POLICY FOR MAINTAINING INSTREAM FLOWS IN NORTHERN CALIFORNIA COASTAL STREAMS

1.0 INTRODUCTION

The State Water Resources Control Board (State Water Board or Board) adopted this state policy for water quality control on _____, 2010. This policy is also known as the North Coast Instream Flow~~flow~~ Policy. It applies to applications to appropriate water, small domestic use and livestock stockpond registrations, and water right petitions.

Water Code section 1259.4, which was added by Assembly Bill 2121 (Stats. 2004, ch. 943, § 3), requires the State Water Board to adopt principles and guidelines for maintaining instream flows in northern California coastal streams as part of state policy for water quality control, for the purposes of water right administration. This policy implements Water Code section 1259.4. The geographic scope of this policy, referred to as the policy area, extends to five counties—Marin, Sonoma, and portions of Napa, Mendocino, and Humboldt counties— and encompasses (1) coastal streams from the Mattole River (originating in Humboldt County) to San Francisco, and (2) coastal streams entering northern San Pablo Bay.

This policy focuses on measures that protect native fish populations, with a particular focus on **anadromous salmonids**[1] (e.g., steelhead trout, coho salmon, and chinook salmon) and their habitat. Beginning in 1996, the National Marine Fisheries Services (NMFS) and the California Department of Fish and Game (DFG) listed steelhead trout, coho salmon, and chinook salmon as "threatened" under the federal Endangered Species Act (ESA) and the California Endangered Species Act (CESA), respectively. In 2005, the coho salmon's status was upgraded from threatened to "endangered" on both the ESA and the CESA lists.

A number of factors led to the decline of anadromous salmonid populations in the policy area. Climatic variation, disease, predation, loss of genetic diversity, fish harvesting, and land and water use all pose an ongoing threat to salmonids. Degradation and loss of freshwater habitat is one of the leading causes for the decline of salmonids in California (DFG, 2004). Historical and continuing urban, agricultural, and timber harvest land use practices affect fish habitat by increasing pollutant loading and causing sedimentation of spawning gravels. Land use practices also result in removal of riparian habitat and physical alteration of stream channels, including the creation of barriers to fish migration. Water diversion results in a significant loss of fish habitat in California (NMFS, 1996). Water withdrawals change the natural hydrologic patterns of streams and can directly result in loss or reduction of the physical habitat that fish occupy. Flow reduction can exacerbate many of the problems associated with land use practices by reducing the capacity of streams to assimilate pollutants. Construction and operation of dams and diversions create barriers to fish migration, thereby blocking fish

[1] The first usage of terms defined in the Glossary of Terms (Appendix I) is indicated in bold.

from access to historical habitat. Dams also disrupt the flow of food (i.e., aquatic insects), woody debris, and gravel needed to maintain downstream fish habitat.

For the processing of water right applications prior to the adoption of this policy, the State Water Board considered the recommendations in the 2002 draft "Guidelines for Maintaining Instream flows to Protect Fisheries Resources Downstream of Water Diversions in Mid-California Coastal Streams" (DFG-NMFS Draft Guidelines) jointly developed by DFG and NMFS. (See Wat. Code, § 1259.4, subd. (b)) The DFG-NMFS Draft Guidelines were specifically developed to protect and restore anadromous salmonids and their habitat. The DFG-NMFS Draft Guidelines were intended to preserve a level of streamflow that protects anadromous salmonids from deleterious effects of water diversions. When the State Water Board developed the scientific basis for this policy, concepts proposed in the DFG-NMFS Draft Guidelines were utilized. Consideration of these concepts aided the State Water Board in developing criteria that are protective, as demonstrated in the Scientific Basis Report[2].

This policy establishes principles and guidelines for maintaining instream flows for the protection of fishery resources. It does not specify the terms and conditions that will be incorporated into water right permits, licenses, and registrations. It prescribes protective measures regarding the **season of diversion**, **minimum bypass flow**, and **maximum cumulative diversion**. Applicants may choose to implement the policy principles through the regionally protective criteria or site specific studies. Site -specific studies may be conducted to develop alternative site-specific protective criteria. The policy also limits construction of new onstream dams and contains measures to ensure that approval of new onstream dams does not adversely affect instream flows needed for fishery resources. The policy provides for a **watershed**-based approach to evaluate the effects of multiple diversions on instream flows within a watershed as an alternative to evaluating water diversion projects on an individual basis. Enforcement requirements contained in this policy include a framework for compliance assurance, prioritization of enforcement cases, and descriptions of enforcement actions. The policy contains guidelines for evaluating whether a proposed water diversion, in combination with existing diversions in a watershed, may affect instream flows needed for the protection of fishery resources.

2.0 POLICY FRAMEWORK

2.1 Principles for Maintaining Instream Flows

Protection of fishery resources is in the public interest. The primary objective of this policy is to ensure that the administration of water rights occurs in a manner that maintains instream flows needed for the protection of fishery resources. This policy establishes the following five principles that will be applied in the administration of water rights:

[2] R2 Resource Consultants and Stetson Engineers, 2007a.

1. Water diversions shall be seasonally limited to periods in which instream flows are naturally high to prevent adverse effects to fish and fish habitat;

2. Water shall be diverted only when streamflows are higher than the minimum instream flows needed for fish spawning, rearing, and passage;

3. The maximum rate at which water is diverted in a watershed shall not adversely affect the natural flow variability needed for maintaining adequate channel structure and habitat for fish;

4. The cumulative effects of water diversions on instream flows needed for the protection of fish and their habitat shall be considered and minimized; and

5. Construction or permitting of new onstream dams shall be restricted. When allowed, onstream dams shall be constructed and permitted in a manner that does not adversely affect fish and their habitat.

As described below, applicants may choose to implement the policy principles through the regionally protective criteria described in section 2.2.1 below, or the protective site-specific criteria described in section 2.2.2. In addition, the Board may approve alternative regional or site specific criteria.

2.2 Protective Instream Flow Criteria

Instream flow criteria may be required for proposed water diversions to comply with policy principles. The instream flow criteria used may either be the regionally protective criteria described below, site-specific criteria described below, or protective site-specific criteria and directions developed by individual applicants or groups of applicants. Any site-specific criteria proposed by an applicant or group of applicants shall be consistent with the principles described in Section 2.1 and shall be approved by the State Water Board Deputy Director for Water Rights (Deputy Director). The site-specific study plan and documents supporting the basis for the criteria shall be reviewed and approved by the Deputy Director.

Alternative Regional Criteria

The State Water Board may approve alternative regionally protective criteria provided the Board finds that data has been provided demonstrating the alternative regional criteria are ~~at least as~~ protective of fishery resources throughout~~as~~ the policy area.~~criteria described below.~~ Parties may petition the State Water Board to amend this policy to allow for alternative regional criteria. The Deputy Director shall review any petition submitted to determine if the proposed alternative regional criteria are scientifically sound. In making that determination, the Deputy Director shall consider whether the proposed alternative regional criteria are: (1) supported by scientific literature, (2) have been peer reviewed and found to be appropriate, and (3) have been validated at sites located in different geographic areas within the policy area. If the

Deputy Director finds that the proposed regional criteria are scientifically sound, the State Water Board may amend the policy to allow for the regional application of alternative criteria. Before the State Water Board approves the alternative approach, it will comply with article 3 (commencing with section 13140) of chapter 3 of division 7 of the Water Code.

The minimum bypass flow is the minimum instantaneous flow rate of water that is important for managing the protection of steelhead and salmon life history needs, such as: (1) maintaining natural abundance and availability of spawning habitat; (2) minimizing unnatural adult exposure, stress, vulnerability, and delay during adult spawning migration; and (3) sustaining high quality and abundant juvenile salmonid winter rearing habitat.

The winter low flow is a streamflow threshold important to maintaining good habitat in Class II streams for protection of aquatic non-fish vertebrates, aquatic benthic macroinvertebrates, aquatic plant, and hydric soils. The regionally protective criterion for the winter low flow is the February median flow.

2.2.1 Regionally Protective Criteria~~protective criteria~~

The policy area is a diverse region. Site specific studies would identify more precisely the fishery resource instream flow needs of a particular location. This policy also allows the use of criteria that were developed to be protective of fishery resources throughout the policy area[3] (regionally protective criteria or regional criteria). The intent of this approach is to provide the applicant an avenue for quicker processing of pending applications while protecting fishery resources. The regionally protective criteria should not be considered to have site-specific precision for every stream. The regional criteria are by necessity conservative and err on the side of resource protection. To be regionally protective, the regional criteria limit water diversions so that adequate flows are available at sites with the greatest instream flow needs. At some sites, therefore, more than adequate flows will be provided by regionally protective criteria. ~~Site specific studies may be used to identify more precisely the fishery resource instream flow needs of a particular location.~~

2.2.1.1 Season of Diversion

The season of diversion is the calendar period during which water may be diverted. New diversions are generally not allowed using the regional criteria during the late spring, summer, and early fall because existing instream flows during this period generally limit anadromous salmonid rearing habitat quantity and quality in the policy area. The regionally protective criteria limit new water diversions in the policy area to a diversion season beginning on December 15 and ending on March 31 of the succeeding year. Site-specific studies may indicate that the season of diversion can be extended into other times of the year.

2.2.1.2 Minimum Bypass Flow

The minimum bypass flow is the minimum instantaneous flow rate of water that is important~~*adequate*~~ for managing the protection of steelhead and salmon life history needs, such~~*fish spawning, rearing, and passage,*~~ as: (1) maintaining natural abundance and availability of spawning habitat; (2) minimizing unnatural adult exposure, stress, vulnerability, and delay during adult spawning migration; and (3) sustaining high quality and abundant juvenile salmonid winter rearing habitat.

With certain exceptions defined below, the ~~measured at a particular point in the stream. The~~ minimum bypass flow must be met on an instantaneous basis at the **point of diversion** (POD) before water may be diverted using the regional criteria. The streamflow may naturally fall below the minimum bypass flow. A minimum bypass flow requirement prevents water diversions during periods when streamflows are at or below the flows needed for spawning, rearing, and passage.

[3] For the scientific basis for the regionally protective criteria, see R2 Resource Consultants and Stetson Engineers, 2007a and 2009.

The regionally protective criteria for the minimum bypass flow are determined using the **mean** annual flow and drainage area of the location being analyzed. The location of the diversion within the watershed is important to know before determining the minimum bypass flow. Diversions within the **range of anadromy** will use the mean annual flow and drainage area at the diversion location to determine the minimum bypass flow. If the diversion is located within the range of anadromy, the size of the drainage area determines which formula in the table below should be used to determine the minimum flow needed for spawning, rearing and passage at the POD. The table below will also be used to assess instream flow needs at locations downstream of the POD. These locations are referred to as **points of interest** (POI). The drainage area at the POI determines which formula in the table below should be used to determine the minimum flow needed for spawning, rearing, and passage at each POI.

If a diversion is located above the **upper limit of anadromy**, the bypass flow at the diversion point is determined based on an evaluation of the effects of the proposed project at the upper limit of anadromy and at other POIs within the range of anadromy, rather than at the diversion location. ~~.~~ Diversions located above the upper limit of anadromy may be able to operate without a minimum bypass flow if the evaluation of the effects of the proposed project demonstrates no impact to downstream fishery resources. Diversions on Class II and Class III streams are evaluated by reference to their cumulative effect on flows at the upper limit of anadromy and POIs downstream from there. The regional criteria require maintenance of the **winter low flow** or greater on Class II streams for diversions above anadromy. The regionally protective criterion for the winter low flow is the February median flow. Methods for calculating the regionally protective February median flow are provided in Appendix B. For further information regarding the process for determining bypass flows for PODs above anadromy, please refer to Policy Section 2.3 and Appendix A Sections A.1.8.1 and A.1.8.2.

The regionally protective minimum bypass flow criteria at PODs and POIs located at and below the upper limit of anadromy are identified in the following table. The regionally protective minimum bypass flow criteria provide protective flows at the upper limit of anadromy and downstream.

Table 2.1. Regional Criteria at PODs and POIs at and below anadromy

Drainage Area at POD or POI	Minimum Bypass Flow Formula
1 square mile or smaller	$Q_{MBF} = 9.0\ Q_m$
Between 1 and 321 square miles	$Q_{MBF} = 8.8\ Q_m\ (DA)^{-0.47}$
321 square miles or larger	$Q_{MBF} = 0.6\ Q_m$

Q_{MBF} = **minimum bypass flow** in cubic feet per second
Q_m = **mean annual unimpaired flow** in cubic feet per second
DA = the **watershed drainage area** in square miles

Methods for locating the upper limit of anadromy are provided in Appendix A Section A.1.4. The selection of POIs is described in Appendix A Section A.1.7. Guidelines for estimating the mean annual unimpaired flow, watershed drainage areas, and the calculation of the regionally protective minimum bypass flow are provided in Appendix B.

2.2.1.3 Maximum cumulative diversion

Adequate magnitude and variability in peak streamflows are needed to meet the habitat needs of anadromous salmonids, including maintaining stream channel geometry, vegetative structure and variability, gravel and wood movement, and other channel features. In this policy these peak streamflows are called **channel maintenance flows**.

Channel maintenance is a long-term process in which the basic habitat structure of a stream is formed and maintained by multiple, variable high flow events recurring on a periodic basis.

The **bankfull flow** is the flow at which channel maintenance is the most effective. The 1.5-year return peak flow is a hydrologic metric that can be used to estimate bankfull flow and effective channel maintenance flows. The **1.5-year instantaneous peak flow** is the annual maximum instantaneous peak streamflow that is equaled or exceeded, on average over the long term, once every one and a half years. The frequency at which this peak flow is expected to occur is referred to as the **recurrence interval**. Limiting the maximum rate at which water is withdrawn by all water diverters in a watershed so that peak streamflows are reduced by no more than a small fraction of the 1.5-year instantaneous peak flow will result in a relatively small change to channel geometry, and will ensure that natural flow variability and the various biological functions that are dependent on that variability are protected.

To ensure maintenance of natural flow variability and protection of the biological functions dependent on it, the maximum cumulative diversion rate is set at the largest value of the sum of the rates of diversion of all diversions upstream of a specific location in the watershed.

The maximum cumulative diversion rate regionally protective criterion is equal to: five percent of the 1.5-year instantaneous peak flow.

For projects located above anadromy, the maximum cumulative diversion rate criterion shall be evaluated at POIs at and/or below anadromy in order to identify the allowable rate of diversion at project PODs. The maximum cumulative diversion rate puts limitations on the cumulative rate of water withdrawal in a watershed, not necessarily the rate of withdrawal at a point of diversion. The rate of diversion limitation for a project is not necessarily equal to the maximum cumulative diversion rate limitation in a watershed. This is because the project's rate of diversion limitation is based on an evaluation of whether the project, together with existing diversions, causes an exceedance of the maximum cumulative diversion rate criterion at points of interest at and/or below the upper limit of anadromy. Guidelines for calculating the maximum cumulative diversion rate criterion and for determining whether a limit on the rate of diversion is needed are provided in Appendix A, Section A.1.8 and Appendix B Section B.5.2.3.

2.2.2 Site-specific studies

~~If the diverter believes that the regional criteria are overly protective for a specific project, the diverter may propose site-specific criteria. The diverter may implement one or more of the regional criteria in combination with site-specific criteria.~~ Site-specific studies may be conducted to obtain site-specific criteria that identify more precisely than the regionally protective criteria the instream flow needs of a particular location. When a site-specific study has been conducted pursuant to an approved study plan and an approved report of the study has been accepted by the Division, the regional criteria will not be considered for parameters for which proposed site-specific criteria have been developed.

~~-~~Appendix C describes the data and reporting requirements for the initial reconnaissance level habitat assessment, the development of the study plan from the results of the initial habitat assessment, and the reports documenting the results of a site-specific study. Appendix C also provides flow management objectives as guidance for site specific studies. The objectives define acceptable cumulative changes in stage and acceptable minimum depth and velocity requirements for salmonids.

An alternative ~~A~~ site-specific approach may be proposed to develop criteria for parameters other than a minimum bypass flow, maximum cumulative diversion, or season of diversion. A description of the alternative approach and a study plan shall be submitted to the State Water Board for review and approval prior to commencement of field work and analysis.

The alternative approach and any proposed site-specific criteria shall be consistent with the principles described in Section 2.1. The State Water Board shall~~may~~ consult with DFG regarding the alternative approach proposal, study plan, and study results. DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment before the State Water Board provides the applicant with written recommendations.

All field work, analysis, and recommendations involving fishery habitat evaluations shall be performed by a qualified fisheries biologist.

2.3 Assessment of the Cumulative Effects of Water Diversions on Instream Flows

The cumulative effects of water diversions on instream flows needed for the protection of fishery resources shall be considered and minimized. This policy requires the evaluation of whether a proposed water diversion project, in combination with existing diversions in a watershed, may affect instream flows needed for fishery resources protection. In addition, the State Water Board must find that unappropriated water is available to supply a proposed project prior to issuing a water right permit. (Wat. Code, § 1375, subd. (d).) This policy requires a water right applicant to conduct a water availability analysis that includes (1) a water supply report that quantifies the amount of water remaining instream after senior diverters are accounted for, and (2) a cumulative diversion analysis to evaluate the effects of the proposed project, in combination with existing diversions, on instream flows needed for fishery resources protection. Applicants may use regional criteria, site-specific criteria, or a combination of the two in the cumulative diversion analysis for assessing whether the proposed diversion affects the instream flows needed for fishery resources. The water supply report and cumulative diversion analysis are described in Appendix A, and guidelines for completing the analyses are provided in Appendix B.

Appendix A, Section~~Sections~~ A.1.8.1 ~~and A~~.1 specifies~~.8.2 specify~~ exemption criteria for projects on Class III streams. For projects on Class III streams, if~~above anadromy. If~~ the analysis shows (1) a project can operate without a minimum bypass flow and maximum rate of diversion and still be protective of fishery resources, and (2) that it can operate in a manner that does not negatively affect the winter low flow on Class II streams, the diverter may be able to operate without application of the regionally protective criteria established~~the instream flow requirements prescribed~~ by this policy.

2.4 Onstream Dams

An onstream dam is a structure in a stream channel that impedes or blocks the passage of water, sediment, woody debris, or fish. Onstream dams can directly impact salmonids if they prevent fish passage and block access to upstream spawning and rearing habitats. Onstream dams can intercept and retain (1) spring and summer flows without providing bypass flows, (2) sediments/gravels that would otherwise replenish

downstream spawning gravels, and (3) large wood that would otherwise provide downstream habitat structure. They also create slow-moving, lake-like habitats that can favor non-native species that either prey on anadromous salmonids or compete for food and shelter.

The following requirements minimize the impacts of onstream dams. The requirements avoid (1) causing individual or additive impacts to flows, (2) interrupting fish migratory patterns, (3) interrupting downstream movement of gravel, woody debris, or **aquatic benthic macroinvertebrate**s, (4) causing loss of riparian habitat or wetlands, or (5) creating habitat for non-native species. In addition to the following permitting requirements, water right applications for onstream dams shall also demonstrate that water is available for diversion (see Appendix A). The following permitting requirements for onstream dams are dependent on the stream classification at the point of diversion. For purposes of this Policy, the stream shall be classified in accordance with the stream classification system described in Appendix A Section A.1.6. Class I streams are streams where fish are always or seasonally present. Class II streams are streams where fish are not present, but **aquatic non-fish vertebrates** and /or aquatic benthic macroinvertebrates exist. Class III streams do not support aquatic life.

2.4.1 Onstream dams on Class I streams

The State Water Board will not approve a water right permit for an onstream dam on a Class I stream unless the following requirements are met:

1. The applicant provides documentation acceptable to the State Water Board that the onstream dam was built prior to July 19, 2006. This is the date the public notice of preparation of the policy was issued. One year after the adoption of this policy, water right applications for onstream dams built prior to July 19, 2006 within the affected policy area will no longer be accepted.

2. Fish passage facilities are constructed in accordance with requirements provided by DFG in a written certification. If DFG determines that fish passage facilities are not needed, this determination and DFG's supporting documentation~~reasons~~ shall be provided in writing to the State Water Board. The applicant shall provide a copy of the DFG certification or determination that passage facilities are not needed to the State Water Board during the environmental review of the application or petition.

3. The applicant signs an agreement to comply with all conditions, including but not limited to, conditions upon the construction and operation of the fish passage facilities, required by DFG.

4. A passive bypass system or automated computer-controlled bypass system is constructed that conforms with the requirements contained in Appendix E.

5. Fish screens are installed in accordance with the requirements contained in Section 6.0.

6. Where needed, mitigation plans for non-native species eradication, gravel and wood augmentation, and/or riparian habitat replacement are developed and implemented. Guidance for developing mitigation plans is provided in Appendix D.

2.4.2 Onstream dams on Class II streams

With the exception below, the State Water Board will not approve a water right permit for a proposed or existing onstream dam on a Class II stream unless the following requirements are met:

1. The applicant provides documentation acceptable to the State Water Board that the onstream dam was built prior to July 19, 2006. This is the date the public notice of preparation of the policy was issued. One year after the adoption of this policy, water right applications for onstream dams built prior to July 19, 2006 within the affected policy area will no longer be accepted.

2. A passive bypass system or automated computer-controlled bypass system, is constructed that conforms to the requirements contained in Appendix E.

3. Where needed, mitigation plans for non-native species eradication, gravel and wood augmentation, and/or riparian habitat replacement are developed and implemented. Guidance for developing mitigation plans is provided in Appendix D.

Notwithstanding requirements number 1 and 2 above, the State Water Board may consider approving a water right permit for a proposed onstream dam on a Class II stream if all of the following conditions are met:

1. The proposed dam is located above an existing permitted or licensed reservoir that provides municipal water supply or is under the jurisdiction of the Federal Energy Regulatory Commission.

2. The existing permitted or licensed reservoir was constructed prior to the adoption of this policy and does not have fish passage facilities, and DFG has provided a written determination that it is not feasible to construct fish passage facilities.

3. The applicant prepares and submits a biological assessment demonstrating that the proposed dam will not adversely affect fish between it and the existing permitted or licensed reservoir.

4. The applicant develops and implements mitigation plans for non-native species eradication, gravel and wood augmentation, and/or riparian habitat replacement,

where needed. Guidance for developing mitigation plans is provided in Appendix D.

5. The applicant prepares and submits evidence demonstrating that the proposed diversion will not adversely affect instream flows needed for fishery resources downstream of the existing permitted or licensed reservoir that provides municipal water supply or is under the jurisdiction of the Federal Energy Regulatory Commission.

2.4.3 Onstream dams on Class III streams

The State Water Board may approve a water right permit for an onstream dam on a Class III stream if the following requirements are met:

1. A passive bypass system, or automated computer-controlled bypass system, is constructed that conforms with the requirements contained in Appendix E, or there is a determination pursuant to Appendix section 1.8.1 that no bypass flow is needed. ~~.~~

2. Mitigation plans for non-native species eradication, and gravel and wood augmentation, are developed and implemented, where needed. Guidance for developing mitigation plans is provided in Appendix D.

3.0 POLICY APPLICABILITY

3.1 Instream Biological~~Fishery~~ Resources Covered by the Policy

This policy establishes principles and guidelines for maintaining instream flows for the protection of native fishery resources in Northern California coastal streams. Many of the ~~The~~ criteria in this policy were developed based on the requirements of anadromous salmonids present with~~, which are among the largest native fish~~ in the policy area. Instream flows that satisfy the needs of anadromous salmonids will also be protective of other~~smaller~~ native fish populations and fish habitat in general. The principles and guidelines in this policy may not apply where they conflict with greater flow requirements for other instream biological resources.

3.2 Geographic Area Covered by the Policy

This policy applies to water diversions from all streams and tributaries discharging to the Pacific Ocean from the mouth of the Mattole River south to San Francisco, and all streams and tributaries discharging to northern San Pablo Bay. The policy area includes approximately 5,900 stream miles and encompasses 3.1 million watershed acres (4,900 square miles) in Marin, Sonoma, portions of Napa, Mendocino, and Humboldt counties, as indicated on Figure 1. Information from the USGS National **Hydrography** Database was used to create a list of named streams within the policy

area, as provided in Appendix K. The policy applies to water diversions from these streams and to water diversions from unnamed and locally named streams that contribute flow to these streams.

The regionally protective instream flow criteria for season of diversion, minimum bypass flow, maximum cumulative diversion, and the cumulative diversion analysis requirements do not apply to water diversions from **flow regulated mainstem rivers**. However, diversions from these streams shall comply with the rest of this policy, including the policy principles and the regionally protective criteria pertaining to onstream dams. Diversions from streams tributary to flow regulated mainstem rivers shall comply with all aspects of this policy.

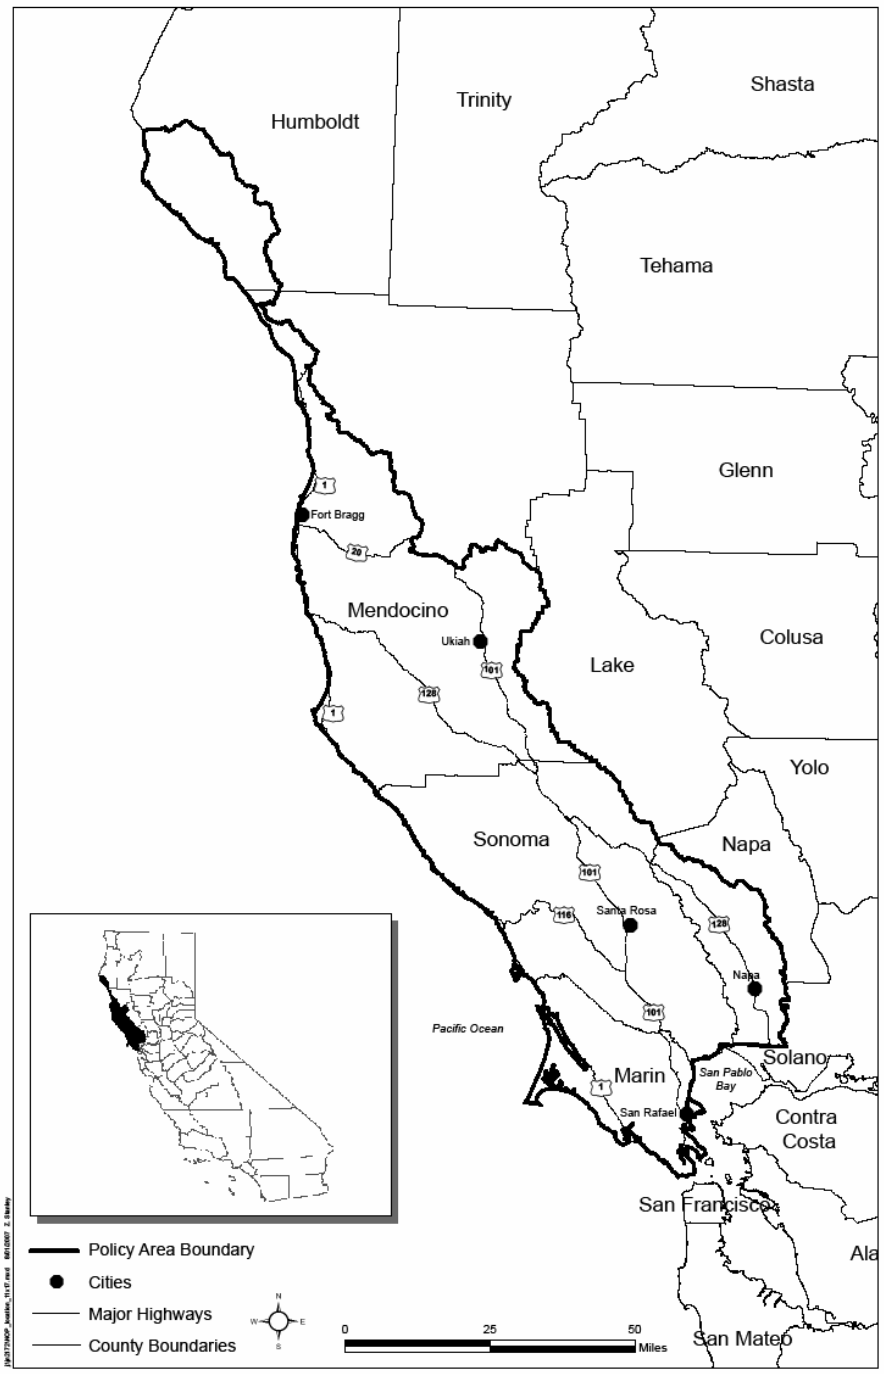

Figure 1 Geographic Area Affected by the Policy

3.3 Water Right Actions Covered by the Policy

This policy applies to applications to appropriate water, small domestic use and livestock stockpond registrations, and water right petitions. Enforcement requirements include a framework for compliance assurance, prioritization of enforcement cases, and timely and appropriate enforcement actions. Information regarding enforcement can be found in Policy Section 8~~9~~.0 and Appendices F, G, and H

3.3.1 Water right applications

Except as provided below, this policy applies to applications to appropriate water from surface water streams or from subterranean streams flowing through known and definite channels.

Applications filed with the State Water Board prior to the adoption date of this policy shall be processed as follows:

1. If prior to the adoption date of this policy, the applicant has submitted a water availability analysis and an analysis of cumulative flow-related impacts the State Water Board will process the water availability aspects of the application using the DFG-NMFS Draft Guidelines. Prior to processing the application using the DFG-NMFS Draft Guidelines the State Water Board must determine that the project is consistent with the recommendations contained therein pertaining to diversion season, onstream dams, minimum bypass flows, protection of the natural hydrograph and avoidance of cumulative impacts. Projects in the process of implementing site specific study plan(s) that have been approved by DFG, NMFS, and the State Water Board meet this requirement. All other aspects of this policy will apply.

2. If the applicant has submitted a water availability analysis and an analysis of cumulative flow-related impacts prior to the adoption date of this policy, and the State Water Board determines that the project is not substantially consistent with the recommendations contained the DFG-NMFS Guidelines, then all of the requirements of this policy shall apply.

3. If a water availability analysis and an analysis of cumulative flow-related impacts have not been submitted prior to the date this policy was adopted, all of the requirements of this policy shall apply. The applicant, however, may request and the Deputy Director for Water Rights may approve continued processing of the application consistent with the DFG-NMFS Draft Guidelines if the Deputy Director for Water Rights finds that an applicant has completed significant work towards the analyses prior to the adoption of this policy.

4. If prior to the adoption of the policy, the State Water Board has circulated for public review a negative declaration, mitigated negative declaration or environmental impact report pursuant to the California Environmental Quality Act, the Board may continue processing the application without applying the instream

flow requirements of the Policy~~regionally protective criteria contained in Section 2.2.1~~.

The Deputy Director may approve an exception to the season of diversion criterion for all or part of an application if the application is for a storage project and the Deputy Director finds that (1) the applicant's existing diversions under another valid basis of right will be reduced as a result of the applicant's ability to divert to storage, and (2) the benefit to fishery resources of the reduction in diversions outweighs the potential impacts to fishery resources of the storage project.

3.3.2 Water right petitions

Under this policy, a petitioner shall provide adequate information for the State Water Board to determine whether the proposed change will affect instream flows.

3.3.2.1 Petitions that do~~will~~ not have the potential to impair instream beneficial uses~~result in decreased flow in a stream reach~~

The policy requirements for diversion season, minimum bypass flow, and maximum cumulative diversion do not apply to petitions that the Deputy Director determines do not have the potential to impair instream beneficial uses.~~result in decreased flow in a stream reach~~.

3.3.2.2 Petitions for short-term change

The policy requirements ~~that~~ do not apply to petitions to change existing water right permits and licenses effective for one year or less, pursuant to Water Code sections 1435 et seq. and section 1725 et seq.

3.3.2.3 Petitions that have the potential to impair instream beneficial uses

Petitions that~~result in decreased flow in a stream reach but~~ involve moving or adding an onstream dam shall comply with the permitting requirements for onstream dams contained in Policy Section 2.4.

~~3.3.2.2 Petitions that may result in decreased flow in a stream reach~~

Approval of a petition for change or extension of time may result in an incremental increase in the amount of water diverted as compared to the amount of water that would be diverted if the petition were denied. For permits, the incremental increase is equal to the full **face value** of permit minus the amount of water put to beneficial use in compliance with all existing permit conditions. Because water right licenses are limited to the amount of water actually put to beneficial use during the permit development schedule, approval of a change petition filed on a license will not result in an incremental increase in the amount of water diverted.

However, some petitioned changes may result in changes in flow of a particular stream reach, particularly those changes that affect the location of a point of diversion or those that result in a change in the timing or location of return flows from the approved use. Any increase in diversion or reduction in return flows corresponds to a decrease in streamflow. If the Deputy Director determines that the ~~The~~ incremental decrease in streamflow resulting from the approval of a petition has the potential to impair instream beneficial uses, then the incremental decrease in streamflow shall be evaluated for adverse effects to fish and wildlife using the cumulative diversion analysis instream flow assessment methods established in this policy. ~~The results of the evaluation may be used to develop terms and conditions for amended permits and licenses.~~ Only the stream reaches potentially affected by the proposed change need be evaluated. The evaluation shall consider the effect of the proposed change on instream flows needed for fishery resources at locations where anadromy exists, after consideration of the flow reductions caused by all authorized diverters. The results of the evaluation may be used to develop terms and conditions of approval. Any such terms and conditions shall be tailored to address the incremental impacts of the change on instream flows.

3.3.2.~~43~~ Voluntary modification of authorized diversions for the enhancement of fish and wildlife resources

Persons who divert water under any legal basis of right, including riparian and permitted and licensed water rights, may petition the State Water Board pursuant to Water Code section 1707 for a "change for purposes of preserving or enhancing wetlands habitat, fish and wildlife resources, or recreation in, or on, the water." The section 1707 petition may be coupled with an application for a water right or a petition to amend an existing permit or license in order to modify an existing project so that diversion will occur in a manner that minimizes impacts to fish and wildlife. For example, a riparian right holder may file an application for offstream winter storage in lieu of summertime riparian direct diversion coupled with a petition to dedicate riparian flows under section 1707.

The Deputy Director may approve an exception to one or more of the diversion criteria for all or part of an application if the application is for a storage project and the Deputy Director finds that (1) the applicant's existing diversions under another valid basis of right will be reduced as a result of the applicant's ability to divert to storage, and (2) the benefit to fishery resources of the shift in timing of diversions outweighs the potential impacts to fishery resources of the storage project.

Other changes that result in enhanced conditions for fish and wildlife may include:

1. removal of an artificial barrier to the migration of anadromous fish;
2. replacement of onstream storage with offstream storage;
3. relocation of a point of diversion to reduce impacts to aquatic resources;
4. changes to frost protection practices undertaken pursuant to an existing water right that improve habitat for aquatic resources (which could include moving a point of diversion, adding or expanding storage in order to reduce

instantaneous demand during frost events, improving efficiency, or implementing alternative frost protection techniques); and

5. other activities that have the effect of creating fish and wildlife habitat with improved streamflows.

The State Water Board will expedite, where feasible, processing of petitions that will result in enhanced conditions for fish and wildlife, including section 1707 petitions and any water right applications or petitions to amend existing permits or licenses that accompany them. Expedited water right processing may occur if the following conditions are met:

1. Documentation is provided showing the change will enhance conditions for fish and wildlife, including proof of past riparian use, if relevant;

2. The petitioner or applicant consults with other agencies, including DFG, NMFS, the Regional Water Quality Control Boards, and other agencies with jurisdictional authority, and the agencies provide written approval or support for the proposed change;

3. The proposed change is consistent with the principles of this policy; and

4. For water right applications, (1) a water availability analysis is submitted pursuant to Water Code section 1375, subdivision (d) that takes into account the **face value demand** of all known **senior diversions**, including senior pending water rights, and (2) the applicant agrees to conditions of approval that will ensure that the water that is the subject of the section 1707 petition will remain instream for purposes of protecting wetlands habitat, fish and wildlife resources, or recreation in or on the water.

3.3.3 Small domestic use and livestock stockpond registrations

A person can obtain a right to appropriate water for a small domestic or livestock stockpond use by registering the use with the State Water Board. (Wat. Code, § 1228 et seq.) A registration of water use must include a certification that the registrant agrees to comply with all conditions required by DFG, including conditions on the construction and operation of the diversion work. (*Id.,* §1228.3, subd. (a)(7).)

An appropriation pursuant to a registration within the policy area is subject to the following conditions:

1. No water may be stored or diverted under the registration by means of an onstream dam constructed on a Class I or Class II stream after July 19, 2006.

2. DFG imposes conditions consistent with the principles of this policy that are stated in Section 2.1. DFG's authority to impose conditions on small domestic use and livestock stockpond use registrations includes, but is not limited to, the

authority to impose bypass flow conditions and monitoring during all or a portion of the authorized season of diversion.

The policy requirements do not apply to the renewal of an existing registration, provided that, in connection with the original registration, the registrant has (1) contacted DFG, (2) certified that the registrant would comply with any terms any lawful conditions imposed by DFG, and (3) submitted the certification and conditions to the State Water Board, as required by Water Code section 1228.3, subdivision (a)(7).

3.4 Review Procedures for Water Right Applications and Petitions

3.4.1 Application and Petition Processing

This policy establishes new procedures for Division processing of water right applications, petitions, and registrations defined in section 3.3, to be implemented when resources become available. Unless otherwise stated, this section shall refer generally to water right application, petition, and registration as "application," and applicant, petitioner and registrant as "applicant." The new procedures in this policy are consistent with and complimentary to existing procedures defined in the Water Code and the California Code of Regulations. Application process flow charts are provided in Appendix L. The State Water Board intends to consider other procedural changes to water application, petition and registration processing, including a pre-decisional review trial program, discussed below.

3.4.2 General Procedures Applicable to All New and Amended Applications

3.4.2.1 Project Scoping Conference for New and Amended Applications

The applicant and Division staff shall have an early conference to discuss the scope of the application, the required environmental and water availability analyses, and the methodologies for those analyses. This procedure shall apply to new applications and for amended applications.

3.4.2.2 Application Work Plan

The applicant and Division staff shall mutually develop a work plan within 60 days from the project scoping conference. The work plan shall delineate the major tasks necessary to process the application and clearly delineate the respective responsibilities of the applicant, the consultants, and Division staff.

3.4.2.3 Early Consultation with Protestants and Responsible Agencies

After public notice, the applicant and Division staff shall have an early consultation conference with protestants and responsible agencies to exchange basic information about the project and concerns with the project. Early consultation may occur through in-person meetings or telephone conversations. Applicants, protestants, and responsible agencies are encouraged to arrange a site visit and to confer regarding the application work plan.

3.4.2.4 Draft Permits and Change Petitions

The Division shall provide applicants, protestants, and responsible agencies with a draft permit or order before the Division makes a final decision on the application or petition, and provide a reasonable time to comment.

3.4.2.5 Coordination of Environmental Impact Analyses

Applicants within a watershed shall coordinate the water availability, CEQA and/or public trust analyses where feasible.

3.4.2.6 Model Environmental Impact Analyses

If adequate resources become available, the Division shall maintain a library of model environmental analyses that represent a reasonable range of water diversions (e.g., onstream storage, diversion to offstream storage, direct diversion, etc.), affected biological resources (e.g., salmonid fishes, non-salmonid fishes, amphibians, etc.), watershed size, and clear impact assessment methodologies or thresholds.

3.4.2.7 Scale of Analyses

The water availability, CEQA and public trust analyses shall consider relevant watershed-scale issues wherever possible.

3.4.2.8 Options for Retention of Consultants for Projects Where the State Water Board is Lead Agency

The State Water Board may employ one of the following arrangements or a combination of them for preparing a draft environmental analysis as provided in section 15084 of the CEQA Guidelines (Cal. Code Regs., tit. 14, § 15084):

1. Preparing the draft environmental analysis directly with its own staff.
2. Contracting with another entity, public or private, to prepare the draft environmental analysis.
3. Accepting a draft prepared by the applicant, a consultant retained by the applicant, or any other person.
4. Executing a third party contract or memorandum of understanding with the applicant to govern the preparation of a draft environmental analysis by an independent contractor.
5. Using a previously prepared environmental analysis.

Before using a draft prepared by another person, the lead agency (State Water Board) shall, as required by the Guidelines, subject the draft to its own review and analysis. The draft environmental analysis which is sent out for public review must reflect the independent judgment of the lead agency. The lead agency is responsible for the

adequacy and objectivity of the draft environmental analysis. (Cal. Code Regs., tit. 14, § 15084.)

Where a new environmental analysis is required and the State Water Board requires the cost of the analysis to be borne by the applicant, in most cases the applicant may elect to prepare a draft environmental analysis or contract with another entity to prepare the draft (option 3) or execute a memorandum of understanding (MOU) for preparation by an independent contractor (option 4).

3.4.3 Pre-decisional Review - Trial Program

The Division shall establish a three year trial program that provides an opportunity for applicants and protestants to seek review by an appointed Member of the Board of Division staff determinations before the Board takes final action on the application, petition or registration. The Division shall determine which issues will be subject to Board member review as part of the trial program. The issues may include, but will not necessarily be limited to, the following:

1. Whether the diversion is from a natural watercourse subject to the permitting jurisdiction of the Board;
2. Whether the project involves diversion of water subject to the permitting jurisdiction of the Board;
3. Whether the application is subject to CEQA, or is subject to CEQA, but categorically exempt from further analysis;
4. Whether a CEQA document satisfies the requirements of CEQA;
5. Whether a water availability analysis satisfies the requirements of the Water Code and this policy;
6. Whether a protest shall be accepted or rejected, or dismissed.

At the end of the trial period, the State Water Board will reevaluate the program and consider whether to extend it. In order to implement this program, the Board will make any necessary revisions to the Board Resolution that specifies the authorities delegated to the State Water Board Members individually and to the Deputy Director for Water Rights.

Where applicants and protestants have been unable to settle a protest by the time the Division is ready to make a decision on the proposed application, the Division shall provide them an opportunity to propose competing draft Division Decisions for the Division's consideration.

4.0 WATERSHED-BASED APPROACHES ~~APPROACH~~

The State Water Board recognizes that a watershed approach for determining water availability and evaluating environmental impacts of multiple water diversions in a

watershed may be an alternative to evaluating individual projects using the regionally protective criteria set forth in this policy. Accordingly, flexibility should be provided to groups of diverters who endeavor to work together to allow for cost sharing, real-time operation of water diversions, and implementation of mitigation measures, as long as the proposed approaches are consistent with the principles for maintaining instream flows provided in section 2.1.

The policy encourages two alternative forms of watershed-based approaches: coordinated management of diversions through watershed charters (sections 4.1-4.6)and coordinated permitting of applications (section 4.7).

The watershed charter approach involves the formation of watershed groups to coordinate the development of technical information for coordinated water right permitting and/or for the coordination of diversion operations. Coordinated water right permitting allows the use of one package of technical documents for all pending applications within the watershed group. Coordinated operation of diversions and implementation of mitigation measures may be proposed through diversion management plans. Depending on the water right priority of the projects involved in a watershed group, participants in a watershed approach may receive expedited environmental review of water right applications. Individual water right permits will be issued for any approved applications that are part of a watershed group, provided that individual applicants accept permit conditions.

4.1 Definition of a Watershed Charter Group

A watershed charter group consists of participants who enter into a formal project charter to develop technical documents to provide the information needed for coordinated processing of all the pending applications in the watershed group, and to develop a diversion management plan if coordination of diversions and implementation of mitigation measures is desired.

4.2 Project Charter

Water right applicants that choose to form a watershed group shall submit a proposed project charter to the State Water Board. The purpose of the charter is to ensure that watershed group participants are in agreement regarding the goals of the group and the tasks that must be completed to achieve these goals. The charter shall contain watershed group participant names, roles, and responsibilities, and a description of the individual water right applications or petitions involved. It shall also describe the key contents of the technical documents that will be prepared by the watershed group, and include an estimated schedule for submitting these documents to the State Water Board. It shall also contain information demonstrating that the participants in the watershed group make the financial commitment to perform the tasks and achieve the listed goals.

In addition to water right applicants, watershed group participants may include existing diverters under other claims of right (appropriative, riparian, pre-1914, etc.), regulatory agencies, conservation groups, other community groups, and other stakeholders who have direct interests or capacity to contribute to the goals and tasks of the watershed group. The number of participants and the size of the watershed involved in each watershed group shall be subject to the State Water Board review and approval.

The State Water Board must review and concur with the proposed watershed project charter before the watershed group commences work. The State Water Board will consider the extent of participation from applicants and petitioners relative to the total number of pending applications and petitions in a watershed as one factor in deciding whether to approve the proposed project charter. The State Water Board may consult with DFG regarding the project charter. If consulted, the DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment on the project charter. Watershed groups already operating prior to policy adoption may participate in the watershed approach provided they are willing to comply with the other requirements of this policy.

4.3 Required Technical Documents

The watershed group shall provide the technical information necessary for the State Water Board to (1) determine water availability, (2) satisfy the requirements of CEQA (if applicable), (3) evaluate the potential impacts of water appropriation on public trust resources, (4) make decisions on whether and how to approve pending water right applications for diverters in the watershed group, and (5) make decisions on whether to approve proposed diversion management plans.

The watershed group shall perform technical work and submit technical documents as described below:

1. Site-specific studies. The watershed group shall perform site-specific studies evaluating the instream flow needs of fish and fish habitat using the site-specific study guidance contained in Appendix C of this policy. After study completion, the watershed group shall submit a report detailing the results of the study to the State Water Board for review and approval. DFG consultations may occur, consistent with the provisions of Appendix C.

2. Environmental documents. The watershed group shall submit information necessary to prepare appropriate environmental documents so that the State Water Board may make a determination of the impacts of the proposed projects to the environment, public trust, and the public interest for the purposes of preparing water right permits for the proposed projects. At a minimum, this information shall include (1) an evaluation of water availability, (2) descriptions of the significance of the potential impacts of the proposed projects caused by

reductions in streamflow and/or the presence of onstream dams, (3) descriptions of proposed mitigation measures for impacts identified as potentially significant, (4) information needed for draft initial studies or other CEQA documents, and (5) an evaluation of the potential impacts of the proposed projects on public trust resources. All documents are subject to State Water Board review and approval. The analysis of water availability shall take into consideration diversions by member diverters and non-member diverters in the watershed. The watershed group shall work with regulatory agencies, as necessary, including NOAA Fisheries, the US Army Corps of Engineers, DFG, the State Water Board, and the North Coast Regional Water Quality Control Board to obtain regulatory approvals, assurances and/or permits under the ESA and CESA and state and federal water quality laws and regulations. CEQA and other environmental reviews of pending applications in the watershed group shall be coordinated to the extent possible. Technical documents prepared by the watershed groups shall be considered elements of the pending applications and, along with the applications, shall be subject to public notice and review and comment by responsible agencies and the public.

3. Diversion Management Plans. Diversion management plans shall be prepared if the watershed group proposes to coordinate operation of diversions and/or implementation of mitigation measures. Diversion management plans are not needed if the watershed group proposes only to coordinate the development of technical information for the permitting process. Watershed management plans shall describe: (a) how diversions will be operated to achieve compliance with streamflow requirements for the protection of fishery resources developed in item 1, above; (b) how diversions will be monitored to demonstrate compliance is achieved, including monitoring and reporting methods; and (c) the mitigation measures that will be implemented, a time schedule for implementation, and how the watershed group will ensure that such measures are implemented.
The diversion management plan shall include a certification that the watershed group has the financial resources to build, operate, maintain, and monitor the proposed projects consistent with the terms of any water right permits issued for the project(s) and shall provide proof of financial resources.

   Diversion management plans shall be consistent with the general requirements of this policy and all appropriate federal, state, and local laws. The diversion management plan shall not propose actions that result in any diminishment of the State Water Board's authority to require or enforce conditions to protect fish and wildlife, other public trust resources, or senior water right holders. Diversion management plans are subject to State Water Board review and approval, and may be incorporated as enforceable terms and conditions in State Water Board orders, decisions, permits, or licenses.

4.4 Approval of Technical Documents

The State Water Board shall review and approve the technical documents before issuing water right permits or approving petitions. The DFG may be consulted regarding any of the technical documents. If consultation occurs, DFG shall be provided a reasonable period of time, not less than 30 days, to review and comment.

4.5 Water Right Permit and License Terms

Individual water right permits and licenses may be issued for any projects with approved applications or petitions that participate in the watershed group. If diversion management and/or mitigation measure implementation will be coordinated with other diversions, additional terms shall be included within each permit or license that describe the operational requirements of each diversion during the period of time the project charter is in effect. The permits or licenses shall also include terms describing the operational requirements of the diversions and/or mitigation measures if the project charter were to be retracted or dissolved.

In addition to standard or special water right permit and license terms, water right permits and licenses for watershed groups operating under a watershed management

plan shall contain special terms designed to assess the effectiveness of the watershed management plan in meeting the requirements of this policy.

4.6 Retraction of State Water Board Approvals

The State Water Board may retract its approval of a watershed group, project charter, and/or diversion management plan, or direct watershed group participants to comply with a time schedule, if the watershed group does not perform its obligations as specified in the project charter or diversion management plan in a timely manner.

4.7 Coordinated Permitting

In some circumstances, it may be desirable for groups of applicants to coordinate permitting even where formation of a watershed charter group is not practical. The State Water Board encourages applicants, on their own initiative, to coordinate in the development of technical information to better understand and mitigate cumulative effects.

4.7.1. Technical Information

Applicants in a given watershed are encouraged to coordinate the development and submittal of water availability analyses, environmental impact assessments, and other technical information needed for State Water Board's determination of the impacts of the proposed projects on senior right holders, the environment, the public trust, and the public interest.

5.0 BYPASS SYSTEMS, FLOW MONITORING, AND REPORTING

This section details the bypass system requirements, monitoring, and reporting necessary for showing compliance with minimum bypass flow requirements. Additional flow and diversion monitoring may be needed to comply with other water right terms and conditions placed in permits and licenses, including monitoring to demonstrate compliance with maximum rate of diversion requirements and any applicable water quality monitoring requirements recommended by the appropriate Regional Water Quality Control Board. Section 10 contains additional reporting requirements that may be implemented as resources become available. .

Minimum bypass flow and maximum rate of diversion permit terms imposed pursuant to this policy shall be met on an instantaneous basis. To ensure compliance with these requirements, all diversions under this policy shall operate using passive bypass systems, with the following exception: Upon State Water Board approval, if physical site conditions prevent the construction of a passive bypass system, an alternative~~automated computer-controlled~~ bypass system may~~shall~~ be designed, installed, and operated. The requirements of passive and computer-automated bypass systems are described in Appendix E.

5.1 Bypass Flow Monitoring and Reporting Requirements for Passive Bypass Systems

Bypass flow monitoring at the POD is not necessary for passive bypass systems. However, permittees and licensees who are required to have passive bypass systems shall annually prepare a signed statement, with photographic evidence, certifying that the passive bypass system is still operational as designed. This certification shall be submitted with Permittee Progress Reports, Reports of Licensee, or whenever requested by the State Water Board. Permittees and licensees may be required to participate in the regional stream flow monitoring program defined in section 10, once such a program is developed.

5.2 Bypass Flow Monitoring and Reporting Requirements for Other~~Automated Computer-Controlled~~ Bypass Systems

If an alternate~~automated computer-controlled~~ bypass system is implemented, compliance with the minimum bypass flow, rate of diversion, and season of diversion requirements (as applicable) shall be demonstrated by continuous ~~hourly~~ recording using automated flow measuring device(s) of at least the following information: bypass amount, and, where applicable, withdrawals (timing and volume) from the reservoir and reservoir stage.)~~.~~ The ~~flow~~ data shall be recorded on an hourly (or more frequent) basis so that it is retrievable and viewable using commonly available computer software. The flow data shall be submitted electronically in a spreadsheet format usable by MS Excel or a similar software program. The hourly data shall be presented both graphically and numerically for the previous reporting period, and shall be submitted with Permittee Progress Reports, Reports of Licensee, or whenever requested by the State Water Board.

6.0 FISH SCREENS AT DIVERSIONS IN CLASS I STREAMS

Fish screens shall be installed at diversions on Class I streams that include direct diversions, diversions to offstream storage, and onstream dams with fish passage facilities, with the following exceptions: Fish screens are not required on **offset wells** or **Ranney collectors**.

NMFS screening criteria shall be used to design the fish screening facilities. The NMFS screening criteria can be found in “Fish Screening Criteria for Anadromous Salmonids”, which may be obtained from the NMFS website at *http://swr.nmfs.noaa.gov/hcd/fishscrn.pdf*. Hard copies of the document are available from the NMFS Southwest Regional Office.

The applicant or petitioner may request the State Water Board to waive the fish screen requirement. Prior to consideration of this request, the applicant or petitioner shall

provide the State Water Board a written determination with supporting rationale from DFG that fish screens are not needed.

7.0 COMPLIANCE PLANS

Applicants and petitioners shall submit a compliance plan for State Water Board's review and approval,. The compliance plan shall identify how the water diverter will comply with the terms and conditions of permits or licenses, and shall include a schedule for the construction of facilities and the implementation of mitigation plans where needed. The compliance plan shall be prepared by a qualified person and is subject to approval by the State Water Board.

8.0 ENFORCEMENT

Timely and appropriate enforcement is critical to the successful implementation of the policy and to ensure that instream flows in north coast streams are maintained. This section of the policy provides guidance in the exercise of the State Water Board's enforcement discretion by establishing a framework for (1) identifying and investigating instances of noncompliance, (2) taking enforcement actions that are appropriate in relation to the nature and severity of the violation, and (3) prioritizing enforcement resources to achieve maximum environmental benefits and compliance with the policy. It also provides notice to the regulated community of the State Water Board's intent to enforce the policy and the methods of enforcement. It is not intended to provide support for any defense raised in response to an enforcement action.

8.1 Compliance Assurance

For compliance assurance, there must be a clear understanding of the requirements that implement this policy and a subsequent review of compliance with those requirements. The State Water Board will assure compliance with this policy by developing clear and enforceable permit terms and conditions, requiring and reviewing compliance plans, reviewing self-monitoring reports, and maintaining a field presence in the policy area through compliance inspections, licensing inspections and complaint investigations. For further details regarding methods of compliance assurance, see Appendix F.

8.2 Prioritization of Enforcement

Every violation merits an appropriate enforcement response. The State Water Board will balance the need to complete its non-enforcement tasks with the need to address violations. It must also balance the importance or impact of each potential enforcement

action with the cost of that action. Informal enforcement actions, described below, have been the most frequently used enforcement response. Such informal actions will continue to be part of this policy for low priority violations. Formal enforcement actions are resource-intensive and must therefore be targeted to the highest priority violations. Some violations, although they may have a low impact individually, may have systemic impacts. The State Water Board will take this into consideration when determining how to set enforcement priorities, recognizing that addressing systemic violations can result in behavioral changes that improve conditions.

The first step in enforcement prioritization is to determine the relative weight of the violation. The criteria for prioritization used in the policy area should be applicable statewide and focus on watershed conditions, the injury—or potential for injury—from the violation, and the project characteristics. In setting the priority of the violation, the Board will also consider the water diverter's history of past violations or submission of willful misstatements, whether the water diverter has implemented an internal mechanism for ensuring compliance, such as internal audits or early detection programs, and the violator's willingness to voluntarily correct violations, especially prior to State Water Board identification of a compliance issue.

The following comprises a non-exclusive list of criteria that State Water Board staff will use in setting enforcement priorities regarding violations. Additional information regarding the criteria listed below can be found in Appendix G.

1. violation within Class I and II streams in the policy area or within an existing or wild and scenic river system;
2. violations within fully appropriated or adjudicated stream systems;
3. potential injury to endangered species;
4. waste and unreasonable use and diversion;
5. injury to prior right holder;
6. large consumptive use projects receiving economic benefit from a violation or unauthorized diversion;
7. recalcitrant violators, repeat violators, and willful misstatements; and
8. other factors as justice may require

State Water Board staff will enter known violations in an enforcement database. Any violation in this database can be further evaluated for possible formal enforcement, and at a minimum shall receive informal enforcement. Violations meeting more than one of the criteria should receive a higher priority ranking. State Water Board staff will conduct a monthly review of the prioritized violations in the database and make a decision about the appropriate enforcement response based on the criteria above. State Water Board staff will assign a relative priority for enforcement for each violation. A description of the enforcement actions the State Water Board make take in response to violations is contained in Appendix H. Appendix H also describes the factors the State Water Board will consider when setting administrative civil liability amounts, which include the State Water Board's policy regarding the use of Supplemental Environmental Projects, and

the steps the State Water Board will take to enforce the requirement that certain diverters in the policy area file Statements of Water Diversion and Use.

8.3 Continuing Authority to Amend Permits and Licenses

The State Water Board has continuing authority to amend or modify water right permits and licenses pursuant to Water Code sections 100 and 275. If, after investigation, the State Water Board determines that a permitted diversion results in an adverse impact to public trust resources or results in a waste or unreasonable use or unreasonable method of use or method of diversion of water, the State Water Board may modify a permit or license term or may impose specific requirements over and above those contained in the permit or license in order to protect the public trust, ensure that the waste is abated, or ensure that the diversion and use of water is reasonable. Similarly, the State Water Board may modify existing permits or licenses if the State Water Board determines that such modification is necessary to meet water quality objectives contained in water quality control plans established or modified pursuant to Division 7 (commencing with section 13000) of the Water Code. The State Water Board will provide any affected permit or license holder with notice of the intent to modify the conditions of the permit or license and with opportunity for a hearing prior to making any modifications.

8.4 Prohibition Against Waste and Unreasonable Use of Water

If after investigation, the State Water Board determines that a water diversion is wasteful or constitutes an unreasonable use, unreasonable method of use, or unreasonable method of diversion of water, the State Water Board may order a party who diverts and uses water to comply with requirements to abate the waste or ensure the reasonable use of water, method of use, and method of diversion. The State Water Board will only take such action after notice to the party and after providing an opportunity for hearing.

8.5 Protection of Public Trust Resources

The State Water Board has an affirmative duty to protect public trust uses, including fisheries, from the effects of water diversion and use. In the exercise of that duty, the State Water Board may order a party who diverts and uses water to comply with requirements to ensure protection of public trust resources if there is evidence that the diversion or use of water is impacting those resources. The State Water Board will only take such action after notice to the party and after providing an opportunity for hearing.

8.6 Enforcement Action where Water Right Application is Pending

Filing a water right application does not shield an unauthorized diverter from enforcement action. In deciding whether or not to take formal enforcement action to address an unauthorized diversion, the State Water Board will consider the applicant's diligence in submitting the information necessary to process the application and the factors set forth in Section 9.2 above and Appendix G. In addition, the State Water Board will consider whether the applicant (1) complies with interim operating conditions consistent with Section 2.2.1 of this policy, including at a minimum the season of diversion regional criterion; (2) conducts hourly monitoring of diversion(s) and makes daily averages of the data available on-line to the State Water Board; and (3) has completed and submitted to the State Water Board a Statement of Water Diversion and Use and submits to the State Water Board an online supplemental statement.

9.0 CASE-BY-CASE EXCEPTIONS TO POLICY PROVISIONS

This section applies to exceptions from policy provisions.

The State Water Board may grant exceptions to specific provisions of this policy where the State Water Board determines that:

1. The exception will not compromise maintenance of instream flows in the policy area; and

2. The public interest will be served.

Requests for case-by-case exceptions shall be submitted to the State Water Board during the environmental review of an application or petition.

Case-by-case exception requests shall contain:

1. a detailed description of the reason for the request,

2. the policy provisions that are involved;

3. documentation of the reasons why the exception will not compromise maintenance of instream flows in the policy area; and

4. an explanation of how the public interest will be served by the exception.

The State Water Board will evaluate whether the request is reasonable and whether sufficient cause exists for an exception. If the case-by-case exception involves potential environmental impacts, it shall be considered under CEQA and the State Water Board's public trust authority. Case-by-case exceptions shall be granted at a public meeting of the State Water Board. The Deputy Director for Water Rights shall recommend to the State Water Board whether to approve or deny the proposed exception.

10.0 MONITORING AND REPORTING OF DIVERSIONS; MONITORING AND REPORTING OF STREAMFLOWS; POLICY EFFECTIVENESS REVIEW

10.1. Monitoring and Reporting of Diversions

Permits shall require continuous monitoring of diversions for each point of diversion and other conditions necessary to demonstrate compliance with permit terms relating to bypass flows, season of diversion, and rate of diversion. For purposes of this Section, "continuous" means at time intervals of 1 hour or less.

Diversion data shall be reported with next Progress Report By Permittee or Report of Licensee, or whenever requested by the State Water Board. Permits shall include a term stating that the State Water Board intends to develop and implement a basin-wide program for real-time electronic monitoring and reporting in a standardized format if and when resources become available; that such reporting will be required upon a showing by the State Water Board that the program and the infrastructure are in place to accept real-time electronic reports; and that it shall not be necessary to amend the permit at that time.

10.1.1 Diversion Monitoring and Reporting for Direct Diversions and Diversions to Storage

Permits for direct diversions and diversions to offstream storage shall require monitoring, recording, and reporting the timing and quantity of water actually diverted from the stream (e.g., with an electronic inline flow meter).

Permits for onstream reservoirs shall require monitoring of reservoir levels, releases from the reservoir to the stream channel, and withdrawals from the reservoir (e.g., using a pressure transducer for the reservoir, and an inline flow meter for the releases and withdrawals from the reservoir, as applicable).

10.2 Monitoring and Reporting of Streamflows

It is the State Water Board's intent to comprehensively manage watershed systems. In furtherance of that intent, permits shall require monitoring and recording of streamflow. Permits shall include a term stating that the State Water Board intends to develop and implement a basin-wide program for real-time electronic monitoring and reporting of streamflow in a standardized format if and when resources become available and that such monitoring and reporting will be required upon a showing by the State Water Board that the program and the infrastructure are in place to accept real-time electronic reports.

Monitoring shall be achieved by either of the following methods:

10.2.1 Individual Stream Flow Monitoring and Reporting

Permittees may install an automated flow measuring device or devices downstream of the point of diversion.

The location of such devices shall be specified in the compliance plan approved by the State Water Board. The flow data shall be recorded on an hourly (or more frequent) basis in a format that can be readily downloaded into a computer spreadsheet program or database for subsequent reporting. The State Water Board may incorporate the data into a Regional Monitoring Program discussed below.

10.2.2 Participation in Regional Stream Flow Monitoring Program

Permittees may participate in the regional monitoring program described in section 10.3. For participating permittees, permits will require payment to the entity designated by the State Water Board pursuant to section 10.3.

10.3 Reporting and Publication on the Internet

Streamflow data required by section 10.2 shall be transmitted, in an appropriate format, not less than hourly, to an internet site accessible to the State Water Board and the public. Streamflow data shall also be submitted with Permittee Progress Reports, Reports of Licensee, or whenever requested by the State Water Board.

It is the intent of the State Water Board, subject to available resources, to prepare and distribute standardized electronic forms for the information required by the policy.

It is the intent of the State Water Board, subject to available resources, to provide the means by which the information required by this policy may be reported electronically. The Board shall require electronic reporting but make allowances for paper reporting for water right holders on a case-by-case basis.

It is the intent of the State Water Board, subject to available resources, to institute a system to publish on the Internet the data required by the policy and developed for the regional program described in section 10.4. The State Water Board may partner with other state or federal agencies or organizations for this purpose.

10.4. Regional Monitoring and Policy Effectiveness Review

It is the intent of the State Water Board to develop a Regional Monitoring and Policy Effectiveness Review program once resources become available.

The purpose of the program would be to develop data through field monitoring and, based on the data, evaluate (1) the effectiveness of whether the standards for maintaining instream flows are protective of anadromous salmonids and their habitat over the medium term, in the range of a 10 to 20 year time horizon, as well as over the long term, and (2) whether the policy may need to be modified in order to support recovery of listed species and otherwise protect beneficial uses. The program would focus on evaluating the effectiveness of the standards for diversion season, minimum bypass flow, maximum cumulative diversion, and onstream dam mitigation measures, as well as other aspects of the policy.

The program would develop data through monitoring of stream hydrology, geomorphology, and anadromous salmonid habitat conditions in selected representative streams throughout the policy area.

Five years from the effective date of the policy, and periodically thereafter, the State Water Board will review the policy and determine whether it should be revised. The program may coordinate with and utilize and incorporate data from other ongoing monitoring programs carried out by other state, federal, and local agencies, to the fullest extent practicable.

If implemented, the program may be coordinated with any monitoring programs developed pursuant to the Russian River Frost Protection program, if it is adopted. The funding and institutional mechanism for the program may be modeled on the S.F. Bay Area Regional Board's Regional Monitoring Program or the Southern California Coastal Water Research Project.

The State Water Board will consider the recommendations contained in Chapter 10 and Appendix K of R2 Resource Consultants (2007a) when implementing this program.

APPENDIX A
Water Availability Analysis Requirements

Appendix A. Water Availability Analysis Requirements

A.1.0 Water Availability Analysis

Before the State Water Board can issue a water right permit, it must find that there is "unappropriated water available to supply the applicant." (Wat. Code, § 1375, subd. (d).) "In determining the amount of water available for appropriation for other beneficial uses, the [State Water Board] shall take into account, whenever it is in the public interest, the amounts of water required for recreation and the preservation and enhancement of fish and wildlife resources." (*Id.*, § 1243.)

A.1.1 Submittal Requirements

A water availability analysis consists of (1) a Water Supply Report, which quantifies the amount of unappropriated water remaining instream after senior rights are accounted for; and (2) a Cumulative Diversion Analysis, which utilizes the instream flow criteria to evaluate the effects of the proposed project, in combination with existing diverters, on instream flows needed for protection of fishery resources.

The following technical reports shall be submitted to document the water availability analysis:

1. Water Supply Report
2. Upper Limit of Anadromy determination, where applicable
3. Cumulative Diversion Analysis
4. Report on site specific studies that were performed to identify more precisely the instream flow needs of the fishery resources at locations at and/or below anadromy, where needed

The technical reports shall document all underlying analyses.

A.1.1.1 Data Submissions

The raw data, spreadsheets, and models used to perform the water supply report and cumulative diversion analysis shall be provided for State Water Board review and approval, and shall meet the following requirements.

1. Analysis reports shall describe the assumptions used, and include a functional electronic version of the spreadsheet(s) that was used to perform the analysis, including the equations, input data and assumptions, and outputs used to complete the analysis.

2. Input files, calibration results, validation results, and output files shall be provided in electronic format with supporting documentation that describes the model's assumptions, underlying modeling principles, and operation.

3. Generally, no proprietary spreadsheets or proprietary computer models will be accepted; however output from proprietary programs used solely to visually summarize or demonstrate the output data or results from public domain spreadsheets or public domain computer programs that meet the above two requirements may be accepted by the State Water Board if the underlying data and assumptions are also submitted.

A.1.2 Water Supply Report

The applicant must demonstrate that there is unappropriated water in the watershed sufficient to supply the proposed project by submitting a Water Supply Report that compares the unimpaired water supply to the demand by senior water right holders, including demand by those claiming riparian and pre-1914 appropriative rights. This analysis is necessary to determine whether a sufficient amount of water remains instream to supply senior priority rights. The analysis shall be performed along the water **flow path** from the proposed point of diversion to the Pacific Ocean. If the State Water Board determines a project would have a de minimus impact on flows in a **flow-regulated mainstem river**, then the water flow path may terminate at the flow-regulated mainstem river. The applicant must consider the water supply impacts of the proposed project only at the points of diversion of senior water rights along this identified flow path; however, the demands of all senior water right holders within the watershed will be needed for the analysis. Only senior water rights with a season of diversion within or overlapping the diversion season of the application need to be considered. Guidelines for completing the Water Supply Report analysis are provided in Section B.2.0 of Appendix B.

The Water Supply Report shall include the following:

1. A map showing the locations of the points of diversion (PODs) of senior priority water right holders and water right claimants in the watershed. The map must conform to the map requirements contained in Section A.1.3;

2. A list of the senior priority water rights (permit, license, certificate, or registration), their seasons of diversion, and **face values** of their permits or licenses. To the extent information is available in the State Water Board's records, or other sources of information, the demand and season of diversion of riparian and pre-1914 appropriative water right holders and claimants shall also be included;

3. A tabulation of the estimated percentages of unappropriated water supply available at the POD for each senior priority water right on the water flow path after accounting for senior demands. This percentage may be obtained using estimates of the unimpaired flow volume of the stream at each senior POD and the seasonal demand volumes of the senior water right holders. For details on calculation methods, please see Appendix B sections B.2.0 through B.2.2. The seasonal demand volume is the sum of the demand volumes of the senior water right holders with the right to divert water during the proposed project's diversion

season that are within the watershed upstream of identified senior PODs along the water flow path. The demand volume shall be determined using the face value or maximum annual use limitation of each water right; however there may be diversions for which proration of face values or maximum annual use limitations may be appropriate (A. Miller, SWRCB Internal Memo, December 2007). For guidance on estimating the demand volumes of the senior water right holders, please refer to section B.2.1.4. All results shall be presented in a table listing the calculated percentage for each identified senior POD;

4. A calculation of the ratio of the proposed project's demand to the remaining unappropriated water supply at each identified senior POD. This analysis is needed for the purposes of (1) identifying locations where the proposed project is likely to have minimal impacts to the rate of flow, and (2) to assist with selection of points of interest for the cumulative diversion analysis. The ratio shall be obtained by dividing the proposed project's water demand volume by the remaining unappropriated water supply at each senior POD. These values shall also be presented in a table.

5. A **flow frequency analysis** of the seasonal unimpaired flow volume. A set of flow frequency analyses shall be provided at the POD(s) of the proposed project, the senior POD at which the percentage calculated in step 3 is the lowest, and any other senior PODs at which the ratio is less than 50%, if any. The frequency of occurrence of the average seasonal unimpaired flow volumes for each year of record should be determined and plotted graphically.

The details of the analysis shall be presented in report format with all necessary tables and graphs.

A.1.3 Map Requirements

The applicant shall provide maps with the Water Supply Report that the State Water Board may use to assist with the selection of POIs. Either digital or hard-copy maps may be submitted. The maps shall be in full color, no smaller than 11"X14", and shall be large enough to present the following information in sufficient detail.

1. The maps shall display topographic contours equivalent to those on USGS 7.5 minute quads.

2. The maps shall be large enough to trace the watershed from the proposed project down to one of the following, depending on the water flow path: (1) the nearest flow-regulated mainstem river, or (2) the Pacific Ocean.

3. All of the PODs associated with the proposed project, including reservoir footprints and place of use footprints. All shall be clearly marked.

4. The identified flow paths of streams affected by the proposed POD(s) shall be clearly marked. If an affected stream is not delineated on a USGS quad map, the applicant shall draw it in manually.

5. The PODs of senior water rights identified along the flow path that were used in the Water Supply Report shall be clearly marked.

6. The applicant shall note on the maps the locations of PODs within the watershed between the proposed POD(s) and the river/ocean used above. Include all pending applications, permits, licenses, small domestic use registrations, livestock stockpond use registrations and certificates, and, to the extent information is available in the State Water Board's records or other sources of information, riparian users and pre-1914 rights.

A.1.4 Determination of the Upper Limit of Anadromy

If there is sufficient unappropriated water to supply the proposed project after considering the rights of senior appropriators, the applicant must then evaluate the effects of senior diversions and the proposed project on instream flows needed for fishery resources to allow the State Water Board to determine if there is unappropriated water available for diversion. The upper limit of anadromy location will aid the State Water Board in selecting points to evaluate whether the proposed diversion may cause an effect on fishery resources.

The upper limit of anadromy is defined as the upstream end of the range of anadromous fish that currently are, or have been historically, present year-round or seasonally, whichever extends the farthest upstream. The upper limit of anadromy may be located on a perennial, intermittent, or **ephemeral stream**.

In some cases, the historic upper limit of anadromy is not known with certainty. In those cases, if the stream reach from which the applicant proposes to divert water appears to support fish under unimpaired conditions, the State Water Board will presume that the POD is located within the range of anadromous fish. This presumption might result in higher calculated minimum bypass flows than would be needed if the POD is actually upstream of the upper limit of anadromy. The applicant may overcome this presumption by demonstrating that the upper limit of anadromy is at a different location on the stream reach between the POD and the basin outlet, based on one of the following:

1. A study, previously accepted by the State Water Board, NMFS, or DFG, that identifies the location of the upper limit of anadromy on the stream reach between the POD and the Pacific Ocean or to a flow-regulated mainstem river, depending on the water flow path. Previous studies or surveys that catalog only the presence or absence of anadromous fish might not accurately define the upper limit of anadromy.

2. Information demonstrating that the gradient of a segment of the stream reach between the POD and Pacific Ocean or to a flow-regulated mainstem river, depending on the water flow path, exceeds a continuous longitudinal slope over a distance of large enough magnitude that anadromous fish can not move upstream beyond the lowest point of the gradient. The gradient shall be a continuous longitudinal slope of 12%, or greater, over a distance of 330 feet along the stream (R2 Resource Consultants, 2007b).

3. Site-specific studies conducted by a qualified fisheries biologist. The applicant may refer to stream classification determinations that were made in accordance with the methods in section A.1.6 for preliminary refinement of the geographic extent of the site-specific study. Fisheries biologist qualifications are described in section A.1.5. Prior to conducting the site-specific study, the name(s) and qualifications of the individual(s) selected to perform the studies shall be submitted to the State Water Board for review and approval. All field work, modeling, analysis, and calculations performed as part of this study shall be documented in detail sufficient to withstand credible peer review. The site-specific studies shall consist of any of the following:

    a. Identification of an impassable natural waterfall. This policy assumes all natural waterfalls are passable unless the applicant provides information satisfactory to the State Water Board that the waterfall is impassable. This information shall include, at a minimum, an evaluation of waterfall drop height, leaping angle, and **pool** depth in comparison to the documented ability for the target anadromous fish species to successfully ascend the barrier. Available references for assessing whether a natural waterfall is impassable include but are not limited to: Part IX of the CDFG California Salmonid Stream Habitat Restoration Manual (DFG 2003), Powers and Orsborn (1985) and Bjorn and Reiser (1991).

    b. Identification of an impassable human-caused barrier. The applicant may choose to demonstrate that the upper limit of anadromy is located below a human-caused barrier such as a dam, culvert, or bridge. This policy assumes that all human-caused barriers are passable or can be made passable unless the applicant provides information satisfactory to the State Water Board that a man-made barrier is impassable and will never be made passable.

    c. Habitat-based stream survey that delineates the upper limit of anadromy based on quantifiable stream conditions

The applicant shall submit a report documenting the upper limit of anadromy determination. The State Water Board shall review the submitted information. If the

State Water Board finds the information does not support the applicant's request to use a different location for the upper limit of anadromy, the applicant shall proceed with the assumption that the POD is within the range of anadromy.

If the applicant conducts site specific studies to document the upper limit of anadromy, the State Water Board shall provide the study results to DFG for review and comment. The DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment on the studies before the State Water Board makes a finding.

A.1.5 Fisheries Biologist Qualifications

A qualified fisheries biologist is a person with a bachelor's or higher degree in fisheries biology, wildlife biology, aquatic biology, wetland ecology or equivalent other course of study; and five or more years of professional experience in conducting fish habitat assessments. Documentation of qualifications shall be submitted to the State Water Board for approval. Examples of documentation include co-authorship of reports on fish habitat assessments and record of ~~-~~presence during field data collection work. Persons proposing to conduct either (1) site specific studies to modify regional policy criteria, or (2) biological assessments for the watershed approach shall provide documentation of direct, substantial participation in at least two previous fish habitat instream flow studies.

A.1.6 Stream Classification System

The presence or absence of **fish** or non-fish aquatic species in a stream affects the extent of the fishery protection needed at water diversions. Streams that contain fish require a higher level of protection than streams that do not contain fish, in large part because fish are mobile and require more physical aquatic habitat (living space) than non-fish species. In order to effectively apply protective measures, this policy uses the following stream classification system:

Class I: Fish are always or seasonally present, either currently or historically; and habitat to sustain fish exists.

Class II: Seasonal or year-round habitat exists for **aquatic non-fish vertebrates** and/or **aquatic benthic macroinvertebrates**.

Class III: An intermittent or **ephemeral** stream exists that has a defined channel with a defined bank (slope break) that shows evidence of periodic scour and sediment transport.

A.1.6.1 Habitat Indicators for Determination of Stream Class ~~by the State Water Board~~

The State Water Board shall make determinationsa ~~determination~~ of stream class ~~at a POD~~ using indicators of habitat, not simply the presence or absence of species. Examples of indicators of habitat include, but are not limited to, **coarse sediment**~~**gravel**~~, channel width, depth, and slope, **instream cover**, **canopy**, surface water, **aquatic plants**, or **hydric soils**.

Class I streams, which may include intermittent or ephemeral streams, may be indicated by the presence or seasonal presence of fish, either currently or historically, or by the presence of habitat to sustain fish. Historical evidence can include fishery agency reports or other scientific studies that provide evidence that a stream reach may have supported fish or fish habitat. Streams that are designated by NMFS as critical habitat for steelhead, chinook, or coho will be assumed to be Class I streams. However designated critical habitat does not encompass all Class I streams, and should not be relied upon as a basis for excluding streams from a Class I designation.

Class II streams, which may include intermittent or ephemeral streams, may be indicated by the presence of aquatic non-fish vertebrates or aquatic benthic macroinvertebrates or combinations of other indicators, such as free water, aquatic plants, or hydric soils. Historical information may be used in areas where habitat is suspected to be degraded. However, in Class II streams fish are never present, either currently or historically.

Ephemeral streams having defined channels with defined banks (slope break) that show evidence that sediment transport processes occur may indicate a Class III stream. For instance, evidence of periodic scour and deposition of sediment are indicators that a Class III stream exists. Class III streams also meet both of the following conditions: (1) fish are never present, either currently or historically, nor does habitat to sustain fish exist, and (2) the stream does not provide habitat for aquatic non-fish vertebrates and/or aquatic benthic macroinvertebrates.

Not all indicators need to be present to suggest aquatic habitat for fish, aquatic non-fish vertebrates and/or aquatic benthic macroinvertebrates. Neither will the presence of isolated indicators always signify that waters contain aquatic habitat for fish, aquatic non-fish vertebrates and/or aquatic benthic macroinvertebrates.

A.1.6.2 Determination of Stream Class by Stream Survey

If the applicant disagrees with the State Water Board'sBoard's initial determination of stream class, the applicant shall conduct a stream survey to support a different determination. The stream survey shall be performed by a qualified fisheries biologist. Section A.1.5 provides the minimum education, knowledge, and experience requirements of a qualified fisheries biologist. Prior to conducting the stream survey, the applicant shall inform the State Water Board of the intent to conduct the stream survey, and shall provide the name(s) and qualifications of the individual(s) selected to perform the stream survey to the State Water Board for review and approval.

All data, studies, analysis, and conclusions obtained from the stream survey shall be provided to the State Water Board for review and approval. The DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment on the stream survey results.

Stream surveys shall be conducted as follows:

1. The stream survey shall extend an appropriate distance within the stream channel. In general, a minimum distance of 25 **bankfull widths** upstream and downstream of the POD and a~~. The~~ total stream survey length shall be a minimum of 50 bankfull widths will capture the variability within a given stream.

2. Quarterly surveys using appropriate sampling and/or collection equipment shall be conducted to determine the presence of fish, aquatic non-fish vertebrates, and/or aquatic benthic macroinvertebrates. These surveys shall be conducted in the spring, summer, fall, and winter, for at least two years; unless it is demonstrated that the presence of fish, aquatic non-fish vertebrates, and/or aquatic benthic macroinvertebrates can be determined in a shorter time period.

3. A survey of instream habitat conditions shall be made at low flows during the diversion season. Examples of instream habitat condition metrics that could be measured include:

    a. Mean **residual pool depth**
    b. Mean **riffle crest** depth
    c. **Mean riffle width**
    d. **Mean channel bankfull width**
    e. **Mean channel longitudinal gradient**
    f. Water temperature
    g. Amount and type of cover
    h. **Substrate** type

4. A visual survey shall be made after a storm runoff event for evidence of sediment transport. Such evidence may include, but is not limited to, the presence of gravel bars and deposits composed of gravel and sand. Annotated photographs must be provided for documentary evidence.

Results of the stream survey shall be summarized and analyzed. A stream class determination shall be made using the following guidance:

A. A stream is a Class I stream if the results of the survey indicate any of the following:

    1. Fish were observed during any of the quarterly surveys; or

2. Instream habitat conditions observed during the requested diversion season provide suitable habitat for fish based on **habitat suitability criteria** provided by the qualified fisheries biologist.

B. A stream is a Class II stream if the results of the survey indicate all of the following:

1. The stream reach is outside of the known historical distribution limits for fish species. The applicant shall provide evidence supporting this finding.

2. Instream habitat conditions for fish were not observed during the requested diversion season based on habitat suitability criteria provided by the qualified fisheries biologist.

3. Non-fish aquatic vertebrate or aquatic benthic macroinvertebrate species, or combinations of other indicators, such as free water, aquatic plants, or hydric soils were observed during one or more of the surveys.

C. A stream is a Class III stream if the quarterly surveys showed evidence of sediment transport, instream habitat conditions for fish were not observed during the requested diversion season based on habitat suitability criteria, and habitat for non-fish aquatic vertebrate, and aquatic benthic macroinvertebrate species were not observed during any of the quarterly surveys.

A.1.7 Selection of Points of Interest (POIs)

After review and approval of the Water Supply Report and the upper limit of anadromy determination, the State Water Board shall select POIs for an analysis of the proposed project's effects on instream flows. A POI is a location on a stream channel where the applicant shall analyze the effects of the proposed project, in combination with other water diversions, on fishery resources. The POIs identified for analysis will be selected by the State Water Board in consultation with DFG. The DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment on the selected POIs before the State Water Board finalizes them.

The number and locations of the POIs selected for analysis shall depend on the stream classification at the location of the POD being analyzed. Stream classification procedures are described in Section A.1.6.

A.1.7.1 PODs on Class III streams

For proposed projects located on Class III streams, POIs shall be selected at the following locations:

1. At least one location on each Class II stream for which the POD's stream provides contributory flows;

2. The upper limit of anadromy; and

3. Locations at which the proposed project may adversely affect instream flows needed for protection of fishery resources. These may include, but are not limited to, locations where fish are present, locations directly upstream or downstream of the confluence of tributaries to the basin mainstem, locations downstream of onstream storage reservoirs, or locations downstream of direct diversion projects or diversions to offstream storage. If the applicant chooses to perform site specific studies, the POI locations below anadromy may be added to the locations at which habitat studies are performed. For more details, see Appendix C, Guidelines for Site Specific Studies.

A.1.7.2 PODs on Class II streams:

For projects located on Class II streams, POIs shall be selected at the following locations:

1. The upper limit of anadromy; and

2. Locations at which the proposed project may adversely affect instream flows needed for protection of fishery resources. These may include, but are not limited to, locations where fish are present, locations directly upstream or downstream of the confluence of tributaries to the basin mainstem, locations downstream of onstream storage reservoirs, or locations downstream of direct diversion projects or diversions to offstream storage. If the applicant chooses to perform site specific studies, the POI locations below anadromy may be added to the locations at which habitat studies are performed. For more details, see Appendix C, Guidelines for Site Specific Studies.

A.1.7.3 PODs on Class I streams:

For projects located on Class I streams, POIs shall be selected at the following locations:

1. The proposed POD;

2. Locations at which the proposed project may adversely affect instream flows needed for protection of fishery resources. These may include, but are not limited to, locations where fish are present, locations directly upstream or downstream of the confluence of tributaries to the basin mainstem, locations downstream of onstream storage reservoirs, or locations downstream of direct diversion projects or diversions to offstream storage. If the applicant chooses to perform site specific studies, the POI locations below anadromy may be added to the locations at which habitat studies are performed. For more details, see Appendix C, Guidelines for Site Specific Studies.

If site specific study information is not available, locations at which the proposed project could not adversely affect instream flows needed for protection of fishery resources may be determined using the ratio of the proposed POD's water demand to the remaining instream flow available after accounting for senior demands, which was calculated in step 4 of section A.1.2. A POI location at or below anadromy at which the proposed project's demand is less than one percent of the remaining unappropriated supply will be considered a location at which the proposed project could not adversely affect instream flows. However, additional POIs may be required if there is substantial evidence showing that the proposed project may have an adverse effect on instream flows at another location.

A.1.8 Cumulative Diversion Analysis

Even if the applicant can demonstrate that there is unappropriated water to supply the proposed project, there could still be impacts to instream beneficial uses caused by the proposed project in combination with **senior diversions**. A Cumulative Diversion Analysis is required to evaluate whether or not the proposed project, in combination with senior diversions, adversely affects instream flows needed for the protection of fishery resources. In cases where the Cumulative Diversion Analysis demonstrates that the proposed project, in combination with senior diversions, significantly affects instream flows, water may not be available for appropriation.

The Cumulative Diversion Analysis requirements vary depending on the proposed project's location in the watershed. The analysis considers senior diversions in the watershed between the proposed project and the most downstream POI, and contributory flows from tributaries draining into the flow path. Contributory flows from tributaries draining into the flow path can reduce the impacts of diversions in Class III or II watersheds on streamflows needed for fish in Class I streams. At points of diversion located above anadromy, the change in hydrology near the POD may appear significant. However, downstream, at and below the upper limit of anadromy, where salmonids can be affected, the change in hydrology can be slight. Depending on the hydrology and level of impairment in watersheds above anadromy, situations may exist in which diversions could operate with reduced or no minimum bypass flows and/or rates of diversion. The Cumulative Diversion Analysis allows projects upstream of anadromy to determine the minimum bypass flows and rates of diversion needed for their project by evaluating whether the project adversely affects instream flows needed for fishery resources where anadromy exists, after consideration of the flow reductions by senior diverters and contributory flows from stream tributaries.

In conducting this analysis, the applicant shall use hydrologic techniques acceptable to the State Water Board. Detailed analysis procedures are provided in Appendix B Section 5. The requirements described below are meant to apply generally on a regional basis and should be used with the regional criteria. If the applicant chooses to apply the regional approach and the analysis demonstrates that any of the tests described below cannot be passed, further site specific studies would be necessary.

The analysis can be used to assess cumulative effects using site specific criteria for the MBF, MCD, and season of diversion, however if a site specific study demonstrates approval of the project will not contribute to cumulative effects to instream resources the Cumulative Diversion Analysis does not need to be used.

A.1.8.1 Diversions on Class III Streams

Depending on the outcome of the Cumulative Diversion Analysis, projects on Class III streams may be required to operate with one of three different bypass flows, depending on the project's cumulative flow effects on points downstream: (1) a bypass term set to maintain the minimum bypass flow on Class I streams (2) a bypass term set to maintain winter low flows on Class II streams, or (3) no bypass term.

The Cumulative Diversion Analysis may be conducted using any minimum bypass flow or maximum rate of diversion at the POD as long as all three conditions described below are met. This may include operating the proposed project without a minimum bypass flow or a maximum rate of diversion. Successful completion of the analysis may require iteration. Projects located on Class III streams may be allowed to operate with the minimum bypass flow, and maximum rate of diversion values that result in compliance with all of the following conditions. ~~The analysis may use any minimum bypass flow or maximum rate of diversion at the POD as long as all three conditions are met. Successful completion of the analysis may require iteration.~~

1. Cumulatively the~~The~~ project and all senior diverters of record will not reduce the number of days the unimpaired winter low~~February median~~ flow is exceeded at the POIs located on downstream Class II streams by more than 10 percent in each month during the diversion season over the period of record for the analysis. This analysis shall be performed using the method described in Appendix B Section B.5.3.6; ~~. There is error associated with the estimation of daily flows. Because of this, on a case-by-case basis, the State Water Board may consider this condition to be satisfied when analyses show a minor change to the numbers of days the February median is exceeded, provided that the minor change is due to a slight variability in the estimation of flow;~~ AND

2. Cumulatively the~~The~~ project and all senior diverters of record will not reduce the~~change the existing~~ number of days the unimpaired flow needed for spawning, rearing, or passage occurs at the POIs located at and below anadromy by more than 10 percent in each month during the diversion season over the period of record for the analysis. This analysis shall be performed using the method described in Appendix B Section B.5.3.4. Regional criteria or site specific criteria for the minimum bypass flow may be used in the analysis of flows at the POIs. ~~The existing number of days that flow needed for spawning, rearing, and passage occurs shall be determined by including the effects of all senior diverters upstream of the POI. There is error associated with the estimation of daily flows. Because of this, on a case-by-case basis, the State Water Board may consider this condition to be met when analyses show a minor change to the number of~~

~~days that the flow needed for spawning, rearing, and passage occurs. Provided that the minor change is due to a slight variability in the estimation of flow~~; AND

3. Either

   a. The project will not change the existing 1.5 year return flow at the POIs located at and below anadromy. The existing 1.5 year return flow shall be calculated considering the effects of all senior diverters upstream of the POI. Upon approval by the State Water Board, the applicant may substitute a site specific threshold for the 1.5 year return flow.

   OR

   b. The project, in combination with senior diverters, will not reduce the unimpaired 1.5 year return flow at POIs located at and below anadromy by more than 5 percent. Upon approval by the State Water Board, the applicant may use a site specific criterion in lieu of the 5% of the 1.5-year return flow criterion.

   The details of these calculations are described in Appendix B Section B.5.3.5.

A.1.8.1.1 Class III Exemption

If the analysis in Section A.1.8.1 shows a project can meet all three conditions without a minimum bypass flow and without a maximum rate of diversion limitation, that project shall also be exempted from the policy's season of diversion regional criteria and the onstream dam provisions contained in Policy Section 2.4.3.

A.1.8.2 Diversions on Class II Streams

Depending on the outcome of the Cumulative Diversion Analysis projects on Class II streams may operate with one of two different bypass flows, depending on the project's contribution to cumulative flow effects on points downstream: (1) a bypass term set to maintain the minimum bypass flow on Class I streams, or (2) a bypass term set to the winter low flow.

Projects located on Class II streams may be allowed to operate with a~~the minimum~~ bypass flow equal to the winter low flow and without a maximum rate of diversion under~~values that result in compliance with all of~~ the ~~following~~ conditions described below.~~. The analysis shall be performed with a minimum bypass flow at the POD that is at least equal to the February median flow estimated at the POD.~~ If the conditions below cannot be met by bypassing the winter low~~a February median~~ flow or without a maximum rate of diversion, the bypass flow or maximum rate of diversion shall be increased until all of the conditions are met. Successful completion of the analysis may require iteration.

1. Cumulatively the ~~The~~ project and all senior diverters of record will not reduce the~~change the existing~~ number of days the unimpaired flow needed for spawning, rearing, or passage occurs at the POIs located at and below anadromy by more than 10 percent in each month during the diversion season over the period of

record for the analysis. This analysis shall be performed using the method describedprovided in Appendix B Section B.5.3.4. Regional criteria or site specific criteria for the minimum bypass flow mayshall be used in the analysis of flows at POIs located at and below points of anadromy. The existing number of days that flow needed for spawning, rearing, and passage occurs shall be determined by including the POIseffects of all senior diverters upstream of the POI. There is error associated with the estimation of daily flows. Because of this, on a case-by-case basis, the State Water Board may consider this condition to be met when analyses show a minor change to the number of days that the flow needed for spawning, rearing, and passage occurs. Provided that the minor change is due to a slight variability in the estimation of flow; AND

2. Either

a. The project will not change the existing 1.5 year return flow at POIs located at and below anadromy. The existing 1.5 year return flow shall be calculated considering the effects of all senior diverters upstream of the POI. Upon approval by the State Water Board, the applicant may substitute a site specific threshold for the 1.5 year return flow.

OR

b. The project, in combination with senior diverters, will not reduce the unimpaired 1.5 year return flow at POIs located at and below anadromy by more than 5 percent. Upon approval by the State Water Board, the applicant may substitute a site specific threshold for the 1.5 year return flow.

The details of these calculations are described in Appendix B Section B.5.3.5.

A.1.8.3 Diversions on Class I Streams

Proposed diversions on Class I streams shall be allowed to operate using the minimum bypass flow and maximum rate of diversion that demonstrates compliance with all conditions below. Successful completion of the analysis may require iteration.

If regional criteria are used, minimum bypass flows that are at least equal to the regional criteria at the proposed POD and the POIs shall be used in the analysis.

If site specific criteria are used, the analysis at the POIs may use the site specific minimum bypass flows and maximum cumulative diversion obtained in lieu of the regional criteria, and the proposed POD may be allowed to operate with the minimum bypass flow and maximum rate of diversion values that result in compliance with all three conditions.

1. Cumulatively the The project and all senior diverters of record will not reduce thechange the existing number of days the unimpaired flow needed for spawning, rearing, or passage occurs at the POIs by more than 10 percent in each month

during the diversion season over the period of record for the analysis.~~located at and below anadromy.~~ This analysis shall be performed using the method described~~provided~~ in Appendix B Section B.5.3.4. Regional criteria or site specific criteria for the minimum bypass flow may be used in the analysis of flows at the POIs~~The existing number of days that flow needed for spawning, rearing, and passage occurs shall be determined by including the effects of all senior diverters upstream of the POI. There is error associated with the estimation of daily flows. Because of this, on a case-by-case basis, the State Water Board may consider this condition to be met when analyses show a minor change to the number of days that the flow needed for spawning, rearing, and passage occurs. Provided that the minor change is due to a slight variability in the estimation of flow~~; AND

2. Either

   a. The project will not change the existing 1.5 year return flow at POIs located at and below anadromy. The existing 1.5 year return flow shall be calculated considering the effects of all senior diverters upstream of the POI. Upon approval by the State Water Board, the applicant may substitute a site specific threshold for the 1.5 year return flow.

   OR

   b. The project, in combination with senior diverters, will not reduce the unimpaired 1.5 year return flow at POIs located at and below anadromy by more than 5 percent. Upon approval by the State Water Board, the applicant may substitute a site specific threshold for the 1.5 year return flow.

   The details of these calculations are described in Appendix B Section B.5.3.5.

A.1.8.4 Documentation Requirements

Cumulative Diversion Analysis reports shall document all methods used and shall include an assessment of the impacts of the proposed project, in combination with senior diversions, on instream flows necessary for the protection of fishery resources. In addition to being consistent with the requirements described in sections A.1.1 and A.1.1.1, Cumulative Diversion Analysis Reports shall include the following information:

1. The minimum bypass flow and maximum rate of diversion that were used to achieve compliance with the cumulative diversion analysis requirements;

2. The details of the minimum bypass flow and maximum cumulative diversion calculations for POIs located at and below anadromy, if regional criteria were used;

3. Where needed, documentation of the site specific studies that were performed to identify more precisely the instream flow needs of the fishery

resources at the POIs located at and below anadromy. (see the site specific study provisions in Appendix C);

4. The details of a daily analysis of the estimated effects of the proposed project and senior diversions on instream flows needed for spawning, rearing, and passage at each POI located at and/or below anadromy, including an evaluation of the number of days that instream flows meet or exceed the minimum bypass flow requirement at each POI located at and/or below anadromy for three flow conditions: unimpaired; impaired without the proposed project; and impaired with the proposed project. The report shall also include the average percent change by month over the period of record between the number of days flow exceeded the minimum bypass flow requirement and/or the winter low flow bypass requirement in the unimpaired condition and the impaired condition. The percent change for the impaired condition shall be evaluated for both scenarios, senior diverters only and senior diverters with the proposed project;

5. The details of a daily analysis of the estimated effects of the proposed project and senior diversions on the natural flow variability of the stream at each POI located at and/or below anadromy, which consists of calculating the 1.5-year instantaneous peak flow for three flow conditions: unimpaired, impaired without the proposed project, and impaired with the proposed project, then either comparing these values against the maximum cumulative diversion criteria or comparing impaired conditions with and without the project (see Appendix B Section B.5.3.4);

6. ~~For proposed PODs on Class III streams, the details of the effects of the proposed project and senior diversions on the number of days the February median flow is exceeded on Class II streams, including an evaluation of the number of days that instream flows meet or exceed the February median flow at each POI located on Class II streams for three flow conditions: unimpaired, impaired without the proposed project, and impaired with the proposed project (see Appendix B Section B.5.3.5);~~

6. During the course of completing the Cumulative Diversion Analysis, the applicant may want to calculate project yields and the number of days available for diversion. If these calculations are performed, the applicant shall submit these results with the Cumulative Diversion Analysis report.

If the analysis shows that the cumulative effects with senior diversions, affects the instream flows needed for fishery resources using the regional criteria then site specific studies may be needed to demonstrate water is available.

If the analysis indicates the proposed project, in combination with senior diversions, affects the instream flows needed for fishery resources using the regional criteria or site

specific criteria, ~~then there may not be enough water available for~~ the project may need to be modified to demonstrate water is available.

If the analysis indicates the ~~as~~ proposed~~.~~

~~If the analysis indicates the proposed~~ project, in combination with senior diversions~~,~~ does not affect the instream flows needed for fishery resources, then water is available for the proposed project.

The documentation required above is necessary for Water Code decisions based on seniority. Projects subject to CEQA may also be required to submit additional documentation such as an estimate of the cumulative effects of the proposed project and other existing or reasonably foreseeable future projects. Junior and future foreseeable diversions do not factor into Water Code decisions that are based on priority, but this cumulative effects analysis may be required by CEQA.

APPENDIX B

Guidelines for Preparation of Water Supply Report and Cumulative Diversion Analysis

Appendix B. Guidelines for Preparation of Water Supply Report and Cumulative Diversion Analysis

The following sections provide guidelines for preparing a Water Supply Report which quantifies the amount of unappropriated water supply remaining instream after senior rights are accounted for, and an Cumulative Diversion Analysis, which evaluates the effects of a proposed project, in combination with existing diversions, on instream flows needed for protection of fishery resources.

B.1.0 Gather Information Needed for Water Availability Analysis

The information needed for the water availability analysis include:

1. Streamflow records from gages near the Point(s) of Diversion (POD) proposed in the application; and,

2. Information from State Water Board files and records on senior water right diverters within the watershed. This includes any unpermitted applications with a higher priority than the project being analyzed and any claims of a pre-1914 or riparian water right. Information gathered for each diverter shall include location of diversion, season of diversion, storage capacity, rate of diversion, and any minimum bypass flow terms.

B.1.1 Obtain Streamflow Records Near the Point(s) of Diversion

Streamflow data is used to estimate unimpaired flow for the water availability analysis. The applicant shall identify all streamflow gages within the **watershed**. Streamflow gaging stations are typically operated by the United States Geological Survey (USGS), the California Department of Water Resources (DWR), or local agencies. Streamflow records may be obtained from the USGS via the internet using their National Water Information System (NWIS) web interface (http://waterdata.usgs.gov/nwis), from DWR via the internet using their California Data Exchange Center (CDEC) online hydrologic data collection network (http://cdec.water.ca.gov/) or from other federal, state, or local agencies, if available. ~~If there are no streamflow gages within the watershed, the applicant shall locate the nearest streamflow gages.~~

The streamflow gage ~~closest to a POD~~ with at least ten **water year**s (October-September) of complete record may be used for analysis, and applicants should use the maximum number of years practicable to demonstrate dry, normal, and wet year variability.

Applicant shall select a stream flow gauge with a period of record no less than 10 water years for their analysis. The streamflow gage used to prorate unimpaired flow should share characteristics of the watershed being examined. Characteristics include, but are not limited to, geology, soils, topography, vegetation, land use, and precipitation runoff processes.~~. Other streamflow gages may be used if sufficient justification is provided.~~

The water years do not have to be over a continuous time period. Missing records that have been filled with estimates by the USGS or DWR based on standard methods may be used. If the selected streamflow gagegage ~~closest to a POD with at least ten years of complete records~~ is influenced by many water diversions, a gage that is less influenced by diversions may be used for the water availability analysis.

The following information is required at each streamflow gage selected for the analysis:

1. Gage location;
2. Gage watershed drainage area;
3. Period of data record at the gage; and,
4. Daily flow time series data for the **period of record** for the gage.

B.1.2 Obtain Information on Authorized Senior Diverters in the Watershed

To determine the scope of information gathering, it is necessary to identify the **flow path** from the proposed point of diversion to the Pacific Ocean. If the State Water Board determines a project would have a de minimus impact on flows in a **flow-regulated mainstem river**, then the water flow path may terminate at the flow-regulated mainstem river. The geographic extent of the analysis includes the **watershed** upstream of the most downstream POD associated with the senior water right that is located the farthest downstream on the identified flow path. The applicant shall identify all senior water rights within the affected watershed that authorize diversion during the diversion season proposed in the application. The applicant shall identify senior water rights using the State Water Board Division of Water Rights files and records. The following information is required for each POD associated with each senior water right:

1. Location;
2. Direct diversion rate, unless a maximum rate of diversion is imposed as a term on the permit or license, in which case the maximum rate of diversion should be used;
3. Storage volume and position relative to the stream (onstream or offstream)
4. Maximum annual use limitation when it is less than the face value of the permit or license;
5. Minimum bypass flow, if imposed as a term on the permit or license. The minimum bypass term is not needed for the Water Supply Report, but will be needed for the cumulative diversion analysis;

6. Diversion season; and

7. Authorized uses at the point of diversion as specified in the permit or license.

B.2.0 Water Supply Report

The applicant must demonstrate that there is unappropriated water in the watershed sufficient to supply the proposed project by preparing a report that compares the unimpaired water supply to the potential demand by senior water right holders, including demand by those claiming unconfirmed riparian and pre-1914 appropriative rights.

B.2.1 Initial Calculations for Water Supply Report

Any senior water right with a point of diversion along the flow path shall be identified as a point of analysis for water supply. The following should be calculated at each identified senior POD along the flow path:

1. Drainage area (section B.2.1.1)

2. Average annual precipitation (section B.2.1.2)

3. Unimpaired seasonal flow volume (section B.2.1.3)

4. Demand volume of all upstream demands (section B.2.1.4)

B.2.1.1 Determine the Watershed Drainage Area Above Each Senior Point of Diversion Identified for Analysis Along the Flow Path

The watershed above an identified POD encompasses the total area that drains to the POD. The drainage area at each identified POD is determined by measuring the area of the upstream watershed. Steps required to measure the drainage area at each POD identified for analysis along the flow path are:

1. Locate the POD on a topographic map (digital or hard-copy map).

2. Delineate the watershed at the POD on the topographic map.

3. Measure the area of the delineated watershed using a manual planimeter or standard Geographic Information System (GIS) methods.

B.2.1.2 Estimate the Average Annual Precipitation for Each Senior Point of Diversion identified for Analysis Along the Flow Path and the Selected Streamflow Gage

The average annual precipitation at each identified senior POD and at the streamflow gage is determined by averaging the average precipitation over its watershed. Steps

required to estimate the average annual precipitation of the watershed upstream of a senior POD or stream gage are:

1. Obtain average annual precipitation maps. Digital maps of average annual precipitation (1961-1990) developed by the PRISM group at Oregon State University (OSU) are available from the National Resource Conservation Service (NRCS) climate mapping web site (*http://www.wcc.nrcs.usda.gov/climate/prism.html*). Hard-copy maps of average annual precipitation (1931-1963) developed by Rantz and Thompson (1967) are available from the USGS.

2. Overlay the delineated watershed for the identified senior POD and the average annual precipitation maps.

3. Divide the watershed into precipitation bands defined by the precipitation contour lines (lines of equal annual precipitation delineated at defined precipitation intervals).

4. Calculate the average annual precipitation over each precipitation band by averaging the annual precipitation of the precipitation contour lines that define the band.

5. Calculate the area-weighted average annual precipitation over the watershed by summing the products, for all the bands, of the area of each band multiplied by its average annual precipitation, and dividing the sum of the products by the drainage area of the watershed.

B.2.1.3 Estimate the Average Seasonal Unimpaired Flow Volume at Each Senior POD Identified for Analysis Along the Flow Path

The average seasonal unimpaired flow volume at the identified POD shall be estimated by one of the following methods: (A) adjustment of streamflow records, (B) using a precipitation-based streamflow model, or (C) another method acceptable to the State Water Board.

A. Adjustment of streamflow records method

Steps for calculating the average seasonal unimpaired flow volume at the identified PODs from streamflow records include:

1. Select a streamflow gage near the POD with at least ten water years of complete record of daily streamflow data (streamflow time series). The applicant shall select a stream flow gage with a period of record no less than 10 water years for the applicant's analysis. The streamflow gage used to prorate unimpaired flow should share characteristics of the watershed being examined. Characteristics

include, but are not limited to, geology, soils, topography, vegetation, land use, and precipitation runoff processes.

2. Calculate the average seasonal flow volume at the gage. Assume this is the average unimpaired seasonal flow volume. For each month in the diversion season, calculate the mean monthly flow volume at the gage. To get the mean monthly flow volume for a particular month, sum the daily flow data for that month to get a total volume, and repeat for that month for each year in the period of record. Next, sum the total monthly volumes for that month and divide by the number of years in the record to obtain the mean monthly volume for the particular month. Repeat these calculations for each month in the diversion season and sum up each mean monthly total to get the average unimpaired seasonal flow volume for the diversion season at the gage.

3. The average unimpaired seasonal flow volume at each identified senior POD along the flow path can be estimated by using the average unimpaired seasonal flow volume at the gage, the watershed area for the gage and at the identified senior POD, and the average annual precipitation at the gage and at the identified senior POD with the following equation:

$$Q_{POD} = Q_{gage} * (DA_{POD} / DA_{gage}) * (P_{POD} / P_{gage})$$

where:

Q_{POD} = average unimpaired seasonal flow volume estimated at the POD, in acre-feet;
Q_{gage} = average unimpaired seasonal flow volume recorded at the gage, in acre-feet;
DA_{POD} = drainage area at the POD, in square miles;
DA_{gage} = drainage area at gage, in square miles;
P_{POD} = average annual precipitation at the POD, in inches; and
P_{gage} = average annual precipitation at the gage, in inches.

B. Precipitation-Based Streamflow Model

Subject to State Water Board approval, the applicant may propose using standard hydrologic techniques or public domain computer models for estimating the average seasonal unimpaired flow volume. Precipitation input data shall be provided over a minimum of ten complete and continuous water years. Model results shall be validated by comparison with recorded flows on or near the POD watershed. The recorded flows do not have to be unimpaired but the applicant shall take the impairment into consideration when calibrating the model. The modeled output flows shall be summed in units of acre-feet to obtain an average seasonal unimpaired volume. Model submittal requirements are described in Appendix A Section A.1.1.1 of the policy.

B.2.1.4 Determine the Demand Volume of all Senior Water Right Holders in the Watershed Upstream of Each Identified POD Along the Flow Path

For each POD identified along the flow path, the senior water right demand in the watershed upstream of that point must be determined for the Water Supply Report. Using the information gathered in section B.1.2, the senior demand should be determined using the face value or maximum annual use limitation of each water right in units of acre-feet, with the following exceptions (Miller, A., SWRCB, December 2007):

1. Only senior water right diverters with an authorized season of diversion during the proposed project's season of diversion shall be used.

2. Because ~~the season of diversion specified in the Policy is October 1 to March 31, and~~ irrigation of crops in the policy area typically does not begin before March 31, senior water rights authorizing direct diversion for irrigation before March 31 do not need to be considered part of the seasonal demand. However, since a post-harvest irrigation may occur between October 1 and October 31, the October demand of senior water rights with an authorized season extending into this period should be included.

3. Because a typical frost season starts around March 15, water rights authorizing direct diversion for frost protection shall use the authorized diversion rate times 10 hrs a day for 8 days between March 15 and March 31.

4. If the direct diversion season is year round or partially within the season of diversion allowed by this Policy, the senior demand shall be prorated by multiplying its face value or maximum annual use by the ratio of the months in the Policy's diversion season divided by the number of months authorized by the senior permit or license, unless more detailed water use information is known.

5. To be conservative, assume storage reservoirs are empty at the beginning of the diversion season. Therefore the demand for the storage right is the capacity of the reservoir, unless the water right for the reservoir authorizes refill. If a reservoir has a minimum pool which is not normally depleted, the amount of water held in the minimum pool may be taken into consideration in calculating the available storage capacity.

6. If the authorized collection season for storage reservoirs extends beyond March 31, either assume the reservoir(s) are full by March 31, or sum up the volume of water collected every month under the senior demand between the start of diversion season and March 31. The water collected to storage each month should be based on the proration methods to calculate the average seasonal unimpaired flow volume described in method A of section B.2.1.3, unless an alternative method is authorized by the State Water Board.

B.2.2 Analysis of Unappropriated Water to Supply the Proposed Project

An analysis of unappropriated water to supply the project is necessary to determine if there is sufficient water to supply the proposed project after senior rights are accounted for. As stated in B.1.2, the flow path from the proposed point of diversion to the Pacific Ocean or to a flow-regulated mainstem river shall be identified for this analysis. Any senior water right with a point of diversion along this identified flow path shall be identified as a point of analysis for water supply. Only senior water rights with a season of diversion within or overlapping the diversion season of the application need to be considered. The analysis includes the following steps:

1. The analysis shall include a tabulation of the estimated percentages of unappropriated water ~~–~~available for appropriation at each identified senior POD after accounting for senior demands. This shall be determined by subtracting the seasonal demand volume of all senior water right holders in the watershed upstream of each identified senior POD from the average seasonal unimpaired flow volume at the identified senior POD, then dividing this quantity by the average seasonal unimpaired flow volume. To obtain a percentage, multiply this value by 100. All results shall be presented in a table listing the calculated percentage for each identified senior POD.

2. To assist with the selection of points of interest, a calculation of the ratio of the proposed project's demand to the remaining unappropriated water supply at each identified senior POD. The remaining unappropriated water supply is determined by subtracting the seasonal upstream demand volume within the watershed of the identified senior POD from the seasonal unimpaired flow volume at the identified senior POD. This value and the proposed project's demand volume shall be compared at each identified senior POD for the purposes of (1) identifying locations where the proposed project is likely to have minimal impacts to the rate of flow, and (2) to assist with selection of points of interest for the cumulative diversion analysis. The ratio shall be obtained by dividing the proposed project's volume by the remaining unappropriated water supply. These values shall also be presented in a table.

3. The Water Supply Report shall include a **flow frequency analysis** of the seasonal unimpaired flow volume. A set of flow frequency analyses shall be performed at the proposed POD, the senior POD at which the percentage calculated in step 1 is the lowest, and any other senior PODs at which the ratio is less than 50%, if any. The frequency of occurrence of the average seasonal unimpaired flow volumes for each year of record should be determined and plotted graphically. The frequency of occurrence can be obtained from the Weibull formula:

   $$F=1-(m/(N+1)),$$

where:

F = the frequency of occurrence,

m = the rank of the average seasonal unimpaired flow volume, with the largest value receiving m=1, and

N = the length of the gage data record, in years.

Generate graphs of frequency of occurrence plotted against average seasonal unimpaired flow volume. Draw a curve of best fit through the data points. A separate graph will be needed for each POD evaluated.

All the analysis described above shall be presented in report format with all necessary tables and graphs.

B.2.2.1 Map Requirements

1. The applicant shall provide maps with the Water Supply Report that the State Water Board may use to assist with the selection of POIs. Map submittal requirements are provided in Appendix Section A.1.3.

B.2.3 Is there unappropriated water to supply the proposed project?

After submittal of the Water Supply Report, the State Water Board will evaluate the unappropriated water supply that exists for the proposed project. This is not a determination of water availability because the effects of the proposed project, in combination with senior diversions, on instream flows needed for fishery resources, have not been evaluated yet.

B.2.4 Can the requested amount for the proposed project be adjusted?

If there does not appear to be a sufficient amount of unappropriated water to supply the proposed project, the applicant must decide whether the proposed project can be modified to use only the available unappropriated water supply. This decision provides the applicant an opportunity to continue with a modification of the requested amount rather than having the application denied.

B.2.5 Insufficient Unappropriated Water Supply

If the Water Supply Report shows that the amount of water requested by the proposed project is greater than the amount of unappropriated water remaining instream after senior vested rights and permits are accounted for, and the requested amount is not modified, the application may be denied.

If there are competing applications on a stream and there is sufficient unappropriated water to supply senior vested water rights and permit holders, but not sufficient unappropriated water available to also supply all competing applications, the State Water Board may choose between the competing applications for the water, and where factual circumstances warrant, adjust the relative priorities of the applications (Wat. Code, §§ 1253 and 1255.) The State Water Board may do so when it is in the public interest.

B.3.0 Determination of the Upper Limit of Anadromy

If there is sufficient unappropriated water to supply the proposed project, the applicant will need to evaluate the effects of senior diversions and the proposed project on instream flows needed for fishery resources to determine if the unappropriated water is available for diversion. Before this evaluation can be completed, the upper limit of anadromy needs to be determined to aid the State Water Board in its selection of points of interest for the evaluation of the effects on fishery resources.

Procedures for determining the upper limit of anadromy are provided in Appendix A Section A.1.4.

B.4.0 Selection of Points of Interest (POIs)

After review and approval of the Water Supply Report and the upper limit of anadromy determination, the State Water Board shall select POIs for an analysis of the effects of the proposed project, in combination with other water diversions, on instream flows needed for fishery resources. Appendix A Section A.1.7 describes how POIs are selected.

B.5.0 Cumulative Diversion Analysis

The Cumulative Diversion Analysis assesses whether a proposed project may cause impacts to the minimum streamflows and the natural flow variability needed for protection of fishery resources. The cumulative diversion analysis requirements are provided in Appendix A Section A.1.8. This section of the Appendix contains procedures for conducting the analysis and for determining if water is available for appropriation.

B.5.1 Will the regional criteria for diversion season, minimum bypass flow and maximum cumulative diversion rate be used?

This decision allows the applicant to choose whether to (1) complete the cumulative diversion analysis applying the regional criteria for diversion season, minimum bypass flow and maximum cumulative diversion at the POIs at and/or below anadromy, or (2) go directly to conducting a site-specific study to develop site-specific criteria, then complete the cumulative diversion analysis using the site-specific criteria. A site specific minimum bypass flow, maximum cumulative diversion rate, or season of

diversion may be used to assess effects on instream flows necessary for maintaining fishery resources.

IdeallyMost applicants would probably perform the cumulative diversion analysis using the regional criteria first, then conduct a site-specific study if the analysis indicates that the proposed project may negatively impact the instream flows needed for fishery resources, or if project yield is affected. However, the applicant has the option to go directly to site-specific studies, especially if existing site specific information is readily available.

B.5.2 Initial calculations needed for Cumulative Diversion Analysis

After the POIs have been selected, the applicant will need additional information to complete the analysis of the impacts to instream flows. The streamflow records and the information on senior water right holders from State Water Board Division of Water Rights files that have already been gathered will be used in this analysis.

Proposed projects on all streams will need to calculate the following at the POIs located at and/or below anadromy.

- Drainage area, using methods previously described in section B.2.1.1;
- Average annual precipitation, using methods previously described in section B.2.1.2;
- Mean annual unimpaired flow (section B.5.2.1);
- Minimum bypass flow (section B.5.2.2), and
- Maximum cumulative diversion (section B.5.2.3).

Additionally, proposed projects on Class III streams will need to calculate the winter lowFebruary median flow at the POIs located on Class II streams (see section B.5.3.6, part 1.b. for method).

B.5.2.1 Estimate the mean annual unimpaired flow at the POIs

Mean annual unimpaired flow is the average rate of flow past a location if no diversions (impairments) were taking place in the watershed above that point.

Mean annual unimpaired flow shall be estimated by one of the following methods: (A) adjustment of streamflow records, (B) using a precipitation-based streamflow model, or (C) another method acceptable to the State Water Board.

A. Adjustment of streamflow records method

Steps required for this method are:

1. From the streamflow records collected in B.1.1, select a streamflow gage near the POI with at least ten water years of complete record of streamflow

(streamflow time series). The applicant shall select a stream flow gauge with a period of record no less than 10 water years for the applicant's analysis. The streamflow gage used to prorate unimpaired flow should share characteristics of the watershed being examined. Characteristics include, but are not limited to, geology, soils, topography, vegetation, land use, and precipitation runoff processes. The water years do not have to be over a continuous time period if not available. Missing data that has been filled with estimates by the agency operating the gage based on standard methods is acceptable for use.

2. Calculate the mean annual flow rate at the gage by summing the recorded daily streamflow data for each day in the period of record and dividing it by the number of days in the period of record. Do not include data recorded for partial water years.

3. If the gage is located in a watershed that is impaired by water diversions, the mean annual flow rate at the gage shall be adjusted for the impairments to obtain an estimate of the unimpaired mean annual flow rate at the gage (Q_{gage}). The details of how the upstream demands were estimated, and how they were used to unimpair the gage shall be detailed in the analysis report. Use of average annual demand is acceptable for the purposes of this analysis.

4. The mean annual unimpaired flow rate at each POI is calculated from Q_{gage} by multiplying by the ratio of drainage areas and precipitation, according to the following equation:

$$Q_{POI} = Q_{gage} * (DA_{POI}/ DA_{gage}) * (P_{POI}/ P_{gage})$$

where:

Q_{POI} = mean annual unimpaired flow rate estimated at the POI, in cubic-feet per second;
Q_{gage} = unimpaired mean annual flow rate recorded at the gage, in cubic-feet per second;
DA_{POI} = drainage area at the POI, in square miles;
DA_{gage} = drainage area at gage, in square miles;
P_{POI} = average annual precipitation of the POI, in inches; and
P_{gage} = average annual precipitation of the gage, in inches.

B. Precipitation-Based Streamflow Model

Subject to State Water Board approval, the applicant may propose using standard hydrologic techniques or public domain computer models for estimating the mean annual unimpaired flow at the POI. This analysis shall be based on a ten-year simulation period, at a minimum. Model results shall be validated by comparison with recorded flows on or near the POD watershed. The recorded flows do not have to be unimpaired but the applicant shall take the impairment into consideration when calibrating the model. Model submittal requirements are described in Appendix A Section A.1.1.1.

B.5.2.2 Regional Criteria for the Minimum Bypass Flow

The regionally protective minimum bypass flow criteria at POIs located at and below the upper limit of anadromy shall be calculated as follows:

If the watershed drainage area at the POI is less than or equal to 1 square mile,

$$Q_{MBF} = 9.0\ Q_m$$

where:

Q_{MBF} = minimum bypass flow in cubic feet per second; and
Q_m = mean annual unimpaired flow in cubic feet per second.

If the watershed drainage area at the POI is between 1.0 and 321 square miles,

$$Q_{MBF} = 8.8\ Q_m\ (DA)^{-0.47}$$

where:

Q_{MBF} = minimum bypass flow in cubic feet per second;
Q_m = mean annual unimpaired flow in cubic feet per second; and
DA = the watershed drainage area in square miles

If the watershed drainage area at the POI is greater than or equal to 321 square miles,

$$Q_{MBF} = 0.6\ Q_m$$

where:

Q_{MBF} = minimum bypass flow in cubic feet per second; and
Q_m = mean annual unimpaired flow in cubic feet per second.

B.5.2.3 Regional Criteria for the Maximum Cumulative Diversion

The maximum cumulative diversion is equal to 5 percent of the 1.5-year instantaneous peak flow, in cubic feet per second. The 1.5-year instantaneous peak flow is the maximum instantaneous peak streamflow that occurs or is exceeded, on average over the long term, once every one and a half years. The frequency at which this peak flow is expected to occur is referred to as the **recurrence interval**. The 1.5-year instantaneous peak flow shall be calculated at each POI located at and below anadromy either by peak flow frequency analysis of instantaneous peak flow records or by other methods acceptable to the State Water Board.

The peak flow frequency analysis methods described below are the annual flood methodology described in Bulletin 17B "Guidelines for Determining Flood Flow Frequency" (IACWD, 1982) and the peaks over threshold methodology (also referred to as the partial duration method) described in Hydrology for Engineers (Linsley, et al, 1982). Although two peak flow frequency analysis methods are described, the peaks

over threshold method is the preferred method, and applicants are encouraged to use it where possible.

The peak flow frequency analysis results provide the 1.5-year instantaneous peak flow at the gage. For this analysis, assume that the calculated 1.5-year instantaneous peak flow data are representative of unimpaired conditions. The 1.5-year instantaneous peak flow at each POI shall be estimated from the 1.5-year instantaneous peak flow at the gage using the proration methods described in method A of section B.5.2.1.

A. Peaks over threshold method

The peaks over threshold method (also referred to as the partial duration method) is more accurate for recurrence intervals less than five years (Linsley et al, 1982). Steps required are as follows:

1. Select a flow threshold where, on a yearly average basis,~~so that approximately~~ three peaks will exceed~~over~~ the threshold. The three peaks shall ~~will~~ be selected from three distinctly different flood events~~recorded per year on average~~.

2. Select all distinct well-separated flood peaks exceeding the selected flow threshold.

3. Rank the peaks from largest to smallest.

4. Estimate the recurrence interval, T, for each peak flow by the Weibull formula:

$$T=(N+1)/m$$

where:

T= recurrence interval in years;
N=the record length in years; and
m=the rank of the peak, the largest peak having m=1.

5. Plot the magnitude of the peak flow versus the recurrence interval on log-log scale and estimate the 1.5-year instantaneous peak flow from a curve fit of the data.

B. Bulletin 17B Flood Flow Frequency methodology

Bulletin 17B provides guidelines for determining flood flow frequency using annual peak flow data in a log-Pearson Type III distribution. Reservoirs in the policy area tend to be associated with small dams that operate without large sudden changes in flow releases. Bulletin 17B notes that "The procedures [contained in this Bulletin] do not cover watersheds where flood flows are appreciably altered by [large] reservoir [flow] regulation..." (p. 2).

The following is a summary of the basic steps needed to determine the instantaneous 1.5 year peak flow based on the Bulletin 17B guidelines. Before starting the analysis, the peak flow from each year of record should be ranked in order of magnitude with the highest annual peak flow in the data set receiving a rank of 1 and the lowest receiving the rank of the N^{th} year of record. After ranking the annual peak flow data the following steps should be taken to determine the instantaneous 1.5 year peak flow for the gage:

1. Calculate the base 10 logarithm (Log) of each annual peak flow value Q_i.
2. Calculate the average of all the Log Q_i values
3. Calculate the **standard deviation** (S) of the Log Q_i values using the following equation:

$$S = \left[\frac{\sum_{i=1}^{N} \left(X_i - \overline{X} \right)^2}{(N-1)} \right]^{0.5}$$

where:

X_i = Log Q_i

$\overline{X}$ = the average of the Log Q values

N = number of years of annual peak flow data

4. Calculate the **skew** coefficient (G) using the following equation:

$$G = \frac{N \sum_{i=1}^{N} \left(X_i - \overline{X} \right)^3}{(N-1)(N-2)S^3}$$

where:

X_i = Log Q_i

$\overline{X}$ = the average of the Log Q_i values

N = number of years of annual peak flow data

S = the standard deviation

5. Using the calculated skew coefficient and an **exceedance probability** of 0.66 (1.5 year recurrence interval) determine the frequency factor K from Appendix 3 of Bulletin 17B

6. Calculate the instantaneous 1.5 year peak flow using the following equation:

$$Q = 10^{\overline{X}+KS}$$

A hard-copy of Bulletin 17B is available for purchase from the National Technical Information Service (NTIS), Springfield VA 22161, as report no. PB 86 157 278.

A digital copy of Bulletin 17B is available for free download in PDF format from the USGS web page at http://water.usgs.gov/osw/bulletin17b/bulletin_17B.html.

B.5.3 Daily Flow Study

The Daily Flow Study assesses the effects of the proposed project, in combination with senior diversions, to instream flows required for fishery resources at each POI located at and below the upper limit of anadromy. Proposed projects on Class III streams will also need to demonstrate that the project will not cause reductions in the number of days the unimpaired winter low~~February median~~ flow is exceeded on downstream Class II streams.

The analysis requirements vary depending on the stream classification at the proposed project's POD. Regional criteria or site specific criteria shall be used to establish protective streamflows at the POIs at and/or below anadromy. There are no regional criteria for Class II and III streams; however, applicants shall demonstrate, by applying project-selected minimum bypass flows and maximum rates of diversion in this analysis, that project operation will not result in impacts to instream flow needs of fishery resources at the POIs at and/or below anadromy.

Proposed projects located on Class III streams: The analysis is iterative. Successful completion of the analysis will be demonstrated when the applicant finds the minimum bypass flow and rate of diversion for the project that results in (1) at POIs located at and below anadromy, no more than a 10 percent change per month over the period of record~~impacts~~ to the number of days unimpaired flow exceeds the minimum flow needs of fishery resources; (2) either no more than a 5 percent change to ~~and~~ the stream's natural flow variability or no change to the existing flow variability; and (3~~2~~) at POIs on Class II streams, no more than a 10 percent change per month over the period of record to~~in~~ the number of days the unimpaired winter low~~February median~~ flow is exceeded. The analysis shall follow the procedures found in sections B.5.3.1 through B.5.3.6.

Proposed projects located on Class II streams: The analysis is iterative. The analysis shall be performed with a minimum bypass flow at the POD that is at least equal to the winter low~~February median~~ flow estimated at the POD. Successful completion of the analysis will be demonstrated when the applicant finds the minimum bypass flow and rate of diversion for the project that results in the following for POIs located at and below anadromy: no more than a 10 percent change per month over the period of record~~impacts~~ to the number of days unimpaired flow exceeds the minimum flow needs of fishery resources; and either no more than a 5 percent change to the stream's natural

flow variability or no change to the existing flow variability. The analysis shall follow the procedures found in sections B.5.3.1 through B.5.3.5. Procedures for calculating the winter low~~February median~~ flow are provided in Section B.5.3.6, part 1.b.

Proposed projects located on Class I streams may apply either the regional criteria or site specific criteria when analyzing effects at the proposed POD. Depending on the level of impairment and the hydrology of the watershed, the analysis may be iterative. The analysis shall follow the procedures contained in sections B.5.3.1 through B.5.3.5.

The following analysis steps are described in detail in sections B.5.3.1 through B.5.3.5~~6~~:

1. Estimate time series of unimpaired daily flow at POIs located at and/or below anadromy during the proposed diversion season for each year in the period of record;

2. Estimate daily time series of impaired flow using all senior diverters of record at POIs located at and/or below anadromy without the proposed project during the proposed diversion season for each year in the period of record;

3. Estimate the daily time series of impaired flow at each POI located at and/or below anadromy with all senior diverters of record and the proposed project during the proposed diversion season for each in year in the period of record;

4. Estimate effects to instream flows required for spawning, rearing, and passage; and

5. Estimate effects to instream flows needed for the maintenance of natural flow variability; and

~~6. For proposed PODs on Class III streams, estimate effects to instream flows at POIs on Class II streams.~~

The analysis description written assumes the applicant applies the regional criteria at the POIs first, however, the applicant may instead perform a site specific study first to obtain site specific criteria at the POIs for use in the analysis.

B.5.3.1 Estimate time series of unimpaired daily flow at POIs located at and/or below anadromy

The unimpaired daily flow is the average daily rate of flow past a point in a stream if no diversions (impairments) were taking place in the watershed above that point. The time series of unimpaired daily flow is a continuous record of unimpaired daily flows. The time series shall include at least ten complete **water years**. Data must be complete for the water years used but the water years do not have to be consecutive if the data is not available.

The time series of unimpaired daily flow past a POI shall be calculated using methods similar to those used to estimate the mean annual unimpaired flow in B.5.2.1. The methods used to estimate the time series required for the daily flow study for~~of~~ the Cumulative Diversion Analysis differ slightly and are as follows:

A. Adjustment of streamflow records method

Collect the daily streamflow data records for the gage selected for analysis in method A of section B.5.2.1. Estimate the time series of daily flow at the POI by multiplying the daily flow at the gage by the ratio of the drainage area and precipitation using the methods described in method A of section B.5.2.1. Most gage data is available on a

~~For the~~ daily time step; however, gages with shorter time steps are being added to streams in the Policy area. Applicants shall use a stream gage located in a watershed having characteristics similar to~~flow study of~~ the watershed being examined. Applicants are encouraged to use~~Cumulative Diversion Analysis,~~ the stream gage with the shortest time step available.

The gaged record may be assumed to represent unimpaired conditions.

B. Precipitation-based Streamflow Model

If a precipitation-based streamflow model was used in the earlier parts of the analysis to estimate the unimpaired mean annual flow, the time series of unimpaired daily flows that was generated shall be used for the daily flow study.

C. Another method acceptable to the State Water Board

If another method acceptable to the State Water Board was used in the earlier parts of the analysis to estimate the unimpaired mean annual flow, the time series of unimpaired daily flows that were generated shall be used for the daily flow study.

B.5.3.2 Impair the unimpaired daily flows at the POIs located at and/or below anadromy using senior diversions without the proposed project.

The time series of impaired daily flows at a POI is estimated by calculating how much flow is diverted at senior PODs in the POI's watershed and how much continues downstream.

To obtain the time series of impaired daily flows at the POI, subtract the sum of the daily diversion rates for individual senior PODs in the POI's watershed from the daily unimpaired flow time series at the POI. The daily diversion rate is the rate at which water is taken based on the amount of water available instream on that day. In the case of direct diversion, the daily diversion rate may be as high as the maximum rate of diversion in the permit or license. For onstream reservoirs, the daily diversion rate is equal to the flowrate available instream until the reservoir is full, unless a maximum rate

of diversion is specified. Daily diversion rates shall account for minimum bypass flow requirements contained in the permit or license. Daily diversion rates may need to be adjusted for multiple diversions in series.

Diversions from individual senior PODs are subtracted from the flow at the POI until the following conditions are reached:

1. For reservoirs add up the volume collected over time until the individual reservoir is full.

2. For direct diversions, convert the daily diversion rate to a daily volume of water collected. Add up the daily volumes until the maximum annual use is reached, or the end of the diversion season is reached if no maximum annual use is provided in the permit or license.

Applicants may refer to section B.2.1.4 for assumptions that may be used for this analysis.

B.5.3.3 Impair the unimpaired daily flows at the POIs located at and/or below anadromy using senior diversions and the proposed project.

Recalculate the impaired flows at the POIs by including the proposed project, using the guidance described in section B.5.3.2.

B.5.3.4 Evaluate whether the proposed project contributes to reductions in instream flows needed for spawning, rearing, and passage

Any time instream flows meet or exceed the minimum bypass flow, conditions are conducive for spawning, rearing, and passage. This analysis provides an estimate of whether the proposed project, in combination with senior diversions, may significantly decrease the number of days that spawning, rearing, and passage could occur.

At each POI located at and below anadromy, calculate the following:

(1) the minimum bypass flow using the regional criteria from methods described in section B.5.2.2, if not already calculated;

(2) the unimpaired flow time series, using the procedure described in section B.5.3.1;

(3) the number of days that the unimpaired flow meets or exceeds the minimum bypass flow on a monthly basis during the proposed diversion season over the period of record;;

(4) the impaired flow time series without the proposed project, using the guidance provided in section B.5.3.2;

(5) the number of days that impaired flows without the proposed project meet or exceed the minimum bypass flow on a monthly basis during the proposed diversion season over the period of record;

(6) the impaired flow time series with the proposed project, using the guidance provided in section B.5.3.3; and

(7) the number of days that the impaired flows with the proposed project meet or exceed the minimum bypass flow on a monthly basis during the proposed diversion season over the period of record.

(8) The percent change between the number of days counted in (3) and the number of days counted in (5) for each month during the proposed diversion season over the period of record. For example all the days counted in (3) for the month of January should be added up for a total number of days unimpaired flow exceeded the minimum bypass flow in January over the period of record. All the days counted in (5) for the month of January should also be added up. In this example, the total for (5) should be subtracted from the total for (3) for the month of January. The result should be divided by the total for (3) for the month of January and multiplied by 100 to get the percent change between (3) and (5) for the month of January. The percent change should be calculated in this way for each month in the proposed diversion season. In order for water to be available the percent change calculated in this step should not exceed 10 percent.
~~If the number of days counted in (7) is equal to the number of days counted in (5), the proposed project does not contribute to a significant reduction in the instream flows needed for spawning, rearing, and passage.~~

(9) The percent change between the number of days counted in (3) and the number of days counted in (7) for each month during the proposed diversion season over the period of record. The example described above should be applied the same way for the days counted per month in (7) to obtain the percent change between (3) and (7). In order for water to be available the percent change calculated for each month during the proposed diversion season shall also not exceed 10 percent.

B.5.3.5 Evaluate whether the proposed project contributes to reductions in instream flows needed for the maintenance of natural flow variability

1. Estimate the 1.5-year instantaneous peak flow using the methods described in section B.5.2.3 for each of the three time series generated in sections B.5.3.1 through B.5.3.3 for each POI located at and/or below anadromy. These are the time series for unimpaired conditions, impaired conditions without the proposed project, and impaired conditions with the proposed project.

2. Calculate the following quantities at each POI:

a. $$1 - \frac{\text{1.5 year instantaneous peak flow for impaired conditions without the project}}{\text{1.5 year instantaneous peak flow for unimpaired conditions}}$$

~~1 – 1.5 year instantaneous peak flow for impaired conditions without the project / 1.5 year instantaneous peak flow for unimpaired conditions~~

b. $$1 - \frac{\text{1.5 year instantaneous peak flow for impaired conditions with the project}}{\text{1.5 year instantaneous peak flow for unimpaired conditions}}$$

3. At each POI evaluate the following two conditions:

   a. Whether the value calculated in 2a is equal to the value calculated in 2b, meaning that the proposed project causes no change to the existing instream flow conditions; or

   b. Whether the value calculated in 2b is less than 0.05, meaning the proposed project, in combination with senior demands, causes less than a 5 percent change to the 1.5-year instantaneous peak flow from unimpaired conditions.

One of these two conditions must be met at each POI in order to show that the proposed project does not cause a reduction in instream flows needed for the maintenance of natural flow variability.

B.5.3.6 Additional Analysis Step for Class III Points of Diversion - Does the proposed project affect the winter low~~February median~~ flow at POIs on downstream Class II streams?

1. Calculate the winter low~~February median~~ flow for each POI located on Class II streams downstream of the proposed project.

   a. Estimate the daily time series of unimpaired daily flow for each POI on the Class II stream(s) using the methods described in Section B.5.3.1.

   b. For each POI on the Class II stream(s), calculate the median of the estimated daily flows that occur in the month of February using the following steps.

      (1) Obtain the daily flow values that occur in February from the estimated daily time series of unimpaired daily flow.

      (2) Sort the daily February flow values from high to low.

      (3) The February median is the value of the data point that occurs in the middle of the sorted set of data points.

2. Impair the unimpaired daily flows at the POI locations using senior diversions without the proposed project. Use the methods described in Section B.5.3.2 to complete this part of the analysis.

3. Impair the unimpaired daily flows at the POI locations using senior diversions and the proposed project. Use the methods described in Section B.5.3.3 to complete this part of the analysis.

4. Is the number of days the winter low~~February median~~ flow is exceeded affected by senior diverters and the proposed project by more than 10 percent in each month of the diversion season over the period of record?

For each POI on the Class II stream(s), calculate the following:

a. The number of days that unimpaired flows exceed the winter low flow for each month of the diversion season over the period of record;

b. The number of days that the impaired flows including senior diverters without the proposed project meet or exceed the winter low flow for each month of the diversion season of the period of record.
~~February median flow;~~

c.

~~b.~~ The number of days that the impaired flows including senior diverters with the proposed project meet or exceed the winter low flow for each month of the diversion season over the period of record~~February median flow~~.

d. The percent change between the number of days counted in (a) and the number of days counted in (b) for each month during the proposed diversion season over the period of record. For example all the days counted in (a) for the month of January should be added up for a total number of days unimpaired flow exceeded the winter low flow in January over the period of record. All the days counted in (b) for the month of January should also be added up. In this example, the total for (b) should be subtracted from the total for (a) for the month of January. The result should be divided by the total for (a) for the month of January and multiplied by 100 to get the percent change between (a) and (b) for the month of January. The percent change should be calculated in this way for each month in the proposed diversion season. In order for water to be available the percent change calculated in this step should not exceed 10 percent. ~~c. If the number of days counted in (b) is equal to or greater than the number of days counted in (a), the proposed project will not reduce the February median flow at the POI.~~

e. The percent change between the number of days counted in (a) and the number of days counted in (c) for each month during the proposed diversion season over the period of record. The example described above should be applied the same way for the days counted per month in (c) to obtain the percent change between (a) and (c). In order for water to be available the percent change calculated for each month during the proposed diversion season shall also not exceed 10 percent.

B.5.4 Does the proposed project affect instream flows needed for fishery resources using the regional criteria?

If the daily flow studies indicate that the proposed project is unable to meet the cumulative diversion analysis requirements contained in Appendix A Section A.1.8 using the regional criteria for POIs located at and/or below anadromy, then there may not be enough water available for the project as proposed.

If the daily flow studies indicate the proposed project meets the cumulative diversion analysis requirements contained in Appendix A Section A.1.8 using the regional criteria for POIs located at and/or below anadromy, then water is available for the proposed project.

B.5.5 Can the project be modified?

If the daily flow studies indicate the proposed project is unable to comply with the cumulative diversion analysis requirements using the regional criteria for POIs located at and below anadromy, the applicant may modify the proposed project so that it complies with the regional criteria, or do site-specific studies to identify more precisely the fishery resource instream flow needs at the POIs.

There are numerous ways in which the applicant could modify the project. Examples of project modifications include, but are not limited to: reductions in the amount of water collected to storage, reductions in the rate of direct diversion, placing a cap on the maximum rate of diversion, or raising the minimum bypass flow.

Depending on the modification to the project, the applicant may need to conduct additional daily flow studies to demonstrate the modified project is protective of the instream flow needs of fishery resources. If the modified project complies with the cumulative diversion analysis requirements using the regional criteria~~cirteria~~, water is available for appropriation.

If the project cannot be modified, or if the modified project still does not comply with the cumulative diversion analysis requirements using the regional criteria, then the applicant may conduct site-specific studies to identify more precisely the diversion season, minimum bypass flow, and/or maximum cumulative diversion requirements necessary to meet the needs of fishery resources at the POIs.

B.6.0 Site-specific Study to Identify More Precisely the Diversion Season, Minimum Bypass Flow and/or Maximum Cumulative Diversion

The applicant may conduct site-specific studies to identify more precisely the fishery resource instream flow needs at the POIs. Details on site specific studies are found in Policy Appendix C.

B.6.1 Does the proposed project affect instream flows needed for fishery resources using the site-specific criteria?

If the daily flow studies show that the proposed project is unable to meet the cumulative diversion analysis requirements using site specific criteria, then the project as proposed does not leave enough water in the stream. Water may not be available for appropriation.

B.6.2 Can the proposed project be modified?

If the daily flow studies show that the proposed project is unable to meet the cumulative diversion analysis requirements using the site specific criteria, the proposed project may be modified so that enough water remains instream. Depending on the modification to the project, the applicant may need to conduct additional daily flow studies to demonstrate the modified project is protective of instream flows. If the project cannot be modified, water may not be available for appropriation, and further environmental analysis should be undertaken to provide information to determine whether a water right permit may be issued for the proposed project. Streams could be considered for placement on the Fully Appropriated Streams List if the State Water Board determines in a decision on a water right application that no water remains available for appropriation. (Wat Code § 1205, subd. (b).)

B.6.3 Modify the Proposed Project so that Protective Instream flows are Maintained

There are numerous ways in which the applicant could modify the project so that enough water remains in the stream for the protection of fishery resources. The end result of the modifications shall result in compliance with the site-specific criteria. Examples of project modifications include, but are not limited to: reductions in the amount of water collected to storage, reductions in the rate of direct diversion, placing a cap on the maximum rate of diversion, or raising the minimum bypass flow.

B.7.0 Water is Available for the Proposed Project

Water is available for appropriation if the water availability analysis demonstrates the proposed project does not impact senior diverters and the proposed project, in combination with senior diversions, does not adversely affect instream flows needed for fishery resources.

APPENDIX C

Guidelines for Site Specific Studies

Appendix C. Guidelines for Site Specific Studies

C.1.0 Site-Specific Studies for Diversion Season, Minimum Bypass Flow and/or Maximum Cumulative Diversion

This policy implements principles for protection of instream flows for fishery resources through the use of a season of diversion, a minimum bypass flow, and a maximum cumulative diversion rate. The season of diversion allows diversion to occur during periods in which instream flows are naturally high to prevent adverse effects to fish and fish habitat. The minimum bypass flow provides protective streamflows for fish spawning, passage, and rearing, and is implemented in the policy as an instream flow below which no diversion is allowed. The maximum cumulative diversion rate provides a limit on the cumulative rates of diversion of all authorized diverters in a watershed to minimize the effects of water diversion on natural flow variability and the various biological functions dependent on that variability.

The regionally protective criteria provide the applicant the opportunity to show that operation of their project will not cause adverse effects to instream fishery resources without the need for conducting expensive site specific fishery studies. To ensure protectiveness throughout the policy area, the regional criteria were designed to protect sites with the greatest instream flow needs. At some sites, therefore, more than adequate flows may be provided by the regional criteria.

Studies may be conducted to obtain site specific criteria that identify more precisely the instream flow needs of fishery resources. The applicant may propose implementing one or more regional criteria in combination with site specific criteria. Site specific studies consist of a reconnaissance-level habitat assessment, development and implementation of a site specific study plan, and a cumulative diversion analysis.

The studies should be guided by the principles and direction stated in section 2.1 and the definitions of minimum bypass flow and winter low flow contained in section 2.2 and Appendix I. The flow management objectives set forth in Appendix C section 1.1.2 may be used as a guide to preparing and evaluating site specific studies.

Provisions for alternative approaches to site specific studies are described in Section C.1.3.

A reconnaissance-level assessment shall be performed to obtain field data to be used in developing a site specific study plan. To expedite processing, results~~Results~~ of the reconnaissance-level habitat assessment and the details of the proposed study plan that describes the work that will be performed in the site specific study should ~~shall~~ be submitted for State Water Board review and approval prior to commencement of site specific studies. The State Water Board shall ~~may~~ consult with DFG regarding the recommendations of the reconnaissance-level habitat assessment and the study plan. DFG shall be provided a reasonable period of time (not less than 30 days) to review and

comment before the State Water Board provides the applicant written recommendations or approvals.

Site specific studies implementing the study plan shall provide field data and analysis supporting any recommendations regarding a site specific minimum bypass flow, maximum cumulative diversion, and/or season of diversion. Site specific study reports shall include a cumulative diversion analysis to determine the effects of the proposed project, in combination with senior diversions, on instream flows needed for fishery resources.

All field work, analysis, and recommendations involving fishery habitat evaluations shall be performed by a qualified fisheries biologist. Fisheries biologist qualifications are described in Appendix A Section A.1.5. Hydrologic, temperature, and channel morphology aspects of the site specific study may require the involvement of a geomorphologist, hydrologist or engineer. Applicants shall provide the name(s) and qualifications of all of the individual(s) selected to participate in the development and implementation of habitat assessments and study plans to the State Water Board for review and approval prior to starting the work described in this section.

Policy Section 4.0 contains provisions for the formation of watershed groups. If a watershed group is formed, it shall study the instream flow needs of fish and fish habitat using the site specific study guidance described in this section.

C.1.1 Development of the Site Specific Study Plan

An initial reconnaissance-level habitat assessment and a proposed site specific study plan shall be prepared and submitted together. The initial habitat assessment evaluates habitat and stream conditions to aid in the development of the site specific study plan that will describe how the site specific studies will be performed. The following sections describe the information needs for these tasks.

C.1.1.1 Reconnaissance-Level Habitat Assessment

Information regarding habitat and populations of anadromous salmonid species during different life history stages and/or stream hydrology and morphology may be needed prior to designing appropriate methods and analyses for the detailed site specific study. The goals of the initial reconnaissance-level habitat assessment are to identify the habitat and stream conditions that will be studied in the detailed site specific study. The reconnaissance-level habitat assessment may also provide watershed specific information that could be used to identify appropriate methodologies for conducting the detailed site specific study.

The assessment reach shall extend from the upper limit of anadromy to the ocean or to the confluence with a flow-regulated watercourse. Field work associated with the reconnaissance-level habitat assessment shall be performed at the times of the year that are appropriate for the habitat types being evaluated. DFG fish survey reports or

reports from other fishery or watershed agencies/organizations may be referenced as part of this assessment.

The report detailing the results of the reconnaissance-level habitat assessment shall, at a minimum, include the following information:

1. Description of the fishery habitat within the assessment reach, including identification of the potential habitat for fish species (i.e., Chinook, steelhead, coho, rainbow trout, and/or other native species) which are currently or potentially could be present. Photographs and maps of the stream reaches surveyed may be provided;

2. Description of the habitat types (e.g., passage, spawning, incubation, adult holding, and/or juvenile rearing) that are present. Include a recommendation, supported by analysis, regarding which habitat types should undergo further evaluation in the detailed study for the purposes of estimating a site specific minimum bypass flow. If a site specific maximum cumulative diversion is also being considered, include a description of the types of habitat that may be present in side channels that may have periodic hydraulic connectivity (access) to the main stream channel;

3. If a site specific maximum cumulative diversion is being considered, provide descriptions of stream channel characteristics that may be used to inform the study, such as substrate composition, distribution and sizes of spawning gravels, channel slopes and widths, streamside vegetation, channel stability, and availability of reference streams;

4. Conclusions regarding the presence or absence of habitat for salmonid life stages, including a description, supported by scientific evidence, of the historical and current presence of anadromous salmonids by fish species and life history stages from the upper limit of anadromy to the ocean or to the confluence with a flow-regulated watercourse. Include a description of the field methodology and scientific analysis used to derive conclusions regarding habitat descriptions, including location of field surveys, dates of visits (and an explanation of why timing was adequate and appropriate), data collected, and analysis methodology used. Include a description of any DFG fish survey reports or reports from other fishery or watershed agencies, if used in the analysis; and

5. Recommendations regarding the goals of subsequent site specific study plans, including the identification of the habitat types that will be studied for the purposes of developing site specific criteria.

C.1.1.2 Site Specific Study Plan Elements

The Site Specific Study Plan identifies the steps or methods that will be used to perform the work necessary for estimating site specific criteria. The study plan will also include a schedule for obtaining data and a timeline for completion of the report documenting the analysis, results, and recommendations of the site specific study. The following sections describe the minimum information needs for various study plan elements.

C.1.1.2.1 Site Specific Minimum Bypass Flow

The purpose of the minimum bypass flow study plan is to direct the field data acquisition, and the subsequent scientific evaluation of the collected data, so that conclusions may be developed regarding the protective minimum flow needs for upstream passage, spawning, and/or juvenile rearing at selected study locations. The site specific minimum bypass flow for the proposed diversion is obtained as a result of applying these protective minimum flow needs at the POIs in a~~the~~ cumulative diversion analysis, as described in Section C.1.2.4.

The results of the reconnaissance-level habitat assessment shall be used to inform the minimum bypass flow study plan regarding the habitat types that will be studied, i.e., upstream passage, spawning, and/or juvenile rearing. At a minimum, the study plan shall provide: (1) the habitat types that will be studied; (2) the locations in the stream channel at which biological and physical data will be collected and the reasons why those locations were selected; (3) a description of the relevant biological and physical data that will be collected and the collection methods; (4) a description of the analysis method(s) that will be used to model habitat conditions and streamflow needs from the collected biological and physical data; and (5) a timeline for completion of study plan steps.

The data and analysis methods for estimating habitat flow needs that will be used to estimate a site specific minimum bypass flow will vary depending on the habitat types that will be evaluated in the site specific study. The study plan shall identify the habitat types that will be studied and their corresponding data and analysis needs.

C.1.1.2.1.1 Upstream Passage Flow

The goal of the upstream passage flow analysis is to determine the flow that is protective of adult fish passage in the most limiting stream sites. The determination of the most limiting stream site shall consider whether there are low flow and/or leaping-flow barriers to upstream passage present in the watershed.

Low Flow Barriers

Cross-sectional transects shall be located at the low flow limiting stream sites. Depth and velocity data collected at cross-sectional transects may be used to develop stage-discharge relationships. Flows necessary to allow fish passage at the transects shall be consistent with minimum upstream passage depth criteria of at least 0.7 ft for steelhead

and ~~, 0.6 ft for~~ coho, and 0.9 ft for chinook. (R2 Resource Consultants and Stetson Engineers, 2007a.) If lower minimum upstream passage depth thresholds are being considered, the desired values, including scientifically defensible justification that considers the protection of habitat for threatened and endangered fish species, shall be provided in the study plan for State Water Board review and approval.

Leaping-flow Barriers

Leaping-flow barriers may be analyzed using scientifically based threshold criteria. Flows necessary to allow fish passage at barrier sites shall be consistent with the leaping capabilities of the salmonid species of concern. Information needed shall include, at a minimum, an evaluation of drop height, leaping angle, pool depth, and the documented ability for the target salmonid species to successfully ascend the barrier. Documented leaping ability thresholds that will be used, including scientifically defensible justification, shall be provided in the study plan for State Water Board review and approval. The following technical references may assist with the determination of leaping ability thresholds. The applicant is not limited to these references:

- Bjorn, T.C., and D.W. Reiser. 1991. Habitat requirements of salmonids in streams. Pages 83-138 in Influence of forest and range management on salmonid fishes and their habitats. American Fisheries Society Special Publication 19, Bethesda, Maryland.

- Powers, P.D., and J.F. Orsborn. 1985. Analysis of Barriers to Upstream Fish Migration: An investigation of the physical and biological conditions affecting fish passage success at culverts and waterfalls. Part 4 of 4. Final Report. Prepared by Albrook Hydraulics Laboratory, Washington State University for Bonneville Power Administration, Portland, Oregon. 120 pp.

- California Department of Fish and Game. 2003. California Salmonid Stream Habitat Restoration Manual, Part IX, Fish Passage at Stream Crossings.

C.1.1.2.1.2 Spawning Flow

The goal of the spawning flow analysis is to determine the flow that is protective of spawning habitat functions at limiting spawning habitat units. The study plan shall describe the locations at which data will be collected, and shall describe the data that will be collected at cross sectional transects within spawning areas at a range of flow levels to develop habitat flow relationships. Flows necessary for maintaining spawning habitat availability shall be at least consistent with the following minimum spawning depth criteria and favorable stream velocity criteria:

Table C-1 Flow Management Objectives for Spawning

Species	Minimum Spawning Depth (ft)	Favorable Stream Velocities (ft/s)
Steelhead	0.8	1.0 - 3.0
Coho	0.8	1.0 - 2.6
Chinook	1.0	1.0 - 3.0

R2 Resource Consultants and Stetson Engineers, 2007a.

If lower minimum spawning depths or favorable stream velocities are being considered, the desired values, including scientifically defensible justification that considers the protection of habitat for threatened and endangered fish species, shall be provided in the study plan for State Water Board review and approval.

C.1.1.2.1.3 Juvenile Rearing

Juveniles may use a range of winter habitats during low flows. While pool habitat can be important, particularly with increasing latitude, the quantity and quality of such habitat is relatively insensitive to changes in low flow magnitude. In addition, where pool habitats are limited, juveniles may overwinter within riffle substrates. The juvenile rearing flow analysis shall provide an estimate of the flows needed to protect the most limiting habitat for juvenile rearing. In most cases, this would be riffle habitat.

Applicants may assume the minimum flows needed for the protection of spawning will also protect juvenile rearing. Otherwise, study plans for juvenile rearing habitat site specific studies shall describe the approach, including the field studies that will be used, to estimate the minimum flows needed for the protection of juvenile rearing habitat. In addition, the protective thresholds that will be used, including scientifically defensible justification, shall be provided in the study plan for State Water Board review and approval.

If a site specific maximum cumulative diversion is being considered, the study plan shall describe the data and analysis that will be used to evaluate how the site specific maximum cumulative diversion may affect access to side channel juvenile rearing habitat.

C.1.1.2.2 Site Specific Maximum Cumulative Diversion

The maximum cumulative diversion rate provides a limit on the total instantaneous rate of withdrawal of water by all diverters in a watershed. -The goal of the maximum cumulative diversion site specific study is to obtain a site specific maximum cumulative rate of diversion that does not lead to measurable long term changes in bankfull width and depth, or measurable long term changes to substrate grain size distribution percentiles in Class I streams downstream of the proposed diversion. Determining a maximum cumulative diversion rate that meets with these goals will also ensure that natural flow variability, and the various biological functions that are dependent on that variability, are protected. The site specific maximum cumulative diversion criterion also

should not cause adverse reductions in accessibility to side channel juvenile rearing habitat, where present.

Anadromous salmonids depend on the natural annual hydrograph for upstream adult migration, successful spawning, egg incubation, juvenile rearing, and eventual smolt outmigration to the Pacific Ocean. Daily changes in streamflow depth (or 'stage'), attributable to natural streamflow fluctuations and water diversions, may be easier to measure, evaluate, and monitor than changes in streamflow.

As an alternative to a geomorphic analysis, the applicant may determine the MCD that results in limiting changes in stage to 0.1 foot when flows exceed the minimum bypass flow. This criterion will serve to (1) minimize unnatural adult salmonid exposure, stress, vulnerability, and delay during adult upstream migration, (2) encourage adult steelhead return to the Pacific Ocean following spawning, and (3) maintain frequent geomorphic processes important to stream channel maintenance and spawning habitat abundance and quality.

Applicants may utilize the 0.1 foot change in depth flow management objective to evaluate the cumulative effects~~Estimates~~ of diversion on natural flow variability. A site specific analysis of the effects of diversion on changes in stage to flows above the minimum bypass flow may be conducted to determine the cumulative effects to natural flow variability and if the proposed project will need to operate with a maximum rate of diversion in order to limit the cumulative effects of diversion.

Changes in stage shall be evaluated through a hydraulic assessment of mapped habitat. The site specific study for the maximum cumulative diversion should consist of determining the stage discharge rating curve at locations of mapped habitat. A daily flow time series should be estimated for the unimpaired flow, impaired flow with senior diverters, and impaired flow with senior diverters and the proposed project. The daily flow time series and the rating curve for the channel should then be used to assess the effects diversions are having on changes in stage.

Applicants that do not utilize the change in depth flow management objective described above may derive from modeling and/or empirical field studies the site specific maximum cumulative diversion criteria that meet the~~these~~ objectives described at the top of this section. The following outlines potential alternatives for estimating the site specific maximum cumulative diversion.~~may be derived from modeling and/or empirical field studies.~~

C.1.1.2.2.1 Modeling

At a minimum, study plans that propose modeling shall include: (a) a description of the model that will be used, including the underlying scientific basis and the science supporting the use of the model to estimate a maximum cumulative diversion rate; (b)

the model assumptions that will be used, including those that may be used to define physical characteristics of the stream, dimensional similarity and/or sediment budgets; (c) the reasons why the model assumptions are appropriate, and the approach that will be used to estimate the level of uncertainty in model results based on the assumptions used; and (d) a description of how the model will provide an estimated site specific maximum cumulative diversion that does not lead to measurable long term changes in bankfull width and depth, or measurable long term changes to substrate grain size distribution percentiles.

C.1.1.2.2.2 Empirical field studies

Empirical field studies may consist of an investigation of conditions on reference streams (physically comparable streams exhibiting conditions associated with relatively unimpaired flows) with a comparison of those conditions against conditions on the affected stream reach. Empirical field studies may also rely on monitoring of changes to bankfull width and depth over time. At a minimum, study plans for empirical studies shall describe what quantitative measurements would be obtained to estimate habitat changes on the affected stream reach in response to diversion, and how the quantitative measurements will be used to develop an estimated site specific maximum cumulative diversion that does not lead to measurable long term changes in bankfull width and depth, or measurable long term changes to substrate grain size distribution percentiles.

C.1.1.2.3 Site Specific Season of Diversion

Salmonid survival is dependent on external water temperatures. Adverse health effects may occur when salmonids are exposed to temperatures outside their optimal range. The Regional Water Quality Control Board Basin Plans contain narrative water quality objectives that state that the natural receiving water temperature shall not be altered unless it can be demonstrated to the satisfaction of the Regional Board that such alteration in temperature does not adversely affect beneficial uses. In addition, there are streams within the policy area that are on the federal Clean Water Act section 303(d) list of water quality limited segments due to elevated surface water temperatures.

The site specific studies for extending the diversion season shall evaluate whether the extended diversion season affects stream temperatures needed for maintaining adequate habitat conditions. Study plans shall include a description of the analysis that will be performed to determine whether the identified season of diversion contributes to elevated water temperatures below the POD that may result in impacts to habitat for threatened and endangered salmonids. It shall also include a description of the locations at which data will be collected and temperature effects will be modeled, including justification of why those locations are appropriate for the analysis. The protective temperature thresholds that will be used, including scientifically defensible justification, shall be provided in the study plan for State Water Board review and approval. The following technical references may assist with the determination of protective temperature thresholds. The applicant is not limited to this list.

- U.S. EPA Navarro River Total Maximum Daily Loads for Temperature and Sediment
  Internet link: http://www.epa.gov/region09/water/tmdl/navarro/navarro.pdf

- California Regional Water Quality Control Board, North Coast Region. 2000. Navarro River Watershed Technical Support Document for the Total Maximum Daily Load for Sediment and Technical Support Document for the Total Maximum Daily Load for Temperature.
  Internet link:
  http://www.waterboards.ca.gov/northcoast/water_issues/programs/tmdls/navarro_river/navarrotsd.pdf

Study plans for requesting an extended diversion season shall include a study plan for estimating the minimum bypass flow needs of the downstream Class I stream during the portions of the diversion season that are outside the December 15 through March 31 diversion season established by the regional criteria. The regional criterion for the maximum cumulative diversion may be applied with the extended diversion season as a starting point, but the applicant may need to perform a site specific study to obtain site specific maximum cumulative diversion criteria that does not adversely affect streamflows or temperatures needed for maintaining habitat for threatened and endangered salmonids.

C.1.2 Documentation of Results of Site Specific Studies

At the completion of the site specific studies, a technical report documenting field studies, modeling, and analysis results shall be prepared and submitted to the State Water Board for review and approval. The field work, modeling, analysis, and calculations shall be documented in detail sufficient to withstand credible peer review. The following sections describe additional minimum reporting requirements.

The State Water Board may consult with the DFG and NMFS regarding study results. DFG and NMFS shall be provided a reasonable period of time (not less than 30 days) to review and comment on the study results before the State Board makes a determination regarding the results. Any site-specific criterion proposed by an applicant or group of applicants shall be consistent with the principles described in Section 2.1 and shall be approved by the Deputy Director.

C.1.2.1 Results of Minimum Bypass Flow Site Specific Studies

The documentation of the results of minimum bypass flow site specific studies shall include, but is not limited to, the following information:

1. A description of the study results and the analysis supporting the conclusions; including, but not limited to: (a) the purpose for any field surveys that were performed, i.e., reasons why the field surveys were undertaken, what habitats and life stages were evaluated and why; (b) the method(s) used to analyze the field data, including the assumptions used and how the field data were used in the analysis; (c) the biologic or physical criteria used as the threshold for determining protective streamflows; if alternative depth criteria or favorable stream velocity criteria were used, the report shall describe why these alternative thresholds were appropriate, including the literature citations used; and (d) a discussion of the protective minimum streamflows needed for each habitat type analyzed, including how the flows were determined. For small streams where spawning gravel availability is limited in area, the minimum bypass flow should be set at a level that protects all good habitat defined as individual habitat units with suitable spawning gravel patches with areas at least 15 ft2 for Chinook and 10 ft2 for steelhead and coho.

2. Field study methods and data obtained, including: (a) a description of the field sampling design used, including the field methods and equipment used to obtain data; upon notice, the applicant may be required to provide literature citations; and (b) descriptions of the locations at which data were collected, including the rationale used to select the locations, the measurements taken at each location, purpose of the selected locations, map(s) depicting the proposed diversion, senior water rights and sampling locations, and sampling equipment used at each location.

Upon request, the applicant may be required to provide an inventory of the collected raw data including, but not limited to, dates of collection, photographs of transect locations, water depth and velocity measurements obtained for each channel cross section evaluated, temperature, GPS coordinates and maps of data collection locations, and purpose of each location.

C.1.2.2 Results of Maximum Cumulative Diversion Site Specific Studies

At a minimum, documentation of a maximum cumulative diversion site specific study shall explain how field data, modeling, and analysis were used to derive a site specific maximum cumulative diversion and how the proposed site specific value does not lead to measurable long term changes in bankfull width and depth, or measurable long term changes to substrate grain size distribution percentiles. In addition, an analysis shall be provided that evaluates whether the site specific maximum cumulative diversion criterion causes any adverse reductions in accessibility to side channel juvenile rearing habitat.

In addition, if modeling studies are used, at a minimum, sensitivity, calibration, and verification results shall be provided, including estimates of the level of uncertainty in the model results. If empirical field studies are performed, at a minimum, results shall include all data, the statistical and geomorphic analyses used to demonstrate that the

reference streams and affected stream have comparable characteristics or that the long term monitoring results show no long-term change to bankfull width and depth, and any statistical or empirical relationships developed to estimate the response of habitat conditions to changes in streamflow.

C.1.2.3 Results of Season of Diversion Site Specific Studies

At a minimum, study results shall include an analysis describing the extent of stream reach downstream of the proposed diversion that would be affected by increased stream temperature caused by the diversion, and whether the increased stream temperature cause adverse effects to salmonid habitat. Changes to the existing temperature conditions within downstream Class I streams may be allowed if the study results demonstrate that the changes do not cause adverse effects to salmonid habitat.

C.1.2.4 Cumulative Diversion Analysis

The results of a cumulative diversion analysis shall be provided that evaluates the effects of the proposed diversion, in combination with senior diversions, on instream flows needed for fishery resources by reference to the principles stated in section 2.1, the definitions in section 2.2 and Appendix I, and the guidance in section C.1.1.2. The cumulative diversion analysis shall consider the locations of the proposed diversion and senior diversions in the watershed, and contributory flows from tributaries draining into the flow path.

The applicant may choose to use site specific criteria for the minimum bypass flow, maximum cumulative diversion, and season of diversion and apply them to the daily flow study Cumulative Diversion Analysis ~~analysis methods~~ described in Appendix A section ~~Section~~ A.1.8 and Appendix B Section B.5 to assess the cumulative effects of diversion. Applicants choosing to use the 0.1 foot change in depth flow management objective for determination of the maximum cumulative diversion shall assess cumulative effects in the following manner:

1. Evaluate changes in stage between the unimpaired stage and the impaired stage resulting from senior diverters only. These changes in stage should be determined during the proposed season of diversion on a monthly basis for the period of record. When evaluating cumulative effects, the change in stage resulting from impaired flow should not exceed 0.1 feet of unimpaired flow when flow is above the flow needed for spawning, rearing, and/or passage more than 10 percent of the time in each month. This should be evaluated over the period of record. For example, if evaluating the percent change for the month of January, the analysis should be based on the change to stage during all the days in each January in the period of record.

2. Evaluate changes in stage between the unimpaired stage and the impaired stage resulting from senior diverters and the proposed project. These changes in stage should be determined during the proposed season of diversion on a monthly basis for the period of record. In order to demonstrate no cumulative effect based on changes in stage when the proposed project is included in the impaired time series, the cumulative change in impaired flow stage should not exceed 0.1 feet of the unimpaired flow when flow is above the flow needed for spawning, rearing, and/or passage more than 10 percent of the time in each month. This should be evaluated over the period of record and take into consideration the example described in step (1).

3. Projects located above anadromy shall evaluate the cumulative effects to changes in stage when flows are near the minimum bypass flow. The impaired flow time series with the proposed project should not cause the unimpaired flow depth to drop below the depth required for the minimum bypass flow no more than 10 percent of the time in each month. For example if unimpaired flow depth was above the depth required for the minimum bypass flow and impaired flows change the depth to drop below the depth required for the minimum bypass flow, this should not occur more than 10 percent of the time. If this occurs more than 10 percent of the time, then the minimum bypass flow at the POD above anadromy may need to be adjusted to reduce the cumulative effects to the minimum bypass flow that needs to be maintained within the range of anadromy. The analysis should be evaluated on a monthly basis over the period of record and take into consideration the example described in step (1).

4. Projects located above anadromy on Class III streams shall also evaluate the cumulative effects to the winter low flow on Class II streams. The daily flow study for the Cumulative Diversion analysis described in Appendix A section A.1.8.1 and Appendix B section 5.3.6 for Class III streams may be used to evaluate cumulative effects to the winter low flow. The applicant may choose to do a site specific evaluation of the flow needed to maintain aquatic habitat on a Class II stream and a site specific evaluation of the cumulative effects to that flow level.

~~.~~ For the purposes of the analysis, the locations at which the habitat studies were performed shall be designated as the POIs located at and below anadromy. At each POI, if a minimum bypass flow study was performed, the minimum streamflow that is protective of all habitat types shall represent the minimum bypass flow at the POI. The analysis shall demonstrate the proposed diversion, in combination with senior diversions, will not adversely affect the instream flows needed for fishery resources.

If the applicant does not plan to use these methods, the study plan shall describe: (1) how the site specific minimum bypass flow and rate of diversion for the proposed diversion will be obtained from the minimum streamflow data that protects habitat types;

and (2) the cumulative diversion analysis that would demonstrate that the proposed diversion, in combination with senior diversions, will not affect instream flows needed for fishery resources.

C.1.3 Alternative Site Specific Approaches

a. Method for Determining Cumulative Effects Based On Changes in Stage

The following flow management objectives are approved for use as guidance for ~~A~~ site-specific studies. The objectives define acceptable cumulative changes in stage when daily average flows are at different levels.

- When daily average flows exceed the minimum bypass flow defined in section 2.2, diversions shall cumulatively cause no more than 0.1 foot change in riffle stage.

- When daily average flows are between the minimum bypass flow and the winter low flow defined in section 2.2, diversions shall cumulatively cause no more than 0.05 foot change in riffle stage.

- When daily average flows are below winter low flows, diversions are not allowed except as defined in section 2.2 and Appendix A sections A.1.8.1 and A.1.8.2.

b. Method for Determining Cumulative Effects of Diversions on Class II or Class III Streams

Class III Streams

Projects on Class III streams may operate with one of three different bypass flows, depending on the project's cumulative flow effects on points downstream: (1) a bypass term set at the minimum bypass flow (2) a bypass term set to maintain winter low flows, or (3) no bypass term.

Projects located on Class III streams may be allowed to operate without a minimum bypass flow, and maximum rate of diversion, or season of diversion values that result in compliance with all of under the following conditions.

- Cumulative depletion (cumulative equals the project and all senior projects) of not more than 5% of the seasonal (November 1 to March 31) volume measured downstream at the ULA and points of interest below; or

- Cumulative depletion of not more than 10% of the seasonal volume measured at the ULA and points of interest below, if reservoirs operating with neither a MBF or WLF bypass collectively deplete no more than 5% average annual volume.

Where cumulative depletion by reservoirs with no MBF or WLF bypass is greater than 5% but less than 10%, the project shall operate with a WLF bypass. Where cumulative depletion is greater than 10% the project shall operate with a MBF bypass.

Class II Streams

Projects on Class II streams may operate with one of two different bypass flows, depending on the project's cumulative flow effects on points downstream: (1) a bypass term set at the minimum bypass flow, or (2) a bypass term set to maintain winter low flows.

Projects located on Class II streams may be allowed to operate with a bypass flow equal to the winter low flow and without a maximum rate of diversion or season of diversion under the following conditions.

- Cumulative depletion (cumulative equals the project and all senior projects) of not more than 5% of the seasonal (November 1 to March 31) volume measured downstream at the ULA and points of interest below; or

- Cumulative depletion of not more than 10% of the seasonal volume measured at the ULA and points of interest below, if reservoirs operating with neither a MBF or WLF bypass collectively deplete no more than 5% average annual volume.

Where cumulative depletion is greater than 10% the project shall operate with a MBF bypass.

c. Additional Approaches

Additional site specific approaches ~~approach~~ may be proposed that may implement parameters other than a minimum bypass flow, maximum cumulative diversion, or season of diversion. A description of the alternative approach and a study plan shall be submitted to the State Water Board for review and approval prior to commencement of field work and analysis.

The alternative approach and any proposed site-specific criteria shall be consistent with the principles described in Section 2.1. The State Water Board may consult with DFG regarding the alternative approach proposal, study plan, and study results. DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment before the State Water Board provides the applicant written recommendations.

C.1.3.1 Development of Site Specific Study Plans for Alternative Approaches

An initial reconnaissance-level habitat assessment and a proposed site specific study plan shall be prepared and submitted together. The initial reconnaissance-level habitat assessment evaluates habitat and stream conditions to aid in the development of the site specific study plan that will describe how the site specific studies will be performed.

Section C.1.1.1 describes the information that shall be provided to document the initial reconnaissance-level habitat assessment.

The study plan shall provide the assumptions and scientific basis for the alternative approach in detail sufficient to withstand credible peer review. The study plan shall also describe, at a minimum: (1) the habitat types that will be studied; (2) the locations in the stream channel at which biological and physical data will be collected and the reasons why those locations were selected; (3) description of the relevant biological and physical data that will be collected and the collection methods; (4) a description of the analysis method(s) that will be used to model habitat conditions and streamflow needs from the collected biological and physical data; and (5) timeline for completion of study plan steps. The approach shall consider the habitat and scientific issues identified in the sections above. A cumulative water diversion analysis shall be performed as part of the site specific study. The methods described in Appendix A Section A.1.8 and Appendix B Section B.5 may be used. Any alternative method for performing a cumulative water diversion analysis for determining the effects of the proposed project and senior diversions on fishery resources shall be described in the study plan in sufficient detail such that it is sufficient to withstand credible peer review.

C.1.3.2 Documentation of Results of Alternative Site Specific Studies

Reports documenting the results of implementing the study plan shall provide relevant details on the problem statement, and the supporting basis for the methods and approach, including relevant hydrology, hydraulics, geomorphology. Reports shall provide sufficient information to demonstrate that the cumulative effects of the proposed diversion on streamflow, stage, and velocity, in combination with senior diversions, will not affect instream flows needed for fishery resources. The State Water Board may consult with the DFG and NMFS regarding study results. DFG and NMFS shall be provided a reasonable period of time (not less than 30 days) to review and comment on the study results before the State Board makes a determination regarding the results. Any site-specific criterion proposed by an applicant or group of applicants shall be consistent with the principles described in Section 2.1 and shall be approved by the Deputy Director.

At a minimum, reports shall include the following information:

1. A description of the study results and the analysis supporting the conclusions; including, but not limited to: (a) the purpose for any field surveys that were performed, i.e., reasons why the field surveys were undertaken, what habitats and life stages were evaluated and why; (b) the method(s) used to analyze the field data, including the assumptions used and how the field data were used in the analysis; (c) the biologic or physical criteria used as the threshold for determining protective streamflows; and (d) the recommended site specific criteria and how it was determined, including a discussion of the protective streamflows for the habitat types analyzed and the habitat type requiring the highest protective streamflows.

2. A cumulative diversion analysis that demonstrates the proposed diversion, in combination with senior diversions, will not adversely affect the instream flows needed for fishery resources.

3. Field study methods and data obtained, including, but not limited to: (a) a description of the field sampling design used, including the field methods and equipment used to obtain data (upon notice, the applicant may be required to provide literature citations); and (b) descriptions of the locations at which data were collected, including the rationale used to select the locations, the measurements taken at each location, purpose of the selected locations, map(s) depicting the proposed diversion, senior water rights and sampling locations, and sampling equipment used for at each location.

4. If modeling studies are used, sensitivity, calibration, and verification results shall be provided, including estimates of the level of uncertainty in the model results

Upon request, the applicant may be required to provide an inventory of the collected raw data including, but not limited to date of collection, photographs of locations of habitat transects and water depth and velocity transects, channel cross sections, temperature, GPS coordinates and maps of data collection locations, and purpose of each location.

Red line Revisions Dated April 27, 2010

Red line Revisions Dated April 27, 2010

APPENDIX D

Guidance for Developing Mitigation Plans

Appendix D. Guidance for Developing Mitigation Plans

Construction and operation of onstream dams have the potential to adversely affect instream flows and fishery resources by interrupting fish migratory patterns; interrupting downstream movement of gravel, woody debris, or benthic macroinvertebrates; causing loss of riparian habitat or wetlands; or creating invasive species habitat. For proposed projects that include onstream dams, the applicant shall be required to prepare mitigation plans for the eradication of non-native species, gravel and wood augmentation, and/or riparian habitat replacement. The State Water Board may waive this requirement if it determines that such measures are unnecessary. The mitigation plans shall be developed by qualified individual(s). The name(s) and qualifications of the individual(s) selected to develop the mitigation plans shall be submitted to the State Water Board for review and approval prior to the preparation of the mitigation plans. The proposed mitigation plans shall be submitted to the State Water Board for review and approval during the environmental review of the water right application. The State Water Board shall consult with DFG regarding proposed mitigation plans. DFG shall be provided a reasonable period of time (not less than 30 days) to review and comment before the State Water Board provides the applicant written recommendations or approvals.

The water right permit shall include terms describing the mitigation that will be implemented, and shall require regular submittal of reports on mitigation plan activities on specified time schedules. The reports shall contain the following information:

1. A description of the methods or approaches used;

2. The frequencies that the methods or approaches were applied;

3. The results of monitoring;

4. An evaluation of the effectiveness and success of the methods or approaches; and

5. Descriptions of the supplements or modifications to the methods or approaches that were or will be implemented, if any.

The water right permit shall allow the State Water Board to modify the mitigation plan if the permittee or licensee provides documentation that indicates that the plan is ineffective, unsuccessful, or no longer required.

The applicant or petitioner shall provide the following information in proposed mitigation plans:

1. Non-native species eradication plan

a. The method by which non-native species present or potentially present in the reservoir will be identified.

b. A description of the approach that will be used to eradicate the species from the reservoir if non-native species are present, including the method and the frequency of applying the method.

c. Description of the criteria that will be used to evaluate the effectiveness and success of the eradication method.

d. Description of the program that will be used for monitoring the effectiveness and success of the eradication method.

e. Description of how the approach will be supplemented or modified if the monitoring program indicates that the current eradication plan is not effective or successful.

f. Time schedule for periodic inspection of the reservoir and eradication of the non-native species from the reservoir, if present.

2. Gravel and wood augmentation plan

a. Estimation of the annual volume of **coarse sediment** and **large wood** that would move past the dam location if the dam were not in place, and the annual volume of coarse sediment and large wood that will be trapped in the reservoir.

b. Determination of the **nature** and size characteristics of the coarse sediment and large wood that will be trapped in the reservoir.

c. Description of the method that will be used to augment gravel and large wood in the stream reach below the POD, including the location, method, nature and size characteristics of the gravel and large wood being added, and the frequency of applying the method.

d. Following are suggestions that may be incorporated into the method.

1) Except as provided in 3) and 4) below, place coarse sediment and large wood into the stream reach downstream of the dam. The coarse sediment and large wood shall have characteristics that are equivalent to the volume, nature, and size characteristics of the coarse sediment and large wood that will be trapped in the reservoir.

2) The same coarse sediment or large wood that accumulates in the reservoir may be used, or suitable coarse sediment or large wood from an outside source may be used.

3) Sediment finer than one quarter-inch does not need to be moved or placed downstream.

4) Wood pieces with lengths shorter than approximately (i) 6 feet, or (ii) half the **mean channel width**, evaluated upstream above the influence of the dam, whichever criterion is shorter, do not need to be moved or placed downstream as these do not contribute substantially to the formation of stream jams. (R2 Resource Consultants, 2007c.)

5) Coarse sediment must be placed near the **channel thalweg** at a point below the dam and bypass return, a half-channel width upstream of a **riffle crest**.

6) Large wood must be placed below the bypass channel return and scattered over an **active bar** at an elevation that is exposed during low winter flows.

e. Description of the criteria that will be used to evaluate the effectiveness and success of the augmentation approach.

f. Description of the program that will be used for monitoring the effectiveness and success of the augmentation approach.

g. Description of how the augmentation approach will be supplemented or modified if the monitoring program indicates that the current augmentation approach is not effective or successful.

h. Time schedule for the periodic implementation of the augmentation approach.

3. **Riparian habitat** replacement plan

a. Characterization of the type, species composition, spatial extent, and **ecological functions and values** of the riparian habitat that will be removed, lost, or damaged by the onstream dam.

b. Description of the approach that will be used to replace the riparian habitat removed, lost, or adversely impacted by the onstream dam, including a list of the soil, plants, and other materials that will be necessary for successful riparian habitat replacement, and a description of planting methods,

spacing, erosion protection, and irrigation measures that will be needed, if any.

c. Description of the criteria that will be used to evaluate the effectiveness and success of the riparian habitat replacement approach.

d. Description of the program that will be used for monitoring the effectiveness and success of the riparian habitat replacement approach.

e. Description of how the riparian habitat replacement approach will be supplemented or modified if the monitoring program indicates that the current approach is not effective or successful.

f. Time schedule for the implementation and monitoring of the riparian habitat replacement.

APPENDIX E

Bypass System Requirements

Appendix E. Bypass System Requirements

To ensure compliance with minimum bypass flow and maximum rate of diversion requirements, all diversions under this Policy shall operate using passive bypass systems. Upon State Water Board approval, if physical site conditions prevent the construction of a passive bypass system, an automated computer-controlled bypass system shall be designed, installed, and operated.

The bypass system must be designed by a civil engineer with a valid California registration. The design must satisfy the minimum bypass flow and maximum rate of diversion requirements for the project, and shall be capable of bypassing the entire streamflow when streamflows are less than the minimum bypass flow, and be capable of bypassing all flow rates above the maximum rate of diversion, where applicable. Design drawings of bypass systems shall be submitted to the State Water Board for review and approval prior to construction. The design drawings shall include sufficient detail demonstrating how the bypass system will function.

Passive bypass structures shall be designed so that the bypass requirements are met through the design of the bypass facility, rather than through frequent human interaction after the bypass facility is built. Passive bypass systems do not need bypass flow monitoring after the initial validation of the design because the installed design characteristics of the structure prevent diversion of water in violation of the bypass flow conditions.

The passive bypass system shall be constructed when the diversion facilities are built. For projects with existing diversion facilities, the passive bypass system shall be constructed before water is diverted under the permit or the order approving a petition. After installation, the registered engineer shall make sufficient flow measurements to confirm bypass flows are satisfied as designed. The data and analysis confirming that bypass flows are satisfied shall be submitted to the State Water Board. Manipulation of a control valve or weir plate by a human operator at the beginning and/or end of the diversion season may be necessary to adjust the structure to satisfy the bypass requirements. If the system is damaged or partially blocked, the system shall be repaired, and flow measurements to confirm bypass flows are satisfied shall be made, if necessary, to verify successful repair. Such verification, and any modifications made to the facility, shall be submitted to the State Water Board.

If automated computer controlled bypass systems are approved, the bypass system shall be constructed when the diversion facilities are built. For projects with existing diversion facilities, the system shall be operational before water is diverted under the permit or order approving a petition. After installation, the registered engineer shall confirm the system is operating as designed. The data and analysis confirming that bypass flows are satisfied shall be submitted to the State Water Board. If the system is damaged, the permit holder shall immediately inform the State Water Board. The State Water Board will determine whether to require diversion to cease until the system is

repaired. After the system is repaired, the permit holder shall provide confirmation to the State Water Board that bypass flow requirements are still being satisfied

APPENDIX F

Compliance Assurance

Appendix F. Compliance Assurance

The State Water Board will assure compliance with this policy by developing clear and enforceable permit terms and conditions, requiring and reviewing compliance plans, reviewing self-monitoring reports, and maintaining a field presence in the policy area through compliance inspections, licensing inspections and complaint investigations.

F.1.0 Enforceable Terms and Conditions of Permits, Licenses and Orders

Water users must have a clear understanding of the terms and conditions that implement this policy. New water right permits issued under this policy will contain terms and conditions implementing policy requirements. The State Water Board also will consider adding terms and conditions to existing water rights or revising ambiguous or inappropriate terms and conditions when analyzing petitions. Additionally, the State Water Board may impose terms and conditions to implement this policy through a public trust proceeding, a proceeding on waste or unreasonable diversion or method of diversion or use or method of use of water, an enforcement proceeding or as a result of a complaint investigation. In all of these situations, the State Water Board will issue permits, license, and orders, with clear and enforceable provisions.

F.2.0 Self-Monitoring Reports

The State Water Board will monitor for compliance by requiring self-monitoring reports. These reports include certain reports that are already required such as the Progress Report by Permittee and the Report of Licensee. Self monitoring reports are signed under penalty of perjury. Special permit or license terms may also require submittal of special reports.

The State Water Board will revise its self-monitoring reports to require a permittee or licensee to clearly identify any violations of applicable requirements and to identify any corrective actions taken or planned within a specified time schedule. State Water Board staff will review the self-monitoring reports, identify potential violations, and determine whether an immediate enforcement action is appropriate. A failure to report a violation or falsification of diversion records will be taken into consideration in determining the scope and magnitude of enforcement.

The State Water Board also receives requests for renewal of small domestic registrations and livestock stockpond registrations. The State Water Board staff will review these requests for compliance with the terms and conditions included therein.

F.3.0 Inspections for Licensing

Water Code section 1605 requires that before issuance of a license, the State Water Board make a full inspection and examination of the works constructed under each

water right permit to determine whether the construction of the works and the use of water are in conformity with applicable law, including the State Water Board's regulations and the conditions of the permit. Licensing of a water right permit represents the culmination of the water right permitting process. A license inspection provides a valuable field check for compliance. A license inspection allows the State Water Board to verify that information submitted in self-monitoring reports is complete and accurate. A recommendation that a license be issued is based on confirmation that a permittee is in full compliance with the terms and conditions of the permit, such as season of diversion, purpose of use, and point of diversion and place of use served. The State Water Board must also identify the maximum amount of water being put to a beneficial use under the permit. Any permit violations identified during license inspections are subject to enforcement.

F.4.0 Compliance Inspections

The State Water Board will conduct a compliance inspection program in the policy area. All permit and license holders will be subject to inspection. The State Water Board generally will contact permit and license holders by letter to inform them of a potential compliance inspection, or may investigate with limited notice. This notification will provide the water right holder with an opportunity for voluntary compliance prior to the inspection. The compliance inspection program initially will target high resource-value watersheds. Targeted watersheds will be selected annually based, in part, on input from the Regional Water Quality Control Boards, the Department of Fish and Game, the U.S. Fish and Wildlife Service, and the National Marine Fisheries Service. For each target watershed, State Water Board staff will develop a project priority list based on diversion quantity, special terms, or potential violations gleaned from self-monitoring reports. State Water Board staff also may perform a watershed-wide investigation of diversion facilities constructed without a known basis of right. The State Water Board may conduct an investigation without first contacting the permittee or licensee by letter.

The State Water Board shall place a priority on compliance inspections within the five-county area covered by this policy. State Water Board staff may also establish random surveillance stations to monitor streamflows below projects having bypass conditions. Violations identified during this surveillance will be prioritized according to the criteria identified in Policy Section 9.2 and Appendix G and may be subject to immediate enforcement action.

The State Water Board will work cooperatively with the DFG, the NMFS, the USFWS, and the North Coast Regional Water Quality Control Board, and local law enforcement agencies to conduct compliance investigations. The State Water Board may request assistance from these agencies and may provide assistance to these agencies in the conduct of multi-agency compliance and enforcement efforts.

F.5.0 Complaint Investigations

The State Water Board relies on local residents, other agencies, and other interested persons to help them identify potential water right violations. The complaint process affords the State Water Board an opportunity to be apprised of unauthorized diversions. Information regarding an actual or potential unauthorized activity is often obtained through a complaint filed by the public or by another public agency. Complaints may be based on allegations that a diversion of water is in violation of permit or license terms or conditions, is without basis of right, constitutes the waste or unreasonable use of water, or adversely affects public trust resources.

The State Water Board responds to all written complaints. State Water Board staff may conduct a field investigation to gather additional information not contained in the complaint or in the water diverter's response to the complaint. State Water Board staff will consider this policy when analyzing complaints and determining enforcement priorities within the policy area.

The State Water Board will work cooperatively with the DFG, the NMFS, the USFWS, and the North Coast Regional Water Quality Control Board, and local law enforcement agencies to conduct investigations of complaints that involve diversions of water that are filed with the State Water Board or with the other agencies. The State Water Board may request assistance from these agencies and may provide assistance to these agencies in the conduct of multi-agency enforcement efforts.

F.6.0 Enforcement Case Record Maintenance and Review

The State Water Board will post copies of water right enforcement notices and all final enforcement Orders on its website. All State Water Board orders, decisions resulting from hearings, or settlement of enforcement actions will also be posted on the website.

APPENDIX G

Prioritization of Enforcement

Appendix G. Prioritization of Enforcement

The following comprises a non-exclusive list of criteria that State Water Board staff will use in setting enforcement priorities regarding violations.

G.1.0 Violation Within Class I and II Streams in the Policy Area or Within an Existing or Wild and Scenic River System

The protection of California's public trust resources is of paramount importance. Class I streams contain habitat for fishery resources, and Class II streams contain habitat for aquatic non-fish vertebrates and/or aquatic benthic macroinvertebrates. Any violations on Class I or Class II streams within the policy area; or within any component of the California Wild and Scenic River System or the National Wild and Scenic River System shall be given enforcement priority.

G.2.0 Violations Within Fully Appropriated or Adjudicated Stream Systems

The State Water Board is responsible to protect existing water rights. Any violations affecting the available water supply of a stream that (1) the State Water Board has declared a fully appropriated stream system pursuant to Water Code section 1205 or (2) a Superior Court has rendered a judgment for the adjudication of water rights shall be given enforcement priority.

G.3.0 Potential Injury to Endangered Species

Any violation that has the potential to cause an adverse impact to threatened or endangered species shall be given enforcement priority. State Water Board staff will work with the DFG, federal fishery agencies, and local law enforcement in prioritizing enforcement regarding this potential injury.

G.4.0 Waste and Unreasonable Use and Diversion

The prevention of waste, unreasonable use or unreasonable method of use of water, unreasonable diversion or method of diversion of water shall be given enforcement priority.

G.5.0 Injury to Prior Right Holder

Any violation that injures a prior right holder shall be given enforcement priority.

G.6.0 Large Consumptive Use Projects Receiving Economic Benefit from a Violation or Unauthorized Diversion

Any large consumptive use project receiving any economic benefit from a violation or unauthorized diversion shall be given enforcement priority. A large project for this policy means a project that (1) directly diverts more than 1 cubic feet per second; (2) collects

more than 50 acre-feet per annum, or stores water via a dam within the jurisdiction of the Department of Water Resources for safety, as defined in Water Code sections 6002 and 6003; or (3) involves one entity that uses numerous diversions that cumulatively satisfies conditions (1) or (2).

G.7.0 Recalcitrant Violators, Repeat Violators, and Willful Misstatements

The State Water Board will give priority in taking enforcement against the following persons who have violated a term of their permit or license:

1. Any person who fails to take corrective actions prescribed by the State Water Board in a previous informal or formal enforcement action within the time provided;
2. Any person shown in State Water Board records to have previously violated a term of their permit or license;
3. A person who willfully submits misstatements to the State Water Board;
4. A person that requested cancellation or revocation of an application, permit or license but continues to divert water.

G.8.0 Other Factors as Justice May Require

In addition to the factors that are discussed above, the State Water Board shall consider any other factors as justice may require when determining the enforcement priority of a violation. For example, the State Water Board shall consider Environmental Justice concerns when determining if a violation is an enforcement priority.

APPENDIX H

Timely and Appropriate Enforcement Actions

Appendix H. Timely and Appropriate Enforcement Actions

The State Water Board has a number of enforcement tools to respond to water right violations. This section describes these options and discusses procedures that are common to some or all of these options.

H.1.0 Informal Enforcement Actions for Lower Priority Violations

For low priority violations, State Water Board staff may recommend an informal enforcement action. The purpose of an informal enforcement action is to quickly bring a violation to the water diverter's attention and to give the diverter an opportunity to voluntarily correct the violation and return to compliance as soon as possible. The State Water Board, however, may take a formal enforcement action in place of, or in addition to, an informal enforcement action. Continued or repeated violations should trigger a formal enforcement action.

H.2.0 Formal Enforcement Actions

A formal enforcement action is a statutorily authorized enforcement action. Formal enforcement actions should contain findings of fact that establish all of the statutory requirements of the specific statutory provision being utilized. The actions listed below present options available for water right enforcement.

H.2.1 Administrative Civil Liability (ACL) Complaints

Pursuant to Water Code section 1052, an unauthorized diversion or use of water is a trespass against the State subject to a maximum civil liability of $500 per each day of unauthorized diversion or use of water. Water Code section 1055, subdivision (a), provides that the Executive Director of the State Water Board may issue an ACL complaint to any person or entity on which the ACL may be imposed.
Water Code section 1055.3 provides that:

> "In determining the amount of civil liability, the board shall take into consideration all relevant circumstances, including, but not limited to, the extent of harm caused by the violation, the nature and persistence of the violation, the length of time over which the violation occurs, and the corrective action, if any, taken by the violator."

The Water Code does not specify how these factors are to be weighed or combined when setting the actual dollar amount of liability. The manner in which the State Water Board considers these factors for any given situation is up to the discretion of the Board within the limits of the statutory maximum. The liability should be high enough to take into consideration the market value of the water used, the costs to the State Water Board in taking enforcement action, and the effects on other water users and instream uses of water of diverting and using water without authorization. The amount of liability should serve as a deterrent to future unauthorized diversions by the diverters. The

liability shall be assessed within the statutory maximum amount and at a minimum at a level that recovers the staff costs and economic benefits, if any, associated with the acts that constitute the violation.

The State Water Board may allow a person or entity to satisfy no more than 50 percent of the monetary assessment imposed in an ACL order by completing or funding one or more Supplemental Environmental Projects (SEPs). SEPs are projects that enhance the beneficial uses of the waters of the State, provide a benefit to the public at large, and are not otherwise required of the person or entity. The State Water Board will consider allowing any person or entity against whom an ACL complaint is issued to satisfy no more than 50 percent of the ACL by completing or funding an SEP if the SEP is consistent with the provisions of the State Water Board's Water Quality Policy on Supplemental Environmental Projects.

The State Water Board will consider the following factors and any other appropriate factors when setting the liability amount:

Avoided Costs

The avoided cost should represent the true cost the violator would have to spend to legally acquire water equivalent to the water supply illegally diverted. This amount is based on the average value of water available in the area of the diversion. If water is not available in the area, the highest regional water cost will be used. Avoided water right fees will be included. Any investment costs for the infrastructure necessary to deliver water to the point of use also may be considered if the infrastructure does not already exist.

Economic Benefit Amount

The Economic Benefit Amount is any savings or monetary gain derived from the acts that constitute the violation in addition to the avoided cost. Economic benefit includes all savings from, and all income and profits resulting from, the use of the illegally diverted water over the time period of that use. This could include benefits resulting from the time value of money.

Deterrent Amount

The civil liability should be set at a level that will deter future noncompliance by the violator or others in the same regulated community. In establishing this amount, the State Water Board will consider both the violator's culpability and the extent of harm associated with the violation as follows:

Culpability

The culpability amount will be determined based on the nature and persistence of the violation, length of time that the violation has continued, the diverter's knowledge of water rights requirements, the diverter's role in construction and operation of the diversion project, responsiveness to previous notifications by the State Water Board or the Division, and any voluntary efforts undertaken or not undertaken to correct the violation. A diverter's knowledge of the water right system will be assessed based on

information in the State Water Board's records. A diverter's participation in construction may be determined using the County Assessor's records (dates of ownership) and aerial or topographic maps (dates for project existence). Finally, the State Water Board will consider any corrective actions that were taken, or actions that were prescribed but not taken, as well as any falsification of records.

Extent of Harm Amount
The State Water Board will estimate an amount that mitigates for any harm to public trust resources known to be specifically caused by the violation. The State Water Board will consult with the Department of Fish and Game, US Fish and Wildlife Services and National Marine Fishery Service estimating liability amount for impacts to fish and wildlife resources.

Staff Costs
Staff costs will be calculated for all State Water Board staff time expended on the investigation of the violation, preparation and review of the staff report, and preparation and review of the enforcement action. The staff costs will include salary, benefits and all overhead costs. The civil liability amount should, at a minimum, be set at a level that recovers economic benefit plus staff costs.

Ability to Pay
There are situations when it is appropriate to consider ability to pay when setting a liability amount. The ability to pay administrative civil liability is limited by diverter's revenues and assets. In some cases, it is in the public interest for the diverter to continue in business and bring operations into compliance. If there is strong evidence that administrative civil liability would result in widespread hardship to the service population or undue hardship to the diverter, it may be reduced on the grounds of ability to pay. Any consideration of ability to pay shall be supported by tax or other financial records. The State Water Board may also consider increasing administrative civil liability to assure that the enforcement action will have a deterrent effect for a water diverter having a greater ability to pay.

H.2.2 Cease and Desist Order (CDO)

The State Water Board may issue an order to cease and desist when it determines that any person is violating, or threatening to violate (1) the prohibition set forth in Water Code section 1052 against the unauthorized diversion or use of water; (2) any term of condition of a water right permit, license, certificate, or registration; or (3) any decision or order of the State Water Board issued pursuant to part 2 (commencing with section 1200) of the Water Code, Water Code section 275, or article 7 (commencing with section 13550) of chapter 7 of division 7 of the Water Code (relating to water reuse).

The State Water Board must provide notice of the proposed CDO by certified mail. The notice shall contain a statement of facts and information that would tend to show the proscribed action and inform the respondent that unless a request for hearing is received by the State Water Board within a certain time period, the State Water Board

may adopt the CDO without a hearing. After notice and an opportunity for hearing, the State Water Board may adopt, modify, revoke, or stay in whole or in part any CDO.

Under this policy, the State Water Board will issue a Notice of CDO commensurate with any ACL complaint issued for the unauthorized diversion or use of water within the policy area. A notice of CDO shall also be issued for any priority violation within the policy area that is not subject to an ACL compliant.

A CDO issued in accordance with this policy shall clearly identify the actions required to come into compliance and a schedule for compliance. Any violation of a CDO adopted by the State Water Board shall be a priority violation. The State Water Board may consider imposing civil liability for an amount not to exceed $1,000 for each day of violation. The State Water Board may also consider requesting the Attorney General to petition the superior court to impose civil liability, or for the issuance of prohibitory or injunctive relief.

H.2.3 Revocation of Permits and Licenses

The State Water Board may revoke a permit or license pursuant to Water Code sections 1410 or 1675, respectively. The State Water Board may revoke a permit to appropriate water if work is not commenced, prosecuted with due diligence, and completed or the water applied to beneficial use in accordance with the permit and applicable statutes or regulations. A license may be revoked if the State Water Board finds that the licensee has not put water to a useful or beneficial use, has ceased to put water to such use, or has failed to observe any of the terms and conditions in the license.

The State Water Board must provide notice of the proposed revocation. The notice must contain a statement of facts and information on which the proposed revocation is based. Unless a request for hearing is received, the State Water Board may act on the proposed revocation without a hearing.

H.2.4 Administrative Civil Liability for Failure to File Statements of Water Diversion and Use

Water Code section 5101 requires persons who divert water to file a statement of diversion and use with the State Water Board unless certain exemptions apply. Pursuant to new legislation that goes into effect on February 2, 2010, any person who fails to file a statement as required by Water Code section 5101 for a diversion or use that occurs after January 1, 2009, is subject to administrative civil liability in the amount of $1,000, plus $500 per day for each additional day on which the violation continues if the person fails to file a statement within 30 days after the State Water Board has called the violation to the person's attention. (Wat. Code, § 5107, subd. (b) & (c)(1), added by Stats. 2009-10, 7th Ex. Sess. 2009, ch. 2, § 6.) The State Water Board will contact the owners of identified water diversion facilities in the policy area with no known basis of right and inform them that they must either file a statement of diversion and use or explain why they are not required to file a statement pursuant to Water Code section

5101. Persons who are required to file a statement but fail to do so within the time allowed will be assessed administrative civil liability consistent with Water Code section 5107. The State Water Board will review the information contained in the statements of water diversion and use that are filed as a result of this notification to identify which water diversions are likely to be unauthorized and to identify the potential impacts of the diversions. This information will be used to determine enforcement priorities within the policy area.

APPENDIX I

Glossary of Terms

Appendix I. Glossary of Terms

Active bar — In a stream channel, regions of distinct deposits of sand, gravel, or cobble that are not yet colonized by older, well-established riparian vegetation, and which may be mobilized during high flow; includes mid-channel island deposits and point bars.

Anadromy (adj. form: anadromous): **—** Migration of fish, as adults or subadults, from salt water to fresh.

Aquatic benthic macroinvertebrate — Aquatic animals without backbones that can be seen by the unaided eye and typically dwell on rocks, logs, sediment or plants. Include, but are not limited to, insects, mollusks, amphipods, and aquatic worms. Common aquatic insects include, but are not limited to, mayflies, stoneflies, caddisflies, true flies, water beetles, dragonflies, and damselflies.

Aquatic non-fish vertebrate — Include, but are not limited to, aquatic mammals, such as beavers, river otters, and muskrats; amphibians, such as frogs and salamanders; and reptiles, such as snakes and turtles.

Aquatic plants — Include **obligate wetland plants** and frequent or dense groupings of **facultative wetland plants**. For complete descriptions, see Reed, USFWS (1988).

Average, also called mean — The sum of measured values divided by the number of samples. The average of a set of measured values is calculated as follows:

$$\text{Average} = \frac{\Sigma x}{n}$$

where: Σx is the sum of the measured values, and

n is the number of samples.

Bankfull flow —The flow rate of a river or stream that completely fills its channel so that the elevation of the water surface coincides with the top of the bank margins.

Bankfull width — The width of the water surface across the stream channel at which the stream first overflows its natural banks.

Canopy — The overhead branches and leaves of streamside woody vegetation.

Channel maintenance flows — Peak streamflows needed for maintaining stream channel geometry, gravel and woody debris movement, and the natural flow variability needed for protection of various habitat needs of **anadromous salmonids**.

Channel thalweg — The line connecting the lowest or deepest points along a stream channel.

Coarse ~~gravel, coarse~~ sediment — Particle sizes~~Stones~~ of ¼ inch ~~size~~ or larger, including particles derived from debris flows, that either contribute directly to spawning gravel, or that reduce~~comminute~~ to a smaller usable size, or influence stream channel morphology by forming a **substrate** framework.

Ecological functions and values (of riparian habitat) — Functions are onsite and offsite natural riparian habitat processes. Values are the importance of the riparian habitat to society in terms of health and safety; historical or cultural significance; education, research, or scientific significance; aesthetic significance; economic significance; or other reasons.

Ephemeral stream — A stream or part of a stream that flows only in direct response to precipitation; it receives little or no water from springs, melting snow, or other sources; its channel is at all times above the water table.

Exceedance probability —The probability that a specified streamflow magnitude will be exceeded. The exceedance probability is equal to one divided by the recurrence interval.

Face value — The maximum amount of water that is authorized to be diverted under a water right permit, license, small domestic/livestock stockpond certificate, or statement of diversion;

Face value demand — The sum of the face values of all water rights above an identified location in a stream channel.

Facultative wetland plants — Plants that usually occur in wetlands. Include, but are not limited to, marsh and rough horsetail, most species of bulrush and flatsedge that are not obligate wetland plants, stream or smooth violet, milk maids, red-osier and brown dogwood, California Spikenard or Elk Clover, blueberry, blackberry (except Himilaya Blackberry), and water birch. For a more detailed list, see Reed, USFWS (1988).

Fish – Wild fish, mollusks, crustaceans, invertebrates, or amphibians, including any part, spawn, or ova thereof (California Fish and Game Code section 45). For the purposes of stream classification fish are defined as finfish.

Flow frequency analysis — A statistical technique used by hydrologists for estimating the average rate at which floods, droughts, storms, stores, rainfall events, etc., of a specified magnitude recur.

Flow path — The direction water flows along its stream course from the point of diversion to the Pacific Ocean. If a project will have a *de minimis* effect on flows in a **flow-regulated mainstem river**, then the flow path may terminate at the flow-regulated mainstem river.

Flow-regulated mainstem river — A river or stream in which scheduled releases from storage are made to meet minimum instream flow requirements established by State Water Board Order or Decision.

Habitat suitability criteria — Structural and hydraulic characteristics of a stream that are indicators of habitat suitability for different fish species and life stages.

Histogram — A graphical representation of a frequency distribution. The range of the variable is divided into class intervals for which the frequency of occurrence is represented by a rectangular column; the height of the column is proportional to the frequency of observations within the interval.

Hydraulic conductivity — A measure of the capacity for a rock or soil to transmit water; generally measured in units of feet/day or cm/sec.

Hydric soils — A hydric soil is a soil that formed under conditions of saturation, flooding, or ponding long enough during the growing season to develop anaerobic conditions in the upper layers. A guide for delineating hydric soils is provided in USDA, NRCS, US Army Corps of Engineers, 2006.

Hydrograph — A graph showing for a given point on a stream the streamflow, stage (depth), velocity, or other property of water with respect to time.

1.5-year instantaneous peak flow — The maximum instantaneous peak streamflow that occurs or is exceeded, on average over the long term, once every one and a half years.

Instream cover — Areas of shelter in a stream channel that provide aquatic organisms protection from predators or competitors and/or a place in which to rest and conserve energy due to a reduction in the force of the current.

Intermittent stream — Has flowing water during certain times of the year, when groundwater provides water for streamflow. During dry periods, intermittent streams may not have flowing water. Runoff from rainfall is a supplemental source of water for streamflow.

Large wood — Wood pieces greater than six feet in length, or greater than approximately half the mean channel width evaluated upstream, above the influence of the dam, whichever is larger (R2 Resource Consultants, 2007c).

Maximum cumulative diversion rate— The sum of the rates of diversion of all diversions upstream of a specific location in the watershed.

Mean, also called average — The sum of measured values divided by the number of samples. The mean of a set of measured values is calculated as follows:

$$\text{Mean} = \frac{\Sigma x}{n}$$ where: Σx is the sum of the measured values, and

n is the number of samples.

Mean annual unimpaired flow – The average rate of flow past a location if no diversions were taking place in the watershed above that point, consisting of the average of the daily unimpaired flows recorded over a one year period.

Mean channel bankfull width — The average top width of the stream channel at **bankfull flows**; in incised channels or steep mountain channels without a floodplain, the average wetted top width at the mean annual flood is a reasonable approximation.

Mean channel longitudinal gradient — The average slope, in the downstream direction, of a defined segment of the stream channel based on measurements taken along the **channel thalweg**.

Mean riffle width — The average width of the stream channel bottom at a **riffle** based on several measurements taken along the entire reach of the riffle.

Minimum bypass flow — The minimum instantaneous flow rate of water at any location in a stream that is adequate for fish spawning, rearing, and passage. In applying the minimum bypass flow to a diversion, it is the minimum instantaneous flow rate of water that must be moving past the point of diversion before water may be diverted under a permit.

Nature [of coarse sediment and large wood] — Characteristics other than size, such as type of wood or rock, angularity, and roundness.

Obligate wetland plants — Plants that almost always occur in wetlands. Include, but are not limited to, Pacific foxtail, water hemlock, arrow-leaved groundsel, cattail, skunk cabbage, most monkeyflowers, many, but not all species of bulrush and flatsedge, most willows, and mountain alder. For a more detailed list, see Reed, USFWS (1988).

Offset well — A well drilled at an offset distance from a river or stream that is considered pumping from the underflow of the river or stream

Permeability — The capability of soil or other geologic formations to transmit water. See **hydraulic conductivity**.

Period of record — The time period for which flow measurements have been recorded. The period of record may be continuous or interrupted by intervals during which no data were collected.

Perennial stream — A perennial stream has flowing water year-round during a typical year. The water table is located above the streambed for most of the year.

Groundwater is the primary source of water for streamflow. Run-off from rainfall is a supplemental source of water for streamflow.

Point of Diversion — A location in a stream at which water is withdrawn.

Point of Interest — A location in a stream at which the proposed diversion's effect on instream flows for fishery resources is evaluated.

Pool — A deeper area of water in a stream channel; usually quiet and often with no visible flow.

Range of anadromy — Length of stream reach between the Pacific Ocean and the upper limit of **anadromy**, where migration, spawning and rearing of **salmonids** occur.

Ranney collectors — A water collector constructed as a dug well from 12 to 16 feet (3.5 to 5 m) in diameter that has been sunk as a caisson near the bank of a river or lake

Recurrence interval — The average time between occurrences of streamflows of a given or greater magnitude, sometimes referred to as the return period. The recurrence interval is equal to one divided by the **exceedance probability.**

Residual pool depth — The difference between the depth of a pool at its deepest point and at its outlet.

Riffle — A shallow area in which water flows rapidly over a rocky or gravelly streambed.

Riffle crest — The highest point along the **channel thalweg** at a riffle.

Riparian habitat — Vegetation growing close to a stream, lake, swamp, or spring that is generally critical for wildlife cover, fish food organisms, stream nutrients and large organic debris, and for streambank stability.

Salmonid – Of, belonging to, or characteristic of the family Salmonidae, which includes the salmon, trout, and whitefish.

Season of diversion — The calendar period during which water may be diverted.

Senior diversions — Diversions that are or may be authorized by senior water rights, including permitted and licensed rights, stockpond certificates, small domestic registrations, and, to the extent information is available in the State Water Board's records or other sources of information, riparian and pre-1914 appropriative water rights. For purposes of evaluating whether water is available for appropriation, senior diversions also include diversions that may be authorized by pending water right applications with older priority dates.

Skew — A measure of the degree of symmetry of a frequency distribution. Positive or negative skew indicate a bunching up of scores at one end of the scale and a smaller tail at the other end.

Standard deviation — A statistical term describing the measure of the variation of data around the mean of the data set, defined as the square root of the sum of squared differences between the average value and all observed values

Substrate — The material (e.g., ~~dirt, rocks,~~ sand, gravel, cobbles, boulders, bedrock, and combinations thereof) that forms the bed of a stream.

Thalweg — see **channel thalweg**

Unimpaired flow — The streamflow that would naturally occur in a stream channel without any diversions or impoundments

Upper limit of anadromy — The upstream end of the range of **anadromous** fish that currently are or have been historically present year-round or seasonally, whichever extends the furthest upstream.

Watershed — The land area that drains into a stream. An area of land that contributes runoff to one specific delivery point; large watersheds may be composed of several smaller "subsheds", each of which contributes runoff to different locations that ultimately combine at a common delivery point. Often considered synonymous with a drainage basin or catchment. Watershed (drainage basin) boundaries follow topographic highs. The term watershed is also defined as the divide separating one drainage basin from another.

Watershed drainage area – The land area that comprises a watershed.

Water year — The time convention used by the USGS for compiling and reporting their streamflow data. The water year for the United States is from October 1st to September 30th. For example, water year 2000 runs from October 1, 1999 to September 30, 2000.

Winter low flow - The winter low flow is a streamflow threshold important to maintaining good habitat in Class II streams for protection of aquatic non-fish vertebrates, aquatic benthic macroinvertebrates, aquatic plant, and hydric soils. The regionally protective criterion for the winter low flow is the February median flow.

APPENDIX K

Streams Within the Policy Area

Appendix K. Streams Within the Policy Area

The policy area includes the counties of Marin and Sonoma, and portions of Napa, Mendocino, and Humboldt counties. Information from the USGS National Hydrography Database was used to create the following list of named streams that are within the policy area. The policy applies to water diversions from these streams and to water diversions from unnamed streams and locally named streams that contribute flow to these streams.

Stream Names

Abalobadiah Creek
Ackerman Creek
Adams Creek
Adobe Creek
Alamere Creek
Albion River
Alder Creek
Allen Creek
Alpine Gulch
American Canyon Creek
Americano Creek
Americano, Estero
Anchor Creek
Anderson Creek
Anderson Gulch
Angel Creek
Anna Belcher Creek
Arroyo Hondo
Arroyo Jan Jose
Arroyo Sausal
Arroyo Seco
Arvola Gulch
Asbury Creek
Ash Creek
Atascadero Creek
Austin Creek
Avichi, Arroyo
Bailey Creek
Baker Creek
Bakers Creek
Bald Hill Creek
Bale Slough
Barlow Gulch
Barnes Creek
Barrelli Creek
Barton Gulch
Beal Creek
Bear Canyon
Bear Creek
Bear Gulch
Bear Haven Creek
Bear Trap Creek
Bear Valley
Bear Wallow Creek
Beasley Creek
Bee Tree Creek
Beebe Creek
Bevans Creek
Bidwell Creek
Big Carson Creek
Big Creek
Big Finley Creek
Big Flat Creek
Big Gulch
Big Oat Creek
Big Pepperwood Creek
Big River
Big Salmon Creek
Big Sulphur Creek
Biggs Gulch
Bill Williams Creek
Billings Creek
Biter Creek
Black Rock Creek
Blossom Creek
Blucher Creek
Blue Jay Creek
Blue Slide Creek
Bluegum Creek

Stream Names

Boardman Gulch
Boggs Creek
Bon Tempe Creek
Bonee Gulch
Booth Gulch
Bottom Creek
Boulder Creek
Boyd Creek
Boyer Creek
Boyes Creek
Brandon Gulch
Bridge Creek
Briggs Creek
Britain Creek
Brooks Creek
Browns Creek
Brush Creek
Buck Creek
Buckeye Creek
Buckhorn Creek
Bull Team Gulch
Bullock Creek
Bunker Gulch
Burbeck Creek
Burns Creek
Burnt Ridge Creek
Burright Creek
Busch Creek
Bush Slough
Buzzard Creek
Canon Creek
Calabazas Creek
Camp Creek
Camp Sixteen Gulch
Campbell Creek
Cannon Gulch
Carneros Creek
Carriger Creek
Carson Creek
Cascade Creek
Caspar Creek
Cataract Creek
Cavanaugh Gulch
Cedar Creek
Chadbourne Gulch
Chamberlain Creek
Champlin Creek
Chaparral Creek
Chapman Branch
Chemise Creek
Cheney Gulch
Cherry Creek
Chileno Creek
Chiles Creek
Chimney Rock Creek
China Gulch
China Slough
Chinese Gulch
Churchman Creek
Clear Creek
Cloverdale Creek
Coast Creek
Cobb Creek
Cold Creek
Cold Springs Creek
Coleman Creek
Coleman Valley Creek
Colgan Creek Flood Control Channel
Con Creek
Conklin Creek
Conn Creek
Cook Creek
Cook Gulch
Coon Creek
Cooskie Creek
Copeland Creek
Copper Mine Gulch
Corral Creek
Corte Madera Creek
Corte Madera Del Presidio, Arroyo
Cottaneva Creek
Covington Gulch
Coyote Creek
Crane Creek
Crawford Creek
Crocker Creek
Cummiskey Creek
Cyrus Creek
Dago Creek

Stream Names

Danfield Creek
Dark Gulch
Deadman Gulch
Deer Creek
Deer Park Creek
DeHaven Creek
Devil Creek
Devils Creek
Dooley Creek
Doolin Creek
Doty Creek
Dougherty Creek
Dowdall Creek
Doyle Creek
Dry Creek
Duck Pond Gulch
Ducker Creek
Duffy Gulch
Duncan Creek
Dunn Creek
Dutch Bill Creek
Dutch Henry Creek
Dutcher Creek
Duvoul Creek
East Austin Creek
East Branch
East Branch Little North Fork
East Branch N. Fork Big River
East Branch N. Fork Jackass Creek
East Branch N. Fork Mattole River
East Branch Russian Gulch
East End Creek
East Fork Cataract Creek
East Fork Honeydew Creek
East Fork Lagunitas Creek
East Fork Russian River
East Fork Swede George Creek
Ebabias Creek
Edwards Creek
Eldridge Creek (historical)
Elk Creek
Elkhead Creek
Elkhorn Creek
Elkins Creek
Estero De San Antonio
Eubank Creek
Devils Gulch Creek
Devils Slough
Dewarren Creek
Dietz Gulch
Digger Creek
Donahue Slough
Donelly Creek

Fairfax Creek
Fall Creek
Felder Creek
Feliz Creek
Felta Creek
Ferguson Gulch
Fern Creek
Fife Creek
Finley Creek
Fish Rock Gulch
Fisher Creek
Flat Ridge Creek
Flat Rock Creek
Fleming Creek
Floodgate Creek
Flume Gulch
Flynn Creek
Foote Creek
Forsythe Creek
Fort Ross Creek
Fourmile Creek
Fowler Creek
Fox Camp Creek
Franchini Creek
Franz Creek
Frasier Creek
Frazer Creek
Freathy Creek
Freezeout Creek
French Creek
Frink Canyon
Fuller Creek
Gallinas Creek
Galloway Creek
Garcia River
Garnett Creek
Gates Creek
George Young Creek

Stream Names

German Creek
Getchell Gulch
Gibson Creek
Gilham Creek
Gill Creek
Gilliam Creek
Gird Creek
Gitchell Creek
Glenbrook Creek
Glennen Gulch
Gossage Creek
Grab Creek
Granny Creek
Grape Creek
Grasshopper Creek
Graveyard Creek
Gray Creek
Green Gulch
Green Valley Creek
Greenwood Creek
Grindstone Creek
Groshong Gulch
Gschwend Creek
Gualala River
Gulch Creek
Gulch Eleven
Gulch Fifteen
Gulch One
Gulch Seven
Gulch Six
Gulch Thirtyone
Gulch Three
Gut Creek
Haggerty Gulch
Hall Gulch
Halleck Creek
Haraszthy Creek
Hardy Creek
Hare Creek
Harris Creek
Harrow Creek
Hathaway Creek
Haupt Creek
Hayfield Creek
Hayshed Gulch
Hayworth Creek
Hazel Gulch
Hensley Creek
Hobson Creek
Hoil Creek
Home Ranch Creek
Honey Creek
Honeydew Creek
Hooker Creek
Hoot Owl Creek
Horns Creek
Horse Creek
Horse Mountain Creek
Horsetail Gulch
Horsethief Creek
Hot Springs Creek
Hotel Gulch
House Creek
Howard Creek
Howell Creek
Hudeman Slough
Huichica Creek
Humboldt Creek
Humbug Creek
Hummingbird Creek
Hungry Hollow Creek
Icaria Creek
Indian Creek
Ingalls Creek
Inglenook Creek
Ingram Creek
Inman Creek
Irish Creek
Jack Peters Gulch
Jack Smith Creek
Jackass Creek
Jakes Creek
James Creek
Jenner Gulch
Jewell Gulch
Jewett Creek

Stream Names

Jim Creek
Jimmy Creek
John Creek
John Gordon Creek
John Smith Creek
Johnson Creek
Johnson Gulch
Juan Creek
Jug Handle Creek
Julias Creek
Kaisen Gulch
Kass Creek
Kelley Creek
Kellogg Creek
Kelly Gulch
Kendall Gulch
Kent Creek
Ketty Gulch
Keys Creek
Kibesillah Creek
Kidwell Gulch
Kimball Gulch
Kinsey Creek
Kolmer Gulch
Kreuse Creek
Lagoon Creek
Laguna de Santa Rosa
Lagunitas Creek
Lake Gulch
Lancel Creek
Larkspur Creek
Larmour Creek
Laurel Gulch
La Rue Gulch
Lawhead Creek
Lazy Creek
Lee Creek
Lewis Creek
Lichau Creek
Little Bear Creek
Little Bear Haven Creek
Little Briggs Creek
Little Creek
Little Finley Creek
Little Howard Creek
Little Jackass Creek
Little Juan Creek
Little N. Fork Gualala River
Little N. Fork Navarro River
Little N. Fork Noyo River
Little N. Fork Ten Mile River
Little Rancheria Creek
Little River
Little Salmon Creek
Little Strawberry Creek
Little Sulphur Creek
Little Valley Creek
Little Warm Springs Creek
Livereau Creek
Log Cabin Creek
Lone Tree Creek
Long Ridge Creek
Lost Creek
Lovers Gulch Creek
Low Gap Creek
Lynch Creek
Lytton Creek
Maacama Creek
Mallo Pass Creek
Maple Creek
Marble Gulch
Mariposa Creek
Mark West Creek
Marsh Creek
Marsh Gulch
Marshall Creek
Marshall Gulch
Martin Creek
Matanzas Creek
Mattole Canyon
Mattole River
McCarvey Creek
McChristian Creek
McClellon Gulch
McClure Creek
McCormick Creek
McDonald Creek
McDonald Gulch
McDonnell Creek
McDowell Valley
McGann Gulch
McGinnis Creek

Stream Names

McKee Creek
McKenzie Creek
McKinnan Gulch
McMullen Creek
McNab Creek
Mettick Creek
Mewhinney Creek
Meyer Gulch
Middle Creek
Middle Fork Cottaneva Creek
Middle Fork Feliz Creek
Middle Fork Hardy Creek
Middle Fork Lagunitas Creek
Middle Fork of North Fork Noyo River
Middle Fork Ten Mile River
Mill Creek
Miller Creek
Millerton Gulch
Milliken Creek
Mills Creek
Minnie Creek
Mira Slough
Mission Creek
Mitchell Creek
Moat Creek
Monahan Creek
Montgomery Creek
Moore Creek
Morrison Creek
Morrison Gulch
Morses Gulch
Mud Hen Slough
Mud Slough
Murphy Creek
Murray Gulch
Mustard Gulch
Napa Creek
Napa River
Napa Slough
Nash Creek
Nathanson Creek
Navarro River
Neefus Gulch
Newton Creek
Nicasio Creek
Niemela Gulch
Nolan Creek
Nooning Creek
Norden Gulch
North Branch
North Branch Little Sulphur Creek
North Branch North Fork Navarro River
North Branch Portfield Creek
North Fork Albion River
North Fork Alder Creek
North Fork Bear Creek
North Fork Big Flat Creek
North Fork Big River
North Fork Buckeye Creek
North Fork Cottaneva Creek
North Fork DeHaven Creek
North Fork Fuller Creek
North Fork Garcia River
North Fork Gualala River
North Fork Hardy Creek
North Fork Hayworth Creek
North Fork Indian Creek
North Fork Jackass Creek
North Fork James Creek
North Fork Juan Creek
North Fork Lancel Creek
North Fork Mattole River
North Fork Mill Creek
North Fork Navarro River
North Fork Navarro River, South Branch
North Fork Noyo River
North Fork Redwood Creek
North Fork Schooner Gulch
North Fork South Fork Noyo River
North Fork Ten Mile River
North Fork Wages Creek
North Mill Creek
Novato Creek
Noyo River
Nye Creek
Oat Creek
Oat Valley Creek
O'Conner Gulch
Oil Creek
Old Mill Creek
Olds Creek
Olema Creek

Stream Names

Onion Patch Gulch
Ornbaun Creek
Osborne Creek
Orrs Creek
Osser Creek
Pacific Ocean
Painter Creek
Palmer Creek
Pardaloe Creek
Park Gulch
Parkinson Gulch
Parlin Creek
Parsons Creek
Patsy Creek
Pena Creek
Peat Pasture Gulch
Pechaco Creek
Pepperwood Creek
Perry Gulch
Petaluma River
Peterson Creek
Peterson Gulch
Phillips Gulch
Phoenix Creek
Pickle Canyon
Picnic Creek
Pieta Creek
Pigpen Gulch
Pike County Gulch
Pine Gulch Creek
Point Arena Creek
Pole Mountain Creek
Pool Creek
Porter Creek
Porterfield Creek
Poverty Gulch
Press Creek
Pritchard Creek
Pudding Creek
Purrington Creek
Quinlan Gulch
Quinliven Gulch
Rail Creek
Railroad Gulch
Railroad Slough
Rainbow Slough
Ramon Creek
Rancheria Creek
Randall Creek
Rattlesnake Creek
Ray Gulch
Rector Creek
Red Hill Gulch
