

APPENDIX G
SUPPORTING DATA FOR ALTERATIVES ANALYSIS

Daily Flow Calculations Methodology for Alternatives Evaluation

Big Sur River Zone 4 to Zone 2 Estimated Daily Flow

USGS Big Sur River gage daily flow rate records, from 1985 to 2004, were used to estimate flow entering Zone 4 within the study area. A linear relationship between USGS flow and measured unimpaired flow was determined to be (Figure 3-35 SGI 2008):

$$Q_{\text{unimpaired}} \text{ entering Zone 4} = 1.3352 * \text{USGS flow rate} - 7.771 \quad (\text{cfs})$$

Estimated groundwater accretion between Zone 4 and Zone 2 is about 1.7 cfs

Therefore, unimpaired flow from Zone 4 through Zone 2 was estimated as:

$$Q_{\text{unimpaired}} \text{ through Zone 4 to Zone 2} = 1.3352 * \text{USGS flow rate} - 7.771 + 1.7 \quad (\text{cfs})$$

Synthetic Daily Flow

For all diversion conditions:

- If unimpaired flow rate was 0, no diversion was applied
- A river flow loss of 0.24 cfs per 1.0 cfs diverted was assumed (Table 3-1 SGI 2008)
- If calculated flow rates were less than 0, a flow rate of 0 was assumed.
- If the diversion reduced river flow to less than 0, a river flow rate of 0 was assumed

Diversion Rate Estimation

Baseline Conditions

Historic monthly average diversion rate, for each year from 1985 through 2004, was used to determine Baseline flow rate Big Sur River Zone 4 through Zone 2 flow rate losses (see El Sur Ranch Monthly Pumping (cfs)). The average diversion rate for each month was applied to each day for the entire month for the applicable year.

Proposed Project

Maximum application diversion rates for May through October (Table 6-1 this DEIR), and annual monthly maximum diversion rate for May and June were used to estimate proposed project effects on Big Sur River Zone 4 through Zone 2 daily flow rates. The remainder of the application allotment was divided equally among the remaining winter months. The table below lists the monthly average diversion rate per day was applied to each day of the month for each year.

TABLE 1	
DIVERSION RATES USED FOR PROPOSED PROJECT DAILY FLOW SIMULATION	
Month	Diversion Rate cfs
January	0.5
February	0.5
March	0.5
April	0.5
May	5.34
June	5.34
July	3.01
August	3.01
September	3.01
October	3.01
November	0.5
December	0.5

No Project Alternative (NPA)

The NPA was assumed to use the same irrigation strategy as historic conditions. Therefore, the application of irrigation water was assumed to be 9 percent of historic uses (25 acres/267 acres). Historic monthly average diversion rate, for each year from 1985 through 2004, was reduced to 9 percent of historic values and these diversion rates (see El Sur Ranch Monthly Pumping (cfs)) were used to determine flow rate losses in Big Sur River Zone 4 through Zone 2 for the NPA. The average diversion rate for each month was applied to each day for the entire month for the applicable year.

Alternate Irrigation Efficiency (AIE)

The AIE assumed an average irrigation efficiency of 80 percent. Historic records of irrigation use were adjusted to reflect an 80 percent irrigation efficiency, compared to historic uses (see Historic Required Irrigation).

This historic required irrigation at 80 percent efficiency rate, for each year from 1985 through 2004, was used for the diversion rates were used to determine flow rate Zone 4 through Zone 2 Big Sur River flow losses. The average diversion rate for each month was applied to each day for the entire month for the applicable year.

Frequency Analysis

A frequency analysis was performed for flow rates in the 20-year synthetic daily flow record (adjusted for the various diversion scenarios as described above). The frequency analysis was used to determine Bankful and Flood flow rates, and critical (0 and 1 cfs) non-exceedence probabilities.

The Bankful flow was estimated as the 1.5-year, 2.0-year, or 2.5-year return period flow, which have a probability of 66.7, 50, and 40 percent, respectively, chance of occurrence in any given year. Flood flow was estimated as the 10-year return flow (10 percent chance of occurrence in any given year).

In addition to the annual critical non-exceedence probability, critical non-exceedence flow probability was also evaluated for the month of November for the 20-year synthetic daily flow record.

HISTORIC IRRIGATION EFFICIENCY

1 from Table 9-1 and 7-9. Based on PG&E electric records and pump test 1967, 1992, 2004. Daily records 1989-2000 and 2004-2006

2 same as 1.

3 from Table 7-8, Based ET_o, K_c = 1.06

4 from Table 7-11. Historic irrigation used for ET. Month to month annual moisture balance and Crop Uptake. Assumes field capacity = 5 inches. (Rootzone of 2ft and FC of .125 in/in = 3 in usable)

5 from Table 9-1. Beneficial Use (ET and LF), assumes LF is a constant 10% of Irrigated Water (1)

9 [8] - [7] = the amount of additional irrigation to achieve the calculated leaching fraction

10 [4]+[9] = Crop ET_c plus newly calculated additional irrigation needed for leaching

11 same as 10 converted to acre-ft.

12 [10]/[1] = new efficiency with revised irrigation rate

13 remove 100%

14 difference between 6 and 13

No Project Alternative (Alt 1) El Sur Ranch Monthly Pumping Reduction on BSR Flow Rates (cfs)
