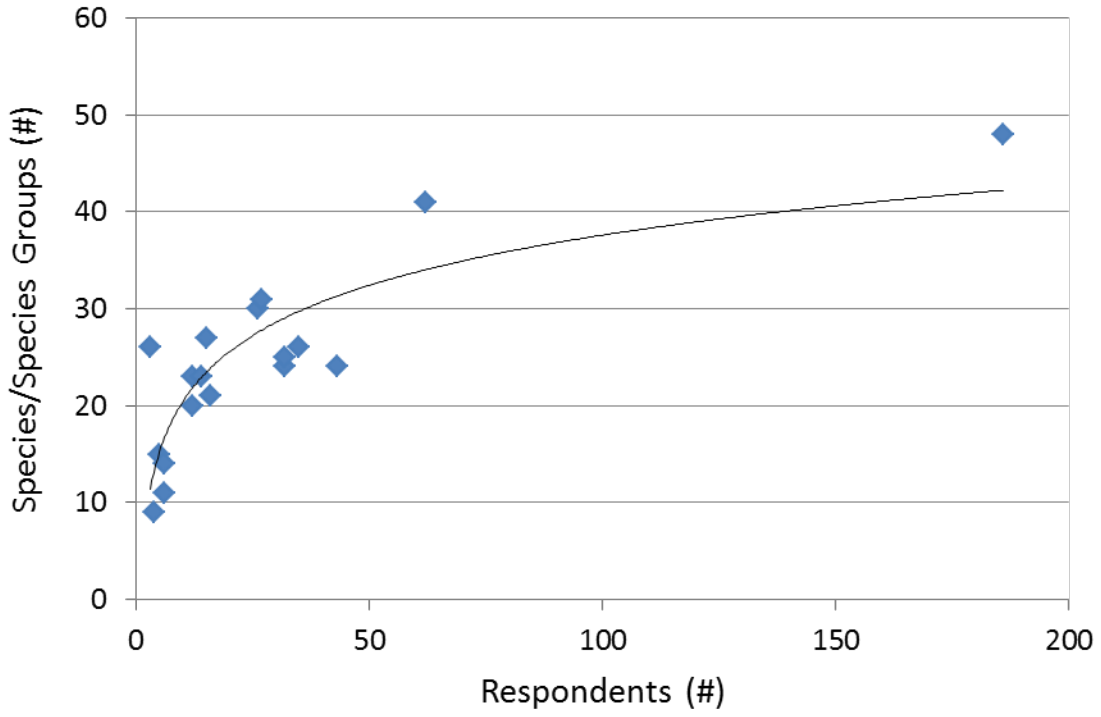

Figure 8. Relationship between # of people interviewed and number of aquatic organisms species and species groups caught and eaten. The log curve fit better than a linear regression (based on R).

Tribe and Region Standard Rates of Fish Consumption

Where there was sufficient information, the contemporary frequency of fish use was compared to the frequency of traditional fish use. For all tribes as a group, there was a significant difference ($P<0.001$) between contemporary and traditional frequencies of using fish. This is

reflected in the distributions of frequencies (Figure 9), with contemporary frequencies of eating fish skewed toward low frequencies (never to once per month) and traditional frequencies skewed toward high frequencies (once per day).

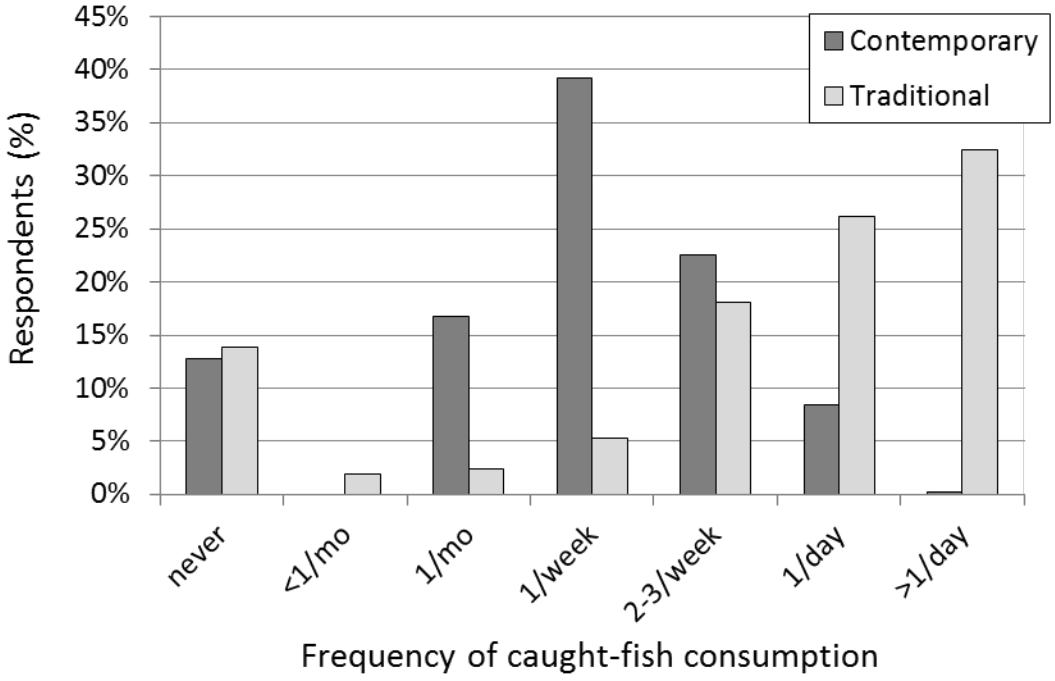

Figure 9. Comparison of contemporary and traditional frequencies of fish use

Tribe-specific rates of fish use were calculated for individual species, groups of species, for all caught finfish, and for all aquatic organism use. Of particular interest for state water policy formulation is the rate of use of caught-fish (all finfish retrieved from state waters). The 95th percentile rate of contemporary caught-fish consumption for all tribes as a group was 141.8 g/day (Table 6). This rate was significantly different from the traditional rate, which was estimated as frequency per individual times average portion size from contemporary consumption. The estimated 95th percentile traditional consumption rate was at least 222.9 g/day (one 7.88 oz average portion size per day) for all tribes interviewed.

Table 6. Contemporary rates of fish and other aquatic organism consumption for all interviewed tribe members.

Component	Min (g/day)	Max (g/day)	95th % (g/day)	99th % (g/day)
Salmon	0	382.7	72.6	179.9
All caught fish	0	623.7	141.8	240.2
Bought fish	0	255.1	60.8	152.1

Other aquatic organisms	0	402.6	27.7	96.8
Total fish	0	623.7	181.9	333.2
Total aquatic organisms	0	708.7	200.0	400.0

Importance of Salmon

Salmon was reported as being currently consumed by almost every tribe member interviewed, regardless of tribe and was the most common single type of fish consumed by tribes individually and collectively (Tables 6 & 7). North Coast tribes generally consumed more salmon and a larger proportion of caught fish as salmon than interior tribes (Central Valley, mountains, and desert). This pattern held when tribes' fish uses were grouped by Water Board Region: Lahontan, Central Valley, North Coast, and Central Coast (Table 8).

Table 7. Proportion of consumed caught-fish composed of salmon for each tribe.

Tribe Name (n)	Salmon (95th % g/day)	Caught fish (95th % g/day)	Total fish (95th % g/day)	% Caught = Salmon
Me-Wuk (32)	22.4	57.2	99.7	39
Maidu (26)	69.1	133.6	183	52
Pit River (17)	196.2	240.4	277.3	82
Paiute (52)	28.3	59.5	81.5	48
Northern Paiute (11)	37.6	63.1	99.9	60
Timbisha Shoshone (14)	39.8	104	257.8	38
Mono (6)	29.8	42.2	52.1	70
Chemehuevi (43)	0	110.3	178.6	0
Pomo (183)	28.3	59.2	101.8	48
Pomo-Wailaki (12)	28.9	34.8	59.2	83
Wailaki (16)	19.8	81.5	85.8	24

Table 8. Proportion of caught fish composed of salmon within each region.

Water Board Region (n)	Salmon (95th % g/day)	Caught fish (95th % g/day), (99th% g/day)	Total fish (95th % g/day) , (99th% g/day)	% Caught = Salmon
Central Valley (288)	42.5	83.1, 203.8	125.1, 264.3	51
Lahontan (135)	20.4	71.9, 126.1	122.6, 206.8	28
North Coast (107)	119.1	162.2, 374.1	180.3, 374.8	74
Central Coast (12)	8.2	29.8, 47.9	55.4, 56.8	27

Barriers to Traditional Fish Use

Tribe members were asked why traditional fishing and fish use practices were not maintained. Responses ranged widely, but centered around two main themes – aquatic ecosystem conditions and being able to fish. Degraded stream/water conditions and the loss of fish populations were the most commonly cited barriers to traditional fish use, followed by regulatory and access restrictions (Table 9).

Table 9. Reasons traditional and contemporary fish use practices were not maintained for all tribes as a group (traditional, n=152 respondents; contemporary, n=394 respondents).

Reasons Traditions Not Maintained	% Traditional Respondents	% Contemporary Respondents
Aquatic ecosystem condition		
Fish declines	45%	24%
Concerns about water/fish quality	42%	11%
Streams dried up	37%	16%
Fish locally extinct	16%	ND
Land/water development	10%	ND
Ability to fish		
Regulation/limits/restrictions	18%	18%

Access to traditional fishing areas	15%	15%
License not affordable	10%	5%
Racism/hostility toward tribe members	2%	0.3%

Relationship Between Fish Use and Income

Like all populations of people, there is variation in income within California tribes. The largest income class among respondents (36% of respondents) had an individual annual income in the range $18,000 to $50,000. This is similar to the distribution of income in 2012 among people in the US, where 25% of people interviewed by the US Census Bureau reported an individual annual income between $17,500 and $50,000 (Source: U.S. Census Bureau, Current Population Survey, 2013 Annual Social and Economic Supplement. http://www.census.gov/hhes/www/income/data/incpovhlth/2012/dtables.html, accessed 7/18/2014). Amounts of salmon, caught fish, bought fish, and total fish varied among income classes. For most income classes, caught fish dominated the fish diet, while for the >$100,000 income class, caught and bought fish were eaten in similar proportions. In the >$100,000 income class, the vast majority of fish consumed was salmon, whereas for other income classes, was closer to half of total caught fish consumed. One explanation for the zig-zag pattern in consumption across income classes is that there may be multiple patterns occurring simultaneously. One possibility is that very low income people have less ability to afford fishing equipment, transportation to fishing sites, and time to go fishing, resulting in less fishing. There may be a threshold when more fish can be acquired through fishing (i.e., >$18,000) and higher thresholds where fish can be bought more readily, possibly replacing caught fish. Finally, greater income may also affect peoples' ability to travel to catch salmon, which are only available in a few places in the state.

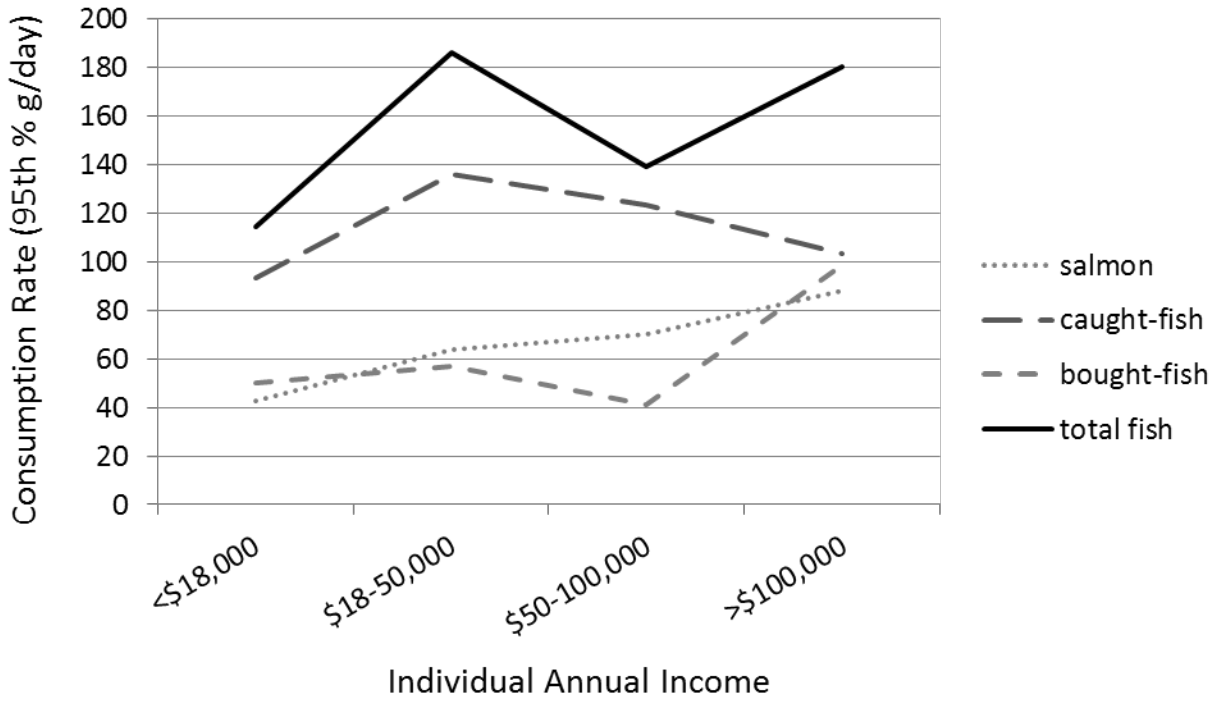

Figure 9. Comparison of patterns of fish-use and individual annual income.

Maintenance of Traditional Practices

Three standards were used for maintenance of traditional fish use by tribes: 1) maintenance of fishing locations, 2) maintenance of fish species range, and 3) maintenance of fish consumption. Comparison of currently-fished areas with traditionally-fished areas revealed that traditional fishing is maintained in most places (Figure 9). Although access was described as a problem (Table 8), tribe members reported that they were able to fish most historically-fished waterways. Similarly, although certain fish species and species groups may have gone locally-extinct or endangered, most tribes reported currently using most species/groups that they traditionally-used (Table 5).

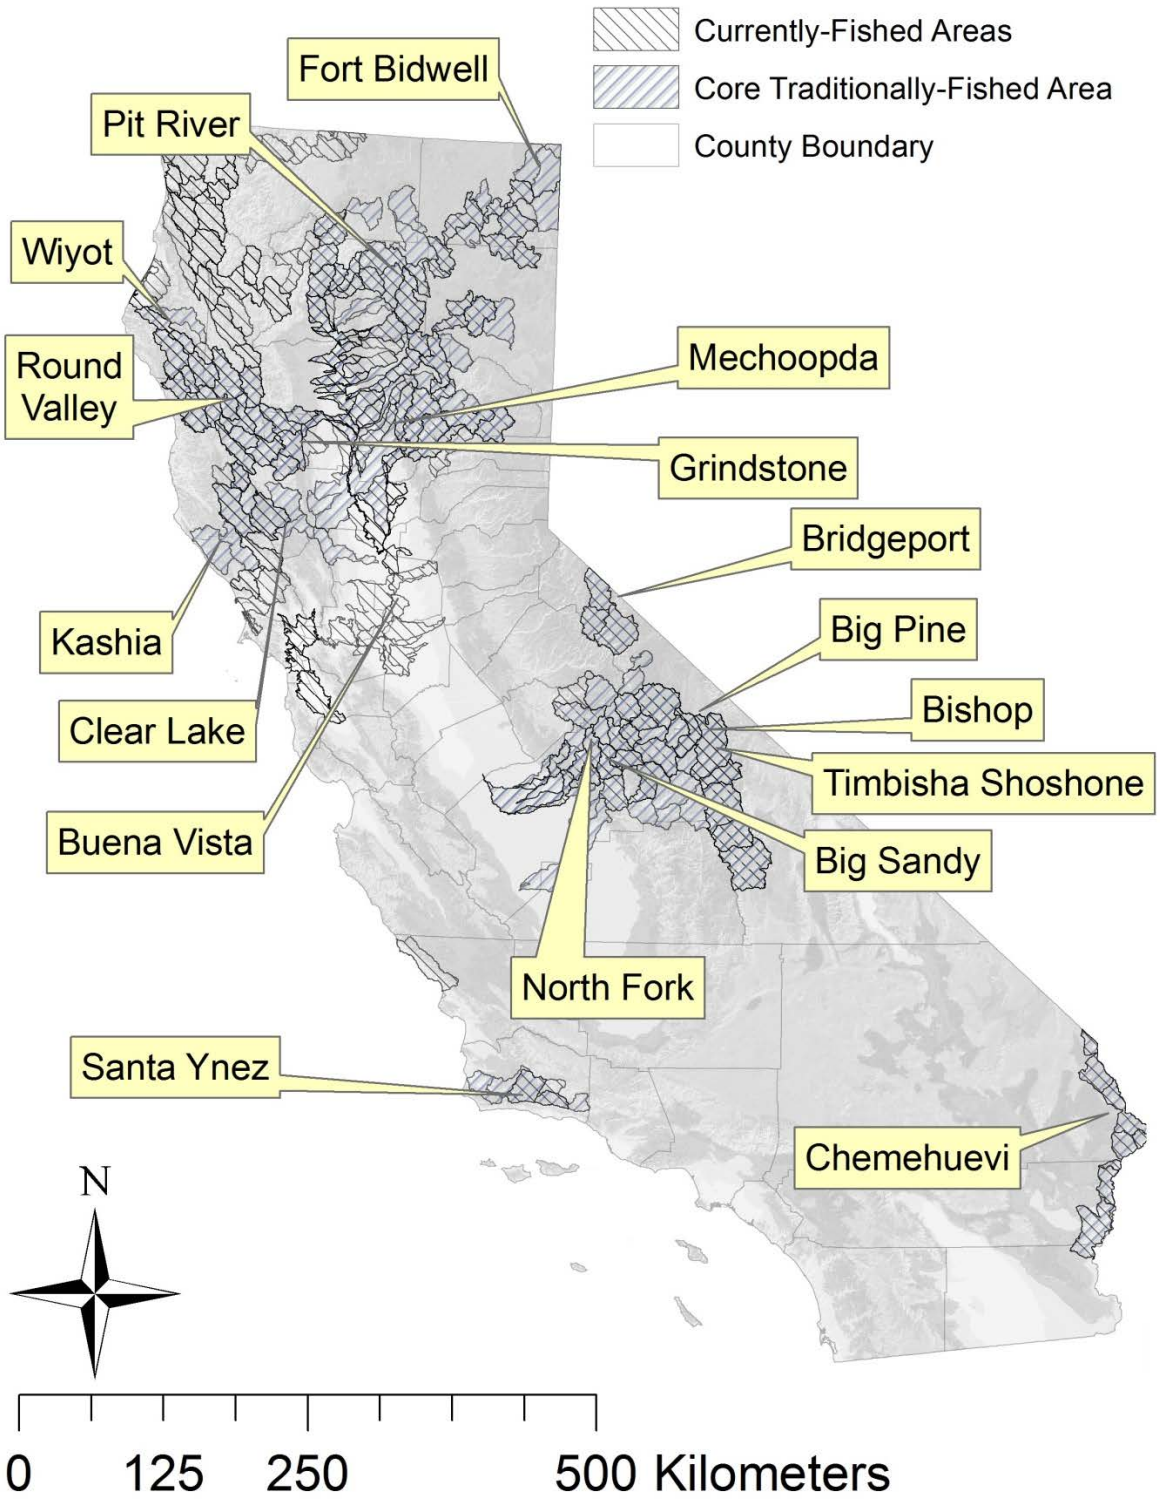

Figure 9. Comparison of currently-fished and traditionally-fished areas (HUC-10 watersheds). Doubly-hatched ("criss-cross" pattern) watersheds were both historically fished and were recently-fished.

Tribe Staff Perspective

Tribe staff were contacted by email and asked various questions about traditional and contemporary fish use. In general their responses were similar to the responses of individual tribe members (see Appendix 4 for more detail). The vast majority of tribe staff responses were consistent with these statements and ideas: fish use was and still is important to tribes for cultural, subsistence, and other reasons; tribe members historically ate fish once per day or more often; aquatic ecosystem conditions and ability to fish (e.g., regulations and access) are barriers to fish use; and tribe members do not eat as much fish as they used to. Tribe staff also expressed the opinion that future projects of this type that rely on interviews of tribe members be conducted and/or led by tribes themselves.

Discussion and Conclusion

Members of California Tribes use fish in similar patterns compared to traditional and historical uses, but sometimes at suppressed rates. The rates of fish consumptions for tribe members are among the highest recorded in California and for many regions are likely to be the highest and therefore the most policy-relevant. Although there are many exogenous barriers to fish use, such as reduced flows from excessive water withdrawals and water quality issues, tribes still practice the main patterns of fish use in terms of broad use of aquatic organisms and wide geographic spread of waterways used. Protection of tribes' use of fish will require target fish tissue concentrations of contaminants to be near background, recovery of fish populations through recovery of aquatic systems/flows, and recognition of accessibility issues that tribes face.

Widespread and Broad Tribe Use of Aquatic Ecosystems and Organisms

The watershed area fished by individual tribes increased with the number of tribe members interviewed and for all regions represented a significant proportion of the total watershed area. Based on the area included after interviewing members of only 10 tribes about historically fished areas and members of 24 tribes about currently fished areas, it is likely that if all tribes were interviewed, the majority of California's waterways and watersheds could be considered traditionally and culturally used by tribes.

Tribe members reported traditional and contemporary use 26 freshwater/anadromous fin-fish species, 23 marine fin-fish species, and 18 other invertebrate, and plant species and groups of species. The more people interviewed per tribe, the longer the list of organisms reported as being used, suggesting that the lists are incomplete. Even with potentially incomplete reporting, about half of the fin-fish reported as being used were fish that had been found during archaeological investigations of middens. The other half of fish reported used was primarily composed of non-native fish that had been introduced since the mid-1800s (e.g., catfish in 1874; Dill and Cordone, 1997).

Importance of Salmon Within and Among Regions

Yoshiyama (1999) provides one of the most exhaustive reviews of the use of salmon by California tribes, particularly in the Central Valley. By his estimate, based on citations, there may have been ~160,000 indigenous people living in the Central Valley and foothills (Cook, 1978; in Yoshiyama, 1999), equaling a density of ~3 people per square mile. Hewes (1947, 1978; in Yoshiyama, 1999) estimated that the per capita consumption rate of salmon among tribes was up to 1 pound (453 g) per day. This rate was likely just part of overall fish consumption, as suggested by archeological investigation suggesting tribes' use of a broad range of fish species (e.g., Gobalet et al., 2004).

Within the primary salmon-bearing areas of the Klamath, Sacramento and San Joaquin Rivers and tributaries, access to salmon runs was the object of some conflict, negotiated fishing rights, and trade of the resulting fish products (reviewed in Yoshiyama, 1999). Tribes from the desert east of the Sierra Nevada may have traditionally crossed the range to catch salmon in the Spring (Jackson and Spence, 1970; in Yoshiyama, 1999), suggesting that salmon was important historically to California desert tribes in the same way that tribes report its importance today.

Because so many salmon runs are listed as threatened or endangered or at risk of becoming so, it is challenging for most native people to practice using what may have been the most important fish to them collectively. The reasons that salmon populations are reduced in California rivers varies among regions, ranging from water quality issues (all rivers), to physical barriers (dams, most rivers), to insufficient flows due to withdrawal for agricultural and urban uses (most rivers). The cause of salmon declines is one of the most well-studied of the ecological impacts of Euro-American settlement of the West. Although the reasons vary for salmon declines, the regulatory (for agencies) and statutory (for the legislature) authority exists to solve most of the problems salmon, and by extension tribes, face for recovery to healthy populations that could support restored traditional use. The current problem with salmon

recovery is usually not lack of knowledge, but rather lack of political will to act to protect salmon and their traditional use.

Tribe and Region Standard Rates of Fish Consumption

The USEPA (USEPA, 2000), San Francisco Bay Regional Water Quality Control Board (SFBWQCB, 2006), and Central Valley Water Quality Control Board (CVRWQCB, 2010) have all supported the use of the 95th or 99th percentile rates of fish consumption to develop water quality criteria and fish tissue criteria that are protective of people catching and eating fish from local waterbodies. These recommendations and actual use of these standards were made without conditioning based on the impact these criteria might have on those responsible for implementing or meeting these criteria, which is consistent with the use of the Clean Water Act as protective of beneficial uses and users without condition.

The standard rates are reported here as 95th percentile rates for individual tribes and for regions. The tribe specific rates presented here are useful in setting water quality criteria and fish tissue criteria at both the local waterbody scale and the region scale. Because tribes reported the waterbodies/HUC-10 watersheds that they had traditionally fished and the waterbodies/HUC-10 watersheds from which they had derived fish in the last 30 days, these criteria can be used at the HUC-10 or more general scale. In order to develop criteria useful at the regional scale, tribes' collective use of fish can be used for all waterbodies in a region, unless absence of use by tribes can be demonstrated.

Suppression, Maintenance and Recovery of Traditional Fish Use

Compared to estimates from archaeological investigations and recall of elder tribe members, use of fish has been suppressed compared to historical rates. The daily use of fish reported by elders for only a couple of generations ago suggests that the suppression has been most severe in recent years. Elder and younger tribe members observed that fish availability, flows, and water quality may all be barriers to catching and eating fish at historical rates. The preponderance of evidence points toward regulated and restorable environmental conditions as being the primary barriers to recovery of traditional uses by tribes. For most tribes, there are individual and groups of tribe members who consume fish at rates similar to historical rates of fish use. This maintenance of traditional fish use points to the possibility that fish use could be

recovered for the majority of tribe members, as has been described for Columbia River tribes (Harper and Harris, 2008).

Recoverable rates of fish use should be established based on tribe or regional standards, based on quantification of "traditional, cultural and subsistence use" of fish based on tribe members' reporting of historical activities. This has been done here for several tribes, but could be expanded to include more tribes who potentially made greater use of fish than those who were interviewed.

Barriers to Traditional and Contemporary Fish Use by California Tribes

Almost half of tribe members interviewed reported declines in fish populations as the primary barrier to maintenance or recovery of traditional rates of fish use. Approximately a third of tribe members reported water flows and quality as critical issues, which is highly correlated with fish declines. Lower proportions reported logistical problems with fish access, ranging from physical access to traditional fishing locations to state regulations and limits and cost of fishing.

Similar patterns were seen for barriers to contemporary fish use. Approximately ¼ of respondents reported declines in fish populations as the primary barrier to being able to use fish. Fewer, but sizable proportions of respondents reported water flows, water quality, regulations/limits, access to fishing sites, and costs as barriers.

The state policy nexus with these barriers to both traditional and contemporary fish use includes many state regulatory frameworks and permitting systems for water use and discharge of pollutants. If tribal traditional, customary, and subsistence use is regarded as a "beneficial use" under the Clean Water Act, then restoration of the use will require recovery of the flows and water quality that will permit healthy and less-contaminated fish populations to return and be used by tribes.

Appendix 1. Traditional Fish Use Questionnaire

Survey #	Card #

California Tribes, Traditional Fishing and Fish Use Survey

Date: _____ Interviewer name: _____ Time start: _____:_____ am pm
end: _____:_____ am pm

Location of Interview:
Tribe:

Hello. My name is _____. Because of concerns expressed by California tribes about fish and fishing, I am conducting a survey for the University of California Davis. We want to learn about the fishing practices and uses of fish by people in your tribe. This will help the tribe and the state set water quality standards to protect your ability to safely eat fish. At the same time, we want to protect your privacy, so I will not be asking your name or collecting personal information. This survey will take about 15 minutes and we are giving this gift to people who participate. Do you agree to let me interview you about your tribe's traditional fishing practices and use of fish?

1a. ☐ **Y agree, proceed**
☐ N (do not proceed)

1b. [IF INDIVIDUAL DOES NOT WANT TO BE SURVEYED] Please note any known reason that they declined:

☐ No time
☐ Language barrier
☐ Appeared threatened/uncooperative ☐ Other:_____
☐ Unknown

1c. [IF NO] Record observed gender:

☐ Male ☐ Female

2. Have you ever been interviewed before about fishing or eating fish
☐ Y (fishing __ eating fish ___) Who?
☐ N (proceed)

3. Did your tribe traditionally rely on fish as a source of food in the past?
☐ Y
☐ N
☐ Don't know/refused

4. Were subsistence practices such as fishing protected under treaties signed by the tribe?
☐ Y
☐ N
☐ Don't know/refused

5. What major creeks, rivers, lakes, or other water-bodies were traditionally fished by your tribe (possibly use map as aid)?

6. What kinds of fish did you traditionally catch and eat?
[List fish by common name, clarify and/or use visual aid if uncertain]

_____

_____

_____

7. How much of each kind of fish did you traditionally eat?

_____

_____

_____

_____

_____

1	> one meal a day
2	1 meal per day
3	2-3 meal per week
4	1 meal per week
5	1 meal per month
6	less often than 1/month

8. Was fishing a culturally important activity in the past?
- ☐ Y
- ☐ N
- ☐ Don't know/refused

9. Was eating fish an important part of culture in the past?
- ☐ Y
- ☐ N
- ☐ Don't know/refused

10. Was eating fish an important part of the diet in the past?
- ☐ Y
- ☐ N
- ☐ Don't know/refused

11. Is this tradition maintained now?
- ☐ Y
- ☐ N
- ☐ Don't know/refused

12. If not, why not?

☐ Fish declines ☐ Fish locally extinct ☐ Streams dried up
☐ Concern about water/fish quality ☐ Don't know/refused

☐ Other: _____

Appendix 2. Contemporary Fish Use Questionnaire

What kind of fish was it? _____

8. Are you able to eat as much fish now as in the past?
☐ Yes
☐ No
☐ Don't know/ Not Sure
☐ Refused

9. What are the main things that affect how much fish you can catch?

_____

_____

10. Are there times of year when you eat more fish? When is that and what kinds of fish

_____

11. What are the main things that affect how much fish you can eat?

_____

_____

HOUSEHOLD & DEMOGRAPHIC INFORMATION

12. In the past year, have any children under 18 in your household eaten fish that you or someone you know caught?

☐ Yes
☐ No
☐ Don't know/ Not Sure
☐ Refused

13. In the past year, have any women between ages 18 and 49 in your household eaten fish that you or someone you know caught?

☐ Yes
☐ No
☐ Don't know/ Not Sure
☐ Refused

14. In the past year, have any women expecting a child or who have a baby in your household eaten fish that you or someone you know caught?

☐ Yes
☐ No
☐ Don't know/ Not Sure
☐ Refused

15. If you don't mind, could you tell me how best to describe your tribal affiliation and ethnicity:

16. If you don't mind me asking, what is your age: [READ CHOICES. CHECK APPROPRIATE BOX.]
1 ☐ Under 18?
2 ☐ between 18 and 34?
3 ☐ between 35 and 49?
4 ☐ over 49?
5 ☐ Refused

17. What city, town or zip code do you live in? _____

18. [RECORD APPARENT GENDER]
☐ male
☐ female

19. I am going to show you a list with some income levels on it, please pick the category that best describes your annual household income from all sources.

☐ Less than $18,000
☐ $18,000 to less than $50,000
☐ $50,000 to less than $100,000
☐ $100,000 or more
☐ Don't know / Not sure
☐ Refused

Appendix 3. Online Surveying Questionnaire

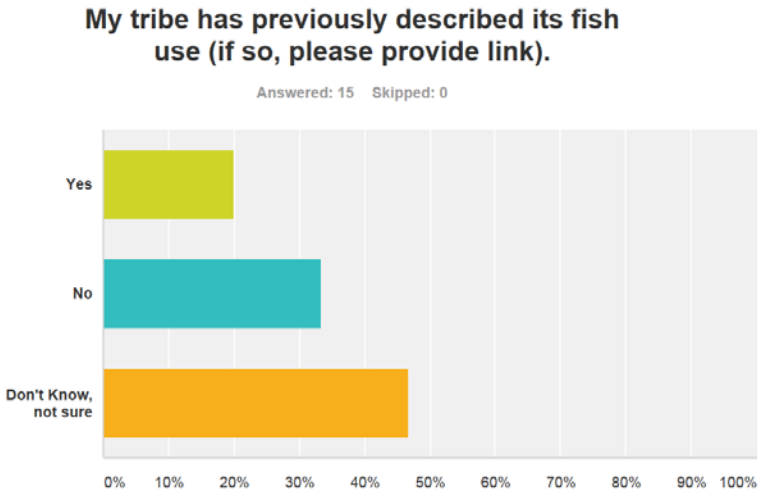
Online Surveying Questionnaire

1. What is your tribe?
2. My tribe has previously described its fish use (if so, please provide link).
3. Would you consider fish important to your tribe for cultural, subsistence, or other reasons?
4. Historically, were fish important to your tribe for cultural, subsistence, or other reasons?
5. What types of fish did your tribe rely on in the past? (Please write in order of importance)
6. What types of fish does your tribe rely on now? (Please write in order of importance)
7. How often did tribe members eat fish in the past?
8. What are the primary impacts or barriers to your tribe's fish use?
9. Do tribe members eat as much fish as they would traditionally?
10. In the future, studies of tribes' fish use should be conducted by...?

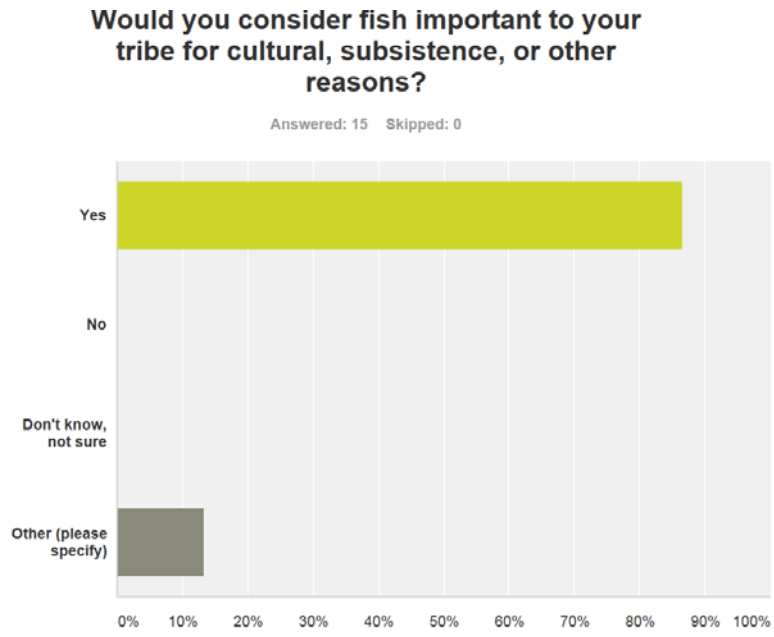
Appendix 4. Tribe Staff Responses to Survey

Question 1. Tribe staff responding: Wilton Rancheria, Karuk, Wintu, Round Valley Tribes, Big Valley Band of Pomo, Noyo River, Bear River Band of Rohnerville Rancheria, North Fork Rancheria of Mono Indians, Pala Band of Mission Indians, Mechoopda Indian Tribe

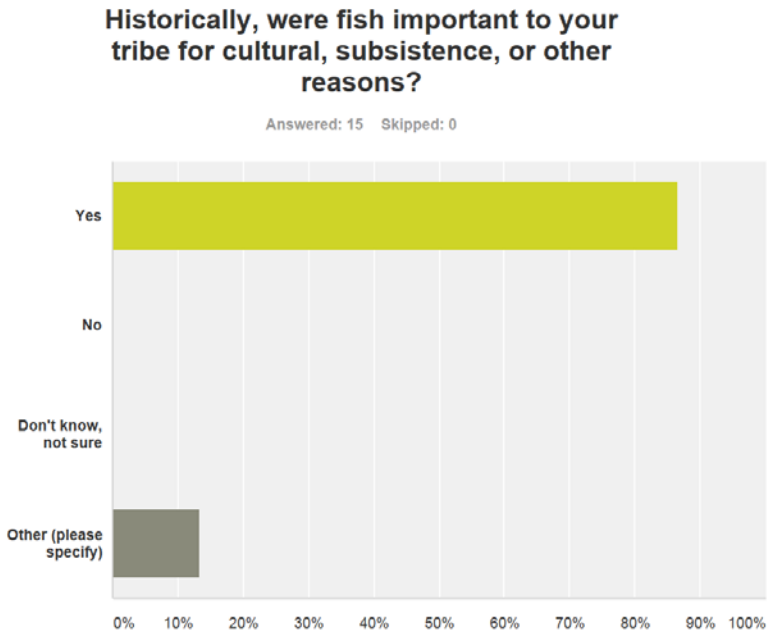
Question 2.



Question 3.



Question 4.

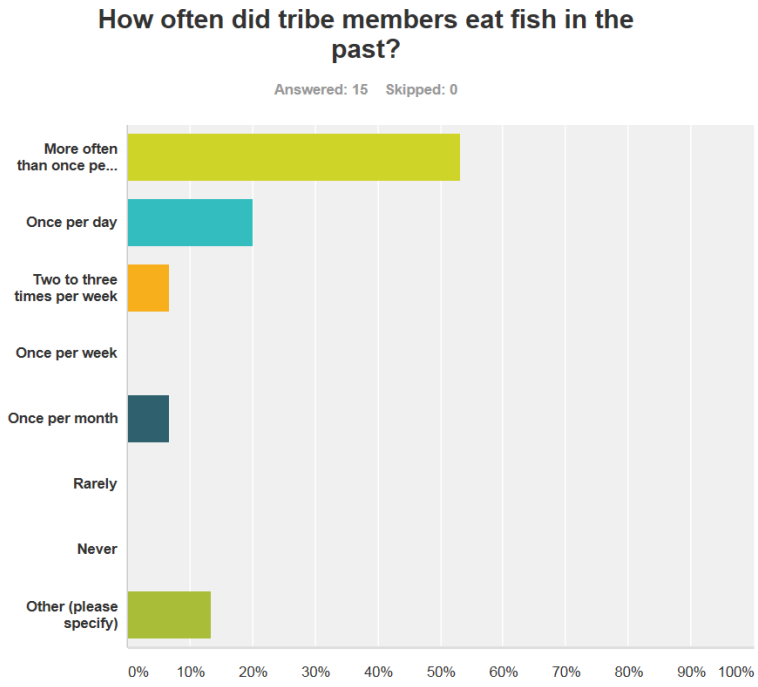


Questions 5 & 6.

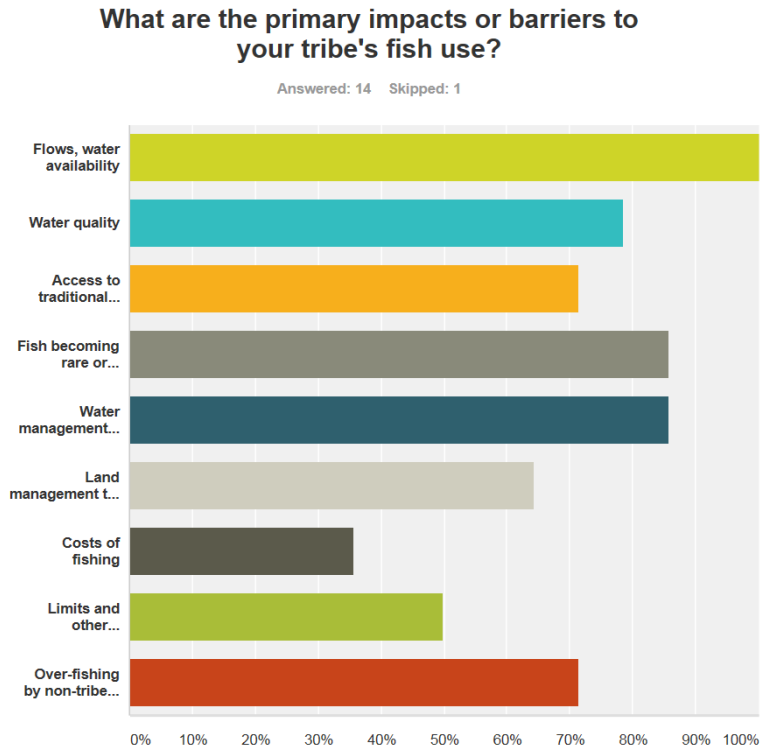
What types of fish did your tribe rely on in the past? (Please write in order of importance) What types of fish does your tribe rely on now? (Please write in order of importance)

Tribe	Past Fish Species/Groups	Current Fish Species/Groups
Wilton Rancheria (Me-Wuk)	Chinook salmon, sturgeon, fresh water eel	Chinook salmon
Karuk (2)	Chinook and coho salmon, sturgeon, eel	Chinook, eel
Wintu	Salmon, trout, sturgeon, eel	Salmon
Round Valley Indian Tribes (5)	Salmon, steelhead, trout, eel	Salmon, steelhead, trout
Big Valley Band of Pomo Indians	Sha (blackfish), hitch, ah-ah-sha (yellow catfish), sha-pal (sim. steelhead), dee-tah (sim. crappie), sun perch, bluegill, trout, black bass, catfish, clams	Store-bought fish, catfish and crappie from lake, clams and crayfish from lake, hitch from creeks, gifted salmon
Noyo River	Salmon, perch, surf fish & all other types of fish from the ocean	Salmon, surf fish, cod, cabazon, & anything else we can catch
Bear River Band of Rohnerville Rancheria	Salmon, lamprey/eel, steelhead, trout	Salmon, lamprey/eel
North Fork Rancheria of Mono Indians	Salmon	Trout
Pala Band of Mission Indians	Trout, bass, ocean shore fish	none
Mechoopda Indian Tribe	“Its not the type of fish, but what is in season and what is needed.”	“It is up to the Tribe and the season of fish that are available.”

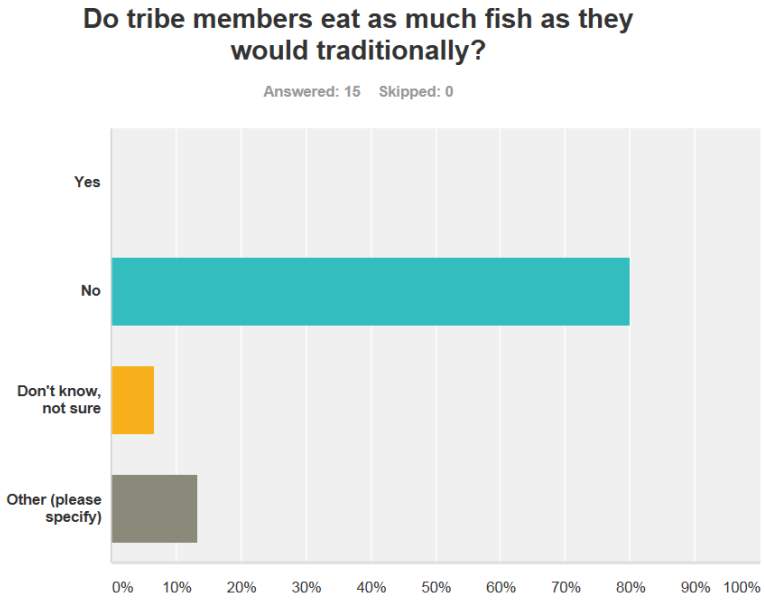
Question 7.



Question 8.



Question 9.



Question 10. In the future, studies of tribes' fish use should be conducted by...?

Type of Entity	Percent of responses
Tribes	40%
State agencies	0
Federal agencies	0
Academia	0
Non-governmental organizations	6.7%
Private consultants	0

Abstract

Since deforestation has recently been associated with increased mercury load in the Amazon, the problem of mercury exposure is now much more widespread than initially thought. A previous exploratory study suggested that fruit consumption may reduce mercury exposure. The objectives of the study were to determine the effects of fruit consumption on the relation between fish consumption and bioindicators of mercury (Hg) exposure in Amazonian fish-eating communities. A cross-sectional dietary survey based on a 7-day recall of fish and fruit consumption frequency was conducted within 13 riparian communities from the Tapajós River, Brazilian Amazon. Hair samples were collected from 449 persons, and blood samples were collected from a subset of 225, for total and inorganic mercury determination by atomic absorption spectrometry. On average, participants consumed 6.6 fish meals/week and ate 11 fruits/week. The average blood Hg (BHg) was 57.1 ± 36.3 μg/L (median: 55.1 μg/L), and the average hair-Hg (HHg) was 16.8 ± 10.3 μg/g (median: 15.7 μg/g). There was a positive relation between fish consumption and BHg ($r = 0.48$; $P < 0.0001$), as well as HHg ($r = 0.34$; $P < 0.0001$). Both fish and fruit consumption entered significantly in multivariate models explaining BHg (fish: $\beta = 5.6$, $P < 0.0001$; fruit: $\beta = -0.5$, $P = 0.0011$; adjusted model $R^2 = 36.0\%$) and HHg levels (fish: $\beta = 1.2$, $P < 0.0001$; fruit: $\beta = -0.2$, $P = 0.0002$; adjusted model $R^2 = 21.0\%$). ANCOVA models showed that for the same number of fish meals, persons consuming fruits more frequently had significantly lower blood and HHg concentrations. For low fruit consumers, each fish meal contributed 9.8 μg/L Hg increase in blood compared to only 3.3 μg/L Hg increase for the high fruit consumers. In conclusion, fruit consumption may provide a protective effect for Hg exposure in Amazonian riparians. Prevention strategies that seek to maintain fish consumption while reducing Hg exposure in fish-eating communities should be pursued.

Keywords: Fish consumption; Fruit consumption; Mercury exposure; Amazon; Brazil

1. Introduction

Over the last decades, the presence of mercury (Hg) in the Amazon and its potential human health risks has given rise to much concern. During the 1970s, intense gold-mining activities were undertaken, with the arrival of thousands of gold miners coming from other regions of Brazil (Cleary, 1990; Santos et al., 1992). Although elevated Hg levels found in the Amazonian environment were initially attributed to these gold-mining activities (Hylander, 1994; Malm et al., 1990; Nriagu et al., 1992), more recent studies have shown high Hg concentrations both in fish and human tissues in regions where there has been no gold-mining (Guimarães et al., 1999; Silva-Forsberg et al., 1999; Dórea et al., 2003). Indeed, Amazonian soils constitute important reservoirs of Hg

(Roulet et al., 1998, 1999, 2000; Fadini and Jardim, 2001), and a significant part of Hg contamination of the aquatic ecosystems is caused by erosion of such soils following deforestation for agriculture and/or cattle (Almeida et al., 2005; Farella et al., 2001, 2006; Roulet et al., 1999). Thus in the Amazonian environment, Hg from different sources is available for methylation processes contaminating the fish resources, which constitute a dietary mainstay for the large population living along the riverbanks (Dolbec et al., 2001; Guimarães, 2001; Lebel et al., 1997). Epidemiologic studies of riparian populations have shown dose-related associations between fish consumption, methyl mercury (MeHg) exposure, and early adverse health effects. Deficits in neurological and neuropsychological functions, as well as cytogenetic changes have been reported among adults and/or children from this area (Amorim et al., 2000; Cordier et al., 2002; Dolbec et al., 2000; Grandjean et al., 1999; Harada et al., 2001; Lebel et al., 1998, 1996; Yokoo et al., 2003). Additionally, recent exploratory studies in the Tapajós region suggest that Hg exposure may be associated with both increased blood pressure (Fillion et al., 2006) and autoimmune dysfunction (Silva et al., 2004).

There is a large variation in Hg levels in fish from the Tapajós region. A recent report indicated Hg concentrations above the recommended value of 0.5 μg/g in 31% of predatory fish species (Silva et al., 2006). Another study presented high mean Hg levels for carnivorous species such as Dourada (*Brachyplatystoma flavicans*: 0.8 μg/g), Surubim (*Pseudoplatystoma* sp.: 0.8 μg/g), Pescada (*Plagisocion squamosissimus:* 0.6 μg/g), and Sarda (*Pelona* sp.: 0.7 μg/g), whereas low levels of Hg have been reported in herbivorous fish such as Aracu (*Leporinus* sp.: 0.07 μg/g), Pacu (*Mylossoma* sp.: 0.05 μg/g), and Tambaqui (*Colossoma macropomum*: 0.08 μg/g) (Santos et al., 2000). In the Tapajós region, fish appear to be the only food source for Hg. A recent study evaluating mercury pollution in cultivated and wild plant parts from the Tapajós region concluded that the translocation of Hg from soils throughout roots to aboveground is not significant (Egler et al., 2006). This is supported by European studies examining Hg levels in agricultural products of Hg-containing soils, which concluded that Hg intake through vegetables and fruits does not represent a health hazard for consumers (Ursinyová et al., 1997; Barghigiani and Ristori, 1994).

Since fish is a central and highly nutritious element in the Amazonian diet, some authors have minimized the importance of Hg exposure, suggesting that changes in fish consumption practices would necessarily have strong negative consequences for human health (Dórea, 2004; Dórea et al., 2005). An alternative public health approach would be to identify elements in the traditional diet that might influence Hg absorption and/or toxicity, thereby providing a way for this population to continue eating fish, while reducing Hg exposure. Despite the recognition that diet and nutrition can influence a population's vulnerability to the effects of MeHg (NRC, 2000), dietary information has not been systematically collected in most epidemiologic studies examining the effects of MeHg exposure (Chapman and Chan, 2000). Although a number of controlled experiments have estimated the effects of specific nutrients on Hg absorption and/or toxicity (Calabrese, 1978; Levander and Cheng, 1980; Imura and Naganuma, 1985; Whanger, 1992; Peraza et al., 1998; Lapina et al., 2000; Rao et al., 2001; Rao and Sharma, 2001; Usuki et al., 2001; Afonne et al., 2002), studies examining the role of diet in determining Hg concentrations in free-living populations are still scarce.

In a hypothesis-generating study of 26 adult women from a riparian village in the Brazilian Amazon, we examined the influence of the consumption of traditional foods on the relationship between fish consumption and Hg exposure (Passos et al., 2003). In that study, the women kept extensive food consumption frequency diaries, which included all food and beverages, for 12 months. The results of this food consumption survey revealed that the strong relationship between fish consumption and Hg exposure was significantly modified by fruit consumption.

The objective of the present study was to determine, in a large riparian population in the Brazilian Amazon, the effects of fruit consumption on the relation between fish consumption and bioindicators of Hg exposure, using an epidemiologic design. It is part of the CARUSO Project, a large interdisciplinary, ecosystemic study on Hg contamination and exposure in the region (CARUSO, 2007).

2. Methods

2.1. Study design and population

A cross-sectional dietary survey was undertaken among 13 riparian communities situated on the banks of the Tapajós River, a major tributary of the Amazon (Fig. 1). These communities were chosen in order to represent the diversity created throughout the colonization process, as some of them were established after colonization began in the early 1960s, whereas others were established up to 100 years before. Because of the difficulties in applying a random sampling strategy in this setting, a convenience sample was used. Age and sex distributions were then compared to the underlying population, which had previously been determined through a house-to-house survey, in each community (Table 1). During this survey, the study was explained at each household and persons were invited to participate. Additionally, community meetings were conducted in each village in order to further explain the study.

Approval was obtained from Ethics Committees of the Federal University of Rio de Janeiro (Brazil) and the University of Quebec in Montreal (Canada). The study was explained individually, and persons agreeing to participate signed an informed consent form that was read to them.

2.2. Assessment of fish and fruit consumption frequency

Because of important seasonal differences in the availability of fish species and types of fruit (Lebel et al., 1997; Dolbec et al., 2001; Passos et al., 2001), a 7-day dietary recall questionnaire (7-DDR) was used in order to determine recent fish and fruit consumption frequency. Development and validation studies of this instrument have shown that it is relatively easily administered and it constitutes a sensitive method to assess short-term food consumption (Hebert et al., 1997).

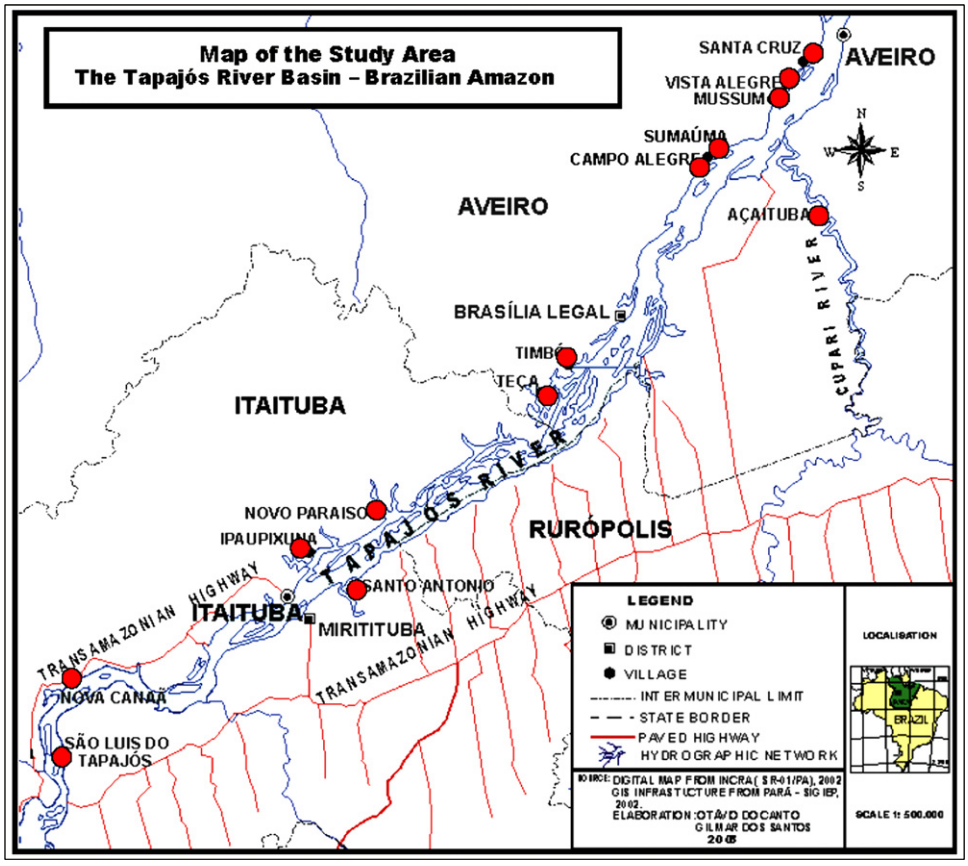

Fig. 1. Map of the study area. Participating communities are identified by a large red dot.

Table 1
Age distribution and rates of participation in the study population

Age category	Total adult population	Study population	% participation
15–24	427	112	26.2
25–34	260	102	39.2
35–44	218	97	44.5
45–54	161	54	33.5
55–64	116	50	43.1
⩾65	104	44	42.3
Total	1286	459	35.7

A list was prepared which included most of the fish and fruit species present in the region. In interviews performed over the months of June–August 2003, participants indicated the number of meals containing fish as well as the fish species that were consumed. As for fruits, the procedure was similar, but in this case, for each fruit species, the participant indicated the number of fruits that had been eaten each day over the preceding 7 days, whether during a meal or not. Fish and fruit species that were not in the initial list were also recorded.

2.3. Sampling and analyses of bioindicators

Hair samples were collected from 449 persons (211 men and 238 women) and blood samples were collected from a subset of 225 persons (114 men and 111 women). Hair strands from the occipital region were cut at the root and then placed in plastic bags, with the root end stapled. The samples were analyzed at the Laboratory of Radioisotopes of the Federal University of Rio de Janeiro (Brazil), by atomic absorption spectrometry with an AA 1475 Varian and a cold vapor generator accessory VGA-76 Varian. Mineralization of samples was done with mixtures of acids (HCl, HNO_3 and H_2SO_4) and oxidants ($KMnO_4$, $K_2S_20_7$ and H_2O_2), with techniques developed and adapted to the flow injection system vapor generator accessory (Malm et al., 1989). This laboratory participates regularly in inter-laboratory comparison programs for total and inorganic mercury analysis (Gill et al., 2002), and analytical quality control was ensured by the use of standard reference materials (Human Hair 085 and 086) provided by the International Atomic Energy Agency (IAEA).

Blood samples were collected by a nurse by venipuncture into 6 ml heparinized Becton Dickinson Vacutainer® (BD7863). All blood samples were kept frozen at -20° until analyzed. Total and inorganic mercury in blood were determined by atomic absorption spectrometry at the laboratory of the Quebec Toxicology Center of the Quebec Public Health Institute (CTQ-INSPQ), Canada, according to the method described by Ebbestadt et al. (1975). The detection limit for blood mercury (BHg) analysis was 0.2 μg/L and analytical quality control was ensured by the use of internal reference samples for blood analysis provided by the Inter-Laboratory Comparison Program conducted by the CTQ-INSPQ.

2.4. Statistical analysis

Descriptive statistics were used to describe the study population, Hg exposure as well as the results of fish and fruit consumption frequency. Correlation analyses were used to examine the relation between the frequency of consumption of specific fish species in relation to BHg and hair mercury (HHg) concentrations. Where appropriate, non-parametric techniques were used for comparisons.

The associations between fish and fruit consumption frequency with respect to BHg and HHg levels were assessed using simple and multiple linear regression models. BHg and HHg levels were the dependent variables in separate linear regression models, which tested for the influence of overall fish and fruit consumption; the latter were included as continuous independent variables.

All pregnant women were excluded from the analyses, and potential covariates such as alcohol consumption, gender, age, schooling, and cigarette smoking were included in the models. Analysis of covariance (ANCOVA) was used to test interactions. Results were defined as statistically significant for a value of $P \leqslant 0.05$. Analyses were performed using Statview for Windows Version 5.0.1 and JMP 5.0.1a (SAS Institute Inc.).

3. Results

Socio-demographic characteristics of the study population are shown in Table 2. Schooling varied between 0 and 12 years (mean 3.8 years $\pm$ 2.7), and the age range was 15–89 years (mean 38.6 years $\pm$ 17.2). Eighty-three percent (83%) of the participants were originally from the State of Pará, and 70% live on the Tapajós River banks, whereas 30% live on one of its tributaries. Fig. 2(A and B) presents the distribution of BHg and HHg levels, respectively. Overall, the average BHg was 57.1 $\pm$ 36.3 μg/L (median: 55.1 μg/L, ranging from 4.8 to 205.4 μg/L), and the average HHg was 16.8 $\pm$ 10.3 μg/g (median: 15.7 μg/g, ranging from 0.2 to 58.3 μg/g). The average percentage of MeHg was 86.8%, ranging from 75.2% to 94.3%. Men had significantly higher HHg levels (mean: 18.7 $\pm$ 11.2) than women (mean: 15.2 $\pm$ 9.1) (Mann–Whitney U, $P = 0.001$), but no significant difference was observed for BHg. There was a strong correlation between BHg and HHg concentrations ($r = 0.73$; $P < 0.0001$).

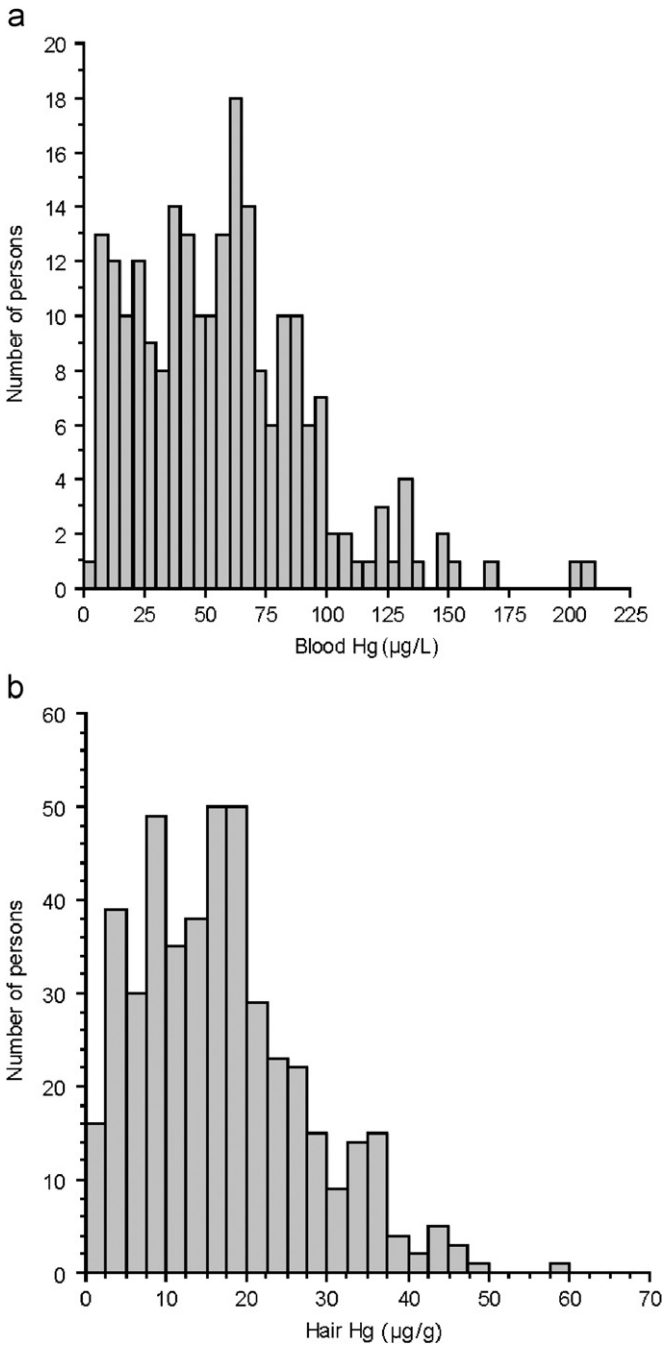

Fig. 2. Distribution of blood (A) and hair (B) total Hg concentrations for the study population.

In this survey, 457 persons consumed at least one meal with fish over the preceding seven days, making up 99.6% of the study population. Of these, 345 persons consumed at least one meal containing a carnivorous species (75.2%), whereas 393 persons ate at least one fish meal containing a non-carnivorous species (85.6%). In all, participants had consumed an average of 6.6 fish meals/week, ranging from

Table 3
Frequency of reports for fish most frequently eaten over the preceding 7 days

Fish species	Feeding habits[a]	Number of fish meals	%
Aracu (*Shizodon* sp.)	n-c	696	23.0
Pescada (*Plagioscion* sp.)	c	602	19.9
Caratinga (*Geophagus* sp.)	n-c	375	12.4
Tucunaré (*Cichla* sp.)	c	291	9.6
Jaraqui (*Semaprochilodus* sp.)	n-c	160	5.3
Pacu (*Myears lossoma* sp.)	n-c	155	5.1

[a]c, carnivorous; n-c, non-carnivorous.

0 to 19 meals/week. Table 3 shows the fish species most frequently eaten over the preceding 7-day period. Carnivorous fish made up an average of 43.5% of the fish diet, ranging from 0% to 100%. No associations were observed between total fish consumption and age, gender, schooling, cigarette smoking, and alcohol consumption. However, significant differences were observed between communities (Kruskal–Wallis, $P<0.0001$), as well as between persons originally from the Tapajós region and immigrants from northeast Brazil (Mann–Whitney U, $P<0.0001$). Those originally from the Tapajós region showed higher HHg levels (mean $= 17.9\,\mu g/g \pm 10.1$) compared to persons who had immigrated (mean $= 12\,\mu g/g \pm 9.9$).

Fig. 3(A and B) shows the relationships between weekly fish consumption (meals/week), BHg and HHg, respectively. Partial correlation analyses of fish consumption, categorized by feeding habits and Hg levels, show that the frequency of consumption of carnivorous fish is significantly correlated to both BHg and HHg ($r = 0.48$, $P<0.0001$ for BHg; $r = 0.34$, $P<0.0001$ for HHg), whereas the frequency of consumption of non-carnivorous fish is not related to BHg ($r = 0.01$, $P = 0.15$), and weakly correlated to HHg ($r = 0.14$, $P = 0.002$). This is reflected in individual species, with the highest correlations observed for large carnivorous fish such as *Pescada*, *Filhote* and *Piranha*. Despite its relatively high consumption, the carnivorous species *Tucunaré* was not significantly correlated to the bioindicators of Hg exposure, while *Aracu* and *Pacu* (non-carnivorous species) showed a weak correlation to HHg. These same relationships were observed when the fish were entered two-by-two into a multiple regression model.

A total of 40 fruit species were recorded during the survey, and 443 persons (96.5%) ate at least one of these fruits in the previous week. Three-hundred twenty-eight (328) persons (71.5%) reported eating bananas (*Musa* spp., Musaceae), the most consumed fruit, while 203 (44.2%) reported eating at least one orange (*Citrus* spp., Rutaceae).

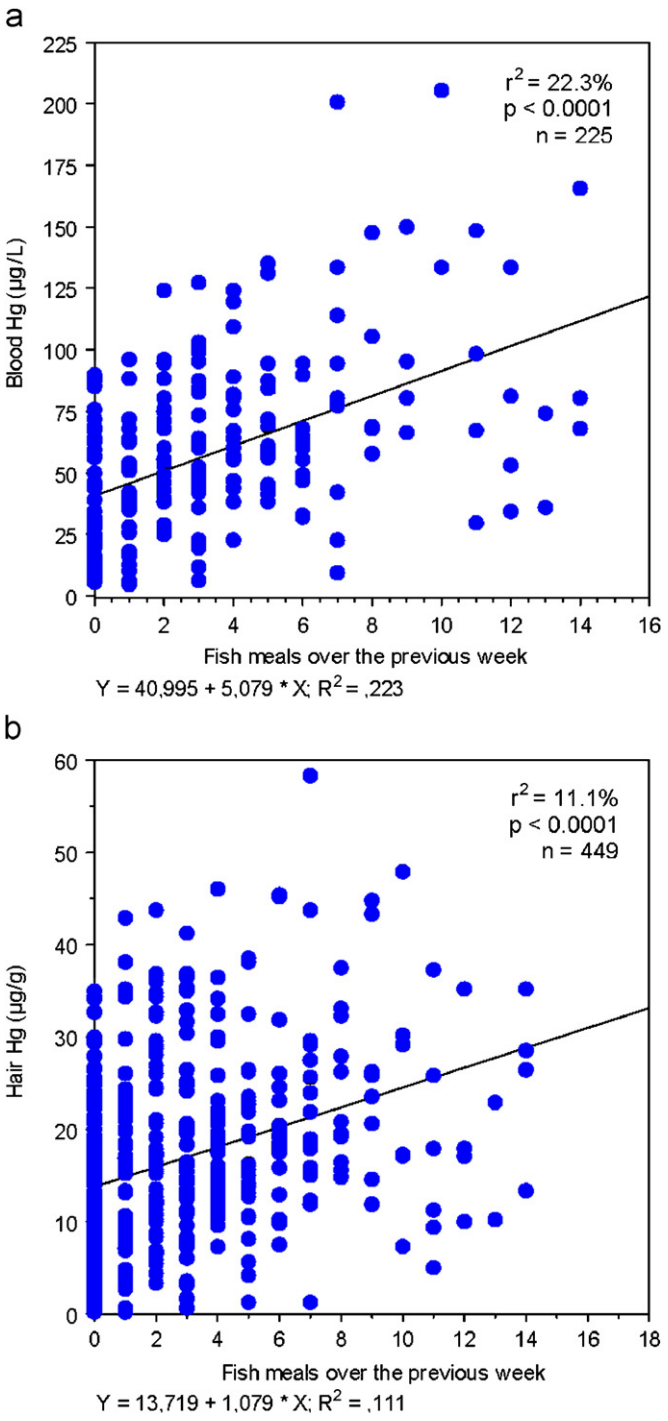

Fig. 3. The relationship between fish consumption (meals/week) and blood (A) and hair (B) total Hg concentrations.

Table 4 summarizes the distribution of persons with respect to fruit species consumption, as well as the frequency of reports for fruits most frequently eaten over the previous 7 days. Because of the important biodiversity in the Amazon, most fruits are consumed by only a small percentage of the participants, whereas only a few fruits are widely consumed by significant portions of the population.

On average, participants ate 11 fruits/week, ranging from 0 to 62 fruits/week. Although many types of fruit are

Total	449	1.2 ($P<0.0001$)	−0.2 ($P=0.0002$)	21.0

[a]Adjusted factors in the regression equation: gender, cigarette smoking, non-carnivorous fish consumption.

seasonally available, the most frequently eaten are bananas and oranges. In this survey, we also observed a relatively high frequency of consumption of other regional fruits such as Tucumã (*Astrocaryum aculeatum*) and Jambo (*Eugenia* spp.), whereas Ingá (*Inga* spp., Leguminosae–Mimosoideae) was hardly consumed in this season. Total fruit consumption was weakly correlated with fish consumption ($r=0.1$; $P=0.003$), and inversely correlated with age ($r=-0.1$; $P=0.02$). It was also weakly correlated with schooling ($r=0.1$; $P=0.02$), but no relation was observed between fruit consumption and cigarette smoking or alcohol consumption. Similar to fish consumption, significant inter-village differences were observed (Kruskal–Wallis, $P=0.004$). Villagers living close to Itaituba City, the only urban center of the upper and middle Tapajós, reported lower fruit consumption as compared to villagers living in the proximity of Aveiro, a small town in the lower Tapajós.

Both fish and fruit entered significantly into the multivariate models explaining BHg and HHg; the regression estimates are presented in Table 5 for both women and men. The inverse relationship between fruit consumption and Hg levels remained significant, even when carnivorous and non-carnivorous fish were included separately. In addition to the overall effect of fruit consumption, multivariate models showed that some individual fruits presented enhanced negative regression estimates. Table 6 shows regression estimates for frequency of specific fruit consumption in multiple linear models with fish consumption and bioindicators of Hg exposure.

Fig. 4(A and B) illustrates the overall influence of these specific fruits (bananas, oranges, and jambos) on the relationship between fish consumption and Hg exposure. The regression lines are plotted for those with low fruit consumption ($\leqslant 3$ fruits/week; $n=64$), medium fruit consumption (>3 fruits/week $\leqslant 10$ fruits/week; $n=86$), and high fruit consumption (>10 fruits/week, $n=75$) in relation to BHg. For HHg, the low consumption group comprises 177 persons, the medium 169 persons, and the high consumers include 113 persons. Analysis of covariance showed that the intercepts of the three regression lines were similar, but their slopes were significantly different (Interaction term for BHg: $F=9.4$, $P=0.0001$; for HHg: $F=5.9$; $P=0.0029$). Thus, for low fruit consumers, each fish meal contributed 9.8 μg/L Hg increase in blood compared to only 3.3 μg/L Hg increase for the high fruit consumers. Similarly, each fish meal contributed approximately 1.7 μg/g Hg increase in hair of low fruit consumers as opposed to 0.5 μg/g increase in hair of high fruit consumers.

Most sociodemographic features such as age, schooling, cigarette smoking, and alcohol consumption were similar between low and high fruit consumers, while some slight differences were observed for a limited number of variables (Table 7). It is interesting to note that high fruit consumers ate more carnivorous fish.

Table 6
Regression estimates for frequency of specific fruit consumption (fruits/week) in multiple linear models with fish consumption (meals/week) as independent variable and bioindicators of Hg exposure

Biological indicator Fruits	Regression estimates		Model R^2 (%)[a]
Blood total mercury (μg/L)	Carnivorous fish	Fruit	
Oranges	5.3 ($P<0.0001$)	−1.6 ($P = 0.0006$)	36.2
Jambos	4.9 ($P<0.0001$)	−1.8 ($P = 0.0245$)	38.9
Hair total mercury (μg/g)			
Oranges	1.0 ($P<0.0001$)	−0.2 ($P = 0.0440$)	23.3
Bananas	1.0 ($P<0.0001$)	−0.2 ($P = 0.0246$)	23.0

[a]Adjusted factors in the regression equation: gender, cigarette smoking, non-carnivorous fish consumption, community.

4. Discussion

The results of the present study show a clear association between fruit consumption and lower Hg levels in this population, thus confirming the findings of our hypothesis-generating study conducted among 26 riparian women in the Amazon (Passos et al., 2003). This protective effect of fruit consumption against Hg exposure via dietary intake of fish is observed both for women and men; it is present in all categories of age and schooling, and occurs independently of other factors with a potential to influence Hg exposure, such as cigarette smoking and alcohol consumption.

A plausible explanation for the findings of this study is that the soluble dietary fiber content as well as other prebiotic nutrients of fruits could be interfering with absorption at the gastrointestinal tract. Indeed, demethylation of MeHg by microflora in the gut is a key and probably a rate-determining process in the removal of MeHg from the body, even though the microbes involved have not been identified nor have the biochemical mechanisms of cleavage of the carbon–mercury bond (Clarkson, 2002). A number of studies have suggested that the demethylation process in the intestine might well constitute an important site for interaction between diet and MeHg accumulation in the body (Chapman and Chan, 2000), the fiber content of the diet having already been shown to affect the excretion rate of MeHg (Rowland et al., 1986). Dietary elements have important effects on the metabolic activity of the intestinal flora (Gibson et al., 2004; Rowland, 1988), including a number of the carbohydrates present in significant amounts in several fruits and vegetables, which are able to stimulate the growth and/or activity of intestinal bacteria associated with health and well-being (Roberfroid, 2005). The effect of fruit consumption on these processes might explain, at least in part, why there is such a broad range of biologic half-times reported for adults exposed to MeHg.

The substantial inverse relation between Hg levels and consumption of oranges, which are known to present high levels of ascorbic acid (vitamin C), is particularly interesting since the role of this nutrient on MeHg exposure and toxicity has been controversial. Although Vitamin C has been implicated in the enhancement of MeHg toxicity (Murray and Hughes, 1976; cited in NRC, 2000), because of its strong reducing capacity, it is supposed to have potent detoxifying properties and has been used in cases of intoxication by heavy metals, including Hg. Sharma and colleagues (1982) demonstrated that ascorbic acid mediated a small but significant degradation of MeHg to inorganic mercury. Also, a more recent study concluded that ascorbic acid prevents mercury-induced genotoxicity in blood cultures due to its probable nucleophilic and detoxifying nature (Rao et al., 2001). In addition to ascorbic acid, oranges are also excellent sources of flavonoids and soluble dietary fiber.

Despite a positive relation between cigarette smoking and Hg levels observed in this population, the influence of fruit consumption remained unchanged. It is known that smokers have lower antioxidant status than non-smokers, but fruit consumption leads to a higher antioxidant status (Dietrich et al., 2003), which might explain the unchanged effect of fruit consumption. Indeed, one of the properties of several antioxidants particularly abundant in fruits is that they can form complexes with reactive metals, thus reducing their absorption (Bravo, 1998). Furthermore, the effect of fruit consumption also remained unchanged despite inter-village differences in terms of fruit consumption. Such regional differences probably reflect the fact that villagers near Itaituba City often buy fruit in the market, whereas those in more remote villages in lower Tapajós acquire fruit more often from their own home gardens.

Over these last years, diet of fish-eating communities has been the subject of much debate because of concerns about the potential health risks of MeHg exposure and, on the other hand, the public health implications of a diminished fish consumption (Arnold et al., 2005; Egeland and Middaugh, 1997; Myers et al., 2000; Weihg and Grandjean, 1998). Indeed, decreases in traditional food use has already been shown to affect diet quality and even to contribute to a number of diet-related health problems in indigenous peoples of Arctic Canada (Receveur et al., 1997). It is interesting that until recently the on-going birth cohort studies of heavy fish consumers of the Seychelles Islands in the Indian Ocean did not reveal adverse effects of MeHg, and some results even indicated beneficial outcomes

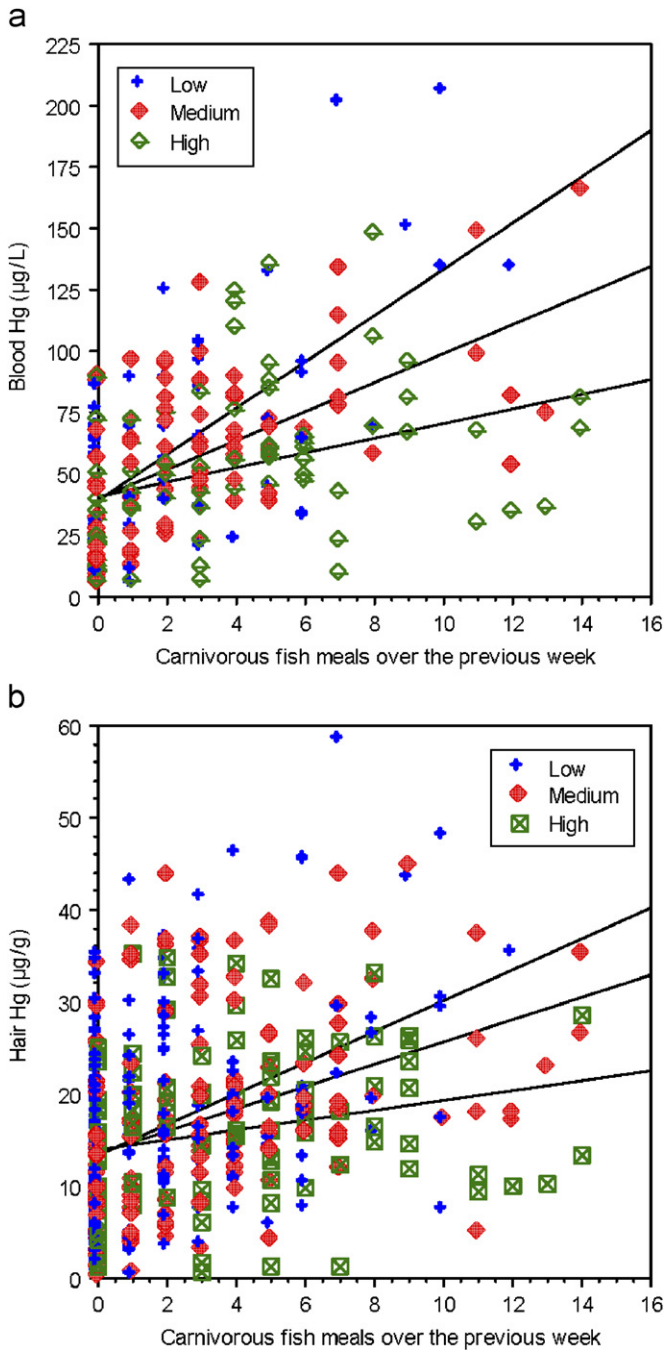

Fig. 4. The influence of fruit consumption on the relationship fish consumption (meals/week) and blood Hg levels (A), and HHg levels (B).

that correlate with Hg levels during pregnancy; the authors suggest a potential role of micronutrients in fish as a possible explanation for such findings (Clarkson and Strain, 2003). The importance of maintaining fish consumption when intervening to reduce Hg exposure in fish-eating populations was stressed by the Joint Expert Committee on Food Additives and Contaminants (JECFA) under the Food and Agriculture Organization (FAO) and the World Health Organization in their recent recommendations for tolerable daily maximum intake for Hg in pregnant/childbearing age women (WHO, 2003).

In the Amazon, recent reports have criticized any eventual suggestion to restrict fish consumption in traditional populations, which rely on fish as the main source of animal protein and other essential nutrients, suggesting that despite high concentrations of MeHg in fish, daily consumption of this food in large amounts poses no health hazards (Dórea, 2003, 2004). Although these reports rightfully point out the public health issues involved in diminished fish consumption, a more comprehensive approach, which takes into account the different sources of pollution as well as the socio-cultural and economic aspects of agriculture and diet, is needed in order to achieve viable risk management in this region. In particular, deforestation should be better controlled, thereby limiting Hg leaching from soils. It will also be necessary to better understand the dynamics involved in methylation in the areas of fish capture and to improve knowledge on the role of other foods able to influence Hg absorption and metabolism.

In this context, the challenge to maintain fish consumption while reducing Hg exposure remains. The encouraging results of a first intervention, which aimed at shifting towards consumption of less contaminated fish species and its impact in lowering exposure in a village on the Tapajós river have been presented elsewhere (Mertens et al., 2005; Bahia et al., 2004; Mergler et al., 2001). Indeed, through education based on posters showing the status of Hg contamination in relation to the fish species, the change in diet habits resulted in a reduction of close to 40% of HHg levels (Lucotte et al., 2004). The findings of the present study confirm a relevant avenue that deserves to be further explored as a potential additional intervention strategy

aimed at achieving the short-term challenge of maintaining fish consumption while reducing Hg exposure in this Amazonian setting.

In public health, it is well known that fruits contain a variety of compounds that may slow or prevent chronic diseases through several possible mechanisms. Components in fruits thought to be associated with the reduction of these conditions include soluble and insoluble dietary fiber, antioxidant nutrients (vitamins C, E, selenium, β-carotene), as well as other phytonutrients including polyphenols, flavonoids, anthocyanins and carotenoids (Feeney, 2004). Our findings indicate that fruit consumption may also be protective against the bioaccumulation of Hg in human populations exposed via dietary intake of fish.

Certain methodological issues of the present study need to be considered. First, there is always a tradeoff between the amount of data that can be collected and the size of the population. In the Passos et al. (2003) study, we opted for a large amount of chronological data collected through food diaries (written record of the foods as they are eaten, thus minimizing under- or over-reporting due to recall bias), and sequential HHg analyses from a small female population in order to identify the relevant food items that could then be used in a study with a much larger population (Passos et al., 2004). For the present study, we used a cross-sectional design on a convenience sample of men and women villagers from numerous riparian communities, assessing fish and fruit consumption frequency through a 7-DDR, and measuring Hg levels both in recent and chronic bioindicators of exposure. While the 7-DDR has been shown to constitute a sensitive method to assess short-term food consumption (Hebert et al., 1997), because of its retrospective nature there might have been some level of under- or over-reporting due to recall bias, especially for food items only moderately consumed (Pereira and Koifman, 1999). In addition, although data collection on convenience samples has been shown to appropriately represent the underlying population in other settings (Kelly et al., 2002; Zelinski et al., 2001), this sampling strategy may have introduced some selection bias in the present study. We did, however, achieve a participation rate of 35.7% in this adult population, well represented in most age categories. Moreover, most characteristics of fruit consumers were well distributed in the three categories of fruit consumption.

Another limitation of the present study is that it did not allow us to examine some of the possible physiologic events that may be involved in the interactions between fruit nutrients and MeHg. Studies examining the use of chelating agents as an intervention strategy to reduce blood lead levels raised questions about whether the process of chelation causes potentially dangerous redistribution of lead to susceptible organs from those less susceptible to lead toxicity (Goyer et al., 1995). Further studies should therefore examine the effect of fruit consumption from a toxicokinetic viewpoint.

5. Conclusion

Despite some limitations, this study constitutes strong evidence that fruit consumption provides a protective effect against Hg exposure in Amazonian riparian communities, whose traditional diet is based on daily consumption of Hg-containing freshwater fish. The results of this epidemiologic study are consistent with our previous findings (Passos et al., 2003) in which 26 riparian women presented lower HHg levels associated with consumption of regional fruit. Even though we did not measure toxicological outcomes in this study, it is reasonable to hypothesize that villagers consuming fruit regularly would be less vulnerable to neurological and/or cardiovascular risks linked to chronic Hg exposure. Future studies should be conducted to identify the specific nutrients responsible for this protective effect and examine the pharmacokinetics involved in these relations.

Acknowledgments

We deeply thank all villagers of the Tapajós River who kindly participated in this survey. We would like to acknowledge the work of all the members of the CARUSO team and thank Marie-Ève Thibault for her administrative support, as well as Luis Otavio do Canto for the cartographic work. This research was financially supported by the International Development Research Center (IDRC) of Canada, and the first author is recipient of a doctoral fellowship from the Brazilian Federal Agency for Graduate Studies (CAPES, Ministry of Education). The authors declare they have no competing financial interests.

ABSTRACT

Management of Hg-contaminated sites poses particular challenges because methylmercury (MeHg), a potent bio-accumulative neurotoxin, is formed in the environment, and concentrations are not generally predictable based solely on total Hg (THg) concentrations. In this review, we examine the state of knowledge regarding the chemical, biological, and physical controls on MeHg production and identify those most critical for contaminated site assessment and management. We provide a list of parameters to assess Hg-contaminated soils and sediments with regard to their potential to be a source of MeHg to biota and therefore a risk to humans and ecological receptors. Because some measurable geochemical parameters (e.g., DOC) can have opposing effects on Hg methylation, we recommend focusing first on factors that describe the potential for Hg bio-accumulation: site characteristics, Hg and MeHg concentrations, Hg availability, and microbial activity, where practical. At some sites, more detailed assessment of biogeochemistry may be required to develop a conceptual site model for remedial decision making. *Integr Environ Assess Manag* 2016;00:000–000. © 2016 SETAC.

Keywords: Methylmercury Site assessment Mercury Sediment Contaminated

Critical Review

INTRODUCTION

Mercury has been used widely in industry and is a contaminant at approximately 50% of all Superfund sites (Mercury Superfund Research Program 2015). At many of these sites, Hg as methylmercury (MeHg) is a risk driver for remediation. Methylmercury is a potent neurotoxin that bioaccumulates in aquatic and terrestrial organisms and is therefore of concern to human and ecological health, primarily due to fish consumption. Prediction of risk associated with Hg in contaminated environments is complicated by the lack of a consistent relationship between MeHg concentrations in fish, soil, sediment, or water and total Hg (THg) concentration in these environmental media. Furthermore, MeHg uptake into the food web and bioaccumulation can vary widely between sites with very similar Hg levels, and elevated Hg concentrations can persist in an ecosystem for decades or longer. A particular concern for site managers is that the development of numerical sediment or water quality guidelines to predict the accumulation of MeHg in fish is difficult because of the lack of a consistent relationship between sediment or water THg concentrations and bioaccumulation into fish tissue (Ingersoll et al. 2000). The US Environmental Protection Agency (USEPA) recognized this challenge in its development of a national recommended water quality criterion for MeHg, which is expressed in terms of fish tissue, for protection of human health exposures due to fish consumption (USEPA 2009).

To effectively manage risk, identification of key parameters that determine the fate of Hg at contaminated sites is critical. Some contaminated sites with relatively high Hg concentrations in soil or sediment have relatively low Hg concentrations in the food web, whereas others exhibit higher Hg concentrations in the biota despite lower Hg in soils or sediments. Our focus is on soils and sediments contaminated by point sources (also known as "legacy sites") rather than by atmospheric deposition of Hg. Although methylation at sites contaminated by atmospheric deposition is controlled by similar geochemical parameters, approaches to management differ.

We synthesize the literature to identify a set of practical parameters to use when evaluating the risk of Hg methylation and bioaccumulation. Most of the discussion is focused on sediment because MeHg concentrations in soil tend to be low (Munthe et al. 2001). Methylation in soil is strongly affected by soil moisture content; otherwise, the processes of microbial methylation in soil and sediment are similar. Much of the research to date and the literature reviewed herein has focused on freshwater systems; however, the basic principles also apply to estuarine or marine sites. Because of the complex interaction of geochemical, biological, and physical parameters, there is no single parameter that will reliably predict the likelihood of Hg methylation and bioaccumulation or the concentration of MeHg in the environment. Thus, from a site management perspective, it is more practical to focus on a suite of measurable parameters that are indicative of risk.

Managing contaminated sites entails the prioritization and implementation of remediation, if warranted. Although a detailed review of remediation technologies is beyond the

DOI: 10.1002/ieam.1822

scope of the present article, consideration of the geochemical conditions can help inform remediation options. Some traditional remediation techniques, such as removal or capping, do not depend on site chemistry. However, geochemical controls are especially relevant to emerging remediation technologies such as the application of activated C, biochar, or nitrate to reduce methylation potential at a site (Todorova et al. 2009; Gilmour, Riedel et al. 2013; Gomez-Eyles et al. 2013; Bussan et al. 2016) and the use of natural attenuation.

The goal of the present study was to examine the large amount of biogeochemical information available for Hg methylation in soils and sediments and to identify the most important measurements to help determine whether remediation is warranted. We describe controls on Hg methylation and bioaccumulation based on review of the literature and our experience in evaluation of Hg-contaminated sites. To highlight site-specific controls on Hg methylation and bioaccumulation, a more detailed examination of 3 Hg-contaminated sites with differing geochemical, biological, and physical characteristics is included. We conclude with specific environmental monitoring suggestions for managers of Hg-contaminated sites.

MERCURY CYCLING IN THE ENVIRONMENT

Mercury species

In the environment, Hg cycles between neutral (i.e., elemental mercury) and positively charged species as well as inorganic and organic forms (Figure 1). The 2 oxidation states for Hg in the environment are Hg(0) (i.e., elemental Hg) and Hg(II or 2+) (i.e., divalent Hg). Elemental Hg exists as a liquid under ambient conditions and can be formed in the environment (through reduction of divalent Hg) either by bacteria or by photochemical reduction (Mason et al. 1995). Elemental Hg is relatively volatile and, once volatilized, is dispersed to the atmosphere. At legacy sites associated with Hg cell chlor-alkali or Hg retort facilities, elemental Hg can persist for decades in soil or buildings. Generally, however, Hg is found in soils, sediments, and waters in the divalent form complexed with chlorides, sulfides, or organic matter. Inorganic Hg(II) may be methylated by microorganisms, resulting in the production of MeHg, an organic species that binds to proteins and can pass through biological membranes. Unlike inorganic Hg, MeHg tends to bioaccumulate within the food web. Thus, the tendency of an environment to produce MeHg from inorganic Hg is important in determining the potential impact of Hg on human health and the environment.

Mercury methylation and demethylation

Methylmercury in the environment is the net result of MeHg production and demethylation, which are both largely microbially mediated (Ullrich et al. 2001; Driscoll et al. 2013). MeHg is formed primarily as a cometabolic product by sulfate-reducing bacteria (SRB) and, to a lesser extent, by Fe(III)-reducing bacteria (Compeau and Bartha 1985; Fleming et al. 2006; Kerin et al. 2006). These bacteria are active under anaerobic conditions, that is, in the absence of O_2 and nitrate, which are more favorable electron acceptors for bacterial metabolism. Mercury also can be methylated by methanogenic microorganisms, suggesting that MeHg production may take place in anoxic freshwater sediment depleted of sulfate and Fe(III) (Hamelin et al. 2011; Yu et al. 2013).

Recently, Parks et al. (2013) identified 2 genes, *hgcA* (which encodes a putative corrinoid protein) and *hgcB* (which encodes a 2[4Fe-4S] ferredoxin), which are required for Hg methylation and which may provide a means of assessing methylation potential in the environment. They found homologs of *hgcA* and *hgcB* in genomes of 52 bacterial and methanogenic archaea. Building on this research, Podar et al. (2015) found the *hgcAB* genes in nearly all anaerobic environments evaluated (i.e., in more than 3500 publicly available microbial metagenomes from a wide range of environments). Although these recent studies indicate a broad diversity of known methylators, sulfate-reducing and Fe-reducing bacteria exhibit the highest methylation rates and tend to dominate methylation when they are present, likely because they are so abundant (Gilmour, Podar et al. 2013). Future application of these genetic techniques may shed additional light on the relative abundance of methylating organisms.

Demethylation occurs both biologically and abiotically. Whereas both aerobic and anaerobic organisms have been found to demethylate MeHg, aerobic organisms are considered to predominate (Ullrich et al. 2001), although sulfate-reducing and methanogenic bacteria (which are anaerobic) have been found capable of oxidative demethylation (Marvin-DiPasquale

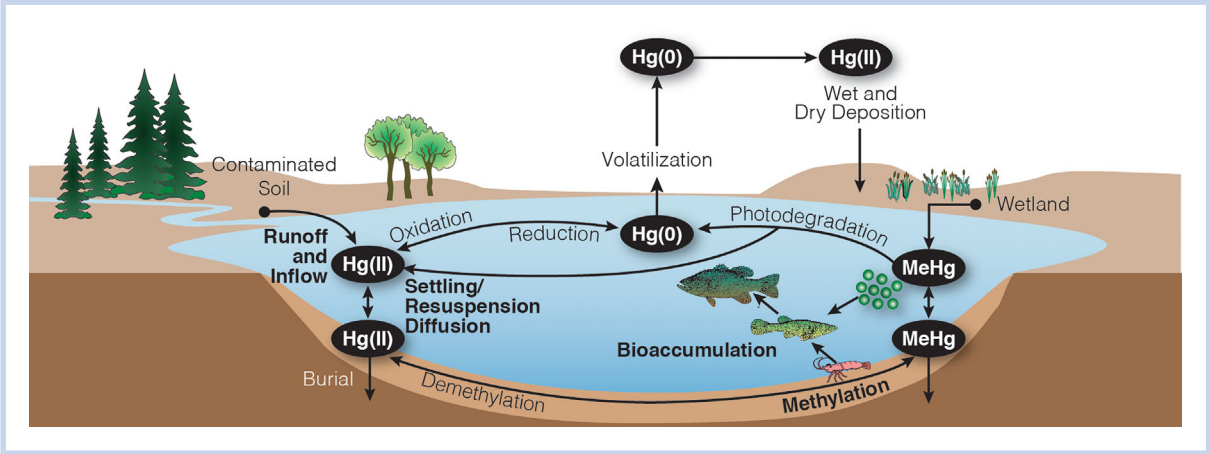

Figure 1. Chemical and biological pathways potentially controlling the fate of Hg. Although the focus of this review is on soils and sediments, methylation (and therefore bio-accumulation) is dependent on the presence of water in all systems. Hg(0) = elemental mercury; Hg(II) = divalent mercury; MeHg = methylmercury.

and Oremland 1998; Marvin-DiPasquale et al. 2000). Photochemical reduction is the only significant abiotic Hg demethylation process (Ullrich et al. 2001) and dominates demethylation in the photic zones of surface waters. Although methylation and demethylation can be studied separately with the help of C and Hg radioisotopes, MeHg concentrations in the environment are the end result of both processes; therefore, the present review focuses on net methylation.

Biogeochemical controls on net methylation

Net methylation is a function of 2 general factors: the geochemical speciation of inorganic Hg(II), which determines its availability to methylating organisms, and the activity of methylating (and demethylating) bacteria, which depends on environmental conditions (Hsu-Kim et al. 2013). Because speciation of inorganic Hg(II) and bacterial activity are important, inorganic Hg(II) concentration in sediment (which is generally well represented by THg) is not a good or consistent predictor of MeHg concentration. Indeed, several authors (e.g., Benoit et al. 2003; Schaefer et al. 2004; Heyes et al. 2006; Cossa et al. 2014) have reported a plateau in MeHg concentration as THg in sediment increases and variable MeHg concentrations at given THg concentrations. This plateau and variability are indications that, as stated by Ullrich et al. (2001), a network of biogeochemical reactions and environmental conditions controls the rate of net MeHg production. The primary parameters involved (S, organic matter, Fe, Se, pH, temperature) as well as 2 other considerations for understanding net methylation (wetting and drying cycles and "new" versus "old" Hg) are reviewed here.

Sulfur. Sulfur biogeochemistry influences Hg methylation by affecting the activity of methylating bacteria and the availability of Hg(II) for methylation. In anaerobic sediment, the presence of sulfate, an oxidized S species, generally increases Hg methylation (Kampalath et al. 2013) because of its role as an electron acceptor for SRB. The end product of sulfate reduction is sulfide, which strongly controls the concentration of dissolved Hg(II) (Paquette and Helz 1997) and may either increase or decrease Hg methylation by influencing the speciation of Hg in sediment. In fact, inorganic speciation of Hg is dominated by Hg sulfide species even at nanomolar sulfide levels. Common dissolved Hg sulfide species in the environment are $Hg(SH)_2$ (aq), $HgHS^{2-}$(aq), $HgS_2{}^{2-}$(aq), and $Hg(Sx)_2{}^{2-}$, whereas HgS(s) is the primary species in solid phase. Uncharged Hg sulfide species (e.g., $Hg(SH)_2$ (aq)) are available for methylation (Drott et al. 2007), because they can pass through bacterial cell membranes where they can be methylated. The formation of solid phases (e.g., HgS(s)) or charged species acts to inhibit methylation (Kampalath et al. 2013) because both are unavailable to bacteria. The extent of Hg methylation has been linked to precipitation and dissolution reactions of HgS(s) and regulation of SRB activity by S(-II) toxicity (Gilmour et al. 1992; Benoit, Gilmour et al. 1999; Gilmour et al. 1992). Although some ligand-promoted dissolution of HgS(s) by dissolved organic matter (DOM) (Waples et al. 2005), sulfide (Paquette and Helz 1995), and polysulfide (Paquette and Helz 1997; Jay et al. 2000; Paquette and Helz 1997) has been noted in experimental systems, the overall solubility of HgS(s) (and thus the availability of Hg(II)) remains extremely low.

Organic matter. Methylmercury and organic C concentrations are often positively correlated in lacustrine waters (Driscoll et al. 1995), and high concentrations of MeHg have been observed in many types of organic C–rich environments. However, because of a myriad of pathways through which organic matter influences the processes controlling methylation, measuring organic C as TOC, DOC, or specific ultraviolet absorbance (SUVA) is informative but not predictive of Hg methylation. "DOM" is a general term that includes the variable and complex ligands that actually bind Hg. However, the units are generally measured in C concentrations (DOC or TOC). We use DOM to refer to both dissolved organic matter that adsorbs ionic Hg and to dissolved organic C that serves as an electron donor for bacterial activity.

In the absence of sulfide, DOM strongly complexes Hg(II) (Ullrich et al. 2001; Haitzer et al. 2002, 2003; Hsu-Kim et al. 2013). In freshwater systems, Hg-DOM complexes are relatively stable; hence, a large portion of Hg(II) is bound to DOM. At equilibrium, DOM can decrease the bioavailability of Hg to methylating microorganisms (Miskimmin et al. 1992; Barkay et al. 1997; Gorski et al. 2008). However, the kinetics of Hg-DOM complexation, rather than its thermodynamic stability, may ultimately control availability to methylating microorganisms (Miller et al. 2009; Chiasson-Gould et al. 2014). For example, Graham et al. (2012) showed that the addition of DOM to mildly sulfidic systems, which would otherwise limit the availability of Hg for methylation, resulted in greater MeHg production. Under nonequilibrium conditions, Chiasson-Gould et al. (2014) showed DOM enhanced Hg(II) bioavailability to bacteria and proposed that Hg(II) becomes less available over time (i.e., within 24 h) due to a series of ligand exchange reactions with some of the thousands of various compounds that comprise DOM and cell membranes (Brown and Markich 2000).

Perhaps the most important and yet poorly understood kinetic species controlling Hg methylation are Hg sulfide (HgS)-DOM nanoclusters. These complex and dynamic species, observed in laboratory studies (Deonarine and Hsu-Kim 2009; Slowey 2010; Gerbig et al. 2011), consist of clusters of particles 10 nm to 100 nm in size. Within this size range, they either pass through the polymer membranes or sorb to smaller pore-sized, metal-oxide membranes that are typically used to filter water, confounding the interpretation of dissolved versus particulate THg analytical determinations (Slowey 2010). HgS-DOM nanoclusters likely play a role in controlling Hg bioavailability when DOM and sulfide are present, which are the same conditions (i.e., anaerobic sulfate-reducing) in which most Hg methylation occurs (Zhang et al. 2012). Dissolved organic C slows but does not prevent the precipitation of Hg(II) and S(-II); rather, DOM facilitates the nucleation of β-HgS (metacinnabar) that is thermodynamically less stable compared to larger and more crystalline α-HgS (cinnabar) (Slowey 2010; Gerbig et al. 2011). Once formed, such nanocrystalline HgS can be redissolved by DOM, after which the newly formed Hg-DOM complexes could be bioavailable to methylating microorganisms (Ravichandran et al. 1998; Ravichandran et al. 1999; Waples et al. 2005).

By forming sorption complexes with Hg, particulate organic C (POC), as well as metal oxyhydroxides, can transport Hg in Hg-contaminated systems such as mine drainage streams (Kim et al. 2004; Lowry et al. 2004; Slowey et al. 2005) and industrial sites (Gagnon et al. 1997; Rolfhus et al. 2003; Bloom

et al. 2004). Settling of particulate sorbed Hg can be a major pathway for Hg transport into the zone of methylation (i.e., sediment) (Lamborg et al. 2002).

Iron. Iron is a redox sensitive element that interacts with S species in anaerobic environments. Fe(III) oxyhydroxides are a common oxidant for S(-II) (Reis et al. 1992; Poulton et al. 2004), and Fe(III) addition to sediment has been hypothesized to decrease MeHg production in sediments by 2 mechanisms. First, it favors Fe-reducing microorganisms rather than sulfate-reducing microorganisms and may shift microbial communities away from ones that are capable of Hg methylation (Derek et al. 1986). Second, it may react with S species to alter the bioavailability of inorganic Hg (Mehrotra and Sedlak 2005). Mehrotra et al. (2003) observed declines in MeHg production from Fe(II)-amended wetland sediment relative to untreated sediment. The authors of this study hypothesized that Fe(II) reaction with S(-II) regulated the concentrations of neutral Hg species [HgS(aq) and $Hg(HS)_2$], which are proposed to be the dominant species available for methylating microorganisms (Benoit, Mason, Gilmour 1999; Benoit et al. 2001). Reactions between Hg(II) and FeS(s) (mackinawite) may result in reduction of Hg(II) to Hg(0), which is volatile, thus reducing exposure to methylating micro-organisms (Bone et al. 2014).

Selenium. Selenium impacts Hg methylation and MeHg uptake into organisms by limiting the availability of Hg for methylation (Jin et al. 1997; Belzile, Chen et al. 2006; Truong et al. 2013). For example, a laboratory incubation study of surface lake sediments from China exhibited slower Hg methylation and faster demethylation at higher solid-phase Se concentrations (Jin et al. 1997). When *Psuedomonas fluorescens* was grown with both Se and Hg, the presence of Se significantly reduced the accumulation of Hg, likely due to the formation of inert Se-Hg complexes such as nano-HgSe clusters, which are analogous to HgS but less soluble (Belzile, Wu et al. 2006). In the presence of both Hg and selenide, laboratory results indicate that the formation of mercuric selenide appears to limit bioavailability of both Se and Hg to SRB (Truong et al. 2013).

In addition to the effect on Hg methylation, an antagonistic effect of Se on both inorganic Hg and MeHg uptake into aquatic food chains has been reported (Khan and Wang 2009). The molar ratio of Se:Hg in fish tissue appears to influence the toxicity of either element, with a ratio greater than 1 purported to limit Hg toxicity to fish consumers (Ralston et al. 2007; Ralston and Raymond 2010). A strong antagonistic relationship between Se and Hg was also reported from lakes in Sudbury, Canada, an area impacted by release of metals due to mining and smelting (Chen et al. 2001). Significant inverse relationships between Se and Hg in perch and walleye tissue were observed, and authors found that Hg concentrations in the fish from lakes near the smelter (where Se concentrations were higher) were low compared to other boreal shield lakes in the region. Also in this region, Se greatly reduced the assimilation of Hg into organisms throughout the food chain (Belzile, Chen et al. 2006). Although Se:Hg ratios greater than 1 are considered protective, some studies have shown wide ranges of Se:Hg ratios in individual freshwater fish from a single site, making it difficult to designate a general ratio for use in risk assessments (Burger et al. 2012), although site-specific assessment may be valuable.

pH. Much of the early research on Hg cycling in the environment focused on lakes experiencing acidification due to atmospheric deposition of S dioxide and N oxide and elevated Hg concentrations in fish tissue. Low pH has generally been thought to stimulate the methylation of Hg (Grieb et al. 1990; Suns and Hitchin 1990; Wiener et al. 1990; Winfrey and Rudd 1990; Driscoll et al. 1994; Watras et al. 1998). Although Winfrey and Rudd (1990) found no significant effect of pH on Hg demethylation rate, other researchers have shown a positive correlation between pH and demethylation rate (Grieb et al. 1990; Suns and Hitchin 1990; Winfrey and Rudd 1990; Miskimmin et al. 1992; Driscoll et al. 1994). However, Gilmour and Henry (1991) concluded that the response was variable, indicating complex interactions between changes in Hg availability and microbial activity.

Similarly, Julian and Gu (2015) concluded that pH and other bulk chemical parameters such as alkalinity, conductivity, and sulfate could be linked to bioaccumulation of Hg in fish, but effects were variable and not well predicted without further insight from more detailed site characterization. Acidic conditions may increase or decrease the ability of Hg to bind to particulate matter and potentially be transported to sediments (Benoit et al. 2001). By itself, pH is not a reliable predictor of methylation or bioaccumulation.

Temperature. The rate of Hg methylation increases with increasing temperature (within the range of ambient conditions) due to an increase in biological activity and chemical reaction rates. For example, Callister and Winfrey (1986) reported a 3-fold increase in methylation rate in Wisconsin, USA, lake sediments incubated in the laboratory when the temperature was increased from 20 °C to 35 °C. Wright and Hamilton (1982) reported a 50% to 70% increase in Hg methylation for temperature increases of 4 °C to 20 °C in lake sediments from Northwestern Ontario in Canada. As summarized by Ullrich et al. (2001), the rate of Hg methylation in aquatic systems typically peaks during the summer months, indicating the strong influence of temperature on overall Hg methylation.

Wetting and drying. Wetting and drying can have a major impact on Hg methylation in soils and sediments. This hydrologic cycling impacts biological activity due to the resulting effect on the O_2 concentration and alternate electron acceptors such as sulfate, the availability of organic C, and the abundance of nutrients. For example, the State of California, USA, investigated 74 reservoirs, mostly impacted by mining wastes, and found that the magnitude of water-level fluctuation was 1 of 3 factors that statistically explained the variability in MeHg concentration in fish (CWB 2013). The 2 other factors were the dissolved THg concentration and the ratio of dissolved MeHg to chlorophyll *a*, which was considered to represent the magnitude of MeHg entering the food web. While this relationship appears to hold at this particular set of similar reservoirs, it is not readily translatable to other sites.

Also in California, managed wetting and drying has been shown to increase sediment and aqueous MeHg concentrations at rice paddies, compared to nonagricultural, permanently flooded and seasonally flooded wetlands (Windham-Myers et al. 2014). Periodic flooding of rice paddies provides abundant water, nutrients, and continuous production of

labile organic C to drive microbial activity. Although flooding promoted MeHg production in the short term, extended flooding promoted the degradation and sequestration of MeHg due to increased concentrations of solid-phase reduced S that lowered Hg bioavailability.

In Everglades, Florida, USA, wetlands, rewetting of dried soils stimulated MeHg production and elevated MeHg concentration in surface water and sediment porewater (Gilmour et al. 2004). Drying of the sediment promoted the oxidation of sulfides in sediment, resulting in high levels of sulfate that were available to SRB upon rewetting. Furthermore, rewetting of sediment also remobilized particle-bound Hg, making additional Hg available for methylation by SRB.

Overall, the cycle of wetting and drying of sediments and soils, especially in managed reservoirs or wetlands, appears to stimulate net MeHg production because it regenerates key reactants such as sulfate, labile DOM, and bioavailable Hg. Further effort is needed to address the potential role of other redox active elements (e.g., Fe, Mn) in regulating MeHg during wetting and drying cycles. The increased MeHg production in managed freshwater reservoirs and wetlands should not be assumed for estuarine tidal marshes that undergo wetting and drying on a diurnal basis, due to differences in hydrodynamics, frequency, and geochemistry. For example, in a comprehensive study of THg and MeHg flux from a Chesapeake Bay tidal marsh in Maryland, USA, Mitchell et al. (2012) reported that the marsh was a net sink for THg and a relatively small net source of MeHg to the estuary, primarily during the growing season.

"New" versus "old" Hg. Mercury that is freshly deposited from atmospheric deposition to freshwater systems appears to be more available for methylation than is Hg that has been present in an environment for a longer period of time (Hintelmann et al. 2002; Chadwick et al. 2013). The variation in reactivity has been demonstrated through the use of enriched stable Hg isotopes applied to a whole lake system (Harris et al. 2007). Newly added Hg was more readily methylated (Harris et al. 2007), volatilized by reduction (Amyot et al. 2004), and available for ligand exchange (Hintelmann and Harris 2004) than was "old" Hg. As the "new" Hg aged, its reactivity declined to that of old Hg in the system. Recent work by Chiasson-Gould et al. (2014) suggests a mechanism to explain the greater bioavailability whereby newly deposited Hg(II) is sorbed to DOM and taken up into aquatic food webs within 24 h of deposition.

In the Everglades, Gilmour et al. (2004) used additions of stable Hg isotopes to examine the influence of sulfate concentration on methylation of new and old Hg in mesocosms with sediments from a low-sulfate Everglades location. Moderate concentrations of sulfate stimulated methylation of new Hg but had little effect on methylation of old Hg (Figure 2).

For legacy sites with elevated Hg concentrations, new Hg from atmospheric deposition is negligible from a mass balance standpoint; however, it may be more rapidly methylated and bioaccumulated than Hg already present in the system. The relative contributions of new and old Hg to bioaccumulation at Hg-contaminated sites has not been assessed, but stable Hg isotope research may provide such insight in the future.

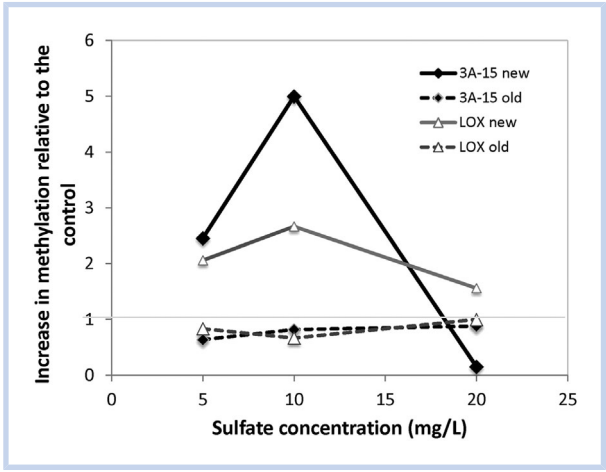

Figure 2. Stimulation and inhibition of Hg methylation in Everglades, Florida, USA, sediments from 2 sites (3A-15 and LOX) based on "new" and "old" Hg measurements. Moderate concentrations of sulfate stimulated methylation of new Hg but had little effect on methylation of old Hg.

Bioaccumulation and exposure pathways

Methylmercury enters the food web through primary producers (e.g., uptake by algae or periphyton) or detritivores and accumulates at each trophic level in a process called "biomagnification." The initial entry of MeHg from water to the food chain is the largest step in biomagnification. For example, the concentration of MeHg in Onondaga Lake, New York, USA, phytoplankton (on a wet weight basis) was 5 orders of magnitude greater than the concentration in filtered water samples (Becker and Bigham 1995). Oligotrophic systems are more susceptible to Hg biomagnification than are eutrophic systems because the lower abundance of primary producers (plankton) in oligotrophic systems results in more concentrated uptake (i.e., less surface area for the uptake of an equivalent mass of dissolved MeHg) (Chen and Folt 2005). The growth rates and lifespans of the organisms inhabiting a system will also affect the ultimate levels measured in the organism themselves. Fast-growing organisms tend to accumulate less MeHg than do more slowly growing organisms, and organisms with longer lifespans tend to accumulate more MeHg (Jenssen et al. 2010).

Consumption of fish is the dominant pathway of Hg exposure to humans (Mergler et al. 2007). Historically, there has been some occupational exposure related to Hg mining or production processes using elemental Hg (e.g., Hg cell chlor-alkali facilities), and humans can be exposed by inhalation of elemental Hg or by incidental ingestion of Hg-contaminated soils and dusts (Nusslein et al. 1995; Davis et al. 1997). Consumption of fish and/or aquatic invertebrates is also the dominant pathway of Hg exposure to most ecological receptors (Tsui et al. 2014); however, recent work suggests that consumption of terrestrial invertebrates (e.g., insects) (Newman et al. 2011) may be an important pathway in some environments.

CASE STUDIES: FACTORS AFFECTING MERCURY METHYLATION AT HG-CONTAMINATED SITES

Three Hg-contaminated sites in the United States—Onondaga Lake (New York), South River (Virginia), and Oak Ridge (Tennessee)—have been the focus of considerable research and monitoring over the past 20 y. Although each is a freshwater system, they vary greatly in physical and chemical

characteristics, Hg source, and management strategy. Nevertheless, they share common factors that impact Hg methylation.

Onondaga Lake

Onondaga Lake is located near Syracuse, New York, and received Hg-containing effluents from the operation of 2 Hg cell chlor-alkali plants. Both plants began operation in 1947; the first plant ceased operation in 1977 and the second in 1988 (Todorova et al. 2009). Remediation of upland sources including the 2 former plant sites, the creek that transported Hg to the lake, and contaminated groundwater (by installation of a barrier wall and groundwater collection and treatment) has significantly reduced releases to the lake (USEPA 2015). Dredging and capping of nearshore sediment was conducted, and natural attenuation of mercury concentrations in sediment underlying deep water continues in order to address sediment as a potential source of Hg to water and biota. In addition, since 2004, increased nitrate loads from the regional wastewater treatment plant (due to installation of a denitrification system to reduce ammonia discharges) have helped limit MeHg concentrations in the anoxic bottom waters of Onondaga Lake during summer stratification (Todorova et al. 2009; Matthews et al. 2013). For microorganisms, nitrate reduction is more energetically favorable than is Fe or sulfate reduction. As a result, once O_2 is depleted in the stratified bottom waters, nitrate can displace Fe and sulfate reduction and therefore can limit Hg methylation and its release from profundal sediment.

The temporal behavior of nitrate, sulfide, and MeHg in Onondaga Lake during stratification demonstrated suppression of sulfate reduction as a major factor limiting MeHg concentrations in the lake (Todorova et al. 2009). Depletion of nitrate was followed by build-up of sulfide and increased MeHg concentrations in the hypolimnion. No nitrate-reducing microorganisms have been found to methylate Hg, so MeHg concentrations remained low as long as nitrate reduction prevailed. Under the supervision of New York State Department of Environmental Conservation (NYSDEC), a 3-y pilot test confirmed that nitrate addition to Onondaga Lake resulted in very low MeHg concentrations in the hypolimnion (Matthews et al. 2013). In conjunction with treatment plant upgrades to reduce ammonia, P, and organic C loading to Onondaga Lake, nitrate addition was accepted by NYSDEC as a means to limit MeHg concentrations in the lake and is currently being implemented during summer months.

South River

South River is a high-gradient and cool-water river located in Virginia. Substrates at South River are primarily composed of coarse materials such as cobbles and boulders with occasional bedrock exposures. From 1929 to 1950, mercuric sulfate was used for the production of acetate flakes and yarn at an industrial facility in Waynesboro, Virginia, along the bank of the river (Carter 1977). During the course of operation, thousands of kilograms of Hg-containing waste were released into the South River, contaminating the river and its floodplain (Flanders et al. 2010). Although use of Hg at the facility stopped more than 60 y ago and Hg loading from this legacy site has declined (Eggleston 2009), MeHg concentrations in fish tissue continue to exceed the USEPA national recommended water quality criterion of 0.3 μg/g in fish tissue (Eggleston 2009).

Biogeochemical and physical conditions of South River typically are not considered optimal for MeHg production. For example, the river has low sulfate and DOM concentrations as well as relatively low abundance of fine-grained substrates. As such, there has been tremendous effort to decipher the physical and biogeochemical controls that impact the fate of Hg and methylation at this site.

Multiple researchers have noted that perpetual river-bank erosion is a key mechanism that transports inorganic Hg into the river, leading to persistent Hg contamination of fish (Flanders et al. 2010). For example, Yu et al. (2012) reported that fine-grained sediment derived from riverbank erosion had higher MeHg concentrations than did coarse sediments from the river, indicating that eroding materials are potential hot spots for methylation. Flanders et al. (2010) found that floodplain soils released more inorganic Hg upon aqueous extraction, compared to fine-grained sediment from the river. The majority of the inorganic Hg released from the floodplain soils was colloidal in nature (Flanders et al. 2010) and was considered to be an ongoing source of Hg(II) for methylation. Sequential extraction coupled to X-ray absorption fine structure (XAFS) analysis showed that Hg speciation in the river-bank sediments mainly consisted of β-HgS with significant amounts of more soluble Hg phases (0.4–33 μg/g) (Desrochers 2013). Desrochers (2013) also conducted erosion simulation experiments that showed that high concentrations of Hg (up to 80 μg/L in water) could be released from riverbank soils.

Although sulfate concentrations are low, there is molecular evidence that sulfate reducers are active, at least seasonally, at the South River (Yu et al. 2012). Sediment RNA extracts showed at least 3 active groups of SRB in South River sediments. A group of Fe reducers was also found in RNA extracts, suggesting a potential role of Fe-reducing bacteria to methylate Hg. Addition of both poorly crystalline Fe oxyhydroxide and sulfate to South River sediment enhanced the Hg methylation rate (Yu et al. 2012). This study shows that both sulfate and Fe-reducing bacteria coexist in South River sediment and likely contribute to Hg methylation. Addition of sulfate and lactate to laboratory columns packed with South River sediments resulted in stimulation of SRB and subsequent production of MeHg (Desrochers et al. 2015). Finally, Yu et al. (2012) reported that demethylation rates were lower than rates found in other systems, which would also contribute to higher net methylation at the South River.

Oak Ridge

During the 1950s and 1960s, roughly 11 million kg of Hg was used at the Y-12 National Security Complex at the Oak Ridge Reservation in Tennessee (Brooks and Southworth 2011). Approximately 108 000 to 212 000 kg of Hg was released into the headwaters of East Fork Poplar Creek (EFPC), which led to high Hg concentrations in floodplain soils and sediments along EFPC on the Oak Ridge Reservation property (Barnett et al. 1995; Campbell et al. 1998; Liu et al. 2006; Jardine 2008). Although remediation is ongoing, a substantial amount of Hg has already been transported downstream (Campbell et al. 1998). Up to several hundred parts per million Hg has remained in the top 8 cm of soil (Barnett et al. 1995), enough of which is accessible to bacteria to induce the expression of detoxification genes (Oregaard and Sorensen 2007).

Although most of the Hg is likely immobilized within EFPC soils in insoluble Hg-sulfide phases, sporadic flooding and anaerobic processes in EFPC soils release Hg that is accessible to methylating bacteria, thus posing long-term ecological risk (Jardine 2008).

Although the occurrence and amount of S(-II) in EFPC is currently unknown, HgS(s) has been found in floodplain soils (Barnett et al. 1997), demonstrating that HgS(s) formed as a secondary phase. The creek contains on the order of 100 μM (~10 mg/L) sulfate (Dong et al. 2010), which is enough to support microbial sulfate reduction but not necessarily enough to impede Fe(III) reduction (Fleming et al. 2006; Kerin et al. 2006). The fact that MeHg is measurable downstream of EFPC (Campbell et al. 1998) suggests that environmental conditions are suitable for sulfate reducers or Fe(III) reducers.

Several researchers have studied the role of DOM on the bioavailability of Hg at EFPC (Miller et al. 2009; Dong et al. 2010), where DOM concentrations range from 2.5 to 3.5 mg/L. Even at this relatively low concentration of DOM, Hg that complexed to S or thiol-like functional groups of DOM appears to control Hg speciation (Dong et al. 2010). Miller et al. (2009) noted that the reaction between Hg and natural DOM is kinetically controlled and complex because of the heterogeneous nature of natural DOM. That is, equilibrium conditions cannot be assumed when assessing Hg speciation at the creek. The importance of Hg interaction with DOM at EFPC has been established; however, the net effect of DOM on Hg methylation is unclear.

Extensive remedial action has taken place at Oak Ridge Reservation and has resulted in the reduction of inorganic Hg concentrations downstream of EFPC (Southworth et al. 2000). However, MeHg concentration in fish has not declined and remains above the USEPA national recommended water quality criterion of 0.3 μg/g fish tissue. At the Oak Ridge Reservation, neither THg concentration nor dissolved inorganic Hg concentration correlates to MeHg concentration, indicating the importance of factors other than THg (e.g., biogeochemical factors) (Dong et al. 2010).

Summary of case studies
