In the reach from Iron Gate Dam to Cottonwood Creek, dam-released sediment may temporarily deposit in pools and other slack water areas (e.g., eddies), at tributary confluences, and potentially along channel margins, where it could have a short-term negative impact on wetland habitat due to temporary burial (USBR 2010). However, the wetland habitat impacts would be localized, and because the transient sediment deposits would be highly erodible during subsequent flow events, the impacts would also be short-term (i.e., likely one year or less except during dry years).

Given that the impacts related to dam-released sediment are likely to be temporary (less than a year) and given that there would not be a substantial modification of federally protected wetlands, there would be a less than significant impact on wetland habitat downstream of the Lower Klamath Project dams.

Significance

No significant impact in the short term and long term

Potential Impact 3.5-4 Effects on riparian habitat downstream of the Lower Klamath Project dams due to short-term and long-term erosion or sediment deposition.

Commenters in the Proposed Project public scoping process expressed concerns regarding erosion and sediment deposition immediately downstream of Iron Gate Dam. Downstream of the Lower Klamath Project dams, river flow rates would not increase substantially above median historical rates. Therefore, rates of bank erosion are not expected to increase significantly (see Potential Impact 3.11-6).

With respect to short-term sediment deposition downstream of the Lower Klamath Project dams, dam-released sediment and sediment resupply would likely extend from Iron Gate Dam to approximately Cottonwood Creek (RM 185.1) (USBR 2012), where reach-averaged deposition of gravel and sediment is projected to be up to one foot between Iron Gate Dam and Bogus Creek (RM 192.68) and up to 0.8 feet between Bogus Creek and Willow Creek (RM 187.8) (see Potential Impact 3.11-5). If rain and snowmelt levels are high during drawdown, relatively less sedimentation would occur in downstream reaches, as there would be higher flows in the system to flush out sediments (Stillwater Sciences 2008). In the short term, reach-averaged sedimentation levels of up to one foot are not expected to substantially negatively impact riparian vegetation downstream of Iron Gate Dam, as vegetation growing within or along the river channel margins is generally adapted to this scale of perturbation due to seasonal and inter-annual sedimentation dynamics typical of river systems. Willow and cottonwood species grow rapidly and can bend, break and re-sprout following sediment deposition (Braatne et al. 1996; Shafroth et al. 2002). Similarly, branches and stems broken off and redeposited with sediment can sprout and grow vigorously on newly deposited alluvium, giving these species a relative advantage over non-sprouting upland or non-native species (Braatne et al. 1996, Rood et al. 2003). Thus, there would be a less than significant effect on riparian vegetation downstream of Iron Gate Dam due to short-term sediment deposition caused by dam removal.

Moreover, sedimentation has the potential to create new surfaces for riparian plants to colonize depending on the sequence of water years following dam removal; under certain scenarios (e.g., wet water year followed by dry water years whereby a lot of sediment is moved and vegetation has time to colonize), this may result in beneficial effects on riparian habitat especially in areas where there is currently less sediment deposit due to upstream sediment trapping in reservoirs (i.e., from Iron Gate to Cottonwood Creek) (Shafroth et al. 2002). Under such scenarios the riparian vegetation would be able to quickly re-establish through colonization. This colonization occurs following disturbance (i.e., deposition-related to removal of the dam) during peak flows that creates substrate for seedlings, followed by declining spring and summer flows that occur during the seed dispersal period. Under this natural process, it is anticipated that new riparian vegetation would become established within three to five years (Riparian Habitat Joint Venture 2009).

In the long term, no permanent loss of riparian habitat due to erosion or sediment deposition is anticipated to occur in any river reach downstream of the Lower Klamath Project dams, and new surfaces for colonization would be created. This would be a beneficial effect.

Significance

No significant impact in the short term

Beneficial in the long term

Potential Impact 3.5-5 Short-term and long-term impacts on native vegetation due to increased invasive plant species establishment.

Under the Proposed Project, there would be potential for invasive plant species in the vicinity to quickly colonize exposed reservoir sediments and other disturbed soil areas and out-compete native plants. In addition, there could be an increase in the transport of invasive plant seeds to downstream areas following removal of the dams, particularly those plants that disperse by water such as Himalayan blackberry and reed canary grass (Nilsson et al. 2010; Merritt and Wohl 2002, 2006; Merritt et al. 2010). Without surveys to document and control invasive plant species they would displace native plants, including special-status species, and degrade habitats, including wetland and riparian vegetation; therefore, this would be a significant short-term impact.

As part of the Proposed Project, invasive plant species would be controlled according to the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*). Actions would include invasive plant surveys initiated prior to dam removal year 1, and invasive monitoring and control over a five-year period with metrics to evaluate success of minimizing invasive exotic vegetation and invasive plant control as necessary. Control methods would include manual weed pulling, mowing or cutting, tilling and disking, grazing, solarization, and the potential use of herbicides. Herbicides would be applied as last resort and only herbicides that have been approved by the BLM, CDFW, RWQCB, USFWS and NMFS would be used. Quarterly inspections would also occur from years 5 to 10 post-dam removal (Table 2.7-1). Additionally, the Reservoir Area Management Plan includes active planting of native species, which will also assist in preventing the establishment of invasive species in disturbed areas. As a result of these actions, potential short- and long-term impacts on native vegetation would be reduced to less than significant.

Significance

No significant impact in the short term and long term

3.5.5.2 Culturally Significant Species

Potential Impact 3.5-6 Short- and long-term impacts on culturally significant species in riparian and wetland habitats.
Many of the species identified by the Native American Tribes in the Klamath River region as culturally significant occur in riparian and wetland habitats. Project activities including construction as well as reservoir drawdown would result in population-level impacts to culturally significant plant species or substantial degradation or removal of wetland and riparian habitat; therefore, there would be a significant short-term and long-term impact on culturally significant species.

The Proposed Project includes several actions to survey for wetlands and encourage rapid revegetation with native riparian species in the reservoir footprints as defined in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) that would ensure no net loss of wetland or riparian habitat acreage and functions. The revegetation mixes will be developed based on updated inventories of existing wetland and riparian vegetation around the reservoir perimeters; therefore, culturally significant species will be documented and incorporated as part of the revegetation effort. In addition, Mitigation Measure TER-1 (see Potential Impact 3.5-1) includes wetland buffers to prevent intrusion in wetland habitats, deter heavy machinery from traversing the wetland, prevent runoff pollution from directly entering the wetland, and avoid substantial degradation in these areas. These measures would ensure that impacts on culturally significant species would be less than significant.

Significance
No significant impact with mitigation in the short term

No significant impact in the long term

3.5.5.3 Special-status Species and Rare Natural Communities

Potential Impact 3.5-7 Short-term impacts on special-status plants and rare natural communities from construction-related activities.
Construction activities including road, bridge, hatchery modifications, and culvert improvements (Section 3.22.2.3 *Road Conditions*) could result in direct mortality or damage to special-status plant species or indirect damage by degrading special-status plant habitat (e.g., introducing invasive plant species) or rare natural communities. Special-status plant species with the potential to occur in the Primary Area of Analysis for terrestrial resources are provided in Table 3.5-4 and rare natural communities with the potential to occur in the Primary Area of Analysis for terrestrial resources are provided in Appendix H. Construction activities would require heavy machinery to move through construction areas, staging areas, and haul roads where these species could occur. Contact with construction vehicles could result in direct mortality or damage to these species or their habitat. Special-status plants and rare natural communities may be present in the areas where construction activities may be performed; without surveys to document these species and habitats and measures to adequately protect them, they would be removed and/or habitat would be degraded; therefore, this would be a significant short-term impact.

As part of the Proposed Project, comprehensive floristic surveys would be conducted for special status-plants within the construction Limits of Work where ground-disturbing activities would occur plus an established buffer (i.e., a 100-meter buffer around disposal sites and a 10-meter buffer along access and haul roads) following the CDFW guidelines (CDFG 2009; Appendix B: *Definite Plan – Appendix J*) and the vegetation maps would be updated to reflect existing conditions including any rare natural communities that may present. The Proposed Project includes avoidance and minimization measures as well as provisions for the establishment of wetland and riparian areas and other sensitive vegetation communities within the project area to result in no net loss of habitat acreage (CDFG 2009; Appendix B: *Definite Plan – Appendix J*); therefore, impacts to rare natural communities would be less than significant.

If any special-status plants are documented, the Proposed Project design would be modified if possible to avoid them. Where avoidance is not feasible, a combination of relocation, propagation, and establishment of new populations in designated conservation areas would be implemented, as determined in coordination with the resource agencies and invasive plant species would be controlled by implementing measures such as routine washing of construction vehicles and equipment (Appendix B: *Definite Plan – Appendix J*). There may be significant impacts on special-status plants where avoidance is infeasible and if replanting does not succeed in re-establishment of new populations at a 1:1 ratio such that there is no net loss of individuals. If implemented as part of the Final Restoration Plan, Recommended Terrestrial Measure 1 would reduce impacts to less than significant. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements. Overseeing development and implementation of terms and conditions relating to protection of terrestrial special-status plants and/or rare natural communities does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board anticipates that implementation of the entire Final Restoration Plan, including the aforementioned additional details and any modifications developed through the FERC process that provide the same or better level of protection for special-status plants, would reduce impacts to less than significant. However, because the State Water Board cannot ensure implementation of the terrestrial aspects of the Final Restoration Plan , it is analyzing the impact in this Draft EIR as significant and unavoidable.

Recommended Terrestrial Measure 1 – Establish Mitigation Ratios for Special-Status Plants.

The Final Restoration Plan shall include a minimum 1:1 mitigation ratio and a Plant Mitigation and Monitoring Plan shall be developed for any special-status species that would be impacted by the Proposed Project. These features of Recommended Terrestrial Measure 1 would be implemented such that any impact to special-status plants would be less than significant.

Significance

No significant impact on rare natural communities in the short term

Significant and unavoidable impacts on special-status plants in the short term

Potential Impact 3.5-8 Short- and long-term impacts on special-status plants from reservoir removal.

Wetland habitat at reservoir margins supports potential habitat for several species of special-status plants (Table 3.5-4). There is potential for special-status plants to occur at the Lower Klamath Project reservoirs, and therefore there would be loss of habitat for these individual plants once the reservoirs are removed. Without surveys to document these species and measures to adequately protect them, they would be removed and/or habitat would be degraded; therefore, this would be a significant short-term impact.

As discussed above, implementation of the Proposed Project may result in a net increase in the areal extent of riparian and wetland habitat within the Primary Area of Analysis, largely as part of natural recruitment along newly-exposed mainstem river channel riparian corridors within the former reservoir footprints, but also as a result of active restoration management as described in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*). The Reservoir Area Management Plan also includes focused surveys (i.e., the species listed in Table 3.5-1, Preliminary List of Special Status Plants with Potential to Occur in or near the Limits of Work) for special-status plants in areas such as reservoir shorelines where changes in hydrology and geomorphology will occur due to the Proposed Project and includes provisions for the establishment of special-status plants, if any are documented within these areas.

There would be significant impacts on special-status plants if those plants are not captured during the targeted surveys and also where avoidance of documented and undocumented special-status plants is infeasible and replanting does not succeed in re-establishment of new populations. If implemented, Recommended Terrestrial Measure 2 and Recommended Terrestrial Measure 1 would reduce impacts to less than significant. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements. Overseeing development and implementation of terms and conditions relating to protection of terrestrial special-status plants does not fall within the scope of the State Water Board's water quality certification authority. The State Water Board anticipates that implementation of the entire Final Restoration Plan, including the aforementioned additional details and any modifications developed through the FERC process that provide the same or better level of protection for special-status plants, would reduce impacts to less than significant. However, because the State Water Board cannot ensure implementation of the terrestrial aspects of the Final Restoration Plan, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Recommended Terrestrial Measure 2 – Update Scoping Lists for Special-Status Plants.

The Final Restoration Plan shall include an updated list of special-status plants with the potential to occur in wetland and riparian habitats.

Significance

Significant and unavoidable in the short term and long term

Potential Impact 3.5-9 Short-term impacts on special-status terrestrial invertebrates from construction-related activities.

The special-status invertebrates identified as having the potential to occur in the terrestrial Primary Area of Analysis include USDA Forest Service and BLM sensitive species, which receive protection on USDA Forest Service and BLM lands, respectively. No construction-related impacts on USDA Forest Service or BLM special-status invertebrates are anticipated on USDA Forest Service or BLM lands. Most of the land within the Limits of Work, where direct construction-related impacts would have the potential to occur, is private and includes reservoir-type habitat, which does not currently provide necessary habitat components required for upland terrestrial invertebrate species. There are no USDA Forest Service land within the Limits of Work, and there is only a very small amount (<3 percent) of BLM lands (Figure 2.1-1).

The Oregon shoulderband, Trinity shoulderband, Siskiyou shoulderband, and Tehama chaparral are terrestrial snails associated with exposed rock or rock talus habitat. This habitat is not present on BLM lands that overlap the Limits of Work (Appendix G). Rock talus habitat is present just downstream of Copco No. 2 Dam and may support habitat for these species. This habitat is present in numerous locations throughout the Primary Area of Analysis for terrestrial resources (Appendix G) and any short-term construction-related activities in this specific area would not be expected to impact any federal species of special concern on a population level, if present.

The Western bumblebee is associated with shrub, chaparral, and open grassy areas, and there is a relatively small amount of this habitat within the Limits of Work, as the majority of these habitats include existing reservoirs and shoreline habitat. If present, the species would likely fly to adjacent habitat as annual and perennial grasslands are common in habitats surrounding the Limits of Work. As a result, no population-level impacts are anticipated.

As no population-level impacts are anticipated on special-status invertebrates, there would be no significant impacts on special-status terrestrial invertebrates due to short-term construction-related activities under the Proposed Project.

Significance

No significant impact

Potential Impact 3.5-10 Short-term impacts on special-status amphibian, reptiles, and mammals from construction activities.

Construction activities including, but not limited to, structure demolition; hatchery modifications (Section 2.7.6 *Hatchery Operations*); road, bridge, and culvert improvements (Section 3.22.2.3 *Road Conditions*); and, use of heavy equipment to transport sediment during reservoir drawdown or to grade floodplain areas to support wetland and restoration of natural habitats (Appendix B: *Definite Plan – Appendix H*), could result in direct mortality or harm to special-status amphibian, reptile, and mammal species or associated habitat with the potential to occur in the Primary Area of Analysis for terrestrial resources (see Table 3.5-5 for the list of species). Construction activities that may affect habitat, result in direct contact to individuals, or result in indirect impacts on individuals, include demolition of structures, digging holes or trenches where wildlife may be trapped, and movement of heavy machinery through construction areas, staging areas, and along haul roads where these species could occur.

Terrestrial resources avoidance and minimization measures included in the Proposed Project, such as installing construction fencing around the work area, would be an effective means to reduce the potential for medium and large mammals to enter the work area and become entrapped; however, the presence of fencing has the potential to keep animals in the work area if they have managed to cross into the work area and/or to become trapped in the fencing. Effects of construction-related noise and vibration are not anticipated to affect amphibians and reptiles, and for mammals dispersing through the Primary Area of Analysis, it is expected that they would move to adjacent suitable habitat. Construction-related noise and vibration impacts on roosting bats are discussed in Potential Impact 3.5-14.

To date, KRRC has conducted the following surveys for the Proposed Project:

- A field reconnaissance survey in July 2017 to gather information on habitat and identify access for subsequent wildlife surveys (spring and summer 2018), focusing on locations within the Limits of Work where special-status species were documented by PacifiCorp in 2001–2003.
- General Wildlife Surveys in May and June 2018, involving documentation of baseline information on the presence of special-status species and their habitats, which included documenting any wildlife signs such as dens or burrows.

The aforementioned short-term construction-related activities would result in a significant impact on special-status amphibians, reptiles, and mammals, if present during construction. The Proposed Project includes multiple components to avoid and minimize construction-related impacts on wildlife species including, but not limited to, the components listed below (additional details are provided in Appendix B: *Definite Plan Appendix J – Terrestrial Resource Measures*). Proposed Project avoidance and minimization measures include the following:

- Developing a Construction Monitoring Plan in coordination with resource agencies
- Providing a biological monitor to ensure compliance with protective measures during clearing and construction activities within designated areas;
- Training employees about special-status species and action to be taken upon sighting of special-status species during construction;
- Fencing construction areas and implementing measures to reduce wildlife entrapment in excavated holes or trenches;
- Monitoring coffer dams following closure and prior to the start of construction activities for the presence of western pond turtles, and if present, capture and relocate;
- Requiring crews maintain a 20-miles per hour speed limit on all unpaved roads to reduce wildlife being harmed via impact with vehicles;
- Requiring proper disposal of trash and food into closed containers generated during construction, and trash to be removed once a week from the site;
- Preventing presence of pets, feeding of wildlife, or use of firearms;
- Maintaining equipment, if necessary, in designated staging areas; and
- Reporting to CDFW and USFWS the observation of any dead, injured, or entrapped state or federally listed species.

While the Proposed Project avoidance and minimization measures would reduce the potential for short-term construction-related impacts on wildlife species within the Primary Area of Analysis, several of the aforementioned components need more specificity to ensure that short-term construction activities would not result in significant impacts on special-status species amphibians and reptiles or substantially interfere with movement and/or migration of these species, or that any remaining potentially significant impacts are mitigated to the extent feasible. Implementation of the mitigation measures below, developed in consultation with CDFW, would reduce potential short-term construction-related impacts on special-status amphibian and reptiles to less than significant.

Further, several of the aforementioned components unrelated to amphibians or reptiles also need more specificity to ensure that short-term construction activities would not result in significant impacts on special-status species or substantially interfere with movement and/or migration of wildlife species, or that any remaining potentially significant impacts are mitigated to the extent feasible. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to protection of terrestrial wildlife species other than amphibians and reptiles to include the Recommended Terrestrial Measures below, which have been developed in consultation with CDFW and USFWS. The Recommended Terrestrial Measures include additional components beyond those listed as part of the Proposed Project and would be necessary to reduce potential short-term construction-related impacts on special-status to less than significant, as specifically discussed in each measure (see Table 3.5-6 and the measures themselves). The Recommended Terrestrial Measures are consistent with widely accepted professional best management practices for environmental protection which would reduce potential harm to special-status species.

Overseeing development and implementation of terms and conditions relating to protection of terrestrial wildlife species does not fall within the scope of the State Water Board's water quality certification authority unless the species has a particular nexus with water – for example, it is a wetland or riparian species or primarily eats fish. In this case, there are mitigation measures pertaining to amphibian and reptiles that the State Water Board can ensure through the water quality certification. Therefore, these mitigation measures (TER-2 and TER-3) are considered as part of the impact analysis and determination of significance.

While the KRRC has initiated a process[113] to reach enforceable good citizen agreements with USFWS and CDFW that will be finalized and implemented, at this time the terms and conditions relating to protection of terrestrial wildlife species without a nexus to water are not finalized and the State Water Board cannot require their implementation.

[113] KRRC submitted the *Klamath River Renewal Project California Environmental Quality Act (CEQA) and California and Oregon 401 Water Quality Certifications Technical Support Document* (AECOM et al. 2017a) to USFWS and CDFW in September 2017 and requested feedback by November 10, 2017.

Accordingly, while the State Water Board anticipates that implementation of the final terms and conditions, including the Recommended Terrestrial Measures, and any modifications developed through the FERC process that provide the same or better level of protection for special-status wildlife, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Recommended Terrestrial Measures, it does not consider the Recommended Terrestrial Measures in this analysis and is analyzing the associated impacts to mammals in this Draft EIR as significant and unavoidable.

Mitigation Measure TER-2 – Amphibian and Reptile Management.
As described in the Draft Clean Water Act Section 401 Water Quality Certification for California Condition 15 *Amphibian and Reptile Management*, no later than three months following issuance of a FERC license surrender order, KRRC shall submit an Amphibian and Reptile Rescue and Relocation Plan (Amphibian and Reptile Plan) to the State Water Board Deputy Director for review and approval prior to drawdown, in-water work, and work in riparian areas. The Amphibian and Reptile Plan shall identify protection measures that when implemented by KRRC will avoid direct mortality or harm to special-status amphibian and reptile species with the potential to occur in the Primary Area of Analysis for terrestrial resources. The Amphibian and Reptile Plan shall also specify survey protocols, locations, and frequency; rescue and relocation techniques; and reporting requirements. Species covered in the Amphibian and Reptile Plan shall include amphibians and reptiles found within the terrestrial Primary Area of Analysis that are listed under the federal ESA or the CESA or are designated as Species of Special Concern by CDFW. These species may include, but are not limited to: southern torrent salamander, Scott Bar salamander, Siskiyou Mountains salamander, Pacific tailed frog, foothill yellow-legged frog, northern red-legged frog, and western pond turtle. These features of TER-2 will be implemented such that there is no significant impact on special-status amphibians and reptiles.

Mitigation Measure TER-3 – Western Pond Turtle Pre-construction Surveys.
As described in the Draft Clean Water Act Section 401 Water Quality Certification for California Condition 15 *Amphibian and Reptile Management,* KRRC shall protect western pond turtle, which has been designated by CDFW as a Species of Special Concern and is present within the Primary Area of Analysis.

KRRC shall conduct western pond turtle pre-construction surveys and reporting, as described below. An on-site biologist approved by the applicable agencies to specifically conduct western pond turtle pre-construction surveys shall be familiar with the ecology of western pond turtle. This on-site biologist shall conduct pre-construction surveys immediately prior to the start of any in-water work each day that in-water work will occur. Any adult western pond turtles that are found during surveys shall be relocated to a safe location, by an agency-approved biologist, outside of the work area and away from indirect impacts. An appropriate relocation site shall be designated prior to the start of construction. Pre-construction surveys shall be consistent with the Amphibian and Reptile Management Plan (TER-2). (This measure is specific to construction activities, such as cofferdams, and is not intended to be implemented during reservoir drawdown.)

A report shall be submitted to applicable agencies within 30 days of completing the Proposed Project. The report shall include the following information regarding all species handled and relocated; location, date, time and duration of the handling; enumeration and identification of species handled; identification of species life stage;

identification of capture personnel; the release location and time; stream, transport, and receiving water temperatures; and location, date, and time of release. These features of TER-3 will be implemented such that there is no significant impact on western pond turtles.

Table 3.5-6. Summary of Proposed Project Components and Recommended Terrestrial Measures.

Proposed Project Avoidance and Minimization Measure Component	Recommended Terrestrial Measure
Biological monitoring and the development of a detailed Construction Monitoring Plan[114] in coordination with the resource agencies	**Recommended Terrestrial Measure 3** further requires agency approval of on-site biologists and identifies monitoring and reporting requirements to incorporate in the Construction Monitoring Plan.
Mandatory biological resource awareness training for all construction personnel	**Recommended Terrestrial Measure 4** requires additional items, including consideration of exotic and noxious species and appropriate decontamination measures as part of the training, identifies the reoccurrence interval of the training, and stipulates that the training shall be interpreted for non-English speaking workers.
Requirements for construction personnel including disposing of trash, maintain construction related-traffic in construction boundaries, no feeding of wildlife, no pets, no firearms, maintaining equipment in staging areas, reporting on state-listed or federally-listed species	**Recommended Terrestrial Measure 5** includes the additional requirements that (1) all food-related trash items would be disposed of in closed wildlife-proof containers to reduce the potential for special-status wildlife to enter the Limits of Work, and; (2) equipment would be power washed prior to arriving at the site to reduce potential for non-native species to enter the Limits of Work and compete with special-status species or spread to nearby habitats.
Requirements for wildlife exclusion and entrapment	**Recommended Terrestrial Measure 6** in addition to providing a requirement for wildlife exclusion and entrapment, this provides an additional requirement for fencing to be checked daily during active construction to ensure that it remains intact.
Surveys to identify special-status amphibian and reptile habitat and quantity affected, mammal sign, including den sites or burrows, will be noted.	**Recommended Terrestrial Measure 7** includes special-status species identified in Table 3.5-5 to be included for habitat assessments, and if present, for inclusion in pre-construction surveys. **Recommended Terrestrial Measure 7** also requires that an on-site biologist preform daily pre-construction wildlife surveys prior to initiating construction activities.
Identifying wolves during general wildlife surveys	**Recommended Terrestrial Measure 8** includes further means to monitor the CDFW gray wolf activity map, and if wolf activity identified on the map overlaps with the Lower Klamath Project, or if a wolf is observed during any Proposed Project survey or monitoring effort, CDFW would be consulted to further evaluate site-specific measures depending on the time of year and information about the individuals in the area.

[114] No specific details were provided in the Construction Monitoring Plan other than the plan would be developed in coordination with resource agencies (Appendix B: *Appendix J – Terrestrial Resource Measures*).

Recommended Terrestrial Measure 3 – On-site Biologist/Construction Monitoring Plan.

The Construction Monitoring Plan, as referenced in KRRC's Definite Plan (Appendix B: *Appendix J – Terrestrial Resource Measures*) shall be developed prior to implementing construction (ground disturbing activities) and include where and when monitoring would occur, requirements and roles of an on-site biologist, resource monitored, and reporting requirements. The Construction Monitoring plan details would include the information below.

An on-site biologist (often referred to as a biological monitor or construction monitor) shall be present during construction-related activities to reduce the potential for impacts on special-status wildlife species and nesting birds that are protected by CDFW and USFWS. The role of the on-site biologist shall include, but is not limited to, identifying wildlife species within or adjacent to the work area that may be affected; clearing each work area daily (including individual areas such as each staging area, structure demolition area, bridge upgrade location) of wildlife species prior to the initiation of an activity (as discussed in Recommended Terrestrial Measure 7); observing changes in wildlife behavior; identifying species if they enter the work area and relocating them to a designated location identified prior to Proposed Project activities; developing site- and species-specific minimization measures to prevent impacts on special-status species or sensitive habitats and advising crew of these minimization measures which could include stopping work until the wildlife was no longer in the work area or implementing buffers; communicating daily at tailboards with the construction crew about special-status wildlife activity in the area; and coordinating with agencies for guidance, as needed. The on-site biologist has stop-work authority for any activity in order to avoid unauthorized take of a special-status species.

The on-site biologist shall be knowledgeable and experienced in the biology, natural history, collecting, and handling of species that may be encountered. CDFW and USFWS must approve the on-site biologist's qualifications prior to start of construction; such approval shall occur within a timely fashion.

During any construction-related (i.e., staging, facility removal, restoration) activity, the on-site biologist shall be present at locations where the activity is occurring. A minimum of one on-site biologist shall be present at each earth-moving or structure demolition location (e.g., dam location, staging area, bridge upgrade). It would be reasonable to assume, depending on the level of proposed activity, one biologist can monitor areas that are immediately adjacent to each other. This measure is specific to construction activities and is not intended to be implemented during reservoir drawdown.

The on-site biologist shall prepare daily written observation and inspection records that summarize observed special-status species and minimization measures employed. These records shall be submitted at least monthly to CDFW, USFWS, and the State Water Board. The on-site biologist shall submit all observations of state species of special concern and candidate, threatened, or endangered species under the state or federal Endangered Species Act (ESA), to the California Natural Diversity Database within 60 calendar days of the observation, and copies of the submitted forms shall be included with the monthly report.

If a species of special concern, candidate, threatened, or endangered species is harmed by the Proposed Project, or found dead within the Limits of Work, initial notification to the respective resource agencies shall include information regarding the location, species, and number of animals taken or injured with 24 hours of discovery. Following initial notification, a written report shall be provided to the respective resource agencies within two calendar days and shall include any additional measures to implement for the duration of the Proposed Project to avoid additional injury to species of special concern, candidate, threatened, or endangered species. The report format shall be developed in coordination with CDFW and shall include the date and time of the finding or incident, the location of the animal or carcass, a photograph (if possible), an explanation as to cause of harm, and any other pertinent information. If the incident was a result of the Proposed Project, the report will include a recommendation that would be implemented in order to avoid additional injury to special-status species of special concern, candidate, proposed, threatened, or endangered species.

Recommended Terrestrial Measure 4 – Biological Resources Education and Awareness Training.
A mandatory biological resource education and awareness training shall be provided by a biologist approved by the resource agencies (USFWS and CDFW) for all on-site Proposed Project personnel and their associated supervisor. All persons shall receive the training prior to performing any ground-disturbing (including vegetation clearing and grading) work. This training shall inform Proposed Project personnel about special-status species that could occur on site. The training shall, at a minimum, consist of: (1) a brief introduction to the special-status species and identifying characteristics, including a short discussion of the biology, life history, habitat requirements, status, and legal protection; (2) measures being taken for the protection of these species and their habitats; and (3) actions to be taken if a special-status species is found within the area during construction activities. Species identification cards shall be issued to shift supervisors; these cards shall have photos, descriptions, and actions to be taken upon sighting of special-status species during construction. The training shall also include information on exotic and noxious species and appropriate decontamination measures. This training shall be repeated at least once annually and shall be provided to any new Proposed Personnel before beginning work activities, and if a change in special-status species occurs that requires further consideration. The KRRC shall provide interpretation for non-English speaking workers. Training Proposed Project personnel on special-status species will increase the potential of documenting special-status species in the construction area and allow for the on-site biologist to implement measures (e.g., rescue and relocate, implement buffers) to reduce impacts on the species to less than significant. Upon completion of the training, all employees shall sign an acknowledgment form stating that they attended the training and understand all protection measures. Tracking of training activities shall be reported monthly to applicable agencies.

Recommended Terrestrial Measure 5 – Requirements for Construction Personnel.
Establishing requirements for construction personnel will reduce the potential impacts on special-status terrestrial resources to less than significant by ensuring construction activities are occurring within designated boundaries and reducing the potential for wildlife to enter the work area or be affected by equipment. These requirements are described below.

- The KRRC shall clearly delineate the Limits of Work and prohibit any construction-related traffic outside of these boundaries.
- KRRC shall require construction crews to maintain a 20 mile per hour speed limit on all unpaved roads to reduce the chance of wildlife being struck.
- KRRC shall require that no deliberate feeding of wildlife shall be allowed and all food-related trash items shall be disposed of in closed wildlife-proof containers (e.g., bear-proof trash cans) and removed at least once a week.
- If vehicle or equipment maintenance is necessary, it shall be performed in the designated staging areas with adequate spill containment.
- Any worker who inadvertently injures or kills a federally or state-listed species, bald eagle, or golden eagle, or finds one dead, injured, or entrapped shall be required to immediately report the incident to the construction supervisor and on-site biologist. The on-site biologist shall notify the resource agencies within 24 hours of the incident.
- All equipment shall be power-washed prior to arriving to and leaving the site to minimize the spread of non-native wildlife and exotic and noxious plants species to reduce the chance of impacts on special-status species and their habitats.
- Tracking of these requirements shall be reported monthly to applicable agencies.

Recommended Terrestrial Measure 6 – Wildlife Exclusion and Entrapment. Construction areas, including staging areas and access routes, shall be fenced with high-visibility fencing to demarcate work areas to reduce the potential for terrestrial species to enter the work area and be harmed by construction equipment. An on-site biologist (see Recommended Terrestrial Measure 3) shall confirm the location of the fenced area prior to habitat clearing, and the fencing shall be maintained throughout the construction period and checked daily when active construction is occurring to ensure that it remains secure and intact and that no wildlife are trapped by the fencing. Additional exclusion fencing or other appropriate measures shall be implemented in consultation with the resource agencies if necessary to prevent use of construction areas by special-status species during construction. Installing visible construction fencing does not apply to the reservoir areas during drawdown or areas being restored with planting of vegetation, but rather staging and active construction areas.

To prevent entrapment of wildlife at construction sites, all excavated, steep-walled holes or trenches in excess of two feet deep shall be inspected by a biologist or construction personnel approved by the resource agencies at the start and end of each working day. If no animals are present during the evening inspection, plywood or similar materials shall be used to immediately cover the trench, or one or more escape ramps shall be set in the trench at no greater than 1,000-foot intervals and constructed of earth fill or wooden planks. Trenches and pipes shall be inspected for entrapped wildlife each morning prior to onset of activity. Before such holes or trenches are filled, they shall be thoroughly inspected for entrapped animals. Any animals so discovered shall be allowed to escape voluntarily, without harassment, before activities resume, or removed from the trench or hole by the biologist and the animals shall be allowed to escape unimpeded.

Tracking of wildlife exclusion and entrapment activities shall be reported monthly to applicable agencies. Should wildlife be found entrapped, the on-site biologist shall identify if modifying construction or monitoring activities would reduce potential for future impacts and implement as feasible to prevent mortality of special-status species.

Recommended Terrestrial Measure 7 – General Special-status Wildlife Surveys and Pre-construction Surveys.
A general special-status wildlife survey shall be conducted within 24 months of initial habitat modification associated with construction activities (e.g., grubbing, structure modification) within the Limits of Work to assess the presence of any special-status species and potential for habitat to be present that could support special-status species identified in Table 3.5-5. Surveys shall be conducted by a qualified biologist; such approval shall occur in a timely fashion. If suitable habitat is present, and there is potential for special-status species to be present, a biologist shall further assess if these special-status species are present in the Limits of Work by conducting general visual observation surveys or protocol-level surveys. Surveys for nesting birds are discussed in Recommended Terrestrial Measure 9, willow flycatcher in Recommended Terrestrial Measure 10, bald and golden eagle in Recommended Terrestrial Measure 11, bats in Recommended Terrestrial Measure 12; surveys to be consistent with the Amphibian and Reptile Management Plan discussed in Mitigation Measure TER-2.

Pre-construction surveys shall be conducted daily by the on-site biologist (as identified in Recommended Terrestrial Measure 3) at each location where construction is occurring prior to initiation of construction. If special-status species are present (excluding state or federally listed as threatened, endangered, or candidate species), they shall be captured and relocated out of harm's way to a suitable area designated prior to initiating the Proposed Project activities that have the potential to affect the species, in a way that is consistent with recommended measures for bats (Recommended Terrestrial Measure 12) and Mitigation Measures for western pond turtle pre-construction surveys (TER-4) and the Amphibian and Reptile Management Plan (TER-2). General special-status wildlife surveys and pre-construction surveys shall be reported monthly to applicable agencies.

Recommended Terrestrial Measure 8 – Gray Wolf.
Every six months, the location of gray wolves shall be assessed using the CDFW gray wolf activity map (CDFW 2018a). If the Lower Klamath Project overlaps with known wolf activity as identified in the CDFW wolf activity map or if a wolf is documented during any Proposed Project surveys or monitoring, CDFW shall be contacted to further determine if activities pose any potential impacts on gray wolves, particularly with respect to potential modification or disruption of key pup-rearing areas such as dens and rendezvous sites. Depending on the time of year and information about the pack or individuals in the area, CDFW may identify additional measures including denning surveys, reduced driving speeds, limited operating periods, disturbance buffers, reduced speed and signage on haul roads, modification of haul roads to avoid key areas, and monitoring. Tracking of gray wolf activities shall be reported every six months to applicable agencies.

Significance
No significant impact with mitigation for amphibians and reptiles

Significant and unavoidable for mammals

Potential Impact 3.5-11 Short-term impacts on nesting birds from construction-related noise and habitat alterations.

In the short term, construction activities including, but not limited to, structure demolition, hatchery modifications (Section 2.7.6 *Hatchery Operations*), road and bridge upgrades (as discussed in Appendix B: *Definite Plan – Appendix K*), and culvert improvements (Section 3.22.2.3 *Road Conditions*) could result in disturbance to or mortality of nesting birds.

Impacts on bald and golden eagles are discussed in Potential Impact 3.5-13 and on northern spotted owl in Potential Impact 3.5-15. Potential impacts on native birds during the breeding season, including several special-status species, many of which are referenced in Table 3.5-5, could occur under the Proposed Project including species such as peregrine falcon and non-special-status species such as swallows (northern rough-winged, tree, violet-green) (eBird 2018). Potential impacts could result from nest abandonment due to construction noise above ambient conditions, as well as habitat removal resulting from construction activities or physical harm. Examples of construction activities that could result in noise disturbance include dam demolition and loud blasting activities, use of helicopters or planes during restoration activities, noise disturbance during removal of transmission lines, and use of general construction equipment (e.g., cranes, dozers, front loaders). Dam removal activities would be initiated in March, which is relatively early in the bird nesting season (February 1 through August 31) (Appendix B: *Definite Plan – Appendix H*). Examples of construction activities that could result in harm to an active nest include removing vegetation, clearing of access and haul roads, removing existing structures, and creating staging and disposal sites. Without surveys to document nesting special-status birds and buffers to prevent noise and habitat removal impacts, special-status nesting bird species, if present, would be displaced resulting in a failed nest or mortality to young, and this would be a significant short-term impact.

The Proposed Project includes multiple components to avoid and minimize short-term construction-related impacts on bird species (Appendix B: *Definite Plan – Appendix J*) which include, but are not limited to, the components below (additional details are provided in Appendix B: *Definite Plan Appendix J – Terrestrial Resource Measures*).

- The following surveys were recently conducted for the Proposed Project.
    - As part of the General Wildlife Surveys, KRRC conducted special-status bird species surveys in May and June 2018 within the Limits of Work and within 0.25 miles of dams and structures to be removed, disposal sites, and haul and access roads. KRRC noted species seen or heard.
    - As part of the Nest Surveys, KRRC conducted nest surveys in May 2018 and focused on special-status species that may return to the same nest location (e.g., osprey, peregrine falcon, greater sandhill crane). Surveys for osprey were conducted at suitable nesting locations within 0.75 mile of the Limits of Work, peregrine falcon nests were surveyed at cliff locations within one mile of the Limits of Work, and greater sandhill crane nesting habitat was surveyed at J.C. Boyle Reservoir. Heron colonies were also surveyed along reservoir and river shorelines within 0.25 mile of the Limits of Work, KRRC noted all species seen or heard, and active nests were documented.

- Future measures include the following:
  - o Implementing pre-construction bird nesting surveys two weeks prior to construction within 300 feet of the Limits of Work and removing non-active nests (i.e., those without eggs) outside of the non-bird nesting season to discourage future nesting.
  - o Surveying for osprey at nest sites identified in 2018 for occupancy in the year construction activities are planned to commence, and consulting with agencies on nests within 0.75 mile of the Limits of Work to block or remove nest to prevent future nesting.
  - o Surveying for heron colonies and peregrine falcon and greater sandhill cranes in the spring of the year prior to drawdown, and if an active nest documented, a spatial buffer may be established in coordination with resource agencies.
  - o Removing nesting habitat for osprey and nests of other raptors (other than eagles) prior to the bird nesting season[115].
  - o Removing vegetation outside of the bird nesting season (February through July)[115].

While the Proposed Project avoidance and minimization measures would reduce the potential for short-term construction-related impacts on nesting birds within the Primary Area of Analysis, several of the aforementioned components need more specificity to ensure that short-term construction activities would not result in significant impacts on special-status species or substantially interfere with movement and/or migration of wildlife species, or that any remaining potentially significant impacts are mitigated to the extent feasible. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to protection of nesting birds to include Recommended Terrestrial Measure 9 below, which was developed in consultation with CDFW and USFWS. This recommended terrestrial measure includes additional components beyond those listed as part of the Proposed Project, including, but not limited to, the following:

- extending the bird nesting season through August 31st (i.e., February 1 through August 31[116,117]);
- implementing pre-construction nesting bird surveys within one week of the construction activity, and include surveys for raptors within 500 feet of the construction activity; and

[115] Removing suitable nesting habitat (e.g., platforms, vegetation) outside of the bird nesting season would reduce the potential for birds to nest in the area and be subject to construction-related disturbance (noise, habitat removal) during the breeding season.
[116] Bird nesting season identified by A. Henderson, CDFW, Environmental Scientist, pers. comm October 2017. Timing may be modified by CDFW based on nesting information collected in the Area of Analysis.
[117] The nesting season identified in the Proposed Project included two date ranges—February through July and January 1 through August 20.

- consulting with CDFW and USFWS for buffer distances associated with (a) special-status species and (b) raptors not included in Table 3.5-5, or if a modified buffer is proposed.

Although removing individual active nests of non-special-status bird or CDFW special-status species would not rise to the level of population-level impacts, loss of a state- or federally- threatened active nest may affect populations levels and thus impacts on one individual or a nest may result in a significant impact.

Overseeing development and implementation of recommended term and conditions relating to nesting birds does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process[118] to reach enforceable good citizen agreements with USFWS and CDFW that will be finalized and implemented, at this time the recommended term and conditions are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the recommended term and conditions, including the Recommended Terrestrial Measures and any modifications developed through the FERC process that provide the same or better level of protection for special-status wildlife, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Recommended Terrestrial Measures, it is analyzing the associated impacts in this Draft EIR as significant and unavoidable.

Recommended Terrestrial Measure 9 – Nesting Birds.

- Removal or trimming of any trees or other vegetation for construction shall be conducted outside of the nesting season (February 1 through August 31[119]). This shall include removal or trimming of trees along access roads and haul routes and within disposal sites. When this activity cannot occur (e.g., unanticipated activity, unanticipated delays, or vegetation re-grew during the growing season), a nesting bird survey (as described below) shall be conducted prior to vegetation removal. Where clearing, cutting, grubbing, or structural removal/modification cannot occur outside the nesting season (e.g., not feasible with construction schedule, unanticipated activity), a nesting bird survey (as described below) shall be conducted prior to habitat removal.
- Nesting bird surveys shall be conducted by a qualified avian biologist approved by CDFW and USFWS. The avian biologist shall survey the nesting habitat (vegetation, buildings) to be removed in the construction area and suitable habitat buffering the construction area—within 500 feet for raptors (other than eagles) and within 300 feet for non-special status non-raptors (e.g., song birds) Surveys should be conducted within one week[120] prior to habitat removal to determine if any native birds are nesting in those areas and have the potential to be affected by habitat removal. Surveys may be repeated beyond that described above (i.e., one week prior to habitat disturbance) to ensure that no nests have become active within vegetation or structures to be removed. If an old nest has been

[118] KRRC submitted the CEQA support document to agencies in September 2017 and requested feedback by November 10, 2017.

[119] Bird nesting season identified by A. Henderson, CDFW, Environmental Scientist, pers. comm October 2017. Timing may be modified by CDFW based on nesting information collected in the Area of Analysis.

[120] Surveys distance and timing identified by CDFW on 29 September 2017.

documented, it shall be removed during the non-nesting season to discourage future use of the nest.

- If potential greater sandhill crane nesting habitat is present within 500 feet of Proposed Project activities, any potential nesting habitat within the 500-foot radius shall also be surveyed for the presence of active greater sandhill crane nests.
- For all raptors (other than eagles), inactive nests shall be considered for removal before the nesting seasons begin, to the greatest extent practicable. (This includes osprey nests within 0.75 mile of construction areas.) For those nests where access is difficult, traffic cones or other deterrents shall be placed in the nest platform to prevent nesting in the year of construction. All deterrents shall be removed as soon as possible after construction activity is ceased within the disturbance buffer (Table 3.5-7 below) for that species.
- The on-site or avian biologist approved by CDFW and USFWS shall be on site prior to and during the bird nesting season to reduce the potential for nesting as much as possible.
- If an active nest is observed for a non-special-status species that is not a raptor, then the on-site biologist may identify an appropriate buffer, considering ambient conditions and response of bird to existing conditions. If this nest is in a location where the Proposed Project would destroy the nest, the KRRC shall attempt to reschedule activities until the young fledge. If the KRRC has considered rescheduling activities and implemented the minimization measures described above (repeated surveys, on-site monitors, removal old non-active nests outside of the breeding season), CDFW shall be contacted to discuss further measures.
- If an active raptor or special-status bird nest is observed, a restriction buffer shall be established. This shall include consideration of noise effects and line-of-sight considerations. (Bald and golden eagle species-specific recommended measures are discussed below in Potential Impact 3.5-13 and Recommended Terrestrial Measure 11)
    - Table 3.5-7 lists the restriction buffer distances and timing for many common raptor species with potential to occur within or near construction areas, as provided by USFWS (Strassburger 2011). All restriction buffers for raptors shall follow the spatial buffers as identified in Table 3.5-7, and consultation with agencies shall occur prior to implementing the activity if: (a) construction activity is within the buffer distance, or (b) the species is not identified in Table 3.5-7.
    - Buffers for passerines not state or federally listed as candidate, threatened, or endangered shall be established by a qualified avian biologist approved by CDFW and USFWS.
    - No vegetation removal or construction activities shall occur within the disturbance buffer until the young have fledged, as determined by the qualified biologist. Monitoring in these cases shall include determining and reporting to CDFW and USFWS the ultimate fate of the nest.
- If an active special-status bird nest is observed where the Proposed Project would destroy the nest, this could be a significant effect and KRRC shall obtain approval by applicable agencies.
- Tracking of nesting birds shall be reported once a month to applicable agencies.

Table 3.5-7. Noise Disturbance Buffers and Seasonal Timing Restrictions for Nesting Raptors.

Species	Noise Disturbance Buffer (miles [feet])	Seasonal Timing Restriction
Bald eagle	1.00 mi (5,280 ft)	Jan 1–Aug 31
Golden eagle	1.00 mi (5,280 ft)	Jan 1–Aug 31
Northern goshawk	0.75 mi (3,960 ft)	March 1–Aug 15
Northern harrier	0.75 mi (3,960 ft)	April 1–Aug 15
Cooper's hawk	0.75 mi (3,960 ft)	March 15–Aug 31
Ferruginous hawk	1.00 mi (5,280 ft)	March 1–Aug 1
Red-tailed hawk	0.75 mi (3,960 ft)	March 15–Aug 15
Sharp-shinned hawk	0.75 mi (3,960 ft)	March 15–Aug 31
Swainson's hawk	0.75 mi (3,960 ft)	March 1–Aug 31
Turkey vulture	0.75 mi (3,960 ft)	May 1–Aug 15
Peregrine falcon	1.00 mi (5,280 ft)	Feb 1–Aug 31
Prairie falcon	0.75 mi (3,960 ft)	April 1–Aug 31
Merlin	0.75 mi (3,960 ft)	April 1–Aug 31
American kestrel	0.05 mi (300 feet)	April 1–Aug 15
Osprey	0.75 mi (3,960 ft)	April 1–Aug 31
Burrowing owl	0.25–0.75 mi (1,320–3,960 ft)	March 1–Aug 31
Flammulated owl	0.75 mi (3,960 ft)	April 1–Sept 30
Great horned owl	0.75 mi (3,960 ft)	Dec 1–Sept 30
Long-eared owl	0.75 mi (3,960 ft)	Feb 1–Aug 15
Northern saw-whet owl	0.75 mi (3,960 ft)	March 1–Aug 31
Short-eared owl	0.75 mi (3,960 ft)	March 1–Aug 1
Northern pygmy-owl	0.75 mi (3,960 ft)	April 1–Aug 1
Western screech-owl	0.75 mi (3,960 ft)	March 1–Aug 15
Barn owl	0.062–0.25 mi (330–1,320 ft)	Feb 1–Sept 15

Source: USFWS (Strassburger 2011)

Significance

Significant and unavoidable

Potential Impact 3.5-12 Effects on willow flycatcher from short-term construction-related noise and short-term and long-term habitat alterations.

In the short term, construction activities including, but not limited to, structure demolition, hatchery modifications (Section 2.7.6 *Hatchery Operations*), road and bridge upgrades (Appendix B: *Definite Plan – Appendix K*), and culvert improvements (Section 3.22.2.3 *Road Conditions*) could result in noise disturbance and habitat removal that may result in significant impacts on willow flycatcher. Significant impacts may result from direct mortality or physical harm to individuals; degradation of habitat or a change in habitat conditions that would result in physiological impairment or that may affect the ability to perform essential behaviors such as migration, feeding, or reproducing; or abandonment of active bird nests. As a result, habitat removal or disturbance during the bird nesting season has the potential to remove a nest directly and/or result in nest failure, which would be a significant impact. The Proposed Project does not include a significant amount of tree removal, but rather it is anticipated that habitat removal could occur if branches or small trees would need to be removed in order to upgrade bridges and roads. As a result, it is not anticipated that the quantity or quality of the habitat would be degraded, but rather the potential for direct or incidental harm from noise or removal of a nest in a branch, if present. There are few locations where modeled willow flycatcher habitat (discussed below) overlaps the Limits of Work. If activities occur in this area, the Proposed Project may cause nest abandonment due to construction noise or direct harm due to physical removal of vegetation, similarly to the impacts described in Potential Impact 3.5-10 for nesting birds. The Proposed Project includes construction activities at Copco Road Bridge over Jenny Creek, which is located in an area of known willow flycatcher use.

Willow flycatcher habitat has been modeled in areas along the Hydroelectric Reach and Middle Klamath River and reservoirs, and most of the habitat is predicted to occur along riverine habitat rather than reservoir habitats (Stermer et al. 2002). Under existing conditions, habitat modeling along the Klamath River between the California-Oregon state line and Cottonwood Creek (approximately 9 RM downstream of Iron Gate Dam) indicates that approximately 10 percent of habitat is suitable for the willow flycatcher (assuming a 0.1-mile buffer). Along reservoir shorelines, modeled suitable willow flycatcher habitat represents only 0.2 percent of existing conditions habitat; the few relatively small patches are located at the upstream-most end of Iron Gate Reservoir at Fall Creek and at Copco No. 1 Reservoir near the confluences of East Fork Beaver Creek and Deer Creek. This modeled willow flycatcher habitat did not identify suitable habitat at the confluence of Jenny Creek and Iron Gate Reservoir, even though willow flycatcher use has been documented at these locations. Under the Proposed Project, the distribution of suitable habitat along the newly formed Klamath River banks in the Hydroelectric Reach is expected to be similar to the relative amount of habitat that is currently present upstream and downstream of the reservoirs, and thus overall the amount of flycatcher habitat would be expected to increase.

Following drawdown and restoration of the reservoir area, the modeled existing riparian habitat located along Fall Creek, East Fork Beaver Creek, and Deer Creek would be expected to continue invertebrate production and thus serve as a resource for willow flycatcher foraging. Further, the riparian habitats supported along these creeks would expand toward the newly formed banks of the Klamath River. While the new riparian habitats are establishing, the existing habitat would continue to be present throughout the Hydroelectric Reach upstream of Copco No. 1 Reservoir and at the confluence of Fall Creek. As a result, the long-term effect of the Proposed Project on willow flycatcher habitat would be beneficial.

The Proposed Project includes components to avoid and minimize impacts including conducting a habitat evaluation to identify suitable habitat, and if it is determined that there would be impacts on the potential willow flycatcher habitat from Project implementation in areas where presence is uncertain or cannot be assumed, the KRRC will conduct protocol surveys for willow flycatcher in the spring of the year prior to drawdown, in coordination with resource agencies (Appendix B: *Definite Plan – Appendix J*). Also, when harvesting willow pole cuttings to support restoration activities, KRRC proposes to avoid areas where there is known habitat for willow flycatcher (Appendix B: *Definite Plan – Appendix H*).

While the Proposed Project avoidance and minimization measures would reduce the potential for short-term construction-related impacts on willow flycatcher within the Primary Area of Analysis, the aforementioned components need more specificity to ensure that short-term construction activities would not result in significant impacts on this special-status species or substantially interfere with movement and/or migration of wildlife species, or that any remaining potentially significant impacts are mitigated to the extent feasible. Implementation of the recommended measure below, developed in consultation with CDFW, would reduce potential short-term construction-related impacts on willow flycatcher to less than significant. KRRC also proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to protection of willow flycatcher to include the Recommended Terrestrial Measure 10 below, which has been developed in consultation with CDFW. The Recommended Terrestrial Measure 10 includes components beyond those listed as part of the Proposed Project and would be necessary to reduce potential short-term construction related impacts on willow flycatcher to less than significant (see Recommended Terrestrial Measure 10). These components include conducting construction activities outside of the bird nesting season, protocol-level surveys in suitable habitat that have the potential to be affect to collect information on the number of flycatchers that may be affected by activities, establishing a no-construction buffer, and removing only the amount of vegetation necessary to implement the action and not affect the overall habitat quality of the patch. The recommended terrestrial measure is consistent with widely accepted professional best management practices for environmental protection which would reduce potential harm to the species; therefore, result in less than significant impacts due to the Proposed Project.

Overseeing development and implementation of recommended term and conditions relating to the willow flycatcher does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process[121] to reach enforceable good citizen agreements with CDFW that will be finalized and implemented, at this time the recommended term and conditions are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the recommended term and conditions, including the Recommended Terrestrial Measures and any modifications developed through the FERC process that provide the same or better level of protection for willow flycatcher, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Recommended Terrestrial Measures, it is analyzing the associated impacts in this Draft EIR as significant and unavoidable.

[121] KRRC submitted the CEQA support document to agencies in September 2017 and requested feedback by November 10, 2017.

Recommended Terrestrial Measure 10 – Willow Flycatcher.

- As proposed by the KRRC, the KRRC shall conduct an assessment to identify potential suitable habitat for willow flycatcher in habitat that has the potential to be affected by the Proposed Project. The assessment would occur in the spring of the year prior to drawdown or before.
- Construction activities within suitable habitat or known willow flycatcher locations (e.g., Jenny Creek Bridge replacement activities) shall occur outside of the bird nesting season and habitat disturbance shall be minimized as much as possible. The on-site biologist (Recommended Terrestrial Measure 3) shall monitor to ensure that habitat removal includes only the amount necessary to implement the action and would not affect the overall habitat quality of the patch.
- If construction activities or habitat removal occurs in potentially suitable habitat during the bird nesting season, protocol-level surveys will be conducted prior to the construction activity or habitat removal, and if the willow flycatcher is documented within an area that has the potential to be affected, coordination with CDFW shall occur to identify an appropriate buffer to be implemented. Any impact resulting from the Proposed Project that would result in the mortality or physical harm or impairment of an individual willow flycatcher would be a significant impact. If activities would need to occur within the buffer, the KRRC shall implement any measures CDFW deems necessary. Report on the status of any willow flycatcher surveys once a month when surveys are conducted to applicable agencies.

Significance

Significant and unavoidable in the short term

Beneficial in the long term due to expansion of riparian habitat in the former location of Copco No. 1 and Iron Gate reservoirs

Potential Impact 3.5-13 Short-term impacts on bald and golden eagles from construction-related noise and nesting habitat alterations.

Short-term construction-related activities including, but not limited to, structure demolition, hatchery modifications (Section 2.7.6 *Hatchery Operations*), road and bridge upgrades (Appendix B: *Definite Plan – Appendix K*), and culvert improvements (Section 3.22.2.3 *Road Conditions*) could result in noise disturbance and habitat removal impacts on bald and golden eagles. Bald and golden eagles are protected by the Bald and Golden Eagle Protection Act that prohibits anyone without a permit to take alive or dead any part of a bald or golden eagle or their nest. Impacts on bald and golden eagles are similar to those described in Potential Impact 3.5-10 for nesting birds. 2018 eagle surveys documented two inactive bald eagle nests—one within 0.5 miles of Copco Reservoir and one located between 0.5–2 miles of Iron Gate Reservoir (S. Leonard, AECOM, Senior Water Resources Engineer, pers. comm, October 2018). Two active golden eagle nests were found within two miles of Copco No. 1 Reservoir and three inactive nests were documented within 2 miles of Iron Gate Reservoir (S. Leonard, AECOM, Senior Water Resources Engineer, pers. comm, October 2018). In May 2018, a golden eagle was observed at Copco No. 1 Reservoir perched on a slope on the northern shoreline, a pair was observed near a northern cove, and one was observed bathing in the shallow water (CDM Smith 2018c).

Bald eagle nesting trees are known to exist within or near proposed Lower Klamath Project construction areas. A bald eagle nest, active from 1986 to 1997, was located approximately two miles from Iron Gate Dam; a nest active from 1993 to 1997 was documented within 0.5 mile of Iron Gate Dam; and an active nest in 2002 was documented within two miles of Iron Gate Dam (Willy 2017, as cited in *Appendix B: Definite Plan*). As bald eagle nests have been previously documented nearby, and as bald eagles may use the same nests in multiple years, there is a potential for bald eagles to nest in these same sites (or locations in similar habitats) and be disturbed by Proposed Project noise. Noise disturbance may cause nest abandonment while physical removal of vegetation may result in direct harm. Construction activities that could result in noise and disturbance impacts on bald and golden eagles include dam demolition, clearing of access and haul roads, creating and using staging and disposal sites, and restoration activities. Project impacts on nesting eagles could occur if individuals are nesting (January 1 through August 31) while construction activities occur—powerhouse and dam removal activities would begin November 1 of the year prior to drawdown and continue through September of the drawdown year (Table 2.8-1). Without surveys to document nesting bald or golden eagles and buffers to prevent noise and habitat removal impacts, bald and golden eagles if present, would be displaced resulting in a failed nest or mortality to young, and this would be a significant short-term impact. (Potential impacts from the loss of reservoir habitat are addressed in Potential Impact 3.5-14 and potential impacts from the reduction in hatchery output are addressed in Potential Impact 3.5-25).

The Proposed Project includes components to avoid and minimize construction-related impacts on bald and golden eagles (Appendix B: *Definite Plan – Appendix J*) which include, but are not limited to, the components listed below.

- The following surveys were conducted for the Proposed Project.
    - Initial ground-based nest search survey in late January/early February 2018 and a second ground-based and aerial survey was conducted in June 2018 covering an area approximately two miles from construction and demolition sites and 0.5 mile from other areas within the Limits of Work including reservoir boundaries where significant demolition and construction activities would not be occurring. The 2018 results are detailed above. (Survey methods were based on established protocols including Jackman and Jenkins 2004 and Pagel et al. 2010).
- Future measures include the following:
    - Conducting an additional survey during the early nesting season of the year prior to drawdown to determine updated activity and to observe eagle activity patterns, to establish a baseline of normal behavior prior to construction.
    - Developing an Eagle Avoidance and Minimization Plan in coordination with the USFWS that identifies procedures and protocols for avoiding and minimizing impacts.
    - When possible, scheduling activities including clearing, cutting, and grubbing outside of the eagle nesting season (January 1 through August 31).
    - Applying a 0.5-mile restriction buffer if a nest is within two miles of the Limits of Work in coordination with resource agencies to ensure nests that are not disturbed. If an eagle nest is within the 0.5-mile buffer, then construction activities would be halted until coordination with resource agencies determine that construction can resume. The KRRC noted that if there are topographic or vegetative features that would block the eagle's line of site to the activity, the buffer could be reduced to 0.25 mile. A further narrowing of the buffer or

identification of specific activities that could be determined in coordination with the biological monitors and the USFWS, as long as the activities would not jeopardize nesting success.

While the Proposed Project avoidance and minimization measures would reduce the potential for short-term construction-related impacts on bald and golden eagles within the Primary Area of Analysis, the aforementioned components need more specificity to ensure that short-term construction activities would not result in significant impacts on bald an golden eagles or substantially interfere with their movement and/or migration, or that any remaining potentially significant impacts are mitigated to the extent feasible. Implementation of the recommended bald and golden eagle mitigation measure below, developed in consultation with CDFW and USFWS, would reduce potential short-term construction-related impacts on bald and golden eagles to less than significant. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to protection of bald and golden eagles to include Recommended Terrestrial Measure 11 below, which has been developed in consultation with CDFW and USFWS. This recommended terrestrial measure includes the following additional components beyond those listed as part of the Proposed Project:

- During the implementation of the 2018 eagle surveys, a two-mile survey area was established surrounding construction and demolition areas and a 0.5-mile survey area surrounding other areas such as reservoirs. Appendix J of the Definite Plan identifies aerial seeding within the reservoir footprint, and as a result the survey area shall reflect the modified noise disturbance areas around the reservoirs by expanding the surveys buffer around the reservoirs from 0.5 mile to one mile. (A minimum of a one-mile survey area is based on the one-mile buffer distance that would be applied if an active nest was present.)
- Consultation with resource agencies shall include both USFWS and CDFW, as the eagles are protected by the federal Bald and Golden Eagle Protection Act and the bald eagle is listed as a state endangered species.
- Nests shall be monitored within buffer zones.

Overseeing development and implementation of recommended term and conditions relating to bald and golden eagles does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process[122] to reach enforceable good citizen agreements with USFWS and CDFW that will be finalized and implemented, at this time the recommended term and conditions are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the recommended term and conditions, including the Recommended Terrestrial Measures and any modifications developed through the FERC process that provide the same or better level of protection for special-status wildlife, would reduce impacts to less than significant, because the

[122] KRRC submitted the CEQA support document to agencies in September 2017 and requested feedback by November 10, 2017.

State Water Board cannot ensure implementation of the Recommended Terrestrial Measures, it is analyzing the associated impacts in this Draft EIR as significant and unavoidable.

Recommended Terrestrial Measure 11 – Bald and Golden Eagle.

- KRRC shall develop an Eagle Avoidance and Management Plan in coordination with USFWS and CDFW.
- A two-year survey for eagle use patterns shall be conducted prior to construction activities.
  - The first-year survey shall determine bird use patterns at any facilities to be removed or modified during the time of year most likely to detect bird usage (this was completed by KRRC in 2017).
  - The second-year survey shall include focused surveys (see below).
  - Surveys shall be conducted by a qualified avian biologist, approved by resource agencies (CDFW and USFWS).
- A focused survey (two site visits) shall be conducted in a single nesting season within two years prior to drawdown to document the presence of nests. These focused surveys shall identify eagle nests within one miles of disturbance areas within the Limits of Work, including but not limited to demolition areas where there may be any loud noise disturbance (e.g., helicopter or plane). The early nesting season survey shall occur at a time when eagles are most likely found at the nest sites, and the second survey shall occur later in the season and prior to the fledglings leaving the nest to confirm nesting activity. All observations shall be reported to CDFW using the California Bald Eagle Nesting Territory Survey Form (CDFW 2017d).
- Within two weeks prior to commencing construction or ground-disturbing activities, KRRC shall conduct at least one pre-construction survey within the survey area defined above.
- Wherever possible, clearing, cutting, and grubbing activities shall be conducted outside of the eagle nesting season (January 1 through August 31[123]).
- If active eagle nests are documented during the surveys, a one-mile[124] restriction buffer shall be established around the nest to ensure that nests are not disturbed. This buffer may be reduced in coordination with USFWS and CDFW, while taking into consideration components such as proposed activity, distance to activity, terrain, and line of site. For example, in coordination with agencies, if a nest is not within line-of-site, meaning that trees or topographic features physically block the eagle's view of construction activities, the buffer could be reduced to 0.25 miles. Further reduction of buffers or allowance of limited activity inside of buffers could occur in coordination with on-site biologist, CDFW, and the USFWS, while being consistent with the Eagle Avoidance and Minimization Plan, if it is determined that the activities shall not jeopardize nesting success.
- Nests within a one-mile buffer shall be monitored by an USFWS- and CDFW-approved biologist when there is a potential for noise disturbance, in order to

[123] Eagle breeding season of January 1 through August 31 identified by A. Henderson, CDFW, Environmental Scientist, pers. comm, November 2017

[124] Eagle nest restriction buffer of 1.0 mile identified by A. Henderson, CDFW, Environmental Scientist, pers. comm, November 2017

assess whether eagle activity patterns are normal, as compared with that observed during baseline surveys described above.

- If activities are anticipated to result in take under the Bald and Golden Eagle Protection Act, it would be considered a significant impact and KRRC will coordinate appropriate measures, including procurement of any necessary take permits, with USFWS and CDFW. Report on the status of bald and golden eagle surveys within one month of the survey to applicable agencies.

Significance

Significant and unavoidable in the short term

Potential Impact 3.5-14 Short- and long-term impacts on bats from construction noise and loss of roosting habitat.

In the short term, construction activities including, but not limited to, structure demolition, hatchery modifications (Section 2.7.6 *Hatchery Operations*), road and bridge upgrades (Appendix B: *Definite Plan – Appendix K*), and culvert improvements (Section 3.22.2.3 *Road Conditions*) could disturb bat roosts through construction noise, physical vibration, and direct removal of roosting habitat.

Structures in the Lower Klamath Project are providing habitat for small day roosts and large maternity colonies. Recent structure assessments and surveys in 2017 and 2018 identified roosts in 22 structures with the largest of colonies (between a few hundred and a few thousand individuals) observed thus far at the Copco No. 1 Dam - C12 Gatehouse, Copco No. 1 Diversion Tunnel, Vacant House #21601 (light yellow house), and Iron Gate Diversion Tunnel (Appendix B: *Definite Plan – Appendix J*; KRRC 2018a, and KRRC 2018b). (see Table 3.5-8).

Table 3.5-8. Evidence of Bat Use at Structures Based on June 2017 Reconnaissance and Available Information from 2018 surveys (Appendix B: *Definite Plan – Appendix J;* KRRC 2018a,b)

Building Name	Evidence of Bat Use
All bridges scheduled for removal or modification	No roosting bats
Copco No. 1 and No. 2 Dams and Facilities	
Schoolhouse	No
House 19038 (next to schoolhouse)	Yes – abundant guano in crawl space.
Vacant House 1 (tan)	Yes – small numbers of bats present under wood panels outside.
Vacant House 2 (blue)	Yes – small numbers of bats present under wood panels outside.
Vacant House 3 (yellow)	Yes – small numbers of bats present under wood panels outside.
Vacant House 3 (yellow)	Yes – large colony in garage behind wood window framing, whole structure is being heavily used.
Vacant House 4 (peach)	Yes – maternity colony between flashing & fascia board all around roof edge; pups present.
Cookhouse	Yes – bats present in awning over side door outside, no sign inside.
Bunkhouse	Yes – guano on bed. Night roosting suspected from

Building Name	Evidence of Bat Use
	staining around outside lighting.
Copco No. 1 Dam - C12 Gatehouse	Yes – abundant guano/staining on the inside and outside of the building; dead bat (Myotis spp.) found outside on windowsill. Documented a large maternity roost of >2,000 Myotis spp. inside structure.
Copco No. 1 Powerhouse	Yes – several dozen bats clustered on wall above Transformer 3781; abundant staining/guano on basement level. Follow-up surveys documented small numbers of roosting bats.
Copco No. 1 Diversion Tunnel (also referenced as Tunnel outside of Copco No. 1 Powerhouse)	Yes – several hundred bats observed during emergence
Copco No. 2 Diversion Dam	No
Vacant House #21601 (light yellow house)	Yes – ~200 bats roosting in attic.
Shed (next to power station)	None found in main portion of shed. Back area of building was inaccessible.
Vacant House (light blue)	Yes – dead bat found in bathroom sink. No guano/staining inside. Attic vents are closed. No points of entry found.
Tin Pumphouse (across from light blue house)	No
Tin Pumphouse at entrance to Copco Village	Yes – small amount of guano outside. Multiple points of entry. Inside inaccessible.
Copco No. 2 Powerhouse	Yes – many dead bats on ground level (on floor, in storage room, control room) and dead pups at bottom of stairs on lower level. More sign/activity found at ground level. Follow-up surveys documented small numbers of roosting bats.
Control Room at Copco No. 2 Powerhouse	Not inspected during reconnaissance survey.
Shop next to power station at Copco No. 2	Not inspected during reconnaissance survey.
Occupied House next to Vacant House 4	Not inspected during reconnaissance survey.
Equipment shed (in front of bunkhouse/cookhouse)	Not inspected during reconnaissance survey.
Waste storage/wood shop by gas pumps (near houses/bunkhouse/cookhouse)	Not inspected during reconnaissance survey.
Iron Gate Dam and Facilities	
Gatehouse for low-level outlet (upstream side of dam)	Yes – night roosting evidence outside. No sign found inside.
Iron Gate Diversion Tunnel (also referenced as Tunnel near Iron Gate Powerhouse)	Yes – several hundred bats observed during emergence.
Iron Gate Powerhouse Intake	Yes - from ground level, bats heard through grating below. Entry via open grate on outside. Two dead bats. Observed abundant guano on plastic sheeting on floor inside.
Iron Gate Emergency Spill Equipment Shed	No

Building Name	Evidence of Bat Use
Iron Gate Hydro Resources Office/Powerhouse	Yes – heavily used night roost by light fixture under stairwell (abundant staining on concrete wall). Sign of significant roost inside concrete shaft (heavy staining/guano). Confined space entry to bottom level of powerhouse, did not inspect.
Bathroom/Storage building near powerhouse	No
Spawning building	Yes – small amount of guano. Potential night roosting outside.
2 storage trailers (parked next to each other)	No
Barn/Garage at Iron Gate Village	Yes – bats present in rafters/ceiling; abundant amount of guano.
Residence 1 (occupied) blue/gray	No–inspected outside only; inside/attic not accessed.
Residence 2 (occupied) tan w/green roof	Yes – 15 bats present behind clock on back porch. Attic access likely through loose screen over vent. Outside inspection only; inside/attic not accessed.

Short-term impacts may occur from disturbing a maternity and/or hibernacula colony, including those possibly used by special-status bat species. Structure modifications or significant noise or vibrational disturbance occurring during the bat maternity season have the greatest potential to affect special-status bats. Maternity colonies may have high numbers of non-volant young (unable to fly) that may be directly or indirectly harmed or killed, resulting in impacts on individuals or a colony. A hibernaculum is a roost that bats use to overwinter, which provides suitable microclimates and allows bats to hibernate by slowing their metabolic rate to survive through low temperatures and low abundance of food. Disturbing a hibernacula roost may interrupt the metabolic rate and cause bats to use limited energy reserves. Impacting a maternity or hibernacula roost has the potential to result in direct impact on individuals and/or colonies and thus result in a significant short-term impact. Working outside of sensitive life history periods (i.e., maternity, hibernacula) and excluding bats from structures prior to construction or during times when bats would be less affected, would reduce the impact on bats.

Although impacting a maternity or hibernacula roost would be considered a significant impact, removal of night roosts used by a few individuals would not represent a significant impact on bats, as (1) structures would not be removed during the night when bats are present and thus no direct impact would occur, and (2) there are homes and other structures within a 15-mile radius (H.T. Harvey and Associates 2004) of the Limits of Work that may provide suitable night roosting habitat.

In the long term, removing maternity or hibernacula roosts has the potential to result in population-level impacts, as it is not known if the bats will relocate or if there is suitable habitat in the adjacent area to support these roosts. Removal of large maternity or hibernacula roosts would result in a significant long-term impact.

Without surveying to document roosting bats, conducting construction within limited operating periods that are least likely to overlap with sensitive bat life histories, and creation of successful replacement roost habitats, impacts on bat in the short term and long term would be significant, as described above.

The Proposed Project includes components to avoid and minimize both short- and long-term construction-related impacts and loss of habitat on roosting bats including, but not limited to, the components below (additional details are provided in Appendix B: *Definite Plan – Appendix* J.

- The following surveys were recently conducted or in progress for the Proposed Project.
    - A site reconnaissance daytime visual inspection (most sites surveyed in July 2017 and May 2018) and emergence surveys and acoustic monitoring surveys in June 2018. Hibernacula surveys conducted in February and March 2018 (Copco No. 1 and Copco No. 2 structures only due to limited access). Surveys to assess migration in spring occurred in April/May and in fall occurred in September/October 2018.
- Future measures include the following:
    - KRRC is also assessing nearby trees scheduled for removal.
    - Removing facilities that support maternity colonies outside of the bat roosting season (March 2–October 31) and removing facilities that support hibernacula roosts when it is determined to be unoccupied.
    - Excluding bats outside of the bat roosting period when feasible and conducting exclusion consistent with a Bat Exclusion Plan that would be provided to CDFW prior to implementing the exclusion method.
    - If a structure is to be removed and contains bats, the KRRC proposes coordinating with agencies to remove habitat at a time when it would have the least impact on bats.
    - For replacement bat habitat, the KRRC proposes giving preference to on-site and in-kind opportunities and retaining existing structures supporting roosts, to the extent practical. For facilities that cannot be retained, the KRRC will construct free-standing bat roosts prior to the removal of the existing facility; the replacement habitat will be informed by features at the structure that currently supports the bat roost(s). The KRRC proposes to develop success criteria in coordination with agencies and bat specialists, as appropriate.

While the Proposed Project avoidance and minimization measures would reduce the potential for short-term construction-related impacts on bats within the Primary Area of Analysis, the aforementioned components need more specificity to ensure that short-term construction activities would not result in significant impacts on special-status species or substantially interfere with movement and/or migration of wildlife species, or that any remaining potentially significant impacts are mitigated to the extent feasible. The recommended terrestrial measure below, developed in consultation with CDFW, include additional components beyond those listed as part of the Proposed Project and would be necessary to reduce potential short-term construction-related impacts on special-status to less than significant, as specifically discussed in the recommended terrestrial measure below. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to protection of bats to include Recommended Terrestrial Measure 12 below, which was developed in consultation with CDFW. This recommended terrestrial measure includes the following additional components: (1) the proposed two-year surveys shall be conducted within five years prior to drawdown; (2) an additional assessment of all structures should be reassessed to detect any changes in use and update baseline data to be as contemporary as possible when used as a comparison for monitoring the success of replacement habitat; (3) additional specificity associated with the timing and required weather conditions during exclusion or habitat removal when bats are present to prevent impacts on individuals; (4) definition of a CDFW-proposed breeding season that is less restrictive than the KRRC-proposed season allowing for additional flexibility; (5) definition of a CDFW-proposed hibernating season that is more restrictive than proposed; (6) definition of protection measures in the event that a few bats are documented during construction at locations where surveys did not previously document use—bats may be captured and released by a CDFW-approved bat biologist; (7) additional options for artificial bat roosts (e.g., bridge enhancement); and (8) specificity regarding monitoring success criteria for replacement roost structures.

Overseeing development and implementation of recommended term and conditions relating to bats does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process[125] to reach enforceable good citizen agreements with CDFW that will be finalized and implemented, at this time the recommended term and conditions are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the recommended term and conditions, including the Recommended Terrestrial Measures and any modifications developed through the FERC process that provide the same or better level of protection for special-status bats, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Recommended Terrestrial Measures, it is analyzing the associated impacts in this Draft EIR as significant and unavoidable.

Recommended Terrestrial Measure 12 – Roosting Bats and Habitat.

- Surveys described below shall be conducted within five years prior to drawdown, and within one year prior to drawdown all structures shall be reassessed to detect any change to the roost (maternity and hibernacula).
- A qualified bat biologist shall conduct two years of bat surveys at the facilities to be removed or modified to determine bat use (species use, roost type [maternity, day, night, hibernacula]) using visual observation/emergence surveys to assess size of roost and using acoustic detectors to identify species (or species group if identification to species is not feasible) present at the roost. Surveys shall be conducted during the time of year most likely to detect bat use during the maternity and hibernacula season.
- If surveys indicate that a structure is utilized as a bat maternity roost, then removal or modification of the facility shall occur outside of the bat maternity season

[125] KRRC submitted the CEQA support document to agencies in September 2017 and requested feedback by November 10, 2017.

(March 1–September 15)[126]. If the facility is used as a winter hibernacula, then removal or modification of the facility shall occur outside of the hibernacula season (October 15–February 28)[127] or when it is determined to be unoccupied. These timeframes may be adjusted based on site-specific conditions, data collected on-site or in the region, and proposed activities, as determined by the qualified bat biologist and in consultation with CDFW.

- No direct or indirect disturbance (exclusion or demolition as discussed below) shall occur during the peak of the maternity season (April 15–August 31)[128].
- Consistent with the KRRC's proposed measure, humane bat exclusion methods to seal facility entry sites (e.g., blocking by netting or installing sonic bat deterrence equipment) may occur to prevent bat use in a structure during the demolition. A Bat Exclusion Plan to identify proposed exclusion methods shall be developed by the qualified bat biologist and approved by CDFW prior to initiation. Exclusion measures shall be put in place when bats are active and weather is fair outside between September 1 and October 15[129]. During this allowable period, these activities may occur when evening temperatures are greater than 45ºF and no more than 0.5 inch of rainfall is predicted within the following 24 hours. The sites shall be monitored to determine whether the exclusion was successful. Humane bat exclusion methods shall be conducted by, or under the supervision of, a qualified bat biologist with experience in conducting humane exclusions that holds a CDFW Scientific Collecting Permit for bat capture.
- If demolition occurs at a time when a structure is occupied by a maternity colony or hibernating colony and exclusion was deemed infeasible, a plan shall be developed (this could be part of the Bat Exclusion Plan) in coordination with a qualified bat biologist and approved by CDFW to carefully remove the occupied bat habitat at a time when it would have the least impact on bats present and in a manner that avoids bat injury and mortality. Demolition shall occur when bats are active and weather is fair outside between September 1 and October 15[129]. During this period, activities to remove the occupied habitat may occur when evening temperatures are greater than 45°F and no more than 0.5 inch of rainfall is predicted within the following 24 hours. During demolition activities, a qualified bat biologist shall be present on site.
- If an on-site biologist (Recommended Terrestrial Measure 3) conducts a daily pre-construction survey (Recommended Terrestrial Measure 7) of a structure previously assessed as not providing habitat for bats and finds a few bats (and confirmed neither a hibernacula or maternity colony), a qualified bat biologist with experience handling bats and approved by CDFW may capture and release the bat(s) at dusk during suitable weather (i.e., not raining, temperatures greater than 45°F).
- To reduce short-term and long-term impacts on bats from the permanent loss of maternity or hibernating roosting habitat, creation and/or enhancement of artificial

[126] Bat maternity season identified by K. Hubbard, CDFW Environmental Scientist, pers. comm., November 2017.
[127] Bat hibernating season identified by K. Hubbard, CDFW Environmental Scientist, pers. comm., November 2017.
[128] Peak maternity season identified by K. Hubbard, CDFW Environmental Scientist, pers. comm., November 2017.
[129] Humane exclusion period identified by K. Hubbard, CDFW Environmental Scientist, pers. comm., November 2017.

roosting habitat shall occur prior to the structures being removed. New artificial bat roosting habitat shall be designed to support equivalent roost (maternity, hibernacula) habitat, numbers, and species excluded from the demolished roosts, with the goal of meeting the success criteria defined below.

- o The total number of artificial bat roosts shall depend on the total number of facilities removed with maternity and hibernacula bat roosts. The size and design of artificial bat roosts shall be informed by the features of the removed structure and the type and size of roost; critical design elements shall include access, ventilation, and thermal conditions.
- o Artificial bat roosts may include, but are not limited, to enhancing bridges to support roosting habitat and constructing free-standing artificial bat roosts on- or off-site in consultation with bat specialists and the resource agencies. Preference shall be given to on-site and in-kind solutions; however, if artificial free-standing bat roosts are unlikely to remain into the foreseeable future (e.g., due to land ownership changing following completion of the Proposed Project), the placement of artificial bat roosts in off-site locations on publicly owned land (e.g., Horseshoe Ranch Wildlife Area) may be considered in coordination with agencies (CDFW).
- o Experienced contractors shall perform the installation of bat roosts. The artificial bat roosts shall meet the applicable specifications of Bats in American Bridges (Keeley and Tuttle 1999) and California Bat Mitigation Techniques, Solutions, and Effectiveness (H.T. Harvey and Associates 2004).
- o Post-construction monitoring of the mitigated enhanced or replacement bat roosts shall occur multiple times of the year and depend on the type of roost being created. At a minimum, roost surveys shall occur seasonally (four times per year). Monitoring surveys may include, but are not limited to, emergence surveys, acoustic monitoring, and guano observation.
- o Monitoring shall occur for at least five years or until the mitigation can be considered successful. At Year 3, artificial bat roosts meeting the success criteria (described below) may be eliminated from the monitoring. Criteria shall be considered successful through concurrence with CDFW or their designated representatives.
  - The mitigated enhanced and/or replacement bat roosts will be considered successful if the following occurs: (1) the mitigation roost provides the function(s) of the demolished roost (i.e., maternity, hibernacula) and (2) the roost is occupied by a similar composition of species and number of bats that were present in the demolished roost (H.T. Harvey and Associates 2004). If this standard is not met, KRRC shall coordinate with CDFW, as appropriate, to ascertain the potential need for further measures (e.g., modifications to the mitigation roost(s), additional monitoring).

- Report on the status of bat surveys, exclusion activities, and success criteria monitoring within one month of the survey to applicable agencies.

Significance

Significant and unavoidable for short-term construction-related impacts

Significant and unavoidable for long-term habitat removal

Potential Impact 3.5-15 Impacts on northern spotted owl and critical habitat from construction-related noise and habitat alterations.

Northern spotted owls can be disturbed by noise, visual, or physical disturbances. The noisiest construction activities are blasting and helicopters (it is uncertain if aerial seeding would be done by plane or helicopter). Blasting has a disturbance distance of approximately one mile and helicopter use has a disturbance distance approximately of 0.5 mile, whereas other activities (e.g., chainsaw use, heavy equipment) have disturbance distances of approximately 0.25 mile (Table 3.5-9); disturbance distances were developed in coordination with the Arcata USFWS office using an estimation of auditory and visual disturbance effects (USFWS 2006) as a basis.

Helicopters can also cause a downdraft that can affect owls and nests. Without an assessment to identify if suitable habitat or owl nests are present or establish no-activity buffers surrounding a known nest location, the Proposed Project would result in direct harm on northern spotted owl, which would be a significant impact.

Table 3.5-9. Disturbance Distances[1] for the Northern Spotted Owl During the Breeding Period.

Source of Noise	Disturbance Distance
Blasting	1 mile
Hauling on open roads	0.25 mile
Heavy equipment	0.25 mile
Rock crushing	0.25 mile
Helicopter—Type I[2]	0.5 mile
Aircraft—Fixed Wing	0.25 mile

[1] Noise distances were developed in coordination with the Arcata USFWS office using an estimation of auditory and visual disturbance effects (USFWS 2006) as a basis.

[2] Type I helicopters seat at least 16 people and have a minimum capacity of 2,300 kg (5,000 lbs). Both a CH 47 (Chinook) and UH 60 (Blackhawk) are Type I helicopters.

The Proposed Project includes an assessment to evaluate suitable habitat and known activity centers, and if suitable habitat is present, to conduct protocol-level surveys, and if owls are present, implement seasonal restriction (March 1–September 30), prevent aircraft flights within or at an elevation lower than 0.5 miles of suitable nesting and roosting habitat during the entire breeding season, unless protocol-level surveys identify no activity centers or it is determined in coordination with the USFWS that there would be no effect on the activity center, and not remove components of owl habitat during the removal of transmission or installation or removal of fencing activities. An assessment conducted by the KRRC determined that there are no existing northern spotted owl activity centers are located within the noise disturbance distance of the construction activities (Table 3.5-9) (Appendix B: *Definitive Plan – Appendix J*).

The closest spotted owl activity center to the Proposed Project is located approximately 1.7 miles southeast of Copco No. 1 Reservoir, which is outside of the blasting disturbance distance from dam removal activities. As the northern spotted owl typically nests from February through September and construction activity would begin prior to the start of the nesting season (Table 2.7-1, Section 2.7 *Proposed Project*), this noise and human presence would likely discourage northern spotted owls from initiating nesting near construction areas. Based on the Northern Spotted Owl Relative Habitat Suitability model output, there is no nesting or roosting habitat within 1 mile of the reservoirs and based on habitat and previously recorded nesting locations, protocol-level surveys were not recommended (R. Carey, USFWS, Supervisory Fish and Wildlife Biologist, pers. comm, July 2018). Any potential impacts are more likely to occur from disturbance during aerial seeding of reservoir areas than to occur as a result of structure (e.g., dam and powerhouse) removal activities.

Helicopters may be used during restoration activities. As critical habitat (discussed below) is present approximately 0.6 mile from Copco No. 1 Reservoir, the Proposed Project avoidance and minimization measure to prevent aircraft flights within or at an elevation lower than 0.5 miles of suitable nesting and roosting habitat during the entire breeding season, unless protocol-level surveys identify no activity centers or it is determined in coordination with the USFWS that there would be no effect on the activity center would ensure that any potential short-term construction-related impacts on northern spotted owl would be less than significant.

No impacts on critical habitat were identified. Northern spotted owl critical habitat is present approximately 0.6 mile southeast of Copco No. 1 Reservoir. Within a 3-mile buffer of Copco No. 1 and Copco No. 2 reservoirs, the critical habitat only makes up approximately 4 percent (2,400 acres) of the upland habitat in this area. USFWS critical habitat designation (USFWS 2012) includes the following Primary Constituent Elements, physical and biological features essential for the conservation of the species—forest stands in early, mid-, or late seral stages, as well as nesting and roosting, foraging, and dispersal habitat as described below (USFWS 2012). However, as no components of critical habitat would be removed or modified, no long-term impacts were assessed and no further analysis was conducted. (Removal of individual or small number of trees or other vegetation to support activities such as widening existing roads are not expected to rise to the level of habitat modification.)

Implementation of the Proposed Project avoidance and minimization measures, as discussed above, would result in a less than significant impact on the northern spotted owl.

<u>Significance</u>
No significant impact

Potential Impact 3.5-16 Effects on special-status amphibians and reptiles in riverine habitats from short-term high suspended sediment concentrations (SSCs) and flows and long-term changes in water quality.
The Proposed Project would result in the release of sediment from behind the dams, causing increased SSCs within the mainstem Klamath River downstream of the dams. The sediment behind the dams is more than 80 percent fine sediment (organics, silts, and clays), which are expected to remain suspended in the Klamath River flow as it moves downstream and out into the Pacific Ocean (see Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). Modeling results indicate elevated SSCs (>1,000 mg/L) in early January of dam removal year 2 when Iron Gate and J.C. Boyle reservoirs begin drawdown and Copco No. 1 Reservoir enters the second phase of drawdown. Depending on the water year type (dry, median, wet), SSCs would peak in February between 7,100 mg/L and 13,600 mg/L, decrease but remain elevated (>1,000 mg/L) between March and June, remain greater than or equal to 100 mg/L in

June and July, and remain greater than or equal to 30 mg/L until December or July of the following year. In a wet-year scenario, a second pulse of SSC greater than 100 mg/L would occur the following November and December (see Section 3.2 Water Quality—Figures 3.2-12 and 3.2-13) (see additional detail in Section 3.2.5.2 *Suspended Sediments*). SSCs in excess of 1,000 mg/L would occur downstream of Iron Gate Dam on a timescale of weeks to months (see Table 3.2-2), as compared with similarly high SSCs (or total suspended solids [TSS]) that can occur in the Middle and Lower Klamath River during winter storm events on a timescale of days to weeks under existing conditions (see Appendix C, Section C.2.2). River flows would be expected to remain below the 10-year flood event of 11,000 cubic feet per second (cfs). Potential impacts as a result of these flows are discussed below.

SSCs are expected to be higher in locations closer to the point of origin of the sediment (i.e., Hydroelectric Reach and Middle Klamath River immediately downstream of Iron Gate Dam) and to decline in a downstream direction due to dilution from tributaries (Stillwater Sciences 2008, USBR 2012). Model results also indicate that dilution in the Middle and Lower Klamath River would decrease SSCs to 60–70 percent of their initial value downstream of Seiad Valley (RM 129.4) and to 40 percent of their initial value downstream of Orleans (~RM 58.9) (Section 3.2.5.2 *Suspended Sediments*).

Elevated SSCs have the potential to adversely affect or cause mortality of sensitive life stages of amphibians and reptiles occurring in the Hydroelectric Reach and the Middle and Lower Klamath River. According to Stillwater Sciences (2009), high SSCs from dam removal could result in a worst-case scenario of 100 percent mortality of all amphibian eggs deposited in the Lower Klamath River. However, the scope of this assessment did not include a detailed species-specific analysis of the timing of the increased SSCs and the life history attributes and habitat use of the potentially affected amphibians and reptiles.

Increased SSCs from dam removal have the potential to decrease food availability by affecting the growth and survival of food sources such as algae, diatoms, and macroinvertebrate populations. This indirect impact of increased SSCs would likely have some effect on all reptile and amphibian species using the Klamath River downstream of the dams. However, this indirect impact is not considered a substantial adverse effect due to the short duration and timing of the impact and the life history attributes of affected species, particularly the seasonality of their habitat use. The potential impacts of high SSCs on specific special-status amphibian and reptile species are discussed below.

Foothill Yellow-Legged Frog

Foothill yellow-legged frog, proposed as threatened under CESA, are known to occur in the lower reaches of the Klamath River, while only historical occurrences are known closer to the Proposed Project. Foothill yellow-legged frogs and egg masses have been observed in mid-June on the Lower Klamath River approximately 13 RM upstream of the estuary (M. Wikaira Yurok Tribe to Parker Thaler, pers. comm., January 2018). The species has also been documented on the Klamath River approximately 20 RM upstream of the estuary by Green Diamond in 1994 (CDFW 2017a) adjacent to Green Diamond lands. Historical occurrences in 1970 documented the frog closer to the Proposed Project approximately 50 RM downstream from Iron Gate Dam, and farther downstream in 1976 (CDFW 2017a). Targeted surveys by PacifiCorp in 2003 did not document the species in mainstem and tributary locations identified as the most likely to support foothill yellow-legged frogs, including Bogus Creek, approximately 0.2 RM downstream of Iron Gate Dam and Cottonwood Creek, approximately eight miles downstream of Iron Gate Dam (PacifiCorp 2004a). Borisenko and Hayes (1999) hypothesized that the absence of foothill yellow-legged frogs was due to poor water quality released from Iron Gate Reservoir and fluctuating water levels.

The absence of foothill yellow-legged frogs during PacifiCorp 2003 surveys supports the hypothesis that they are no longer present downstream of Iron Gate Dam. However, PacifiCorp (2004a) indicates that historical records of foothill yellow-legged frogs occurred in Jenny Creek (a tributary to Iron Gate Reservoir) and Cottonwood and Little Bogus creeks, located downstream of Iron Gate Dam. Although it is not known how common the species was before the construction of the Lower Klamath Project, the foothill yellow-legged frog may be affected by loss of river habitat, predation by the non-native bullfrog and other aquatic predators, and desiccation or scour of egg masses resulting from flow alterations (PacifiCorp 2004a). Limiting factors downstream of Iron Gate dam may be more associated with flow patterns than with water temperatures, as water temperature conditions may be sufficiently suitable to support the frog. Foothill yellow-legged frog breeding is typically triggered by warming water temperatures between 50 and 53.6ºF. Daily average water temperatures in the Klamath River downstream of Iron Gate Dam (~RM 192), near Seiad Valley (RM 132.7), and at Orleans (RM 58.9) indicate that generally by mid-May water temperatures are 50–53.6ºF, which would be suitably warm to trigger breeding (Figures C-3 and C-4, Appendix C). According to Lannoo (2005), the foothill yellow-legged frog typically breeds between late April and June. In California, egg masses have been found between April 22 and July 6, with an average of May 3 (Lannoo 2005). In the Trinity River, a major tributary to the Lower Klamath River, Ashton et al. (1998) found that foothill yellow-legged frogs lay eggs throughout a three month period of April to June. Eggs generally hatch within 5–37 days (AmphibiaWeb 2018).

Elevated flows and release of suspended sediments on the foothill yellow-legged aquatic stages were evaluated downstream of Iron Gate Dam. As discussed in additional detail in Section 3.2.5.2 *Suspended Sediments*, SSCs would peak in February and remain elevated between March and June downstream of Iron Gate Dam. Dilution in the Middle and Lower Klamath River would decrease SSCs to 40 percent downstream of Orleans (~RM 58.9) (Section 3.2.5.2 *Suspended Sediments*). The early period (late April) of the foothill yellow-legged frog egg laying season overlaps with elevated SCCs between March and June (see Table 3.2-2).

High SSCs could have a short-term significant impact on the foothill yellow-legged frog egg masses and tadpoles, if present. Silt has often been observed on the outer surfaces of egg masses, which may make the eggs less conspicuous and thereby possibly reducing predation by visual predators (Lannoo 2005). However, a study to evaluate the growth and survival of western toad tadpoles from initial pulses of 130 and 260 mg/L of suspended sediment documented slower growth rates and reduced survival to metamorphosis as a result of tadpoles consuming the sediment (Wood and Johnson 2009). Therefore, suspended sediment may result in mortality or harm to state-candidate-threatened foothill yellow-legged frogs through reduced survival and growth of egg masses and tadpoles, which would be a significant impact.

Although river flows during reservoir drawdown may result in short-term impacts on foothill yellow-legged frogs due to scour of egg masses or displacement of tadpoles (if these lifestages are present), drawdown flows would be expected to remain below the 10-year flood event[130] and so would not be a change from existing conditions. If high flows occur early in the foothill yellow-legged frog breeding season, it is possible that adults may avoid direct impacts of high flow and associated SSCs by delaying breeding (Gonsolin 2010, GANDA 2008).

Although survey data are limited for characterizing the distribution of foothill yellow-legged frog in the Klamath River, recent occurrences have been documented in the Lower Klamath River and tributaries, and presumably individuals have the potential to be present in the Middle Klamath River. Due to the listing status of the foothill yellow-legged frog (state Candidate Threatened), take of a single individual (including egg masses as described above) would result in a significant impact and would require approval by applicable agencies. Mitigation typically employed to reduce impacts was considered for this Proposed Project; however, the action of rescuing and relocating eggs is infeasible due to the low likelihood of locating eggs during high levels of turbidity. In the long term, it is anticipated that improved water quality (i.e., elimination of blue-green algae blooms and their associated toxins) and elimination of existing peeking flows as a result of the Proposed Project may enhance habitat for the species and reducing potential for scouring of egg masses.

Juvenile and adult foothill yellow-legged frogs are semi-terrestrial. Foothill yellow-legged frogs breed in rivers and spend a significant amount of time in adjacent riparian and wetland habitats, and in tributaries to mainstem rivers. As such, juveniles and adults would have the ability to avoid the short-term impacts of high SSCs by moving up-slope or up tributary channels during the reservoir drawdown period. Thus, high juvenile and adult mortality is not expected from high SSCs in the Hydroelectric Reach or the Middle or Lower Klamath River.

Pacific Tailed Frog and Southern Torrent Salamander

Both the Pacific tailed frog and southern torrent salamander live in high-gradient headwater stream habitat and have been documented in tributaries to the Lower Klamath River. These species would not be expected to occur in the Lower Klamath River itself. High flows and sediment released from behind the dams would be transported downstream within the Lower Klamath River mainstem, whereas tributaries would not experience elevated SSCs. Therefore, short-term SSCs in the Middle and Lower Klamath River are not expected to affect the Pacific tailed frog or southern torrent salamander.

Northern Red-Legged Frog

The northern red-legged frog breeds in still or low-velocity ponds, pools, side-channels, and wetlands in the coastal areas of the Lower Klamath Basin, generally within 12 miles of the river mouth. Northern red-legged frogs lay their eggs on aquatic or submersed herbaceous emergent vegetation. As their egg-laying habitat requires still water or very low flow, their breeding sites are typically more up-slope and disconnected from the Lower and Middle Klamath River. These breeding sites would only be connected with the Klamath River during extreme high-flow events, in which case egg masses would likely experience high rates of mortality. Adult northern red-legged frogs are mostly terrestrial and spend substantial time foraging in upland habitats. Thus, short-term high

[130] A 10-year flood event results in flows of 11,000 cfs.

flows and high SSCs in the Middle and Lower Klamath River are not expected to result in substantial negative effects on eggs, tadpoles, or adult northern red-legged frogs.

Western Pond Turtle

Western pond turtles in the Middle and Lower Klamath River and Hydroelectric Reach use the mainstem channel as well as side-channels, backwaters, and adjacent wetland and riparian habitat. They often move to off-channel habitats, such as oxbows, or uplands during high flow events.

Although the western pond turtle is considered an aquatic species, they are known to spend a considerable portion of their lives in upland habitats. They may travel across terrestrial habitats as much as 0.6 mile from aquatic habitat and radio-tracking studies have recorded individuals occurring on land for up to seven months out of each year (Bury and Germano 2008). Some animals may be active year-round, while others may enter terrestrial overwintering sites in October or November and reemerge in March or April (Bury and Germano 2008). Turtles from river and stream habitats often leave the watercourse in late fall and move up to 1,500 feet into upland habitats to overwinter (Bury and Germano 2008).

The increased flows and SSCs during reservoir drawdown could result in impacts on the western pond turtle if conditions cause turtles to move away from underwater refugia and thus become more vulnerable to predators, or if conditions diminish foraging opportunities. Increased SSCs following dam removal for 2 to 4 months depending on the water year type) would have a short-term but unsubstantial effect on this species' foraging and habitat use because of their ability to forage in, and escape to, adjacent upland habitat if needed. In addition, as discussed in Appendix C, Section C.2.2, elevated SSCs are natural during winter and spring in the Middle and Lower Klamath River and western pond turtles are adapted to these conditions. Other important habitat features, such as availability of basking sites, are not anticipated to be impacted by the short-term increase in flows and SSCs. Both adults and hatchlings that emerged the spring of dam removal year 2 (year of drawdown) may be present during these flows and affected by increased sediments. As western pond turtle eggs are laid in upland habitats, neither flows or SSCs would affect this life stage.

Significance

No significant impact for amphibians (Pacific tailed frog, southern torrent salamander, northern red-legged frog) and reptile (western pond turtle) populations due to short-term increases in SSCs or flows

Significant and unavoidable impact for individual foothill yellow-legged frog egg masses, if present, due to short-term increases in SSCs

Beneficial for all amphibian and reptiles due to long-term improved water quality

Potential Impact 3.5-17 Effects on benthic macroinvertebrates short-term dewatering and sedimentation and long-term alterations to habitat.

Impacts to benthic macroinvertebrates (BMIs) are anticipated on populations present in the reservoir footprint as a result of reservoir drawdown and drying of the habitat, and downstream of iron Gate Dam as a result of sediment transport and deposition. During reservoir drawdown, it is anticipated that the removal of reservoirs would result in mortality to invertebrates through desiccation, except in locations where tributaries continue to provide streamflow.

Dam removal would result in sedimentation downstream of the reservoirs in the Hydroelectric Reach and the Middle Klamath River, from Iron Gate Dam to approximately Cottonwood Creek (see also Potential Impact 3.11-5). In the short term, the Proposed Project could alter bedload sediment transport and deposition and affect BMIs (Reid and Anderson 2000, Orr et al. 2008). As a result, impacts on BMI would be most substantial between Iron Gate Dam and Willow Creek (about 4.5 river miles downstream of Iron Gate Dam), but extend to Cottonwood Creek (approximately eight RMs downstream of Iron Gate Dam) (see also Potential Impact 3.11-5). Impacts are expected to include physiological stress, reduced growth, and potentially mortality.

While a large proportion of the BMI population in the Hydroelectric Reach and in the Middle Klamath River downstream of Iron Gate Dam would be affected in the short term, BMI populations would be expected to recover quickly due to the many sources for recolonization (i.e., tributaries) and their rapid dispersion through drift or aerial movement of adults. In a summary of multiple dam removal studies, Foley et al. (2017) report that following dam removal, BMI abundance tends to increase downstream of a dam and species assemblages transition to resemble sites upstream of the former dam. Furthermore, some BMI species can double their population size in days to weeks, such that they quickly recover once the initial sediment pulse has passed. Full recovery of BMI communities is typically observed within a year following disturbance (Tsui and McCart 1981, Anderson et al. 1998). Tullos et al. (2014) found that BMI communities downstream of the Brownsville (Calapooia River, Oregon) and Savage Rapids (Rogue River, Oregon) dams resembled upstream control sites within a year after dam removal.

In the long term, the Proposed Project would restore connectivity among the Lower Klamath Basin, the Hydroelectric Reach and its tributaries, and the Upper Klamath Basin, and would rehabilitate and increase availability of riverine habitat within the Hydroelectric Reach. Increased habitat availability and improved habitat quality would be beneficial to BMI populations.

Additional information regarding sedimentation impacts and BMI analysis is provided in Section 3.3.4.10 *Benthic Macroinvertebrates* and Section 3.3.5.8 *Aquatic Resource Impacts*.

Significance

No significant impact in the short term

Beneficial in the long term

Potential Impact 3.5-18 Short-term impacts on amphibian and reptile in riverine habitats from sedimentation.

Dam removal would result in sedimentation downstream of the reservoirs in the Hydroelectric Reach and the Middle Klamath River, from Iron Gate Dam to approximately Cottonwood Creek, located approximately eight RM downstream of Iron Gate Dam (see also Potential Impact 3.11-5). These sediment inputs are expected to result in sand and finer bedload sediment transport and deposition in river reaches downstream of the reservoirs, which could fill riffle substrate in some areas, reducing localized habitat for the larval phases of amphibian species (e.g., Pacific giant salamander). Western pond turtle adults may move upland during the sediment release, and since their eggs are laid on land, this life stage would not be affected.

As discussed above in Potential Impact 3.5-16 (potential impacts due to short-term elevated SSCs), targeted foothill yellow-legged frog surveys by PacifiCorp in 2003 did not document the species in mainstem and tributary locations identified at as the most likely to support the foothill yellow-legged frog, including Bogus Creek located approximately 0.2 RM downstream of Iron Gate Dam and Cottonwood Creek located approximately eight miles downstream of Iron Gate Dam (PacifiCorp 2004a), and as a result no impacts are anticipated. If suspended sediment settles further downstream, and/or foothill yellow-legged frogs are present, the presence of settled fine silt in slow moving portions of the river reaches would not likely affect the adhesion of egg masses based on foothill yellow-legged frogs loosen algae and sediment that could enhance the ability of egg masses to adhere to the substrate (Rombough and Hayes 2005).

In the short term, these transient sediment deposits would be highly erodible during subsequent high flow events, leading to a short residence time (i.e., likely one year or less except during dry years) (see also Potential Impact 3.11-5). As a result, the impacts would be less than significant in the short term.

Significance

No significant impact in the short term

Potential Impact 3.5-19 Impacts on native amphibians from loss of reservoir habitat.

The loss of reservoir habitat will reduce lake and pond-type habitat that supports the non-native American bullfrog (PacifiCorp 2004a), which are known to prey upon and out-compete native amphibians (CDFW 2018b). The American bullfrog range includes Northern California (California Herps 2018a) and the species has been documented in the Primary Area of Analysis. PacifiCorp (2004a) noted that the bullfrogs were widely distributed and included reservoir habitats such as Iron Gate Reservoir, but also noted that breeding habitat was present in shallow and backwater habitats in low gradient reaches, located between the Copco No 1. Reservoir and the Oregon-California state line (PacifiCorp 2004a). Although removing reservoir habitat would reduce pond and lake-type habitat for the American bullfrog, suitable bullfrog habitat would remain on the Klamath River, and would including restored backwater and wetland habitat. Therefore, native amphibians would continue to experience similar predation effects as observed where species ranges overlap with the American bullfrog, as a result, there is no significant impact as a result of the Proposed Project.

Significance

No significant impact

Potential Impact 3.5-20 Short- and long-term impacts on western pond turtle and amphibians from reduced BMI populations.

Dam removal would result in sedimentation downstream of the reservoirs in the Hydroelectric Reach and the Middle Klamath River, from Iron Gate Dam to approximately Cottonwood Creek, located approximately eight RM downstream of Iron Gate Dam (see also Potential Impact 3.11-5). The period of greatest initial impact would occur during the months following drawdown where BMI production would likely decrease in the reach from Iron Gate Dam to approximately Cottonwood Creek, located approximately miles downstream of Iron Gate Dam. As discussed in Potential Impact 3.5-17, BMI populations would be expected to recover quickly because of the many sources for recolonization, their rapid dispersion through drift or aerial movement of adults, and ability to double their population size in days to weeks, and as a result, long-term impacts on foraging turtles from a short-term reduction in BMI sources would be less than significant. Further, western pond turtle do not exclusively rely upon BMIs in their diets. Turtles also forage on aquatic plants, frogs, crayfish, frogs, and fish. As a result of western pond turtle's diverse diet, and the presence of BMI sources in tributaries to the Hydroelectric Reach and Middle Klamath River, short-term impacts on foraging turtles from reduced BMI populations would be less than significant.

Special-status amphibians were considered for impacts from reduced BMI populations; however, no short-term or long-term impacts were identified. Foothill yellow-legged frogs were not documented during PacifiCorp (2004a) surveys in reaches downstream to Cottonwood Creek and are not anticipated to be present and affected by reduced BMI populations. Pacific tailed frog and southern torrent salamander habitat is not present in this reach, as they use high-gradient headwater stream habitat.

Significance

No significant impact

Potential Impact 3.5-21 Short- and long-term impacts on birds and bats from loss of aquatic reservoir and shoreline vegetative habitat.

Following dam removal, reservoir aquatic habitat would transition to wet or upland habitat depending on future hydrologic and physical (topographic) conditions. Following drawdown of the reservoirs, existing upland vegetation is expected to remain unchanged and contribute to successional processes on newly exposed areas. Surrounding the reservoirs, upland tree-dominant vegetation types include Montane Hardwood, Montane Hardwood-Conifer, and Juniper (Section 3.5.2.1 *Vegetation Communities*; Appendix G). Trees dominant in these vegetation types are native trees and drought tolerant; although some of the trees immediately adjacent to the reservoir may currently be benefiting from an elevated water table, lowering groundwater following reservoir drawdown it is not expected to result in a large die-off. In contrast, tree-dominated wet habitats surrounding the reservoir (i.e., Montane Riparian and Palustrine Forested Wetland [Section 3.5.2.1 *Vegetation Communities*; Appendix G]) may transition to upland and existing trees including Oregon ash and bigleaf maple may be impacted; they may turn to snags for perching, form cavities for nesting birds and bats, or ultimately fall to the ground to provide habitat for small mammals and insects which birds and bats may forage. The Proposed Project includes several actions to encourage rapid revegetation with native riparian species including trees as defined in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) which will ultimately provide for tall structure habitat adjacent to the water course to support nesting birds and bats, and provide cover for other wildlife species. (Additional information available above under Potential Impact 3.5-2).

Water birds that currently use the reservoirs seasonally during migration and/or for overwintering would be affected by the loss of this aquatic habitat for nesting, foraging, loafing (resting on the water), and roosting. The loss of aquatic reservoir habitat would also reduce foraging opportunities for fish-eating birds including bald eagle, osprey, merganser, cormorant, egret, and heron (including the great blue heron rookery documented at Copco No. 1 Reservoir (PacifiCorp 2004b). Historically, two bald eagle nests were documented near Copco No. 1 Reservoir: one within 0.5 mile in 2002, and a second within two miles, which was monitored between 1993 and 1997 (*Appendix B: Definite Plan – Appendix J*). Bald eagles are opportunistic foragers and hunt mainly for fish and waterfowl (Peterson 1986, Zeiner et al. 1990b); however, they will also feed on small mammals and other small vertebrates and carrion (Buehler 2000). During and following reservoir drawdown, eagles would likely consume a variety of live and dead mammals and birds present year-round; there may be also be an enhanced opportunity for eagles to consume stranded or dead fish as a result of the Proposed Project. Bald eagles would use riverine habitat, along with other fish-eating species, or other aquatic habitat outside the Proposed Project for foraging. The initial drawdown of the reservoirs may strand invertebrates or fish and provide short-term foraging opportunities for a variety of birds. In addition, there may be an increase in foraging opportunities for these species presented by the return of salmon to the riverine system that replaces the reservoirs.

Changes in food availability for birds such as dabbling ducks that consume aquatic vegetation and invertebrates would occur. For example, these species would use the river or other aquatic habitat outside the Proposed Project for foraging once the reservoirs are gone. Similarly, foraging over aquatic habitat by swifts and bats that feed on flying insects would be reduced; however, as discussed in Potential Impact 3.5-17, once BMI populations reestablish after drawdown, swifts and bats would be able to feed over riverine habitat. Although golden eagles will eat fish, they primarily feed on small to medium-sized mammals (e.g., rabbits, squirrels), and therefore, are unlikely to be substantially affected by the change in aquatic habitat.

It is anticipated that birds (e.g., ducks, eagles, swifts) and bats would continue to use the river for foraging, or would use other aquatic habitat outside of the terrestrial resource Primary Area of Analysis; therefore, impacts in both the short- and long-term would be less than significant.

Significance

No significant impact

Potential Impact 3.5-22 Short-term and long-term impacts on western pond turtle from loss of aquatic habitat.

In the short term, reservoir drawdown would affect shoreline habitat currently used by western pond turtle. The potential impacts on western pond turtle may occur from turtles being entrapped during sediment redistribution, change in temperature on overwintering turtles in reservoir sediment from drawdown, and entrapment in cracks and increased predation during migration over the reservoir footprints following drawdown. As Copco No. 2 Reservoir has not been documented to support western pond turtles and limited habitat is available (e.g., lack of basking areas); the analysis below focuses on Copco No. 1 and Iron Gate reservoirs.

The KRRC proposes to draw down reservoirs between January and March at a maximum drawdown rate of five feet per day (Table 2.7-1, Appendix B: *Definite Plan – Appendix H*). Exposing reservoir sediment to ambient air conditions during and following drawdown will change the temperature of the sediment (more solar exposure and colder nights and possible wind shear). Turtles overwintering in the sediment would then be subject to these changing temperature stresses. There is a potential for erosion and shallow slides to occur at locations currently along the reservoir rims and existing water surface elevations. At Copco No. 1 Reservoir in particular, diatomite (fine-grained sedimentary rock formed from consolidated diatomaceous earth) terrace deposits surround much of the shoreline and extend below the surface waters. These deposits would exhibit low shear strength and would likely be unstable, potentially resulting in shallow slides that could entrap juvenile and adult turtles. Following drawdown, juvenile and adult western pond turtles may be affected including those that may be overwintering in the sediment or are present in the reservoir; turtles overwintering or present on land would not be affected by the sediment redistribution. The KRRC identified the locations of overwintering aquatic habitat (i.e., reservoir levels two meters deep) based on bathymetry data (AECOM et al. 2017), and in considering proximity to suitable basking and nesting habitation locations identified by PacifiCorp (2004a), the locations where there is the highest potential for redistribution of sediment to affect turtles at Copco No. 1 Reservoir are the northern arm of the reservoir near Beaver Creek and at Iron Gate Reservoir in the southeast cove, north cove at Camp Creek, and at the confluence of Jenny Creek and Fall Creek (Figures 3.5-7 and 3.5-8).

These locations are also consistent with the locations where the majority of turtles were documented during the 2018 wildlife survey—most observations at Copco No. 1 Reservoir were northern Beaver Creek and Raymond Gulch coves and most observations at Iron Gate Reservoir were along the northern half of the reservoir (Mirror Cove and near Camp Creek and Jenny Creek) (CDM Smith 2018c).

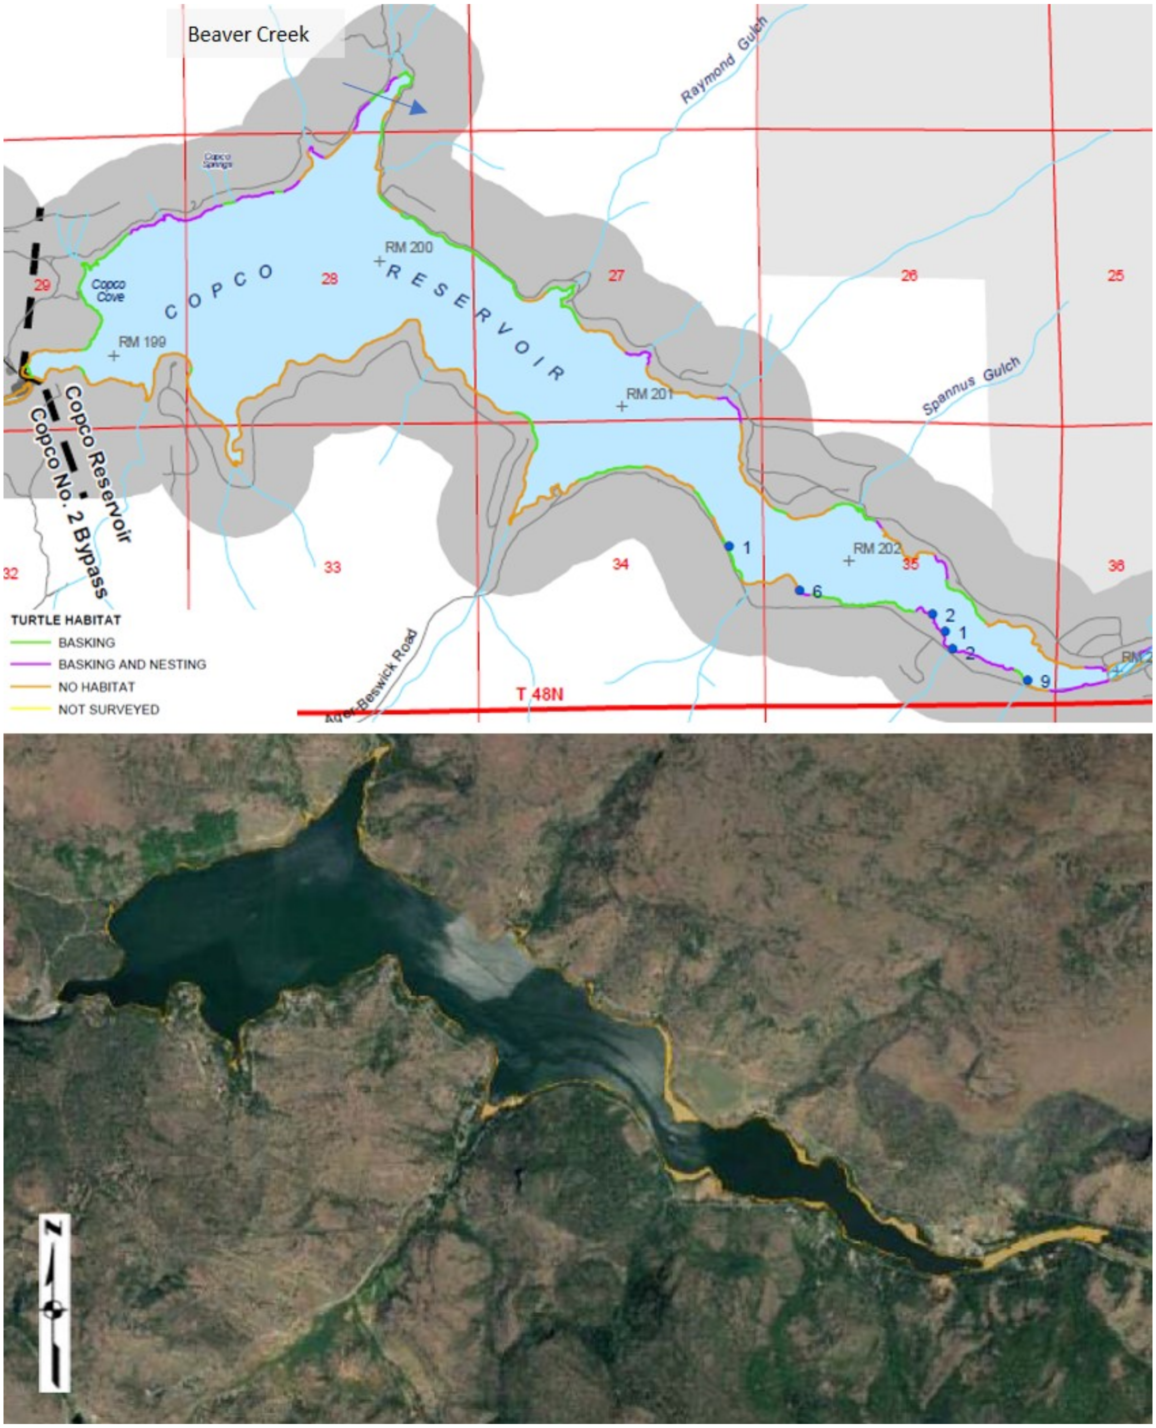

Figure 3.5-7. Western pond turtle suitable basking and nesting habitat in green and purple (top) and potential aquatic overwintering habitats in water depths of less than two meters in yellow (bottom) at Copco No. 1 Reservoir (PacifiCorp 2004a, AECOM et al. 2017).

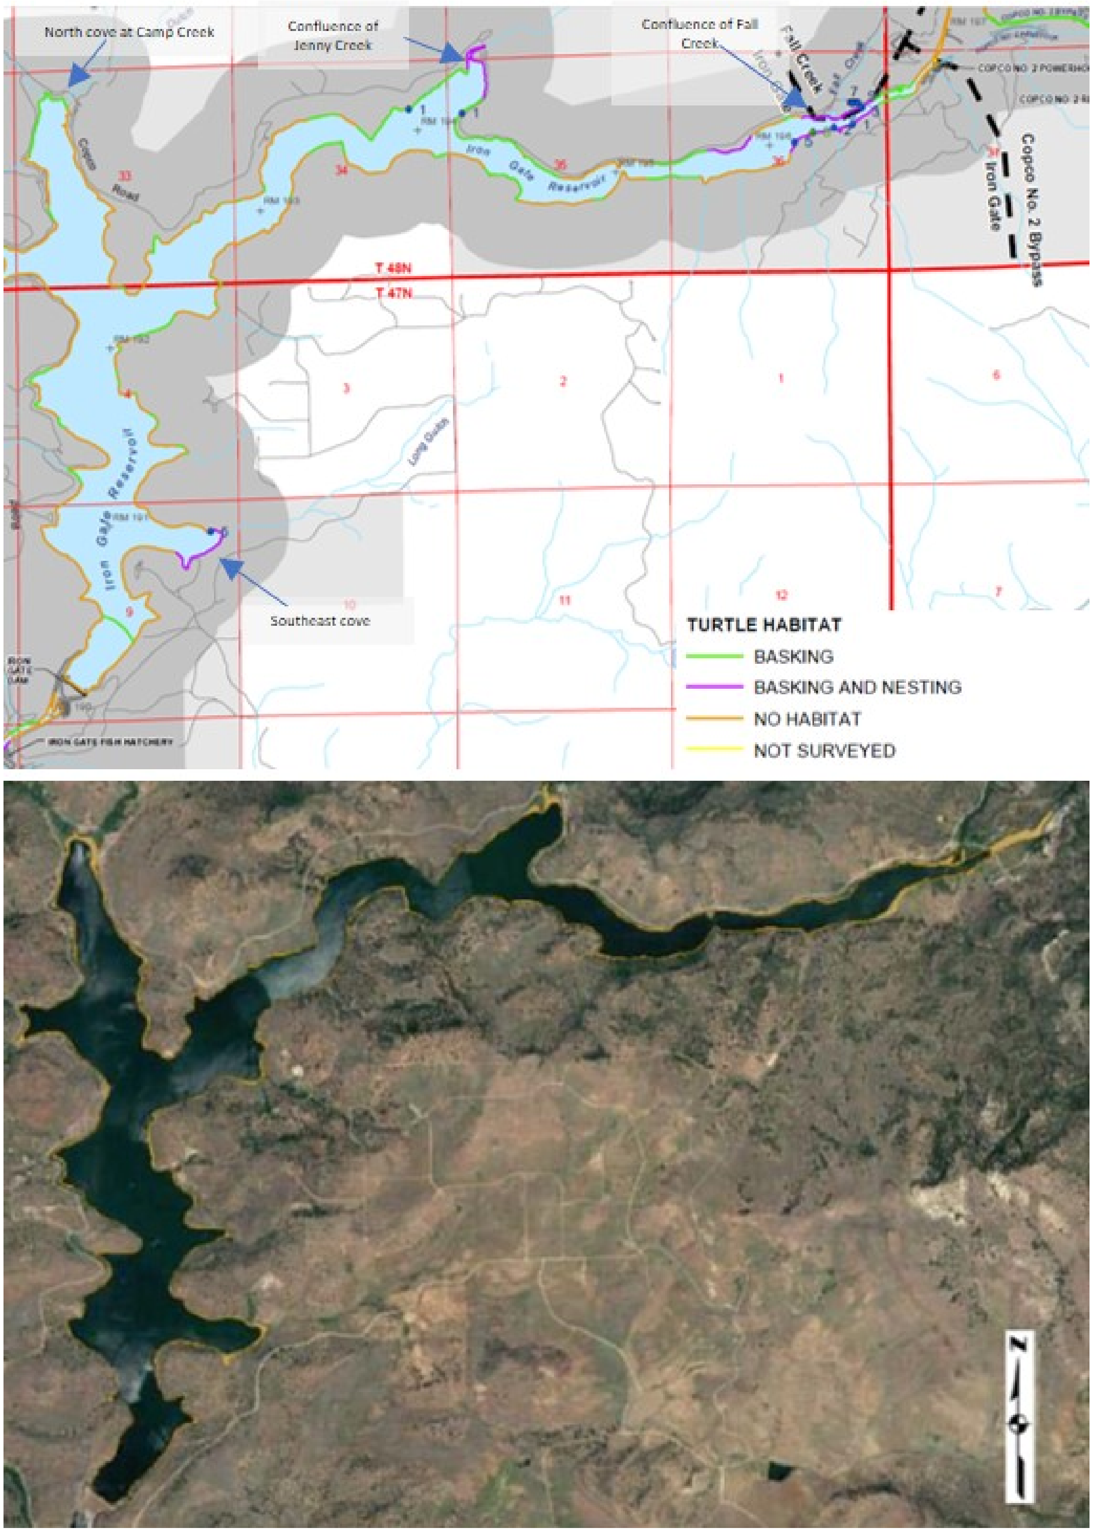

Figure 3.5-8. Western pond turtle suitable basking and nesting habitat in green and purple (top) and potential aquatic overwintering habitats in water depths of less than two meters in yellow (bottom) at Iron Gate Reservoir (PacifiCorp 2004a, AECOM et al. 2017).

There is also the potential for western pond turtles to be entrapped in cracks in the sediment deposits remaining in the reservoir footprints following drawdown (see also Potential Impact 3.11-5). The sediment underneath the reservoir is approximately 80 percent water by volume, and after the reservoir is drawn down, the sediment is expected to dry, decrease in thickness, and form cracks. The sediment drying process may result in turtles becoming trapped in the cracks and subject to predation.

Additionally, migrating hatchlings that emerge in spring could travel distances over barren soil to the river and may become entrapped in cracks formed by the mud and subject to increased predation from avian predators. Draining the reservoirs may also leave western pond turtles vulnerable to predation from a limited cover and forage (lack of vegetation and invertebrates along the shoreline) and subject to thermal stress. In one study, emerged hatchlings moved in short (<150 feet) increments, from one stop-over site to another until reaching aquatic habitat, and hatchlings tend to bury themselves under vegetation or debris and remain inactive for up to 21 days (Rosenberg and Swift 2010). With drying sediment and inability to hide under vegetation or debris, this may increase the potential of predation and thermal stress on hatchlings migrating during the spring of the drawdown year.

The western pond turtle population in the Klamath River has been estimated to be approximately 5 to 15 turtles per river mile (Bury 1995, as noted in PacifiCorp 2004). At this estimated density, turtles in Copco No. 1 Reservoir would number between 24 and 43 and in Iron Gate would be between 31 and 56. (The length of the reservoirs was calculated using the middle line of the reservoirs [i.e., Copco No. 1 Reservoir at 4.8 miles and Iron Gate Reservoir at 6.2 miles]). Available information regarding western pond turtle sightings is from 2002 and 2018 (PacifiCorp 2004a; K. Stenberg, Principal, CDM Smith, pers. comm., July 2018). Surveys conducted in Copco No. 1 Reservoir in 2002 documented 12 turtles while surveys in 2018 documented 31 to 36, which are similar to the anticipated density estimate. Surveys conducted in Iron Gate Reservoir in 2002 documented 8 turtles, while surveys in 2018 documented 17, which is lower than the anticipated density estimates. However, the goal of these surveys was not to document all individual turtles in the reservoirs, but rather note individuals basking; surveys were not inclusive of turtles underneath the water nor on land. As a result, the number of turtles documented using the reservoirs are likely an underestimate of the reservoir population.

It is not possible to predict how many hatchlings, juveniles, or adults would be affected in the short term by the potential effects described above. As discussed above, the survey results may not account for all turtles in the reservoir, as some may be underneath the water or on land. Also, an estimate of hatchlings is not possible as the age of the turtles is not known (females reach sexual maturity when they are about 8 to 10 years old]) and not all females lay eggs each year, while some may lay two clutches (California Herps 2018b). In addition, some turtles may be overwintering on land during the drawdown and not affected by sediment redistribution, and juveniles, adults, and hatchlings may not migrate over the dewatered reservoir, but rather may go around within more vegetated habitats or disperse into nearby tributaries.

Although exact numbers of take are not possible to identify, the impact on the reservoir population may be significant. Implementation of Mitigation Measure TER-4 (western pond turtle rescue after reservoir drawdown operations), developed in coordination with CDFW, would reduce these potential short-term impacts to less than significant.

Please note that in addition to requiring Mitigation Measure TER-4, the State Water Board has authority to review and approve any final plan developed to protect western pond turtle through its water quality certification under Clean Water Act Section 401. The State Water Board has issued a draft water quality certification[131] which sets forth monitoring and adaptive management requirements for an Amphibian and Reptile Management Plan as Condition 15.

In the long term, riverine habitat would continue to support the life history functions of western pond turtle. Although western pond turtles are documented throughout the Proposed Project reservoirs and along several reaches of the terrestrial resources Primary Area of Analysis, precise population data are not available. Thus, it is not possible to quantitatively assess population-level effects as a result of the Proposed Project. However, it is possible to assess the long-term potential for change in the amount of suitable habitat for supporting western pond turtle populations.

Based on the turtle nesting habitat suitability mapping conducted in 2002 for Copco No. 2 Bypass, Copco No. 1 Reservoir, and Iron Gate Reservoir, of the 40 miles of existing river and reservoir shoreline, only approximately 5.4 miles (13 percent) possess suitable nesting and basking habitat. An additional 13 miles (33 percent) have suitable basking habitat structure (i.e., logs, large rocks, or patches of persistent emergent vegetation), but do not possess high-quality potential nesting habitat because of steep slopes, developed shorelines, or shorelines with dense understory vegetation (PacifiCorp 2004a).

Under the Proposed Project, approximately 90 percent of the existing aquatic surface area would be removed. Aquatic habitat at the reservoirs would be converted to riverine, riparian, and upland habitat, depending on future hydrologic and physical (topographic) conditions. The existing surface area of the three California reservoirs is approximately 1,950 acres (Copco No. 1 Reservoir [1,000 acres], Iron Gate Reservoir [944 acres] [FERC 2007], Copco No. 2 Reservoir [6 acres]). Based on historical maps and aerial photos, PacifiCorp (2004a) estimated that approximately 227 acres of aquatic riverine habitat occurred historically (119 acres at Copco No. 1 Reservoir and 108 acres at Iron Gate Reservoir; Copco No. 2 Reservoir was not mapped). Although the overall surface area of aquatic habitat would decrease substantially (i.e., to approximately 195 acres) under the Proposed Project, the impact on western pond turtle would be more directly related to a change in the amount of shoreline habitat.

It is uncertain whether the number of western pond turtles currently present in the Hydroelectric Reach would allow for additional population growth or exceed the carrying capacity of habitat that becomes available along the restored riverbanks in the Hydroelectric Reach. Providing riverine habitat may support a higher density of turtles than that currently observed in the reservoirs. However, if the number of western pond turtles does exceed the carrying capacity of the available habitat along the restored riverbanks, it is uncertain whether they would then disperse into available habitat upstream or downstream along the Klamath River and/or upstream into tributaries that would then be present following the removal of the reservoirs. It is estimated that there are currently 18.4 miles of suitable nesting and basking habitat (PacifiCorp 2004a)

[131] The State Water Board's draft water quality certification is available online at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/lower_klamath_ferc14803/lkp_dwqc.pdf (Accessed December 19, 2018).

surrounding Copco and Iron Gate reservoirs. Following the removal of the reservoirs, approximately 17.7 miles of mainstem and tributary reaches would be re-exposed in the reservoir footprints (see Reservoir Area Management Plan [Appendix B: *Definite Plan – Appendix H*]). Shoreline habitat would then be present on either side of the newly exposed mainstem channel and tributaries (i.e., approximately 17.7 miles), or providing approximately 35 miles of shoreline habitat. Following drawdown, it is anticipated that river flow through the area previously occupied by the Copco No. 1 Reservoir would meander and provide wetland/riparian habitat for turtles, while the river channel in Iron Gate Reservoir would be narrower, with historical channels associated with Jenny Creek and the Camp, Scotch, Dutch creek systems establishing riparian communities (AECOM et al. 2017). Although it is uncertain how much of the newly created mainstem and tributary shoreline habitat would be suitable for western pond turtle, the proposed habitat restoration in these areas would also create and enhance habitat for western pond turtle. The proposed habitat restoration is designed to slow water velocities along the riverbanks and thus has the potential to create backwater and basking habitat used by turtles. Proposed habitat restoration components include manually creating connectivity to tributaries, incorporating floodplain habitat features (e.g., wetlands, swales, side channels), creating shoreline complexity to slow water velocities, and placing large wood habitat features (see Reservoir Area Management Plan [Appendix B: *Definite Plan – Appendix H*]).

For context, the Lower Klamath Project reservoirs represent a small amount of the available open water/shoreline habitat in the Klamath Basin. While quantified information about suitable shoreline habitat in the upper basin is not available, the existing surface area of the Lower Klamath Project reservoirs is approximately 1,950 acres, which is relatively small when compared with the large open water areas and wetland complexes of Upper Klamath Lake (approximately 77,000 acres), Tule Lake (approximately 13,000 acres), or Lower Klamath Lake (approximately 22,000 acres of which approximately 2,200 acres are permanently flooded). Thus, population-level adverse effects to turtles would not be anticipated in the Klamath Basin due to the loss of aquatic reservoir habitat under the Proposed Project.

As a result of the restored Klamath River shoreline within the Hydroelectric Reach, including specific habitat restoration elements that would benefit western pond turtles (e.g., wetlands, swales, side channels) and a relatively small overall change in reservoir habitat throughout the Klamath Basin, there would be a less than significant long-term impact of the Proposed Project on western pond turtles.

Mitigation Measure TER-4 Western Pond Turtle Rescue After Reservoir Drawdown Operations.

Prior to implementing reservoir drawdown, KRRC shall develop a Western Pond Turtle Rescue and Relocation Plan in coordination with applicable agencies to identify a means of relocating as many turtles as feasible along the reservoir shoreline, assuming conditions are safe for all personnel. It is understood that not all turtles will be found, and not all turtles seen will be able to be captured and relocated. The goal of the plan shall be to apply a good-faith effort to reduce the number of turtles that are subject to mortality such that there will not be a significant impact on Western Pond turtles. The plan shall identify the following components:

- survey timing to cover multiple life stages (adults, overwintering adults, emerging hatchlings) present between initial reservoir drawdown and emergence;

- survey periodicity, focusing observations during periods of highest likelihood of observing these life stages—surveys may be considered complete after an identified number of surveys (e.g., three) does not detect turtles;
- survey locations that focus on suitable nesting habitat and locations where high numbers of turtles were documented during the general wildlife surveys (e.g., Copco Reservoir near Beaver Creek Raymond Gulch coves and at Iron Gate Reservoir in the southeast cove, north cove near Camp Creek, and at the confluence of Jenny Creek and Fall Creek);
- relocation areas in suitable habitat (that provide cover and food resources), which may include lower reaches of tributaries to the Klamath River;
- survey methodology—as nests and young are difficult to locate, an approach of using a trained dog to identify nests should be considered; and
- reporting of survey results within 60 days of the completion of surveys to applicable agencies and the State Water Resources Control Board.

Significance

No significant impact in the short term with mitigation

No significant impact in the long term with mitigation

Potential Impact 3.5-23 Long-term effects on deer from alterations to winter range habitat.

At Copco No. 1 and Iron Gate reservoirs, there are approximately 1,400 acres of inundated land that would become upland habitat (PacifiCorp 2004a). Under the Proposed Project, removing Iron Gate and Copco No. 1 reservoirs would not impact migratory wildlife corridors for deer nor impact deer wintering areas as identified in the Siskiyou County General Plan (Siskiyou County 1980, n.d.); rather the Proposed Project would increase the number of available acres of habitat within critical deer winter range in the long term, benefiting deer by expanding winter range habitat (Hamilton 2011).

Significance

Beneficial in the long term

Potential Impact 3.5-24 Effects on terrestrial species from herbicide use during reservoir restoration activities.

As part of the Proposed Project, the KRRC proposes initiating invasive plant control prior to dam removal year 1, continuing through the plant establishment period (post-dam removal year 1) until post-dam removal year 5 or until the vegetation restoration criteria have been met. The focus areas include newly exposed areas of the reservoir footprints and upland areas. Chemical herbicides would be used as a last resort when all other methods (e.g., manual weed pulling, mowing or cutting, tilling and disking, grazing, solarization) prove to be ineffective (Appendix B: *Appendix H – Reservoir Area Management Plan*).

The KRRC proposes to only use herbicides that have been approved for use by the BLM, CDFW, RWQCB, USFWS, and NMFS and herbicides would be applied by hand either by brushing (stumps and cut stems), wicking and/or spraying by a certified applicator and in accordance with all applicable laws and regulations. Because the herbicide application would be targeted to populations of invasive plants and applied in a very select manner, there would be no significant short-term impacts to special-status plants. There would likely be long-term beneficial effects to rare natural communities, wetlands and riparian vegetation as habitat conditions would be improved by reducing competition from invasive species.

Although the Reservoir Area Restoration Plan (Appendix B: *Definite Plan – Appendix H*) does not identify the types of herbicides that would be used, the KRRC has evaluated several herbicides, and is recommending glyphosate as the primary herbicide to control most of the invasive plant species (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). Glyphosate may be formulated with surfactants to increase their efficacy, and in some cases, toxicity data have indicated that surfactants added to glyphosate are more toxic than glyphosate itself. For example, a Syracuse Environmental Research Associates (SERA 2002) study to evaluate effects of surfactants on the toxicity of glyphosate, noted a major qualitative difference between the effect of glyphosate and glyphosate formulations with a polyethoxylated tallow amine surfactant (used in Roundup) on aquatic and terrestrial organisms. However, a study conducted by the USDA-FS found no evidence that a nonylphenol ethoxylate-based surfactant lead to any level of concern for terrestrial wildlife (Bakke 2003, as cited in CINWECC 2004). Effects of the commonly used glyphosate and glyphosate-based herbicides with surfactant additives are analyzed below.

- Studies and assessments of glyphosate show that ecological risks for focused, short-term eradication efforts are small (Monheit 2003).
- While highly toxic to plants, glyphosate is non-toxic to animals (Williams et al. 2000, as cited in Monheit 2003).
- Glyphosate is poorly absorbed by the digestive track and is excreted essentially unmetabolized (Cornell University EXTOXNET database, Williams et al. 2000, both as cited in Monheit 2003).
- There is no evidence indicating that glyphosate is an immunotoxicant, neurotoxicant, or endocrine disruptor (SERA 2002, as cited in Monheit 2003).
- At typical application rates, none of the acute scenarios studied presented unacceptable risks to wildlife, including predatory birds consuming small mammals (Bautista 2007).

Raptors and terrestrial mammals prey mostly on small mammals and fish[132], and it is plausible that there is a potential risk to the prey species from direct or indirect application of herbicides. However, potential short-term and long-term impacts to raptors would be less than significant because KRRC proposes to (a) only apply herbicides approved by applicable agencies, (b) only apply when it is the most effective control method, (c) only apply by hand and by a certified applicator and in accordance with all applicable laws and regulations, and (d) would not target plants that provide habitat for raptor prey.

Special-status invertebrates were considered, and these invertebrates include pollinators such as the western bumblebee, which is a USDA Forest Service special-status species. There are no USDA Forest Service lands within the Limits of Work where herbicides may be applied, and thus no nexus to evaluate a USDA Forest Service species.

[132] Northern spotted owls prey primarily on small mammals (e.g., mice, voles), golden eagles primarily prey on birds, reptiles, and insects, and bald eagles and osprey primarily prey on fish.

However, potential impacts on pollinators would be less than significant because KRRC proposes to (a) only apply herbicides approved by applicable agencies, (b) only apply when it is the most effective control method, and (c) only apply by hand and by a certified applicator and in accordance with all applicable laws and regulations. As a result, no population-level impacts are anticipated.

Significance

No significant impacts in the short term on special-status plants and wildlife

Beneficial in the long term for rare natural communities, wetlands, and riparian vegetation

Potential Impact 3.5-25 Effects on wildlife from increased habitat for salmonids and changes in hatchery production.

Special-status wildlife such as bald eagle, Barrow's goldeneye, common loon, and western pond turtle may forage on out-migrating natural and hatchery-produced salmonids and/or on returning adult carcasses. The Proposed Project includes continued operation of Iron Gate Hatchery (IGH) and reopening of Fall Creek Hatchery (FCH)[133] for eight years following dam removal.

As discussed in Section 2.7.6 *Hatchery Operations* and Section 3.3.5.6 *Fish Hatcheries*, the total production goals for steelhead and fall-run Chinook salmon at Iron Gate Hatchery would be reduced from the current goal[134], and goals for coho yearling production would remain the same for eight years following dam removal. No data are available to accurately estimate the number of naturally produced smolts in the watershed in comparison with hatchery production, but based on adult returns (Section 3.3.2 [Aquatic Resources] Environmental Setting), hatchery-origin out-migrating fall-run Chinook salmon yearlings and smolts currently comprise approximately 35 percent of all fall-run Chinook salmon smolts outmigrating in the mainstem Klamath River. Under the Proposed Project (Potential Impact 3.3-7) hatchery production of fall-run Chinook salmon would be reduced by around 43 relative to current production (2005 through 2018) for eight years following dam removal. There would be no reduction in smolt outmigration relative to current levels for coho salmon for eight years following dam removal, and no reduction in steelhead (since no steelhead have been released since 2012).

For the first eight years following dam removal, the effect of hatchery production on terrestrial resources would be similar to current conditions. Once hatchery production is ceased (i.e., post-dam removal year 8), the hatchery fish would continue in the system for the next few years (see Section 3.3.5.6 *Fish Hatcheries*). However, in the year of dam removal (i.e., Year 2), both hatchery and natural-origin adults for all species would have access to new habitat for spawning, and thus production from Chinook salmon in new habitat would occur in Year 3 and coho and steelhead in Year 4.

[133] Fall Creek Hatchery ceased fish production in 2003.

[134] Goals at Iron Gate Hatchery for fall-run Chinook salmon yearlings would be reduced by approximately 87 percent, goals for fall-run Chinook salmon smolts reduced by approximately 33 percent, goals for steelhead would be reduced by 100 percent (no steelhead have been released since 2012 steelhead production is not a part of the Proposed Project)

Overall, the Proposed Project would open access to additional habitat for fish spawning, production, and migration and would increase prey and overall nutrient distribution for wildlife (see Section 3.3.5.9 *Aquatic Resource Impacts*). It is anticipated that juvenile fish production would increase as early as dam removal Year 3, and an increase in adult returns as soon as dam removal Year 4 (when the first progeny of adults using newly accessible habitat would return). Special-status bald eagle, Barrow's goldeneye, common loon, and western pond turtle forage on a variety of prey, including fish, and increasing juvenile and adult fish in the Klamath River system would result in an overall beneficial effect on these special-status wildlife.

Significance
Beneficial

Potential Impact 3.5-26 Impacts on special-status wildlife from Bogus Creek flow diversions.
Under the Proposed Project, up to 8.75 cfs of water would be diverted from Bogus Creek to operate Iron Gate Hatchery for eight years (through post-dam-removal Year 7), as described in Section 2.7.6 *Hatchery Operations*. Seasonal diversions would range from zero cfs during the summer (June through September), to 6.5 cfs during fall (October and November), 8.75 cfs during winter (December), 3.75 cfs during the late winter (January through March), and 8.25 cfs during spring (April through May). The precise diversion location is not proposed at this time, but it is anticipated to be within Bogus Creek less than 1,000 feet upstream from the confluence with the Klamath River. This would result in a maximum 1,000-foot bypass reach in lower Bogus Creek, which would experience lower fall, winter, and spring flows than occur under existing conditions.

Flow diversions have the potential to affect aquatic amphibians and reptiles, if present. Based on PacifiCorp surveys in 2002 and 2003 throughout the lower 492 feet and lower 0.5 mile of Bogus Creek, respectively, no special-status amphibians or reptiles were documented. Results specifically noted that no special-status foothill yellow-legged frogs or Pacific tailed frogs were present. Non-special-status species including common garter snake and fence lizards were observed during these surveys.

The proposed lack of diversions during June through September, and the proposal to operate the hatchery diversion to maintain a minimum of 50 percent of the instream flow in the creek at the point of diversion, means that flow-related adverse impacts on special-status wildlife in the Bogus Creek bypass reach, if they are present, are unlikely to occur. The KRRC also proposes to coordinate with NMFS and CDFW to assess conditions in Bogus Creek and to minimize the potential effects of Bogus Creek diversions on Coho salmon and their critical habitat (Section 2.7.6 *Hatchery Operations*). If sufficient water is maintained in the channel to support anadromous fish passage, then habitat would also be suitable for any special-status wildlife that are present.

However, based on the potential for low flows (less than 4.5 cfs) in the Bogus Creek bypass reach during some years, and the uncertain commitment under the Proposed Project to ensure flows to protect anadromous salmon volitional migration, there could be significant flow-related impacts to any special-status wildlife that are present. Mitigation Measure AQR-3 is included in this EIR (Section 3.3.5 *Potential Impact 3.3-23*) to ensure that the minimum flow requirement for anadromous fish species is released, and this would also provide assurance of suitable habitat for special-status amphibians and reptiles in the Bogus Creek bypass reach, if they are present. Implementation of Mitigation Measure AQR-3 would reduce potential impacts to less than significant.

Significance
No significant impact with mitigation

Potential Impact 3.5-27 Impacts on special-status wildlife from Fall Creek flow diversions.
Under the Proposed Project, up to 9.24 cfs of water would be diverted from Fall Creek to operate Fall Creek Hatchery for eight years (through post-dam-removal Year 7), as described in Section 2.7.6 *Hatchery Operations*. Seasonal diversions would range from 0.58 cfs during June, to 8.48 cfs during October, 9.24 cfs during November, and less than 2 cfs during the spring (February through May) (Section 2.7.6 *Hatchery Operations*). In addition, the City of Yreka maintains a water right to divert up to 15 cfs from Fall Creek for municipal purposes (City of Yreka 2012).

The City of Yreka is required to bypass a minimum flow of 15 cfs or the natural flow of Fall Creek, whenever the natural flow is less than 15 cfs. The Fall Creek Hatchery diversion and return flow points would occur between the City of Yreka water supply intake and the City's compliance point for the Fall Creek minimum flow, which is at the Fall Creek USGS gage (USGS 11512000). Between the Fall Creek Hatchery diversion and return flow points, the flow remaining in Fall Creek after the diversions for the City of Yreka and the Fall Creek Hatchery would usually be greater than 15.0 cfs, but it could occasionally be slightly less than 15.0 cfs in late summer to early fall (i.e., mid-July to mid-September) when Fall Creek flows reach a minimum (Figure 2.7-13). However, the flow downstream of the hatchery return flow would be generally similar to the flow under existing conditions and a substantial reduction in instream flows is not anticipated due to operation of Fall Creek Hatchery.

Surveys conducted at Fall Creek by PacifiCorp (2004a) documented northern sagebrush lizard (BLM sensitive) at Lower Fall Creek Falls and western pond turtle in a ponded wetland area that was created by a beaver pond near Iron Gate Reservoir. Non-special-status species documented include Pacific chorus frog, Pacific giant salamander larvae above and below Fall Creek diversion dam, western fence lizard, terrestrial garter snake, and common kingsnake. Mammals observed included bobcat and deer. As the Proposed Project would maintain approximately 15 cfs or greater flows in Fall Creek, there would be no impact to special-status wildlife compared to existing conditions.

Significance
No significant impact

Potential Impact 3.5-28 Impacts on sensitive habitats and special-status terrestrial wildlife and plant species from construction activities on Parcel B lands.
The Secondary Area of Analysis was used to evaluate potential impacts on sensitive habitats and special-status species on Parcel B lands. As discussed in Section 2.7-10 *Land Disposition and Transfer*, as part of the Proposed Project, Parcel B lands would be transferred to the states (i.e., California, Oregon), as applicable, or to a designated third-party transferee, following dam removal. The outcome of the future Parcel B land transfer is speculative with regard to land use; while the lands would be managed for the public interest, this could include open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially others.

It is likely that there would be at least some construction for recreation facilities, active restoration, fencing, trail-building, or other land management activities. To the extent there are construction activities, these could involve the same types of potential short-term impacts to sensitive habitats and to special-status terrestrial wildlife and plant species as described in Section 3.5.5.1 *Vegetation Communities*, 3.5.5.2 *Culturally Significant Species*, and Section 3.5.5.3 *Special-status Species and Rare Natural Communities*. Future land use activities that involve active wetland and riverine restoration would be likely to result in long-term benefits to sensitive habitats and special-status terrestrial wildlife and plant species within the Secondary Area of Analysis. The special-status species that have the potential to occur within the Secondary Area of Analysis would be a subset of the species evaluated for the Primary Area of Analysis (Table 3.5-4 and 3.5-5), since the Secondary Area of Analysis is proximal to a portion of the Primary Area of Analysis. In the long term, if managed grazing activities were to occur beyond the level occurring under existing conditions, this could result in reduced habitat diversity and erosion-related significant impacts on special-status species, vegetation communities, and wetlands within the Secondary Area of Analysis.

To the extent there are construction activities under future land uses, it would be appropriate to implement the terms and conditions recommended to FERC relating to protection of sensitive habitats and special-status species and to include measures that provide the same or better level of protection for sensitive habitats and special-status terrestrial wildlife and plant species as the measures specified in Mitigation Measures WQ-1 and TER-1 through TER-4, and Recommended Terrestrial Measures 1 through 13, as modified for construction involved in the particular future land use activity or activities that result from the transfer of Parcel B lands. These measures represent protection under a broad range of large and small construction projects, both in-water and in the dry, and are likely to cover the range of construction activities that would support the various public land uses anticipated under the KHSA. If implemented as part of construction activities under future land uses, these measures would reduce impacts to less than significant. However, because the State Water Board cannot ensure implementation of these future measures, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance
Significant and unavoidable

3.5.5.4 Wildlife Corridors and Habitat Connectivity

Potential Impact 3.5-29 Long-term effects on wildlife from alteration of wildlife movement corridors.
Removal of the Lower Klamath Project reservoirs, penstocks, and restoration of the pre-dam river channel would eliminate areas of wide, deep water crossings that currently represent a hindrance to large and small mammal movements from one side of the river to the other or upland migration for reptiles. Following removal of the reservoirs, relatively narrow and shallow water crossing points would be available for both large and small terrestrial species to move across the river. This would provide long-term benefits to wildlife in the terrestrial resources Primary Area of Analysis by increasing the amount of habitat available to these species, making them less vulnerable to disease, malnutrition, and other environmental stressors as compared with existing conditions.

To facilitate the restoration of reservoir habitat and growth of planted vegetation, permanent cattle exclusion fencing would be installed around the reservoir restoration areas (Appendix B: *Definite Plan - Appendix H*) prior to drawdown or shortly after the pioneer seeding. (It is unknown at this time if this fencing would remain following the transfer of Parcel B lands.) Cattle are currently allowed to free-range graze on the hillsides adjacent to the Lower Klamath Project reservoirs, and the purpose of proposed cattle exclusion fencing would be to prevent cattle from grazing on newly restored vegetation once the reservoirs are drawn down. The fencing would be wildlife-friendly and as such would allow for deer, turtles, and small mammals to move under or over the fencing, while preventing cattle from moving beyond the fencing. As wildlife would be able to safely move under or over the cattle exclusion fencing, there would be no long-term impact due to alteration of wildlife movement corridors.

Significance

Beneficial in the long term due to overall increased wildlife movement opportunities

No significant impact with respect to the use of wildlife-friendly fencing

Potential Impact 3.5-30 Long-term effect on terrestrial wildlife from an increase in the distribution of salmon-derived nutrients upstream of Iron Gate, Copco No. 1 and Copco No. 2 dams.

The Proposed Project would result in changes to the amount and distribution of habitat types and consequently to the species that depend on them, as described in Potential Impact 3.5-25. Removal of the Lower Klamath Project would enable salmon and other fish species to migrate to reaches upstream of Iron Gate Dam, providing nutrient-rich food for terrestrial species, including bald eagles, osprey, and many other species of birds and mammals. These consumers would subsequently deposit these marine-derived nutrients into terrestrial habitats, increasing productivity of riparian vegetation and benefiting the terrestrial ecosystem as a whole (Hilderbrand et al. 2004, Merz and Moyle 2006, Moore et al. 2011). This would be a beneficial effect.

Significance

Beneficial

3.6 Flood Hydrology

This section focuses on potential changes to flood hydrology due to the Proposed Project. Historical and current surface water hydrology in the Klamath Basin are complex; however, only elements of the hydrology related to the Proposed Project's potential to impact floodplain inundation extent and flood risk to people and/or structures are described in this section. The potential for changes in flood hydrology and/or floodplain inundation extent to impact aquatic resources is discussed in Section 3.3; the potential to impact terrestrial resources is discussed in Section 3.5. Other sections of this EIR discuss water quality (Section 3.2), groundwater (Section 3.7), and water supply/water rights (Section 3.8).

Many comments were received during the NOP public scoping process relating to flood hydrology (Appendix A). These comments were primarily concerned with the potential effects of dam and reservoir removal on flood hydrology and impacts to flood inundation areas downstream of the Lower Klamath Project. Examples of specific concerns include the potential for flooding to become more likely and/or flood inundation areas to expand, and concerns about the associated economic impacts, loss of structures, and public safety. See Appendix A for further summary of the flood hydrology comments received during the NOP public scoping process, as well as the individual comments themselves.

3.6.1 Area of Analysis

The Area of Analysis for flood hydrology includes the Klamath River downstream of the California-Oregon border, which lies in portions of three California counties (Siskiyou, Humboldt, and Del Norte). Hydrologic characteristics of features in the Upper Klamath Basin in Oregon are discussed in this section as they pertain to potential impacts to stream flow inputs into California.

The downstream outlet of Upper Klamath Lake in Oregon is the Link River Dam which releases water into the Link River. About one mile below the Link River Dam, the Link River flows into Keno Reservoir/Lake Ewauna. The Keno Reservoir/Lake Ewauna is controlled by the Keno Dam near Keno, Oregon. The Klamath River begins at the historical outfall of Lake Ewauna, which is upstream of Keno Dam. Water impounded by Keno Dam floods the historical Lake Ewauna outfall. The Klamath River flows approximately 250 miles from the historical outfall of Lake Ewauna, through Keno Dam, through the Lower Klamath Project, and to the Pacific Ocean near Klamath, California (see Figure 3.6-1).

The Upper Klamath Basin upstream of Iron Gate Dam includes Upper Klamath Lake and its tributaries, Link River, the Keno Reservoir/Lake Ewauna, and the Hydroelectric Reach (from J.C. Boyle Dam to Iron Gate Dam). Facilities that are part of the Klamath Hydroelectric Project and USBR's Klamath Irrigation Project control surface water distribution in the Upper Klamath Basin via diversions from the Upper Klamath River (FERC 2007) (see also Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*). The Mid Klamath Basin includes the areas of the Klamath Basin from Iron Gate Dam downstream to the Trinity River confluence. Tributaries to the Mid Klamath Basin include the Shasta, Scott, and Salmon Rivers. The Lower Klamath Basin extends from the Trinity River confluence to the Pacific Ocean and includes the Klamath River Estuary and mouth, which are on the northern California coast approximately 50 miles south of the Oregon border.

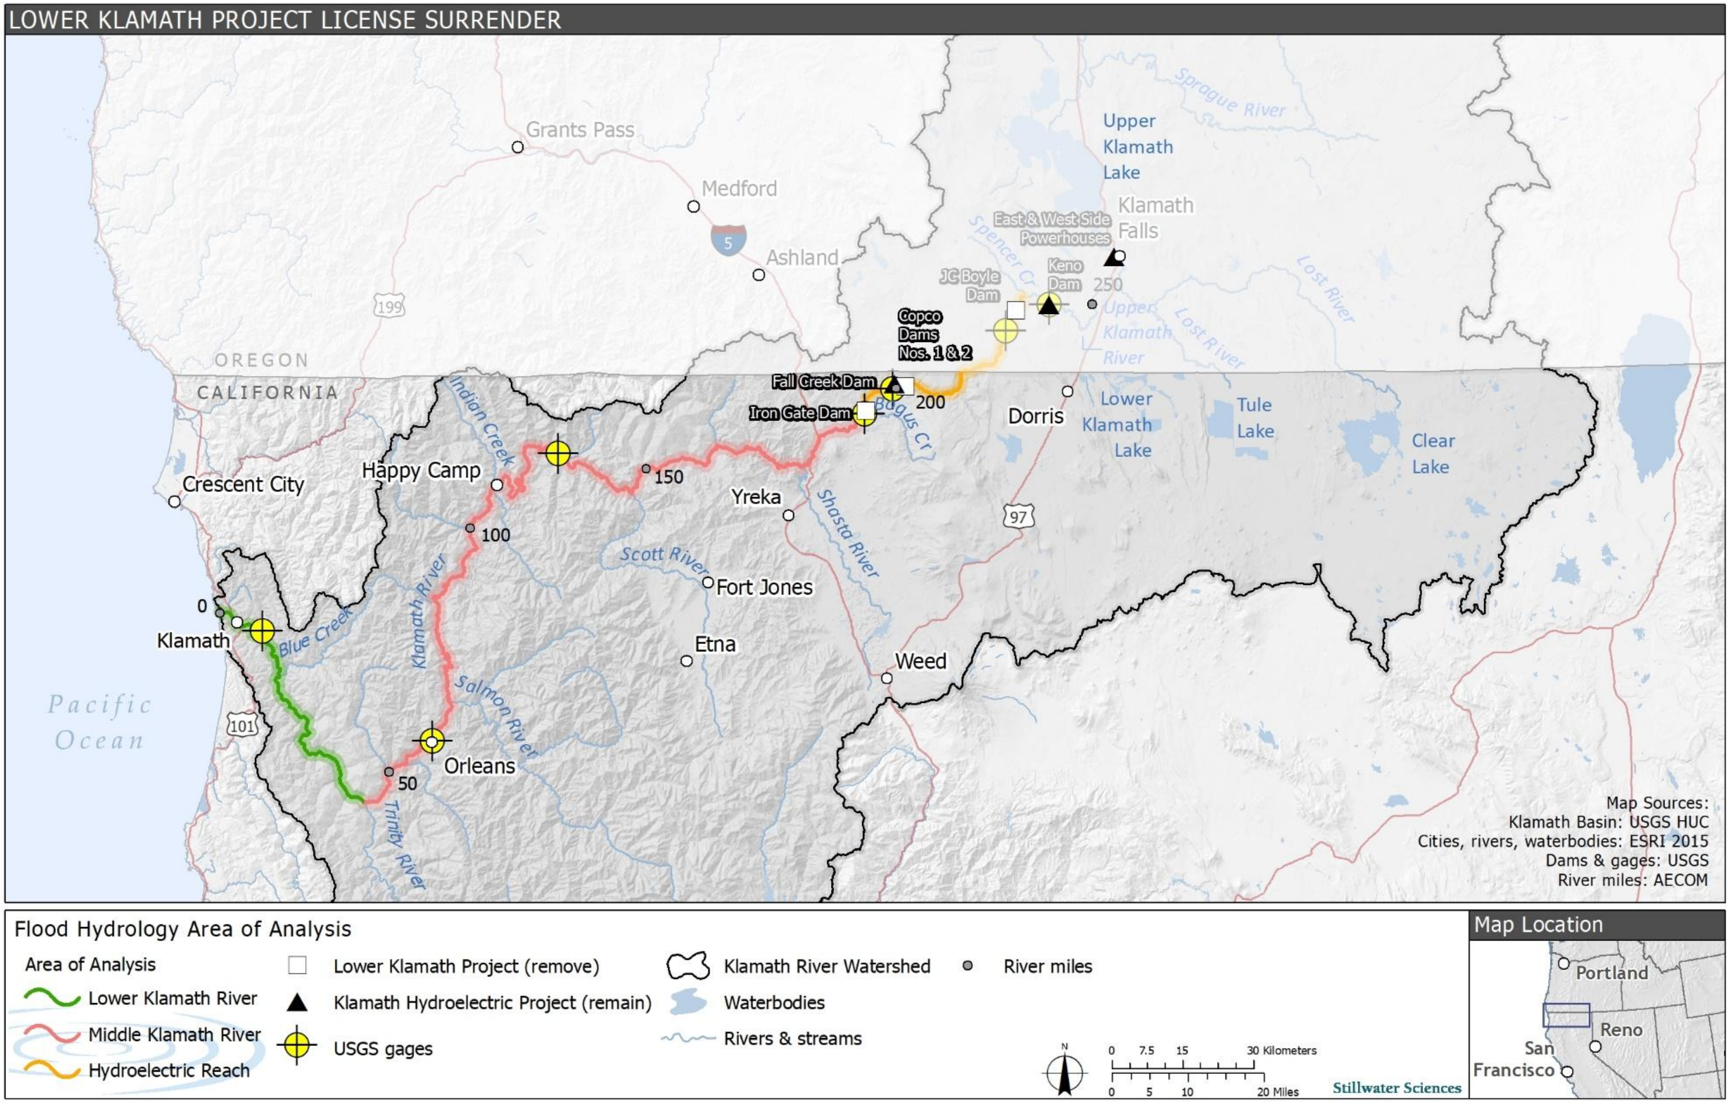

Figure 3.6-1. Flood Hydrology Area of Analysis.

3.6.2 Environmental Setting

This section describes the hydrologic conditions of surface waters in the Klamath Basin. Figure 3.6-1 shows the Area of Analysis. This section includes a description of basin hydrology including precipitation; reservoirs; major rivers and tributaries; lakes; springs and seeps providing measurable flow; historical stream flows; and flood hydrology. Existing average daily and monthly river flows and their relationship to USBR's Klamath Irrigation Project and PacifiCorp's Klamath Hydroelectric Project are also described throughout this section.

3.6.2.1 Historical Hydrologic Conditions

Pre-Dams and Pre-Klamath Irrigation Project Hydrology

Several studies have been conducted to determine the natural flow conditions of the Klamath Basin (USBR 2005); however, these studies are limited by a lack of flow data. Prior to development of dams and implementation of USBR's Klamath Irrigation Project, the Upper Klamath Basin contained lakes and large areas of marshes and wetlands. Upper Klamath Lake was not much larger than its current size; however, Tule Lake and Lower Klamath Lake were much larger. Tule Lake was approximately 7 times larger and Lower Klamath Lake was as much as 35 times larger (Dicken and Dicken 1985). Springs, snowmelt, and groundwater-dominated rivers carrying water from the Cascades and other highlands in the Upper Basin contributed greatly to Upper Klamath Lake, the Klamath River, and the wetlands and marshes in that area (Akins 1970). The elevation of Upper Klamath Lake was originally bedrock-controlled at its outlet. Water then flowed 1.3 miles down the Link River to Lake Ewauna. Lake Ewauna developed because of another natural bedrock control point near Keno, Oregon. Before construction of dams and other water control structures, the Klamath River began at the outfall of this bedrock control forming Lake Ewauna.

During high flow events out of Upper Klamath Lake, some water would flow down the Lost River Slough and into Tule Lake, another natural sump and wetland area. Water that flowed into the Klamath River reached another split near Keno (Akins 1970).

During flood conditions, water would also back up from the Keno bedrock control point and flow into the Klamath Straits and down to Lower Klamath Lake. The Lower Klamath Lake and Tule Lake areas once contained large areas of wetlands and marshes. The Lost River flowed from Clear Lake to Tule Lake. A diversion currently provides water from the Lost River to the Klamath River (Akins 1970).

The presence of both historical Tule and Lower Klamath lakes influenced flows in the Klamath River. Lower Klamath Lake (approximately 47 square miles of open water and 86 square miles of marsh) was connected to the Klamath River through the Klamath Straits. The historical Tule and Lower Klamath lakes saw increased flood inundation and lake surface area during spring snowmelt and subsequent draining of the inundated areas during the late summer and fall. Lower Klamath Lake provided some short-term storage by reducing the total volume of water leaving the upper watershed as well as delaying the peak flow. Tule Lake received overflow during high flow periods from the Klamath River near Klamath Falls, Oregon. Tule Lake was a terminal lake system; the overflow through the Lost River Slough reduced peak flows in the Klamath River in late winter and spring (Abney 1964).

Historical Land Uses Affecting River Flows

Prior to the discovery of gold in California in 1848, which prompted a dramatic influx of European immigrants to California and the Klamath Basin, the region had been inhabited for millennia by native peoples belonging to the Klamath Tribes, Shasta, Karuk, Hoopa, and Yurok. Euro-American settlement in the Klamath River watershed continued throughout the 19th Century. Sustained logging enterprises appeared in the 1880's, and the first hydroelectric development in the Klamath Basin was established in 1891 in the Shasta River Canyon below Yreka Creek.

Additional hydrologic changes to the mainstem of the Klamath Basin were triggered by the passage of the Reclamation Act of 1902 (Reclamation Act) by the U.S. Congress and the subsequent authorization of USBR's Klamath Irrigation Project in 1905. The Reclamation Act supported development in the "arid West" by allowing the Federal Government to fund irrigation projects (USBR 2010). In 1905, the Oregon and California legislatures and the U.S. Congress passed the Cession Act for all necessary legislation to begin USBR's Klamath Irrigation Project (USBR 2011). Afterwards, USBR began building the Klamath Irrigation Project, which led to the construction of the Link River Dam, hundreds of miles of irrigation ditches and large canals and pumping plants to divert water from the Klamath River watershed for agricultural use (FERC 2007). This infrastructure supported the agricultural community which was already well established in the Upper Klamath Basin and allowed for reclamation of additional wetlands for agricultural use (FERC 2007).

Development of hydroelectric plants in the Klamath Basin began as early as 1891 in the Shasta River Canyon to provide electricity for the City of Yreka. In 1895, another facility was constructed on the east side of the Link River to supply power to Klamath Falls, Oregon. Additional power suppliers developed facilities in the area on Fall Creek and the West Side plant on the Link River (FERC 2007).

3.6.2.2 Basin Hydrology

This section begins with an historical description of changes to Klamath River hydrology that have occurred associated with development of water management features in the past century and longer. The section then summarizes basin precipitation and stream flows before describing reservoirs, rivers, and creeks in the affected environment. Various springs and seeps occur in the vicinity of Iron Gate, Copco No. 1, Copco No.2, and J.C. Boyle dams and contribute flows to surface waters. Springs around Upper Klamath Lake provide inflow to many of the streams feeding the lake and also provide stability for area wetlands (Akins 1970). Section 3.7.2.1 *Regional Groundwater Conditions* describes the locations of springs and seeps in more detail. Some measurable inflows from springs and seeps to various surface waters are described below. Figure 3.6-1 shows the major rivers, dams, and reservoirs in the Klamath Basin, as well as USGS gaging locations.

Historical Water Management Changes to Klamath River Hydrology

The following provides a brief description of changes to Klamath River hydrology that have occurred through development of water management features related to irrigation, power generation, and environmental requirements over the past century and longer. The major hydrologic time periods discussed include a description of: 1) natural hydrology prior to development of major reclamation or hydroelectric facilities (pre-1903; 2) major hydrologic alterations caused by development of power peaking facilities (1903 to 1962); and 3) hydrology following construction of Iron Gate Dam in 1962 through 2000, when ESA flow requirements began to influence water releases downstream from Iron Gate (for more detail see Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*).

Owing to the long history and early development of water resources within the basin, little hydrologic data exist to describe the natural flow patterns that existed prior to construction of USBR's Klamath Irrigation Project. The first streamflow records on the Klamath River began on June 1, 1904, when the USGS began operating a flow gage on the Klamath River at Keno (USGS Gage No.11509500). River flow data for the USGS gage at Keno are available for water years 1905 through 1912, after which the gage was discontinued until 1930. The Lost River Diversion Dam was completed in 1912, which affects Klamath River hydrology (Hecht and Kamman 1996). Therefore, flow data collected at Keno from 1905 through 1912 provide the best record of unaltered hydrologic conditions prior to construction of major irrigation facilities in the upper basin. Although the 1905 through 1912 period is known to be slightly wetter than normal, the general flow conditions are still useful for understanding the general timing, magnitude, and duration of flow throughout the year under near natural conditions. Over this eight-year period the total annual discharge at Keno ranged from a low of 1,345,000 acre-feet to a high of 1,952,000 acre-feet and averaged about 1,558,000 acre-feet. Examination of three different water years, representing conditions that range from dry to wet, provide a sense of the natural flow variation that existed under natural conditions (Figure 3.6-2). Average daily flows for the 1905–1912 water years therefore provide the most reasonable set of data to assess hydrologic changes in the Klamath Basin through time as various irrigation and hydropower generation facilities were constructed. For the purposes of the following discussion, the term "natural" applies to the period prior to construction of either the hydroelectric or irrigation systems in the Klamath Basin, with river flows best represented by the 1905–1912 data.

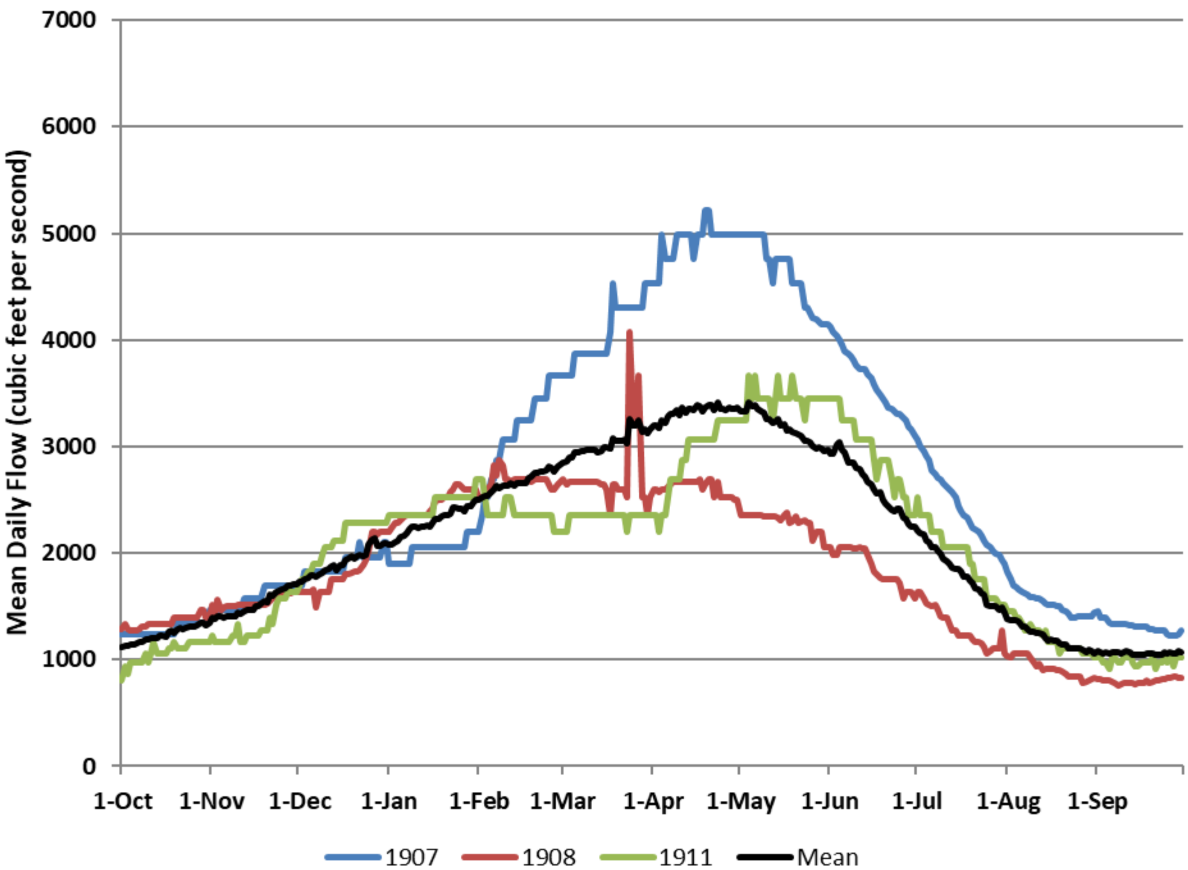

Figure 3.6-2. Mean Daily Flows (cubic feet per second) for the Klamath River at the USGS Gage at Keno for three Different Water Years, Generally Representing Drier (1908), More Normal (1911), and Wetter (1907) Conditions. Mean daily flows for water years 1905 through 1912 are also displayed to illustrate the natural flow regime that existed prior to development of major reclamation or hydroelectric projects.

Although there are no empirical river discharge data downstream from Keno prior to implementation of USBR's Klamath Irrigation Project, modeling results of flows near Iron Gate Dam without USBR's Klamath Irrigation Project show similar patterns to the natural discharge downstream of Keno (USBR 2005). Spring peaks from snowmelt in tributary basins reliably provided an increase in discharge, typically near the end of April (NRC 2004), with base flows subsequently declining to a minimum in the beginning of September.

As described below in the Keno Reservoir/Lake Ewauna section, bedrock originally controlled the elevation of Upper Klamath Lake and river flows downstream to the Link River. The Link River is only 1.3 miles long and ends at the upper extent of Lake Ewauna and the Keno Reservoir. Though a range is not identified, historical accounts describe the occurrence of extremely low flows in Link River during prolonged dry spells. These extremely low flow conditions were most likely caused by strong south winds (i.e., blowing upstream) forming seiches[135] (within Upper Klamath Lake which greatly diminished flows to the Link River for brief periods of time (Dicken and Dicken 1985). Inputs from tributary streams and natural springs downstream from Keno would have maintained flow in the Klamath River and prevented it from drying completely farther downstream near the current location of Iron Gate Dam.

In the Lower and Mid Klamath basins, the hydrologic pattern of the Klamath River was primarily dominated by rainfall events in the fall, winter and spring. In the middle and lower portions of the Klamath River, discharge responds rapidly to rainfall due to the relatively short length of lower tributary sub-basins (e.g., Salmon River). The natural Klamath River hydrology was diverse, with a range of hydraulic conditions affected by both the Upper Klamath Basin patterns previously described (e.g., Figure 3.6-2) and lower basin tributary inputs (see *Precipitation and Stream Flows* subsection, below).

Copco No. 1 and Copco No. 2 facilities were constructed to generate hydroelectric power and their operation greatly altered flow patterns downstream. The USGS gage on the Klamath River near Fall Creek, downstream from Copco No. 1 and Copco No. 2 dams, began recording flows at this location in October 1923 (USGS Gage No. 11512500). Flow data are available from USGS Gage No. 11512500 until 1962 when construction of Iron Gate Dam inundated the river at this location. Hydroelectric power peaking operations at Copco No. 1 and Copco No. 2 caused major changes to the hydrograph downstream from the Copco No. 2 powerhouse (Figure 3.6-3). Rapid changes in flow associated with hydropower generation, commonly referred to as power peaking, created both hazardous conditions for recreational fishermen and inhospitable conditions for aquatic species downstream. Mean daily flows fell below 100 cfs at USGS Gage No. 11512500 on 50 occasions between water years 1931 and 1937. Thus, hydropower peaking between 1918 and the construction of Iron Gate Dam to re-regulate flows in 1962 may explain some anecdotal accounts of the occurrence of low flows in the Klamath River in the past that were submitted by citizens during public scoping of the 2012 KHSA EIS/EIR (USBR and CDFG 2012) and the Lower Klamath Project EIR (see Appendix A).

Iron Gate Dam was completed in 1962 to re-regulate peaking flow releases from the Copco facilities upstream. At that time minimum flow releases downstream were stipulated by FERC under Article 52 of the FERC License for operation of Project No. 2082. Article 52 required the following minimum flows downstream from Iron Gate Dam: 1,300 cfs from September 1 through April 30; 1,000 cfs from May 1 through May 31; 710 cfs from June 1 through July 31; and 1,000 cfs from August 1 through August 31. These flow requirements provided more stable flow conditions downstream; however, they also altered the timing of base flows and did not attempt to restore or simulate the natural hydrograph. Fall flows were slightly increased while spring and summer flows were substantially reduced compared to natural flows. Figure 3.6-4 illustrates this alteration.

[135] A seiche is a standing wave oscillating in an enclosed, or partially enclosed, body of water (NOAA 2018). Seiches are typically caused when atmospheric (i.e., wind or pressure) or seismic forces push water from one end of the body of water to the other. Eventually, the water rebounds to the other side of the body of water and then continues to oscillate back and forth for hours or even days.

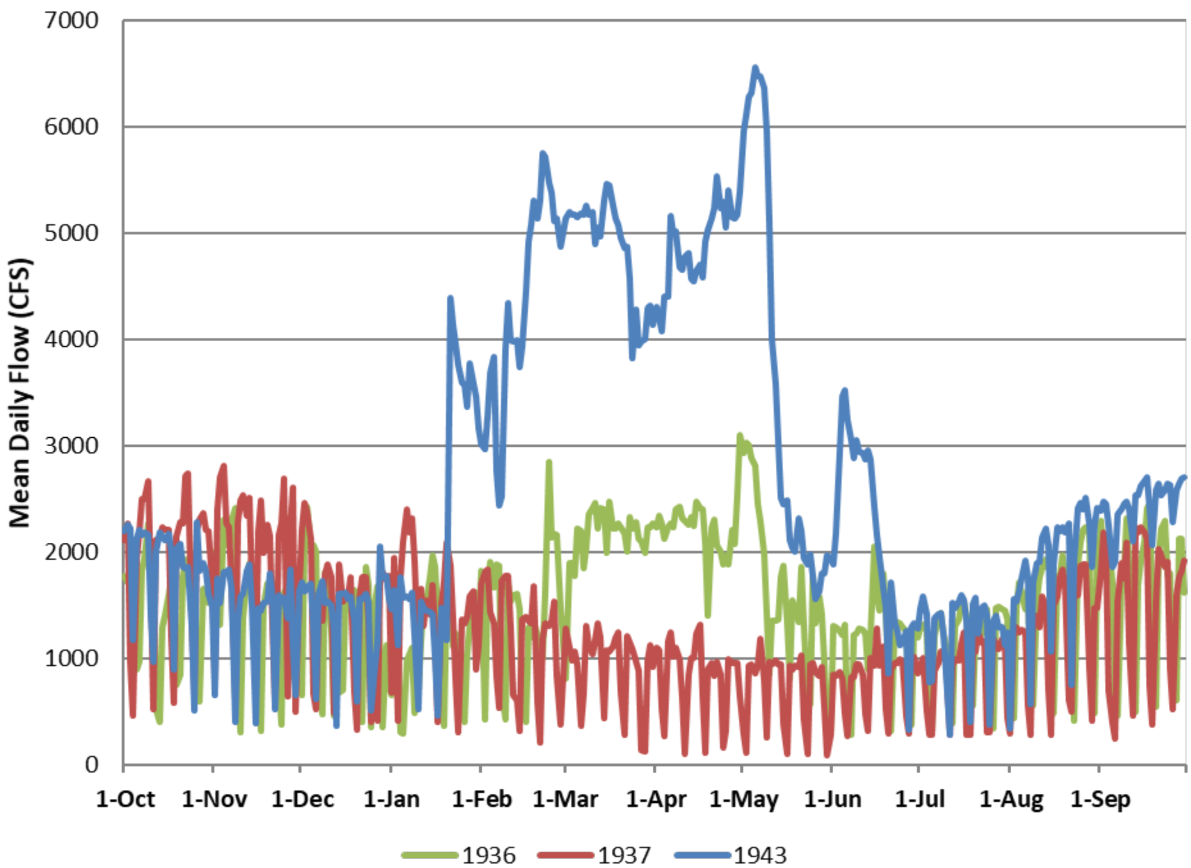

Figure 3.6-3. Mean Daily Flows (cubic feet per second) for the Klamath River at the USGS Gage Near Fall Creek (Gage No. 11512500) for Three Different Water Years, Generally Representing Drier (1937), Normal (1936), and Wetter (1943) Conditions.

Hecht and Kamman (1996) analyzed the hydrologic records for similar water years (pre- and post-Project) at several locations along the Klamath River. The authors concluded that the timing of peak and base flows changed significantly after construction of USBR's Klamath Irrigation Project (KIP), and that the operation of the KIP increases flows in October and November and decreases flows in the late spring and summer as measured at Keno, Seiad, and Klamath USGS gage sites. Comparison of mean daily flows recorded at Keno (USGS Gage No. 11509500) from 1905 to 1912 with mean daily flows recorded at Keno and Iron Gate (USGS Gage No. 11516430) in more recent years (1961–2000) illustrate these findings (Figure 3.6-4).

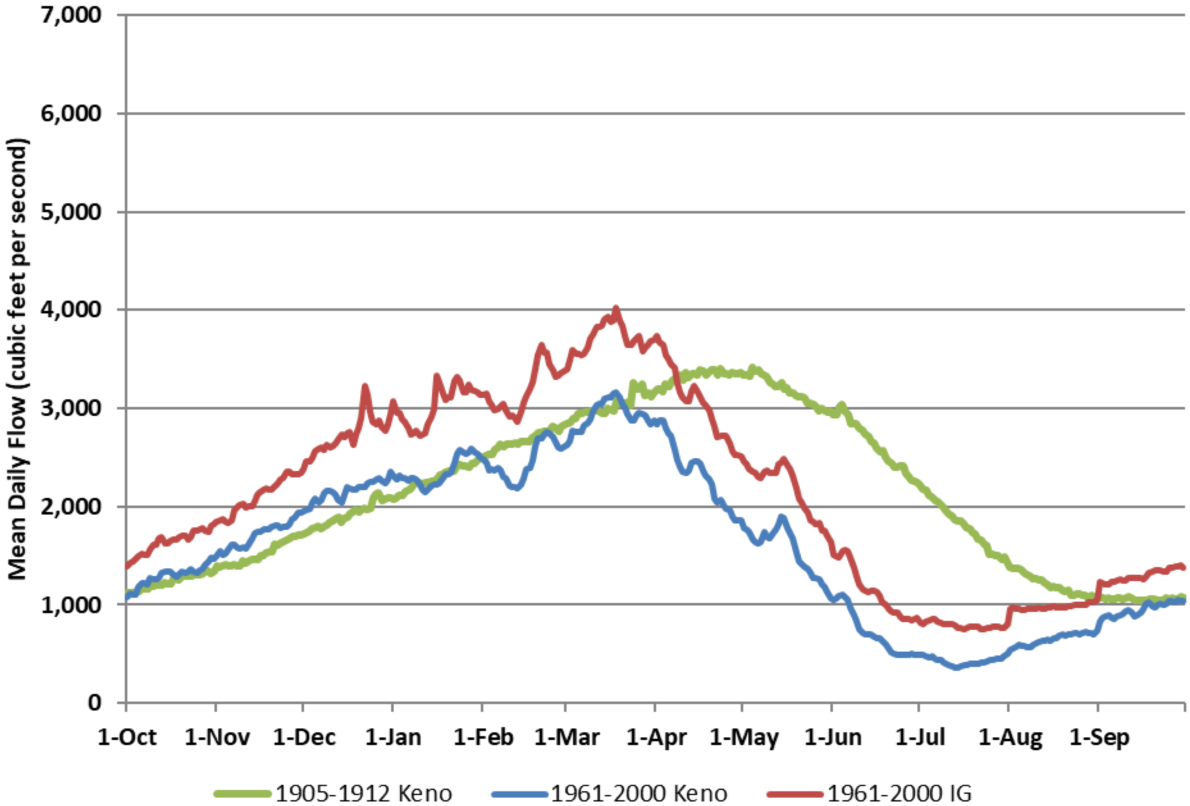

Figure 3.6-4. Comparison of Mean Daily Flows Recorded at Keno (USGS Gage No. 11509500) Historically (1905–1912) with More Recent Conditions (1961–2000). Mean daily flows recorded at Iron Gate (USGS Gage No. 11516530) are shown to depict both the mean daily accretions and similarities that exist in the hydrograph between Keno and Iron Gate.

During the period from 1961 through 2000, the timing and magnitude of average flows in the Klamath River at Keno changed relative to the natural flow regime (Figure 3.6-4). USBR's Klamath Irrigation Project water diversions from the Klamath River in the spring and summer significantly reduced flow volumes in the Klamath River from approximately April until September. The extraction of water significantly accelerated the decline of flow rates during the spring runoff and had the effect of moving the spring runoff peak from the end of April and beginning of May to the middle of March, a shift of more than one month. Although most of the diverted water remained within the basin, a combined total of about 30,400 acre-feet of water was diverted annually from Jenny Creek (tributary to the Klamath River at Iron Gate Reservoir) and Fourmile Lake (tributary to Upper Klamath Lake) to the Rogue River Valley for irrigation and hydropower production. Under natural conditions, river discharge did not reach base (minimum) flow, until September. Operation of USBR's Klamath Irrigation Project caused a shift in the onset of minimum base flow levels by about two months earlier in the summer from September to July. Tributary inflows and spring flow accretions, the most prominent being Big Springs (about 250 cfs) in the J.C. Boyle Bypass Reach, accounts for the difference in mean daily flow between Keno and Iron Gate.

Minimum flow requirements, based on consideration of ESA species, at Iron Gate Dam have gone through multiple iterations (e.g., 2002 Biological Opinion, 2008 Biological Opinion, KBRA/2010 Biological Opinion) and are currently operated under the 2013 Joint Biological Opinion (BiOp) and court-ordered flushing flows (for more detail see Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project,* and the *Iron Gate Reservoir* subsection below) (NMFS and USFWS 2012, U.S. District Court 2017).

Precipitation and Stream Flows

The Upper Klamath Basin receives rain at all elevations and snow at elevations above 4,000 feet (above mean sea level [amsl]) during the late fall, winter, and spring. Snow is the primary form of precipitation in the upper watershed. Depending on the elevation and location, the amount of precipitation ranges from approximately 10 to more than 50 inches per year. From 1907 through 1997 the average annual precipitation at Klamath Falls was 13.4 inches and from 1959 to 2009 it was 20 inches at Copco No. 1 Dam (USBR 2010). Peak stream flows generally occur during snowmelt runoff from March through May. After the runoff has stopped, flows drop to low levels in the late summer or early fall. Fall storms may increase flows compared with the lower summer flows. Generally, conditions in the Upper Klamath Lake area are drier than the area where the Klamath River reaches the ocean (Figure 3.6-5). The reaches downstream from the confluence of the Klamath and Shasta rivers receive higher levels of precipitation than other reaches in the Klamath Basin (FERC 2007). Average annual precipitation is 49 inches at Happy Camp from 1914 to 2010 and 80 inches at Klamath between 1948 and 2006 (Desert Research Institute 2011).

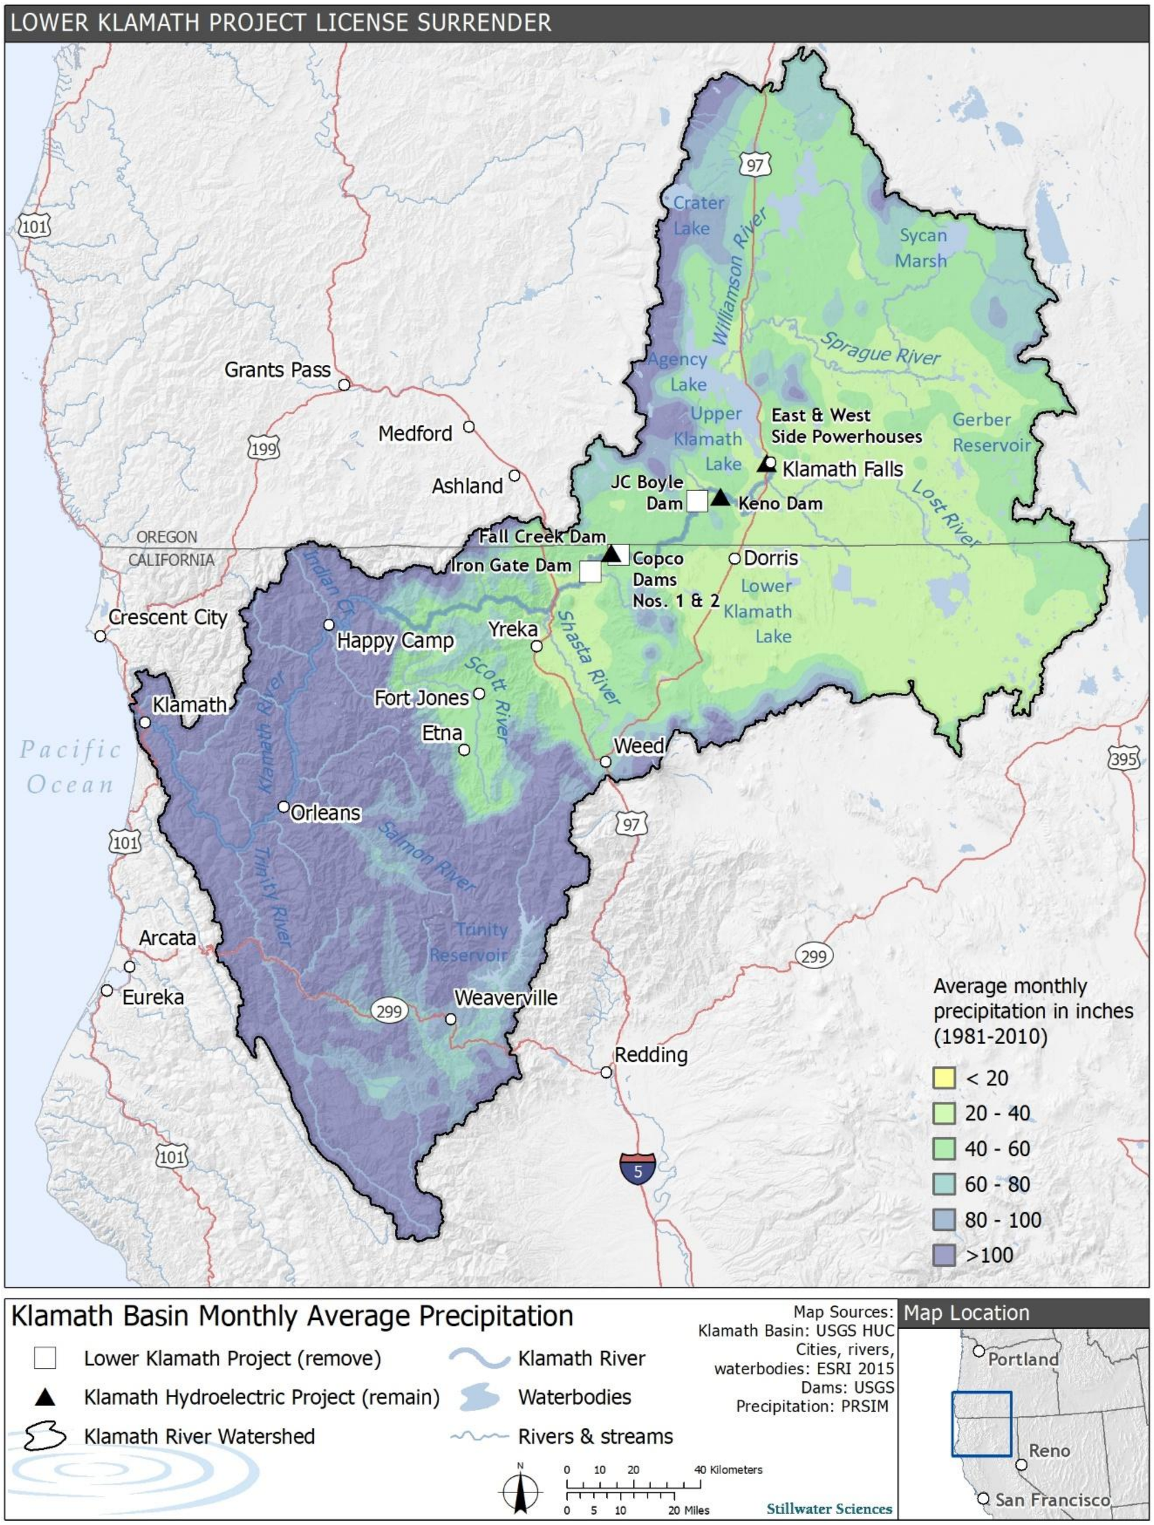

Figure 3.6-5. Mean monthly precipitation across the Klamath River watershed (1981–2010).

The following graphs and tables provide more detail regarding precipitation and streamflow from the upper to the lower watershed, as well as information on the range of hydrologic conditions. The USGS stream gages on the Klamath River are summarized in Table 3.6-1 and Figure 3.6-1. Summer and early fall periods (July through October) generally have much lower flows than during spring runoff. Tributaries downstream from Iron Gate Dam contribute substantial amounts of flow. Figure 3.6-6 shows historical daily average stream flows at several locations on the river using USGS monitoring data from 1961 to 2009 (USGS 2011). Flows are substantially higher during wet years; Table 3.6-2 shows historical average monthly flows during wetter years (represented by flows exceeded 10 percent of the time) using the same USGS data (USGS 2011). Table 3.6-3 shows the daily average flows at the four primary hydroelectric dams. The column indicating “Percent of time equaled or exceeded” indicates the hydrologic conditions, with 99 percent being extremely dry conditions and 1 percent being extremely wet conditions.

Upper Klamath Basin

Upper Klamath Lake and Link River Dam

Link River Dam was constructed in 1921 at the natural outlet of Upper Klamath Lake by California Oregon Power Company (now PacifiCorp). The dam, deeded to the United States, is operated and maintained by PacifiCorp under the direction of USBR. Upper Klamath Lake has active total storage capacity of approximately 629,780 acre-feet including areas restored by levee and dike breaches at Tulana Farms and Goose Bay and pumped storage at Agency Lake and Barnes Ranches (Table 3.6-4) (FERC 2007). Currently, USBR manages Upper Klamath Lake for irrigation delivery and in accordance with USFWS and NOAA Fisheries Service biological opinions regarding lake levels and downstream flows, based on current and expected hydrologic conditions (USBR 2010).

Table 3.6-4. Klamath River Reservoir Information.

Reservoir	Surface Area (acres)	Average Yearly Inflow [a] (cfs)	Average Depth [a] (feet amsl)	Maximum Depth [a] (feet amsl)	Active Storage (acre-feet)	Total Storage (acre-feet)	Retention Time (days)
Upper Klamath Lake	67,000[a]	1,450	9	60	486,830[a, b]	629,780[a, b]	219[a]
Keno	2,475[a]	1,575	7.5	20	495[a, b]	18,500[a, b]	5.9[a]

Copco No. 2	N/A[c]	1,585	[e]	[e]	0[a, b]	70[c]	0[a]
Iron Gate	942[c]	1,733	62	167	3,790[a, d]	50,941 [c]	14.8[a]

Notes:
[a] Source: FERC (2007).
[b] Storage volumes are from Table A2.1-1 of PacifiCorp's Exhibit A, as cited in FERC (2007).
[c] Source: AECOM et al. (2017). Data have been adjusted from those reported in FERC 2007 and USBR 2012a based on available data (e.g., as-built drawings, aerial photographs, topographic information).
[d] Storage for Copco No. 1 Reservoir between the normal maximum water level and the invert of the penstock intakes is approximately 20,000 acre-feet. Storage for Iron Gate Reservoir between the normal maximum water level and invert of the penstock intake is approximately 24,000 acre-feet, as reported in FERC (2007).
[e] Very small reservoir, no information on depth provided.

Outlets from Upper Klamath Lake include the Reclamation A Canal, PacifiCorp's East Side and West Side development canals and the Link River Dam. Water that passes through the East Side and West Side development canals re-enters the Link River downstream from the dam where it eventually enters Keno Reservoir/Lake Ewauna (FERC 2007).

USBR's Klamath Irrigation Project (KIP)

Operation of USBR's Klamath Irrigation Project affects Klamath River flows and Upper Klamath Lake water surface elevations. Link River Dam is the primary structure controlling the level of Upper Klamath Lake and releases of water to the Klamath River. Upper Klamath Lake water level fluctuation is approximately four to five feet annually, reaching a maximum (about 4,143 feet amsl, USBR datum) near the beginning of the irrigation season in April, and often dropping below 4,139 feet amsl, USBR datum, at the end of the irrigation season in October. The range of water levels in Upper Klamath Lake depends on many factors, including hydrologic conditions, flood risk management, agricultural demands for irrigation deliveries, and ESA requirements to protect listed fish.

Section 3.8 *Water Supply/Water Rights*, describes the scope of USBR's Klamath Irrigation Project in more detail, including the water supply diversions and amount of water diverted. As a federal agency, USBR is required to comply with the ESA. To meet ESA requirements, USBR operates the Klamath Irrigation Project in compliance with the most recent biological opinion. To comply with ESA, USBR operates the Klamath Irrigation Project to maintain: (1) water surface elevations in UKL for ESA-listed sucker fish; (2) minimum flows in the Klamath River below Iron Gate Dam for threatened Coho salmon. Though Iron Gate Dam is owned and operated by PacifiCorp, PacifiCorp makes releases from Iron Gate Dam for USBR's flow requirements as a result of PacifiCorp's requirements under a habitat conservation plan for coho salmon. Refer to Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and the *Iron Gate Reservoir* subsection below for additional information on biological opinion flow requirements.

Keno Reservoir/Lake Ewauna and Keno Reach

Lake Ewauna existed before the construction of Keno Dam due to a natural bedrock control point or "reef" as described by others (e.g., Akins 1970). In 1931, Needle Dam was built on the Klamath River near Keno, Oregon and, in 1967, Keno Dam was built to replace Needle Dam. With construction of Keno Dam, the waterbody of Keno Reservoir/Lake Ewauna became a long and narrow lake that begins where the Link River ends, 1.3 miles downstream from the Link River Dam, and ends at Keno Dam. The Keno Dam is owned and operated by PacifiCorp as part of the Klamath Hydroelectric Project. The operations are coordinated with the operations of Link River Dam. Before Keno Dam, the river meandered through swamps for approximately 20 miles. It took two to four days for water released at Link River Dam to reach Copco No. 1 Dam. With the construction of Keno Dam, and dikes along the shores of Keno Reservoir/Lake Ewauna, this travel time has been reduced to 12 hours. The currently normal water surface elevation is 4,085 feet amsl in Keno Reservoir/Lake Ewauna (USGS 2009).

On an annual basis, the majority of the water entering Keno Reservoir/Lake Ewauna comes from Upper Klamath Lake through the Link River. Several notable federal and private facilities upstream of Keno Dam transport water to or from the river including: Lost River Diversion Channel, Klamath Straits Drain, and Ady Canal. The surface elevation of Keno Reservoir/Lake Ewauna is maintained to facilitate the operations of these facilities (FERC 2007).

Historical daily mean discharge for the Klamath River at Keno Dam for the period of record from water years 1961–2015 are shown in Figure 3.6-7.

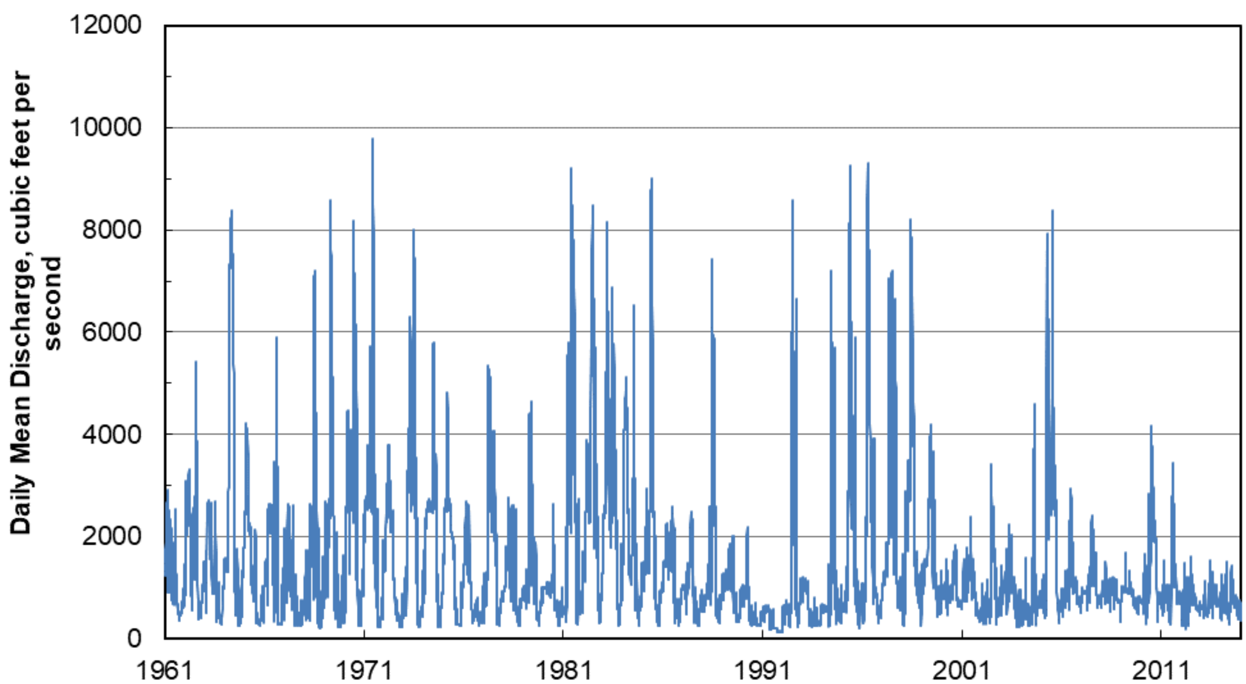

Figure 3.6-7. Discharge for the Klamath River at Keno Dam, 1961–2015. Source: USGS 2016.

J.C. Boyle Reservoir

J.C. Boyle Reservoir is approximately five miles downstream from Keno Dam. PacifiCorp operates J.C. Boyle Reservoir to produce hydroelectric power. Current operations of the reservoir follow Interim Measures from the Interim Conservation Plan effective as of February 2010. Water is spilled from the dam during high flow months of January through May and when inflow exceeds the capacity of the J.C. Boyle powerhouse and low flow requirements (see Table 3.6-5) (FERC 2007).

Table 3.6-5. Average Spillage at J.C. Boyle, Copco No. 1, and Iron Gate Dams from January 2, 1990 through December 5, 2004.

J.C. Boyle Bypass Reach

The J.C. Boyle Bypass Reach is a moderately steep (approximately 1.7 percent grade), 4.6-mile reach of the Klamath River between the J.C. Boyle Dam and Powerhouse. One-half mile downstream from the dam, flows are increased by groundwater entering the bypass reach. There is currently a 100 cfs minimum required release from J.C. Boyle Reservoir into the J.C. Boyle Bypass Reach (NOAA 2010). The average accretion due to groundwater inflow/spring inflow is an additional 220 to 250 cfs and varies seasonally and from year to year (FERC 2007).

J.C. Boyle Peaking Reach

The J.C. Boyle Peaking Reach is downstream from the J.C. Boyle Powerhouse, so flows vary based on releases from the powerhouse. Typically, the reach has high flows during the day as a result of powerhouse flows used to provide peak energy demand. The powerhouse flows may be reduced to zero at night when J.C. Boyle Reservoir is refilled. The powerhouse ramps up flow for either a one-unit operation (up to 1,500 cfs) or a two-unit operation (up to 3,000 cfs). Normal daily average flows in the peaking reach during periods with no power generation range from 320 to 350 cfs, which includes 80 cfs from the fish ladder and 20 cfs from the juvenile fish bypass system. Additional water enters the reach from springs. Figure 3.6-8 shows historical flows for the Klamath River below J.C. Boyle Powerhouse (USGS Gage No. 11510700) for the period of record from January 1, 1959, through the end of water year 2015. This gage is located at RM 224.5, about 0.7 mile downstream from the powerhouse.

Commercial whitewater rafting and boating occurs during the same months as peak power demands, May through October (see also Section 3.20 *Recreation*). Under PacifiCorp's current annual FERC license, upramping and downramping flows occur at a rate of 9 inches per hour (FERC 2007).

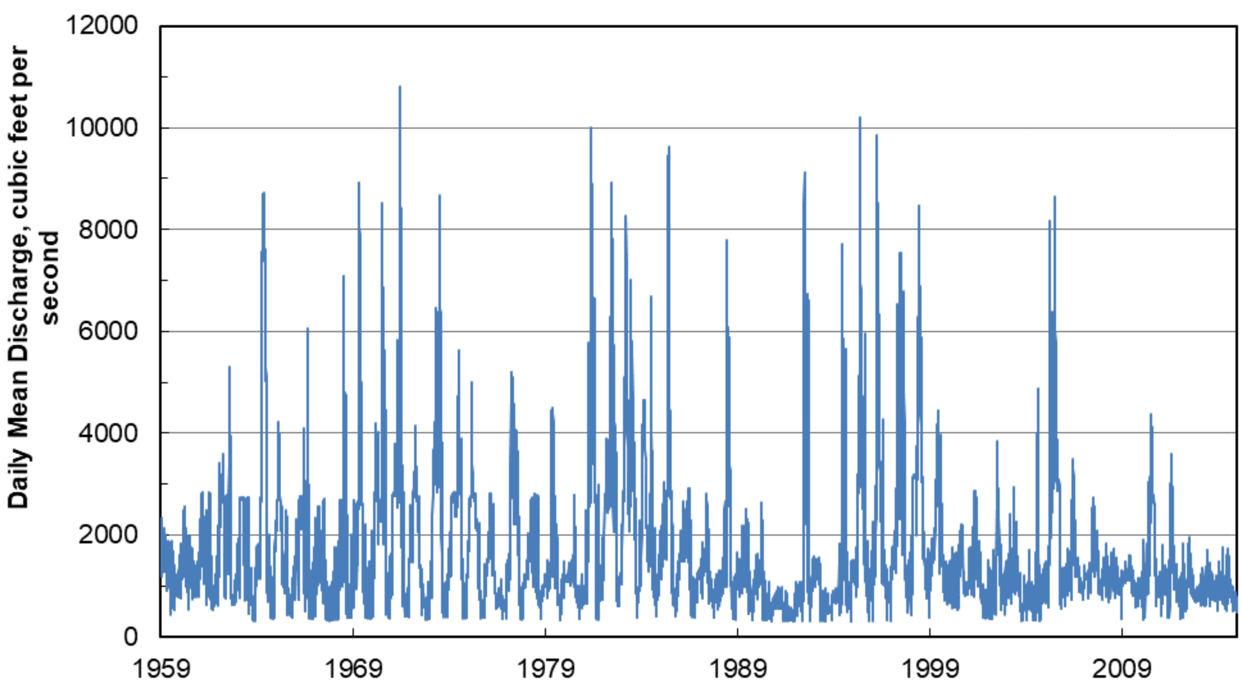

Figure 3.6-8. Discharge for Klamath River Downstream from J.C. Boyle Powerhouse, 1959–2015. Source: USGS 2016.

Copco No. 1 Reservoir

PacifiCorp operates Copco No. 1 Reservoir for hydroelectric power generation through Copco No. 1 Dam. With the most active storage volume of all the Lower Klamath Project reservoirs (6,235 acre-feet for power production), Copco No. 1 Reservoir has a total storage capacity of 46,867 acre-feet (USBR 2012). This reservoir is deeper than both Keno Reservoir/Lake Ewauna and J.C. Boyle Reservoir (FERC 2007).

Copco No. 2 Reservoir and Bypass Reach

Copco No. 2 Reservoir, a small impoundment, receives discharges from Copco No. 1 Reservoir through Copco No. 1 Dam and provides flow to Copco No. 2 Powerhouse through a 1.5-mile conveyance of tunnels and penstocks. The maximum hydraulic capacity is 3,650 cfs, which is the capacity of flow from Copco No. 1 Powerhouse to Copco No. 2 Reservoir. Copco No. 2 Dam controls the flow from the reservoir, and only spills when inflow to the reservoir exceeds storage capacity. Spillage from the dam is rare and typically only happens from November through April. PacifiCorp releases between five to 10 cfs at the bypass reach below Copco No. 2 Dam under normal conditions. Copco No. 2 Powerhouse discharges water to Iron Gate Reservoir (FERC 2007).

Spring, Fall, and Jenny Creeks

Two perennial tributaries, Jenny and Fall creeks, enter Iron Gate Reservoir. Spring Creek is a tributary to Jenny Creek, which flows for 1.2 miles from its source at Shoat Springs before it enters Jenny Creek at RM 5.5. Flow in Jenny Creek is altered by upstream reservoirs that store water during the high runoff season for irrigation as part of the Rogue River Irrigation Project. Approximately 24,200 acre-feet, which is approximately 30 percent of the annual mean runoff of the Jenny Creek watershed, is diverted north into the Rogue River Basin. PacifiCorp estimates that normally between 30 and 500 cfs enters Iron Gate Reservoir from Jenny Creek.

PacifiCorp operates a small diversion dam on Spring Creek that diverts up to 16.5 cfs into Fall Creek, and another dam on Fall Creek that diverts flow into a canal and penstock system leading to the Fall Creek Powerhouse. PacifiCorp states that the Spring Creek diversion was unusable for most of the 1990's, and until 2003, due to a water rights lawsuit with a local landowner, but that the lawsuit was decided in favor of PacifiCorp in 2003. The Spring Creek diversion is located a half mile upstream of its confluence with Jenny Creek, and diverted flow is carried through a 1.3-mile-long canal where it enters Fall Creek, about 1.7 miles upstream of the Fall Creek diversion. PacifiCorp estimates the minimum observed flow in Spring Creek is five cfs. The diversion dam on Fall Creek diverts up to 50 cfs of flow that bypasses 1.5 miles of a steep gradient section (approximately 9 percent) of Fall Creek, leading to the Fall Creek Powerhouse. PacifiCorp's current license requires minimum flows of 0.5 cfs below the Fall Creek diversion and 15 cfs (or natural stream flow, whichever is less) downstream of the powerhouse.

USGS operated Gage No. 11512000 on Fall Creek a short distance downstream of the Fall Creek powerhouse, the fish hatchery, and the City of Yreka intakes during most of the period between 1933 and 1959. From October 1, 2003, until September 30, 2005, Gage No. 11512000 was reactivated, and, during this time, the gage recorded a mean flow of 40 cfs and a minimum flow of 21 cfs. According to data from this gage, flow within Fall Creek does not vary much seasonally due to a reliable baseflow from groundwater springs and typically ranges from 30 to 50 cfs.

The City of Yreka, California, operates a water supply intake downstream of the Fall Creek Powerhouse and withdraws up to 15 cfs (see also Section 2.7.6.2 *Fall Creek Hatchery* of this EIR). Intakes to the currently non-operating Fall Creek rearing facility are downstream from the Yreka water supply intake.

Iron Gate Reservoir

Iron Gate Reservoir is downstream from the Copco No. 2 Dam and also receives water from Jenny and Fall creeks. PacifiCorp operates the Iron Gate Dam complex as a re-regulating facility for peaking operations at the other three hydroelectric power dams. Iron Gate Reservoir is the deepest of the four reservoirs in the Hydroelectric Reach. The total storage at this reservoir is approximately 58,794 acre-feet of which 3,790 acre-feet is available for power production (USBR 2012). Iron Gate Powerhouse, at the base of the dam, has a maximum hydraulic capacity of 1,735 cfs. Cool water is diverted from the reservoir to the Iron Gate Fish Hatchery, downstream from the dam (FERC 2007). USGS Gage No. 11516530 on the Klamath River, downstream from Iron Gate Dam, provides flow monitoring data regarding compliance with biological opinions. Bogus Creek and effluent from the hatchery enter the river upstream of the gage and downstream from the dam (USGS 2009b). Figure 3.6-9 shows Klamath River flows downstream from Iron Gate Dam for water years 1963 to 2015. Data for the same period are summarized in Table 3.6-6. The Lower Klamath Project's effect on peak flow events is discussed in sections 3.6.2.3 *Flood Hydrology* and 3.6.5 *[Flood Hydrology] Potential Impacts and Mitigation*. Recent flows for water years 2009 through 2015 are highlighted in Figure 3.6-10. The earlier highlighted years represent flows under the 2008 and 2010 BiOps. The graph also shows actual flows released in accordance with the current 2013 BiOp, as well as the recent drought years.

Table 3.6-7 shows the ramping rate criteria for Iron Gate established in the 1961 FERC license amendment and the 2013 BiOp (NMFS and USFWS 2013).

Table 3.6-7. Ramping Rate Requirements for Iron Gate Dam.

Flow Range	Maximum Decrease	Source
General	250 cfs per hour or 3 inches per hour whichever is less	FERC 1961 license amendment
Greater than 3,000 cfs	Follows a 3-day moving average of net inflow into UKL and accretions between Link River Dam and Iron Gate Dam	NMFS & USFW 2013
Above 1,750 cfs and less than or equal to 3,000 cfs	not more than 125 cfs per 4-hour period and not exceeding 300 cfs per 24 hours	NMFS & USFW 2013
1,750 cfs or less	not more than 50 cfs per 2-hour period and not exceeding 150 cfs per 24-hour period	NMFS & USFW 2013

Source: NMFS and USFWS 2013

Flows downstream from Iron Gate Dam are the result of the Link River Dam releases from Upper Klamath Lake, Link River Dam to Iron Gate Dam flow accretions, and management of the Klamath Hydroelectric Project by PacifiCorp. Since approximately 1997, Iron Gate Dam minimum flow releases have been stipulated by various BiOps, which was discussed in detail in the 2007 FEIS as well as the 2008 and 2010 BiOps (FERC 2007).

In 2008, the USFWS issued a BiOp to USBR on the operation and maintenance of USBR's Klamath Irrigation Project. This BiOp outlined measures to improve the habitat for the Lost River sucker and shortnose sucker, affected by USBR's Klamath Irrigation Project operations. Among other measures to protect the suckers, the BiOp required that specific surface elevations of Upper Klamath Lake be maintained.

In 2010, NMFS also issued a BiOp to USBR, requiring releases from USBR's Klamath Irrigation Project to release specified rates of flow for the Klamath River downstream from Iron Gate Dam, based on the habitat needs of coho salmon. Target flow rates in the Klamath River downstream from Iron Gate Dam varied by month and were dependent in part on the amount of water entering Upper Klamath Lake.

Currently, flow releases at Iron Gate Dam are dictated by the 2013 BiOp and court-ordered flushing flows, which were designed to protect federally listed coho salmon, Lost River sucker, and shortnose sucker (NMFS and USFWS 2013, U.S. District Court 2017c). The court-ordered flushing flows became effective in February 2017, after the Notice of Preparation (NOP) was filed by the State Water Board in December 2016, and are therefore not part of the Existing Conditions for the Proposed Project. This section notes, and as appropriate discusses, the potential differences to the Existing Conditions and the impact analysis based on the newer flow requirements. The current flow regime does not result in any changes to the findings of significance and does not result in any changes regarding mitigation measures.

USBR uses the monthly 50 percent exceedance inflow forecasts from the Natural Resources Conservation Service (NRCS) as the basis for Klamath Irrigation Project operations to manage Upper Klamath Lake and the Klamath River during the spring-summer irrigation season (March 1 through September 30). To estimate the water supply available from Upper Klamath Lake and the Klamath River, USBR relies on actual inflows to Upper Klamath Lake and NRCS inflow forecasts for Upper Klamath Lake to determine three key operational values: (1) the volume of water to be reserved in Upper Klamath Lake to maintain lake elevations analyzed in the BiOp; (2) the volume of water designated for the Klamath River, referred to as the environmental water account (EWA); and (3) the volume of water available for delivery for irrigation purposes to the Klamath Irrigation Project (USBR 2016).

USBR makes a preliminary calculation of these three operational values on March 1; however, those estimates are subject to change, based on actual Upper Klamath Lake inflows after March 1 and subsequent NRCS inflow forecasts. USBR recalculates these values on April 1, based on actual Upper Klamath Lake inflows observed in March and NRCS Upper Klamath Lake inflow forecast for April 1 to September 30. This April 1 calculation establishes the initial volume of water available for irrigation from the Upper Klamath Lake and the Klamath River during the spring-summer irrigation season.

The 2013 BiOp established average daily minimum target flows below Iron Gate Dam. Maximum target flows are established for July, August, and September, and are based on the EWA volumes. These target flows are summarized in Table 3.6-8.

In addition, increases to the target flows in Table 3.6-8 can occur in late August or early September to support the Yurok Tribal Boat Dance Ceremony. To ensure adequate flow for the Yurok Tribal Boat Dance Ceremony, which occurs during even calendar years, flow releases at Iron Gate Dam can be increased. The volume of water required for the ceremony is estimated to be between 2,000 and 4,000 acre-feet depending on real-time hydrologic conditions (NMFW and USFWS 2013). Deviations to the flow targets in Table 3.6-8 can also occur based on other circumstances, such as large fish disease events or flood hazard risks.

Table 3.6-8. Iron Gate Dam Target Flow Release Criteria According to the 2013 Biological Opinion.

Month	NMFS & USFWS 2013 Biological Opinions Iron Gate Target Flows (cfs)[2]	
	Average Daily Minimum	Average Daily Maximum[3]
April	1,325	--
May	1,175	--
June	1,025	--
July	900	1,000 cfs @ EWA = 320,000 acre-feet 1,500 cfs @ EWA ≥ 1,500,000 acre-feet
August	900	1,050 cfs @ EWA = 320,000 acre-feet 1,250 cfs @ EWA ≥ 1,500,000 acre-feet
September	1,000	1,100 cfs @ EWA = 320,000 acre-feet 1,350 cfs @ EWA ≥ 1,500,000 acre-feet
October	1,000	--
November	1,000	--
December	950	--
January	950	--
February	950	--
March	1,000	--

Notes:
"--" none specified, but regulated per ramping rates shown in Table 3.6-7.
cfs = cubic feet per second; EWA = Environmental Water Account

Mid Klamath Basin

The Middle Klamath Basin includes the area downstream from Iron Gate Dam to the confluence of the Trinity River, which includes 150 miles of river. The major tributaries entering the Klamath River along these reaches include the Shasta, Scott, and Salmon rivers. The Klamath Basin is heavily influenced by these three rivers because they provide 44 percent of the average annual runoff (FERC 2007). Below are brief descriptions of these three rivers and other reaches along the Middle Klamath River.

Shasta River

The Shasta River enters the Klamath River at RM 179.5, 13.5 miles downstream from Iron Gate Dam. The Shasta River watershed includes the glaciated slopes of Mount Shasta but is largely rangeland with substantial amounts of irrigated pastureland and agricultural area. The average precipitation in the watershed varies greatly with exposure and elevation but is about 15 inches per year due to the rain shadow effects of the mountains to the west of the watershed.

The hydrograph for the Shasta River near the confluence with the Klamath River shows a peak in the winter and minimum median flows under 40 cfs during July and August (see Table 3.6-9). The current hydrology of the Shasta River is affected by surface-water diversions, alluvial pumping, and the Dwinnell Dam which creates Lake Shastina. Historically, springs and seeps dominated the hydrograph of the Shasta River resulting in a cool and stable river flow. Dwinnell Dam, about 25 miles upstream from the Klamath River at a location that controls 15 percent of the total drainage area of the Shasta River, was constructed in 1928 and has a normal storage capacity of 50,000 acre-feet.

The majority of the water in Lake Shastina is retained during the winter and early spring and then used for irrigation during the later spring and summer. A 2013 settlement between the Karuk Tribe and the Montague Water Conservation District mandates a flow release of 2,250 to 3,000 acre-feet per year from Lake Shastina to support endangered coho salmon. Farther downstream, there are seven major diversion dams and numerous smaller dams or weirs on the Shasta River and its tributaries. When these diversions are in operation during the irrigation season, they substantially and rapidly reduce flows in the mainstem causing complete dewatering of the main channel in some reaches of the river during the late summer of dry years.

Scott River

The Scott River enters the Klamath River at RM 145.1, 47.1 miles downstream from Iron Gate Dam. The Scott River watershed includes the heavily forested and relatively wet Salmon Mountains on its western divide, but these mountains create a rain shadow for the rest of the watershed. Similar to the Shasta River Valley, many areas in the Scott River Valley have been extensively altered for grazing and agriculture. Although the Scott River watershed is almost the same size as the Shasta River watershed, the hydrograph for the Scott River near the confluence with the Klamath River has four to five times higher median monthly flows in the winter and spring months (see Table 3.6-6). Somewhat similar to the Shasta River, the minimum monthly median flows near 50 cfs occur during August and September.

Klamath River at Seiad Valley

A USGS flow gage is on the Klamath River at Seiad Valley, downstream from its confluence with the Scott River. During the low flow months of August through November, approximately 75 percent of the water flowing past this gage is attributed to Iron Gate Dam releases. During the months of April through June approximately 50 percent of the water flowing past this gage is attributable to Iron Gate Dam releases (FERC 2007). Figure 3.6-11 shows daily flow at the Klamath River at Seiad Valley from water years 1963 to 2015.

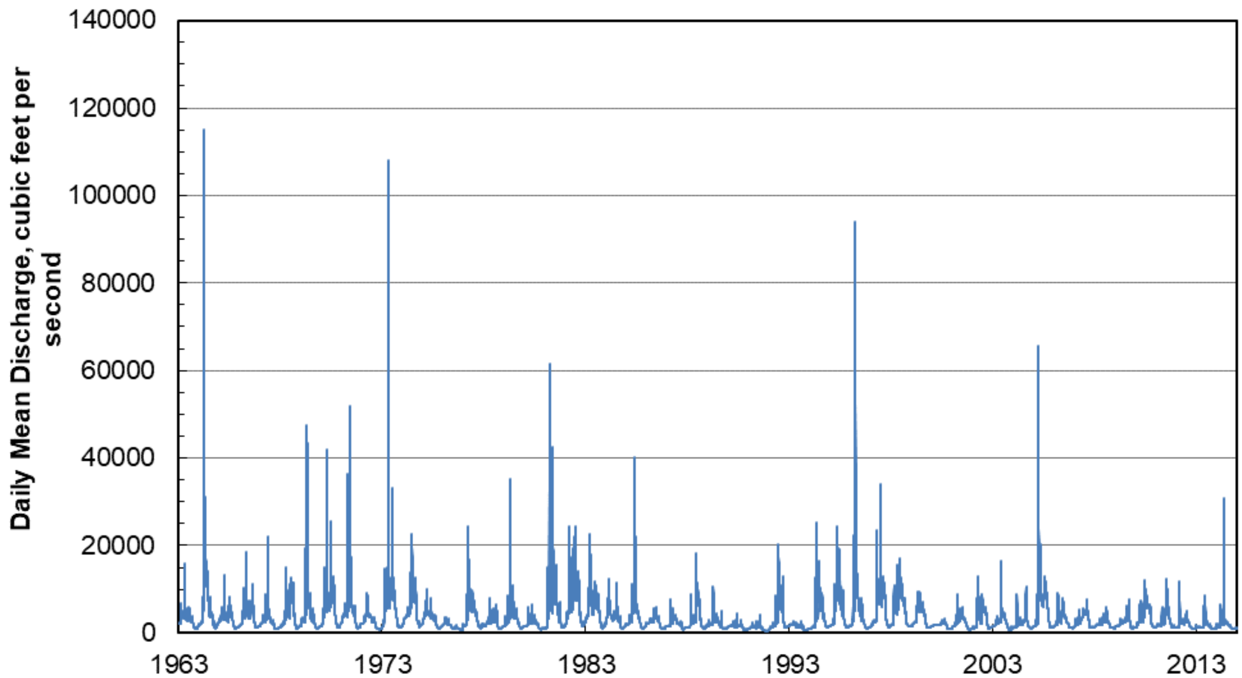

Figure 3.6-11. Discharge for Klamath River at Seiad Valley, 1963–2015. Source: USGS 2016.

Salmon River

Approximately 77 miles downstream from the Scott and Klamath rivers confluence, the Salmon River enters the Klamath River at RM 66.3. The Salmon River flows through the Klamath National Forest and many designated wilderness areas. The region surrounding the Salmon River is mainly forested with some agricultural activity. High monthly average flows (3,375 cfs) occur in January, which is the winter peak for flooding as rain and rain-on-snow events occur (see Table 3.6-6). In April and May, the Salmon River has a high monthly average flow (2,660 and 2,630 cfs, respectively) from snowmelt at higher elevations. The Salmon River has its lowest monthly average flow at about 200 cfs in September, which is later than for other tributaries upstream including the Shasta River where lowest monthly average flow occurs in July (FERC 2007).

Klamath River at Orleans

USGS Gage No. 11523000 is at Orleans, downstream from the confluence of the Salmon and Klamath rivers and other smaller tributaries within the Middle Klamath Basin. This area receives a high amount of precipitation compared to other reaches upstream of the Shasta River; therefore, higher flows than in upstream reaches occur here in the winter and spring months. Iron Gate Dam releases account for approximately 20 percent of the flow during these high flow periods and over 50 percent of the flow during the late summer and fall (FERC 2007). Figure 3.6-12 shows daily flow at USGS Gage No. 11523000 from water years 1963 to 2015, the same period of record summarized for this gage in Table 3.6-6.

Lower Klamath Basin

Trinity River

The Trinity River enters the Klamath River at RM 43.3, 150 miles downstream of Iron Gate Dam. The Trinity River is the largest tributary to the Klamath River. The Trinity River watershed is generally wet, steep, forested, and largely federally owned within several national forest and wilderness areas. As shown in Table 3.6-9, the Trinity River hydrograph at the confluence with the Klamath River has peak median monthly flows in February and March near 7,000 cfs, gradually declining to about 600 cfs in September.

A main feature of the Trinity River watershed is Trinity Lake. This reservoir has a storage capacity of 2.4 million acre-feet and is located 119 miles upstream from the Klamath River along the main branch of the Trinity River. Both Trinity Lake and the much smaller downstream Lewiston Reservoir were constructed in the early 1960's as part of the Central Valley Project's Trinity River Division (TRD). For the first 10 years of full operation, an average of nearly 90 percent or 1.2 million acre-feet of the annual river flow at the Lewiston Reservoir (drainage area of 692 square miles) was diverted via the Clear Creek Tunnel to Whiskeytown Lake and then to the Sacramento River system (FERC 2007). The California Department of Water Resources estimates that about 1.1 million acre-feet per year were diverted during 1964 to 1986 and 0.73 million acre-feet during 1987 to 2000.

The current flow release program from Lewiston Dam to the Trinity River is based on the Trinity River Mainstem Fishery Restoration EIS, completed in October 2000. In December 2000, USBR issued the Record of Decision (Trinity ROD) for the Trinity River Mainstem Fishery Restoration, but these flows did not go into full effect until November 2004.

Figure 3.6-13 shows the daily flow from the Trinity River at the confluence with the Klamath River for water years 1963 to 2015. Data for this same period that represents post-TRD operations are summarized in Table 3.6-9.

The Trinity ROD directed for approximately 50 percent of the Trinity River's flow to remain in the river (i.e., would not be diverted to the Central Valley) and for the Trinity River Restoration Program (2016) to recommend how water was to be released for restoration of the river and its fisheries.

Restoration flows are intended to: clean spawning gravels, build gravel/cobble bars; scour sand out of pools, provide adequate temperature and habitat conditions for fish and wildlife at different life stages, control riparian vegetation, and perform many other ecological functions. To mimic some of the inter-annual variation that is naturally found within the Trinity Basin, the Trinity ROD defines five water year types along with a minimum volume of water to be released into the Trinity River for each year type, as summarized in Table 3.6-10.

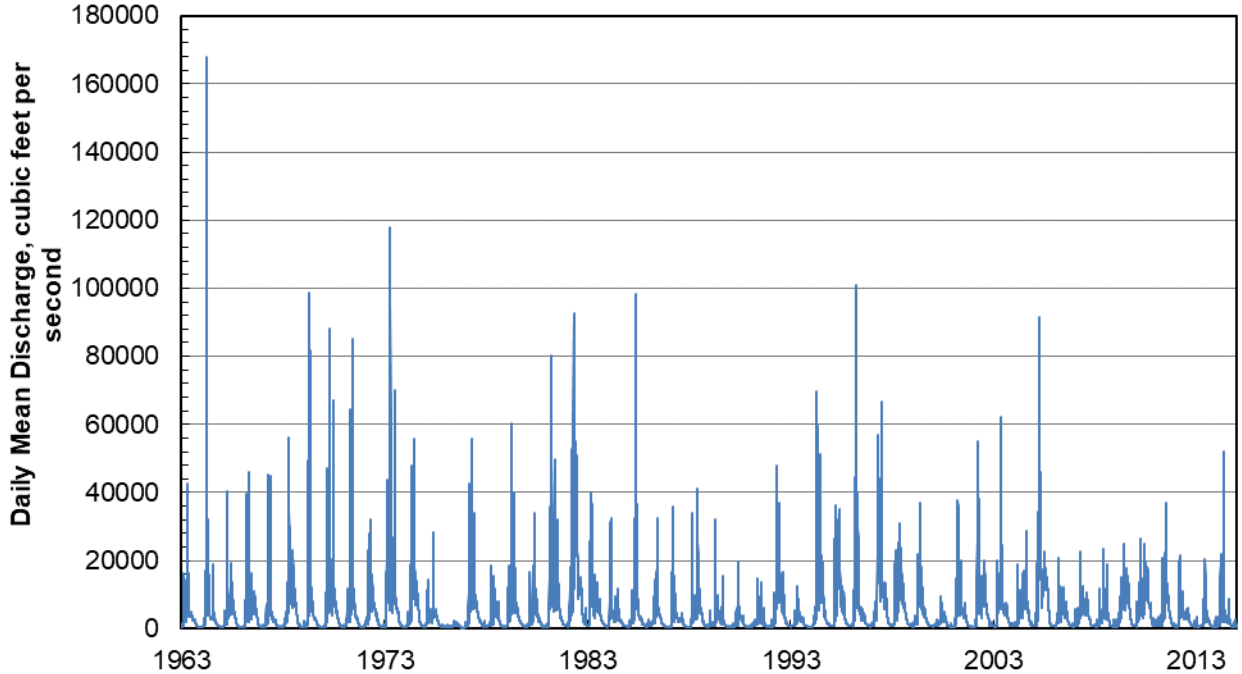

Figure 3.6-13. Daily Inflow from the Trinity River at the Confluence with the Klamath River, 1963–2015. Source: USGS 2016.

Table 3.6-10. Minimum Releases for Trinity River Restoration.

Water Year Type	Minimum Release Volume (acre-feet)
Critically Dry	369,000
Dry	453,000
Normal	647,000
Wet	701,000
Extremely Wet	815,000

Source: Trinity River Restoration Program 2016

Typical flow releases for each month of the five water year types are determined based on forecasted inflows to Trinity Reservoir on April 1. Each year, the water not allocated to the river for restoration purposes is available for export to the Central Valley Project for water supply and power generation.

During the recent drought from 2012 to 2016, USBR's drought plans included flow augmentation for the lower Klamath River from the Trinity Reservoir in addition to curtailing deliveries to Klamath Irrigation Project contracts. Abnormally dry hydrologic conditions led to very low Klamath River accretion forecasts, prompting concerns of a disease outbreak. Tribes, sport-fishermen groups, and other fishery advocates formally requested that USBR take action. Chinook in-river run size projections were at all-time highs in 2012, 2013, and 2014 (USBR 2015). Flow augmentation during these three drought years was as follows:

- **2012**: Ultimately 39,000 acre-feet was released for preventative purposes and no emergency releases were required. No substantial disease outbreak was noted by any tribes or fishery resource agencies during the return period. The fall Chinook return, post-season estimate was 292,000 adults.

- **2013**: Flows were augmented to a rate of 2,800 cfs in the lower Klamath River from August 15 through September 21. Ultimately 17,500 acre-feet was released for preventative purposes in 2013, and no emergency releases were required. No substantial disease outbreak occurred, although the Yurok Tribe reported that several fish had died from Columnaris. The post-season run size estimate was 165,100 adults.
- **2014**: Outbreaks of Ich drove the need for two emergency releases from Lewiston Dam. The volume of water initially released under the emergency criteria (from August 23 through September 16) totaled approximately 22,700 acre-feet, while the emergency flow doubling that (from September 17 through September 24), excluding ramping, totaled 41,300 acre-feet, for a grand total of 64,000 acre-feet. The fall Chinook return, post-season estimate was 160,000 adults.

USBR reported that the average volume released from Trinity Reservoir for augmentation in previous and recent dry periods (i.e., 2003, 2004, 2012, 2013, and 2014) was 38,963 acre-feet. USBR anticipates that a similar quantity will be sufficient in the majority of years when augmentation is required. However, as demonstrated by conditions experienced in 2014, the volume of release may exceed 40,000 acre-feet in any given year (USBR 2015).

Klamath River at Klamath
USGS Gage No. 11530500 is near the mouth of the Klamath River where it meets the estuary within the Lower Klamath watershed (see Table 3.6-9). During the September to October low flow periods, the releases from Iron Gate Dam account for approximately 40 percent of flow. However, the area surrounding the Klamath River reach downstream from its confluence with the Trinity River receives a heavy amount of precipitation, and during the winter months approximately 85 percent of the flow comes from other sources than Iron Gate Dam releases (FERC 2007).

Figure 3.6-14 shows daily flow from water years 1963 to 2015. Flows for July 2014 in the Lower Klamath River tied with 1994 for the second lowest on record (period of record from 1963 to 2015, with 1992 also similar). However, releases from Iron Gate Dam on the Klamath River were 300 cfs lower in July 1994, compared to 2014 (with Lewiston Dam releases on the Trinity River being equivalent), meaning that accretions were approximately 300 cfs lower in July 2014, compared to the exceptionally dry year of 1994. The extreme drought year of 1977 had the driest July and September on record, yet flows increased on September 20 of that year, to over 3,200 cfs from precipitation. In 1994, flows also increased in September (on September 1) to approximately 2,000 cfs (Strange 2014).

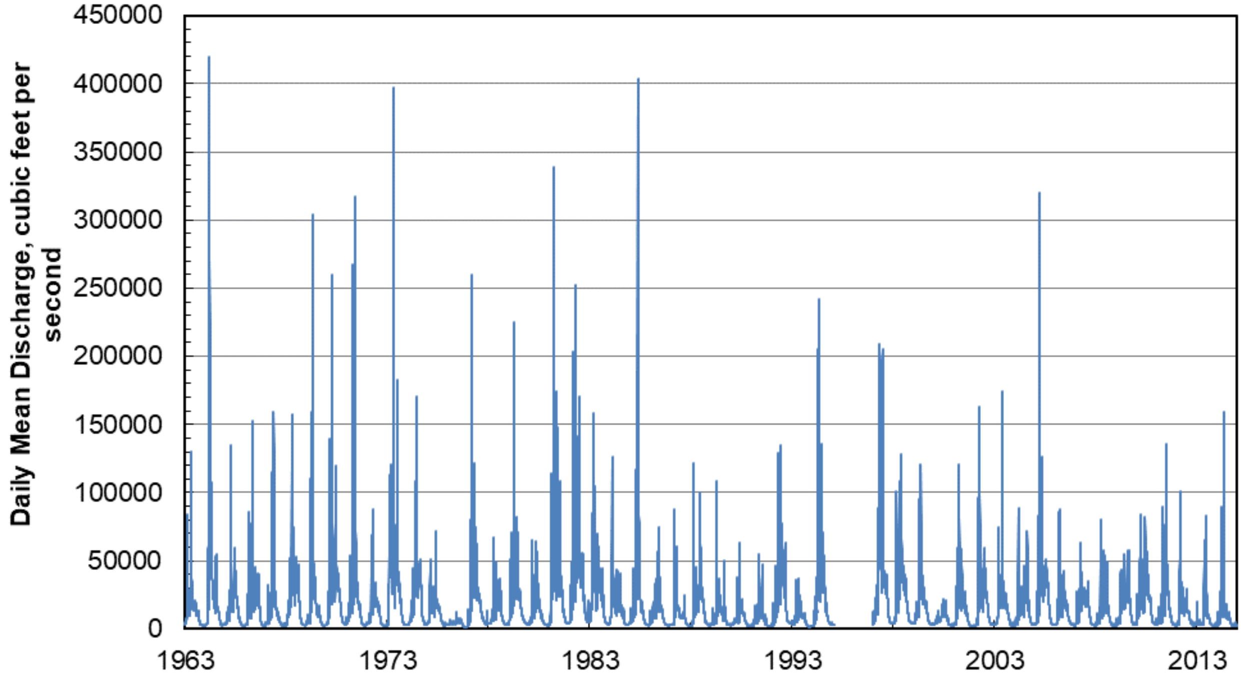

Figure 3.6-14. Discharge for Klamath River at Klamath, 1963–2015. Source: USGS 2016.

Klamath River Estuary

The Klamath River Estuary spans approximately four to five miles upstream of the mouth. The tidal influence normally extends approximately four miles upstream of the mouth during high tides greater than six feet upstream of the U.S. Highway 101 bridge. Past studies have observed the formation of a sill at the river mouth in late summer or early fall causing a standing water backup up to six miles upstream. During high tides saltwater was observed in the summer and early fall from the mouth upstream ranging approximately 2.5 to four miles depending on the time period samples were taken. The saltwater recedes during low tides (Wallace 1998).

3.6.2.3 Flood Hydrology

The active storage capacity at Upper Klamath Lake is approximately 579,200 acre-feet and includes areas restored by levee and dike breaches at Agency Lake, Barnes Ranch, Tulana Farms, and Goose Bay (USBR 2012). Active storage at Keno, J.C. Boyle, Copco No. 1, Copco No. 2 and Iron Gate reservoirs totals approximately 12,244 acre-feet (FERC 2007). Approximately 98 percent of the active surface water storage along the Klamath River is provided by Upper Klamath Lake behind Link River Dam. Keno, J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams provide approximately two percent of the active storage on the river.

Flood frequency analyses for 10-year to 100-year events were performed for seven USGS gages along the Klamath River. The analysis used a Log-Pearson III distribution and methods consistent with USGS Bulletin 17B (Table 3.6-11) (USGS 1982). The flows at Keno, J.C. Boyle, and Copco gages are highly regulated by impoundments and diversions upstream of the Keno gage. To better model those effects and improve the fit of the frequency curve to the data, a gage base discharge was applied to censor the data. This was done based on the assumption that the peak discharges above the gage base discharge represent what would be expected during unregulated conditions. The analyses do not include peaks below the gage base discharge to estimate the frequency curve statistics because they are regulated and cannot be modeled using the same distribution. Following the procedures of USBR (2012) the gage base discharges used for Keno, J.C. Boyle, and Copco were 4,000 cfs, 4,000 cfs, and 5,400 cfs, respectively. The Iron Gate, Seiad Valley, Orleans, and Klamath gages are not significantly impacted by the regulation upstream of Keno and therefore the data from these gages were not censored for the flood frequency analyses.

To create a common period of record, the gage records at J.C. Boyle and Copco were extended based on correlation to Keno. The gage data at Keno was correlated to the J.C. Boyle and Copco data for the overlapping years of record when the peak discharges at both gages were from the same flood event. The Iron Gate, Seiad Valley, Orleans, and Klamath gage records do not correlate well with the Keno record and thus they were not extended.

Table 3.6-11. Annual Flood Frequency Analysis on Klamath River for 10-Year to 100-Year Flood Events.

Data Source: USGS 2017
Notes:
[1]Gage base is a threshold above which peak discharges represent what would be expected during unregulated conditions. Peak discharges below the gage base are influenced by regulation and are omitted from the analysis.
Periods of record (gaged and correlated) (water years):
Keno 1905–1913, 1930–2016
J.C. Boyle 1959–2016. 1905–1913 and 1930–1958 correlated based on Keno gage.
Copco, 1924–1961. 1905–1913 and 1962–2016 correlated based on Keno gage.
Iron Gate 1961–2016
Seiad Valley 1913–1925, 1952–2016
Orleans 1927–2016
Klamath 1911–1927, 1932–1994, 1996–2016

The flood frequency analyses use the most recently published USGS streamflow data (Table 3.6-11) to provide an update to USBR (2012), which conducted comparable flood frequency analyses to support the hydrologic and hydraulic modeling of 100-year floodplain inundation (presented in Appendix K). USBR (2012) states that under the Proposed Project during a 100-year event the largest water surface elevation increases would be approximately 1.5 feet downstream of Iron Gate Dam, and that the error in computed water surface elevations is one to two feet at most modeled cross sections. USBR (2012) acknowledges their computed water surface elevation increases are conservative overestimates. The 100-year peak flow estimate for Iron Gate Dam (the flow used in model calculations to compare the Proposed Project with existing conditions) presented in Table 3.6-11 differs from that given in USBR (2012) by less than one percent.

Results of the flood frequency analyses indicate that peak flows at Iron Gate Dam are substantially greater than peak flows at J.C. Boyle Dam (Table 3.6-11). This is because of flows from the tributaries that enter the Klamath River between the two dams. In particular, Jenny Creek contributes a large amount to the peak flow during the winter and spring months. The watershed area of Jenny Creek is 210 square miles, and it is the largest single tributary to the Klamath River between Keno Dam and Iron Gate Dam (USBR 2012).

During extremely wet years, surface water elevations rise in Upper Klamath Lake. Agency Lake, Barnes Ranch, and the Nature Conservancy-owned lands provide over 108,000 acre-feet of storage around and near Upper Klamath Lake due to recent breaching of local dikes and levees, which can help to reduce flooding downstream. In contrast, there is minimal surplus storage in the Lower Klamath Project to help control flooding downstream of Iron Gate Dam. During wet years, decreased irrigation demands in the upper basin may allow for more water to remain in Upper Klamath Lake for use later in the year. The amount of water retained in Upper Klamath Lake is determined under the 2013 BiOp and depends on decisions related to ESA-listed suckers and the magnitude of spring flushing flows and fall migration flows downstream of Iron Gate Dam (NMFS and USFWS 2013) (see also Section 3.1.6.1 Klamath River Flows under the

Klamath Irrigation Project's 2013 BiOp Flows). The 2013 BiOp also includes provisions for average and wet years that increase minimum flow requirements at Iron Gate Dam and surface water elevations in Upper Klamath Lake to more closely mimic natural flow and lake-level conditions and provide storage for surplus water (NMFS and USFWS 2013).

3.6.2.4 Risks of Dam Failure

Dams are man-made structures and do include some risk of failure that could result in flooding downstream. According to the Association of State Dam Safety Officials (ASDSO), dams fail due to one of five reasons (ASDSO 2011):

1. Overtopping caused by water spilling over the top of dam;
2. Structure failure of materials used in dam construction;
3. Cracking caused by movements like the natural settling of dam;
4. Inadequate maintenance and upkeep; or
5. Piping—when seepage through a dam is not properly filtered and soil particles continue to erode, and form sink holes in the dam or its foundation.

In California, weighted point systems are used during inspections to classify both the hazard or damage potential and condition of the dam. Once classified, the frequency of inspections and return period for hydrology studies are selected. The classifications used for damage potential are extreme, high, moderate and low and refer to the possibility of loss of life and property downstream from the dam if it were to fail. The classifications of the condition of the dam are poor, fair, good, and excellent and are determined based on the age, general condition, and geologic and seismic setting. Dams may be reclassified after improvements or other changes have occurred (ASDSO 2000).

Siskiyou County recently developed a Multi-Jurisdictional Hazard Mitigation Plan which addressed, among other issues, flood and dam failure hazards. Maps are currently available that describe dam inundation areas based on potential failure of J.C. Boyle and Iron Gate dams as well as a domino effect, depicting the inundation area if multiple dams were to fail at the same time (Siskiyou County 2011). FERC staff have conducted safety inspections of the dam structures as part of the licensing program over the past 50 years. Every five years J.C. Boyle, Copco No. 1 and Iron Gate dams are inspected and evaluated by an independent consultant and reports documenting the evaluation are submitted to FERC for review (FERC 2007).

3.6.3 Significance Criteria

Criteria for determining significant impacts on flood hydrology was informed by Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and based on professional judgment. Effects on flood hydrology are considered significant if the Proposed Project would result in exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding, where substantial risk is associated with structures located within the FEMA 100-year floodplain inundation extent. These impacts are broadly divided into short-term flood risks that could occur during reservoir drawdown and long-term, permanent changes to the downstream floodplain elevations (i.e., permanent changes to the FEMA 100-year floodplain) as a result of dam removal.

The potential for changes in flood hydrology and/or in the extent of floodplain inundation to impact aquatic and terrestrial resources are discussed in Sections 3.3 *Aquatic Resources* and 3.5 *Terrestrial Resources*, respectively.

3.6.4 Impacts Analysis Approach

The assessment of the environmental impacts on flood hydrology that would result from implementation of the Proposed Project and its alternatives determines whether changes in stream flows would cause flooding within the Area of Analysis. The impact assessment is based on the USBR's hydrologic and hydraulic modeling, which covers the Proposed Project and the No Project Alternative. USBR used a one-dimensional HEC-RAS model that assessed hydrologic conditions for these two alternatives and analyzed modeling output to determine how frequently the current FEMA floodplain is inundated and how the floodplain could change under the Proposed Project. This information was presented in the *Hydrology, Hydraulics, and Sediment Transport Studies for the Secretary's Determination on Klamath River Dam Removal and Basin Restoration* (USBR 2012). The model results under the Proposed Project and No Project Alternatives provide adequate information to estimate the relative effects of the other alternatives not modeled.

USBR used KBRA flows as the hydrologic input for modeling floodplain inundation (USBR 2012). The 2013 BiOp changed the likely flow regime under which dam removal would occur in 2020 (i.e., no longer using KBRA flows). However, the differences in hydrology between KBRA and 2013 BiOp flows are minor (see Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* for further details regarding KBRA and 2013 BiOp flows).

The model results include predictions of the river flows that would occur if the four dams in the Lower Klamath Project were removed. The modeling effort provided useful information for assessing the impacts on flood hydrology in the long term but provides limited information about the construction period. Flood risks associated with dam removal activities are described qualitatively and quantitatively using the HEC-RAS and SRH-1D modeling results completed by USBR, and the analysis includes the measures incorporated to reduce these risks (USBR 2012).

The following sources were assessed to determine the scope of existing local plans and policies relevant to the Proposed Project:

- Del Norte County General Plan (Mintier & Associates et al. 2003):
    - Section 2 Safety and Noise
        - General Policies: 2.A.1, 2.A.2
        - Flood Hazards Policies: 2.D.1, 2.D.4, 2.D.6
        - Disaster Planning Policies: 2.G.1
- Humboldt County General Plan for Areas Outside of the Coastal Zone (Humboldt County 2017):
    - Chapter 14 Safety Element
        - General Policies: S-P1, S-P4
        - Flooding Policies: S-P12, S-P13, S-P14, S-P15

      - Flood Management Standards: S-S5, S-S6, S-S8
- Siskiyou County General Plan (Siskiyou County 1980)
  - Chapter 3 Land Use Policies
    - Flood Hazard Policies: 21, 22, 23, 24, 26
    - Surface Hydrology Policies: 27

Most of the aforementioned policies and standards are stated in generalized terms, consistent with their overall intent to address flood hydrology impacts. By focusing on the potential for impacts to specific flood hydrology issues within the flood hydrology Area of Analysis, consideration of the more general local policies listed above is inherently addressed by the specific, individual analyses presented in Section 3.6.5 *[Flood Hydrology] Potential Impacts and Mitigation;* and the more general local policies are not discussed further.

3.6.5 Potential Impacts and Mitigation

3.6.5.1 Flood Hydrology

Potential Impact 3.6-1 Reservoir drawdown and dam removal could result in short-term increases in downstream surface water flows and result in exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.

Reservoir drawdown activities would begin on November 1 of the year prior to drawdown at Copco No. 1 Dam, and on January 1 of the drawdown year at J.C. Boyle, Copco No. 1, and Iron Gate dams (see also Table 2.7-1 and Section 2.7.2 *Reservoir Drawdown*). The KRRC would control the releases that would vary by reservoir depending on the type of dam, discharge capacity, water year type, and the volume of water and sediment within the reservoir. The resultant reservoir water surface elevation after the initial drawdown would be generally higher in a wetter year than in a drier year at all the dams (see also Section 2.7.2 *Reservoir Drawdown*).

Reservoir drawdown in the Proposed Project includes considerations for minimizing potential flood risks. These considerations include carefully drawing down the Lower Klamath Project reservoirs using controlled flow releases (see Section 2.7.2 *Reservoir Drawdown*) and the increased storage availability in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs once drawdown has begun. If a flood event occurred during drawdown, the KRRC proposes to retain flood flows using the newly available storage capacity and continue drawdown after flood risks have ended. Existing conditions do not allow these reservoirs to assist in flood prevention in this manner.

At J.C. Boyle Dam, the KRRC would begin reservoir drawdown activities in January of the drawdown year (see also Table 2.7-1), while stream flows are still high. Controlled releases would initially be through the gated spillway and power intake, with drawdown increases to the existing river flow ranging from a minimum of 19 cfs (on average) to a maximum of 138 cfs (on average), assuming a continuous 5 feet per day drawdown (Appendix B: *Definite Plan*).

Because J.C. Boyle Reservoir has very little storage capacity, release flows would fluctuate throughout the drawdown period due to changes in reservoir inflow rate. Occasional periods of rapid increases in release flows would occur, with a total maximum drawdown release flow of approximately 3,000 cfs occurring for approximately 2-3 hours, then dropping back to near inflow values over a total of 6-8 hours (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). The maximum capacity of the power intake is approximately 2,800 cfs. Therefore, flows above approximately 2,800 cfs would go over the spillway. Storm inflows large enough to cause refilling of the reservoir would also pass over the spillway. The reservoir drawdown is planned be completed by January 31 of the drawdown year, to minimize potential impacts at the downstream dam removal sites. The potential formation of reservoir ice in January at J.C. Boyle would not affect reservoir drawdown substantially during this period because reservoir releases at the dam would be maintained below ice cover (Appendix B: *Definite Plan*). Drawdown would proceed through the spillway and penstock, which would access the liquid portion of the reservoir. As the water level drops, surface ice would lower and start to crack. Broken ice on the reservoir surface would provide some amount of roughness that slows the flowing water in the canyon portion of the reservoir as well as reduces the entrainment of reservoir sediment. As a flowing condition is restored, surface ice would melt and be reduced because moving water mixes temperatures between the air and ground, the latter of which does not get cold enough in the Area of Analysis to freeze. The J.C. Boyle powerhouse successfully operates throughout the winter even with lake ice present (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., November 2018).

The additional controlled releases that would occur for the purposes of drawing down J.C. Boyle Reservoir would be unlikely to increase flood risks downstream of the California-Oregon state line because releases from the dam would be within the range of historical flows and so would not be a change from existing conditions. The 2-year and 5-year flow events downstream of J.C. Boyle Dam are 4,736 cfs and 7,719 cfs, respectively. A 10-year flow at J.C. Boyle results in an estimated flow of 10,362 cfs (see Table 3.6-11), and the maximum daily winter flow (January through March) is in excess of 8,000 cfs (USGS 2011). The average monthly flow below J.C. Boyle Dam for the period 1961−2009 was approximately 2,380 cfs in January, 2,450 cfs in February, and 2,890 cfs in March. Therefore, temporarily increasing the flow to approximately 3,000 cfs during reservoir drawdown would not result in exposing people or structures to substantial flood risks downstream of the California-Oregon state line.

Removal of the J.C. Boyle Dam embankment would occur in late June, July, and August of the drawdown year (see also Table 2.8-1) and would initially (June 15 to June 30) progress to no lower than elevation 3,778 feet amsl to provide sufficient elevation above a 150-year flood plus approximately 5 feet of freeboard. In July and August, the upstream cofferdam crest would not go below 3775 feet amsl to endure a 150-year flood plus approximately 5 feet of freeboard, and in September the cofferdam elevation would not go below 3771 feet amsl to endure a 100-year flood plus 0 feet of freeboard (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). This drawdown scenario would involve flows up to approximately 3,500 cfs through the left abutment. The upstream cofferdam would be armored with rockfill to allow a controlled breach to fully drain the reservoir prior to September 30 of the drawdown year. Reservoir releases would temporarily exceed inflow by up to approximately 5,000 cfs, depending upon the rate of breach development, but would remain below the downstream channel capacity of 6,957 cfs (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). Although the breach flow would quickly attenuate as it moved downstream due to the very small reservoir volume, the Iron Gate cofferdam would be breached before breaching the J.C. Boyle cofferdam as a precaution against the potential increased inflow to the Iron Gate impoundment (Appendix B: *Definite Plan*).

Although a limited drawdown (i.e., two feet per day) of Copco No. 1 Reservoir would begin on November 1 of the year prior to drawdown to allow early removal of the spillway gates and crest structure using a barge mounted crane, the primary drawdown and sediment release of Copco No. 1 Reservoir would begin January 15 of the drawdown year. Increased drawdown rates of five feet per day are delayed two weeks after drawdown releases begin at Iron Gate Dam (i.e., January 1) to create additional reservoir capacity at Iron Gate, which would better handle drawdown releases from Copco No. 1 Reservoir and help attenuate outflows from Iron Gate Reservoir due to storms. Drawdown would be limited to five feet per day to maintain reservoir rim slope stability and control drawdown releases from both reservoirs upstream of Iron Gate Reservoir. Maximum additional discharge downstream of Copco No. 1 Dam due to drawdown activities is anticipated to be about 6,000 cfs when the gate is opened on January 15. During other times the flow increase is generally 1,000 to 2,000 cfs. The total discharge capacity of the new gate structure with the reservoir at the spillway crest elevation of 2,597 feet amsl is about 12,000 cfs. If water levels increase above the spillway crest, the gate would be closed down to limit the total discharge to 13,000 cfs to avoid high water levels that would interfere with power production at Copco No. 2 Powerhouse. For reference, the 10-year, 20-year, 50-year, and 100-year flow events downstream of Copco No. 1 are 11,910 cfs, 13,543 cfs, 14,702 cfs, and 15,821 cfs, respectively. Storm inflows large enough to cause refilling of the reservoir would pass through the spillway.

Beginning January 15 of the drawdown year, as the Copco No. 1 Reservoir is drawn down through the new large gate structure at the downstream end of the diversion tunnel, penstocks, abutment gate houses, and above ground powerhouse equipment would be removed. After April 15 of the drawdown year Copco No. 1 Dam would be excavated in 12-foot lifts. Concrete rubble from the dam and powerhouse would be removed by truck. Temporary cofferdams in the river channel would be constructed as required for removal of the powerhouse and diversion tunnel control structures. The cofferdams would be removed once no longer needed and the upstream and downstream diversion tunnel portals would be plugged with concrete (Appendix B: *Definite Plan*).

Copco No. 2 Dam does not provide any meaningful storage, and the reservoir is very small compared to the other reservoirs, with little or no impounded sediment. Dam removal would begin on about May 1 of the drawdown year. No additional releases would be made from the upstream reservoirs during this time as they would have already been mostly drained. The KRRC would use cofferdams to isolate areas of the small concrete dam during demolition and would remove them once they were no longer needed (Appendix B: *Definite Plan*).

Reservoir drawdown at Iron Gate Reservoir would begin from normal operating elevation of 2,331.3 feet amsl on January 1 of the drawdown year by making controlled releases through the modified diversion tunnel. Reservoir drawdown would be limited to a maximum of five feet per day to maintain reservoir rim slope stability. Maximum additional discharge downstream of the dam due to drawdown activities would be approximately 4,000 cfs. Total discharge capacity of the modified diversion tunnel with the reservoir at spillway crest elevation of 2,331.3 feet amsl is about 10,000 cfs

(Appendix B: *Definite Plan*). For reference, the 10-year flow event downstream of Iron Gate Dam is 14,854 cfs.

Results from reservoir drawdown modeling (USBR 2012) indicate that during representative drier water years, Iron Gate Reservoir would be drawn down by early February of the drawdown year, and it would not refill after that point. During wetter water years the reservoir would be completely drawn down by March 1, but it could partially refill during storms later in the drawdown year. The majority of the accumulated sediment would mobilize during the initial drawdown, and subsequent reservoir filling and drawdown would be expected to cause only moderate increases in suspended sediment relative to background (USBR 2012). During the wettest water years, the reservoir would be completely drawn down by early March (Appendix B: *Definite Plan*).

Dam removal at Iron Gate Dam would begin following spring runoff on June 1 of the drawdown year and be completed by October 15. The removal plans require that sufficient freeboard be maintained to pass a 100-year flood at all times for those months between the elevation of the excavated embankment surface and any remaining reservoir water surface to reduce to potential for flood flows overtopping the embankment. During dam removal between June 1 and August 31, sufficient embankment elevation would be maintained to endure a 150-year flood event plus approximately 5 feet of freeboard. In September, the upstream cofferdam crest elevation would be maintained to endure a 100-year flood event plus 0 feet of freeboard (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). September is the month that the cofferdam would be breached.

Dam excavation would proceed at an estimated 7,500 cubic yards (CY) per day in June, 14,250 CY per day in July, and 16,000 CY per day in August and early September, leaving an upstream cofferdam. Minimum reservoir flood release capacities would be approximately 7,700 cfs in June, 7,000 cfs in July, and 3,000 cfs in August and September, to accommodate the passage of at least a 100-year flood during those times of the year. By late September, the reservoir would be drawn down to the maximum possible extent, minimal streamflow would be occurring, and drawdown releases from upstream reservoirs would have ended. The upstream cofferdam would be armored with rockfill to allow a controlled breach. The cofferdam at Iron Gate Dam would be breached prior to breaching the cofferdam at J.C. Boyle Dam to minimize potential downstream impacts. The breach flow from J.C. Boyle Dam would quickly attenuate as it moved downstream due to the very small reservoir volume.

This analysis uses the reservoir drawdown release rates at Iron Gate Dam to determine the level of significance of adverse impacts downstream because Iron Gate Dam has the largest reservoir, provides the highest amount of discharge, and is the most downstream from all the dams that would be removed. The release rates that would occur during drawdown of the reservoir would be in the range of historical flows during an extremely wet year (one percent exceedance probability or 100-year flood event). While the release rates that would occur during reservoir drawdown would be greater than the flows at the same time under the existing conditions, and in some months above the historical monthly maximum flow (e.g., September), they would be lower than the overall peak flows for extremely wet years recorded during the period of record in each reach. Because the flows would stay below historical peak flows, they would not change the floodplain or flood risks in comparison to the existing conditions. Thus, the short-term increases in downstream flows and changes to flood risks resulting from reservoir drawdown would be less than significant.

Significance
No significant impact

Potential Impact 3.6-2 Under the Proposed Project recreational facilities currently located on the banks of the existing reservoirs would be removed following drawdown and could change flood hydrology.
The existing recreational facilities provide camping and boating access for recreational users of Copco No. 1 and Iron Gate reservoirs. Once the reservoirs are drawn down, most of these facilities would be removed (see also Section 3.20.4.3 *Reservoir-based Recreation*). These facilities would be well above the new river channel, and deconstruction would not place anything in the channel or otherwise impede low or high flows in the Klamath River. Therefore, there would be no impact to flood hydrology from the removal of recreational facilities.

Significance
No significant impact

3.6.5.2 River Floodplain

Potential Impact 3.6-3 The long-term FEMA100-year floodplain inundation extent downstream from Iron Gate Dam could change between river miles 193 and 174, potentially exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.
Hydrologic and hydraulic modeling of floodplain inundation shows that removal of the Lower Klamath Project dams could alter the 100-year floodplain inundation area downstream of Iron Gate Dam between RM 193 and 174 (i.e., from Iron Gate Dam to Humbug Creek) (USBR 2012). The modeling indicates that the differences between existing conditions and the Proposed Project are minor. Floodplain inundation maps illustrating these model results are presented in Appendix K of this EIR. The mapping includes the effects of the increase in the 100-year flood peak flow rate and the small amounts of sediment deposition in the river channel following removal of the Lower Klamath Project dams.

Modeling of flood flows downstream of Iron Gate Dam indicates that the Lower Klamath Project dams provide a slight attenuation of peak flood flows. USBR (2012) estimated that the discharge of the 100-year peak flood immediately downstream of Iron Gate Dam would increase by up to seven percent following dam removal (Table 3.6-12) and flood peaks would occur about 10 hours earlier. This increased discharge would result in flood elevations that are 1.65 feet higher on average from Iron Gate Dam (RM 193) to Bogus Creek (RM 192.6) and 1.51 feet higher on average from Bogus Creek to Willow Creek (RM 188) (Appendix B: *Definite Plan*). The impact of dam removal on flood peak elevations would decrease with distance downstream of Iron Gate Dam, and USBR (2012) and the KRRC (Appendix B: *Definite Plan*) estimated that there would be no significant effect on flood elevations downstream of Humbug Creek (RM 174) because flow attenuation would occur in the mainstem channel and tributary peak flows would not coincide with the peak flow downstream of RM 193 (i.e., current location of Iron Gate Dam).

Table 3.6-12. Flood Attenuation of Iron Gate and Copco No. 1 Reservoirs on Flows at RM 193.

Flood Event	Peak Flow	Peak Flow - Proposed Project	Percent Reduction With Dams In
Synthetic 100-yr flood	31,460	33,800	6.9
1989	10,200	10,300	1.2
1993	11,100	11,400	2.7
1996	11,200	11,300	1.1
1997	20,500	21,400	4.0
2005	12,400	12,800	3.0

Source: USBR 2012

Changes in flood peak elevations and the extent of floodplain inundation under the Proposed Project could affect properties and structures along the river downstream of Iron Gate Dam during a flood event. The Klamath Basin is currently subject to flooding and FEMA has developed flood insurance risk maps that Siskiyou County has recognized in regulations concerning development along the river.

USBR (2012) estimated the number of residences and structures located along the Klamath River between Iron Gate Dam (RM 193) and Humbug Creek (RM 174) that would potentially be affected should the dams be removed. This estimate was based on photo interpretation and field visits. Structures along the Klamath River were categorized according to whether they are within the existing 100-year floodplain or would be in the altered 100-year floodplain following dam removal. The KRRC revisited the aerial photo analysis using the USBR (2012) floodplain boundaries and determined that a total of 34 legally-established habitable structures are located within the existing 100-year floodplain between Iron Gate Dam (RM 193) and Humbug Creek (RM 174), and an estimated 2 additional legally-established habitable structures would be within the altered 100-year floodplain in the same reach following dam removal, for a total of 36 legally established habitable structures within the altered 100-year floodplain following dam removal (Appendix B: *Definite Plan*). The KRRC defines legally established habitable structures as those that have running water, electricity, appliances, and sanitary service (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., September 2018). This includes residential and commercial structures that are intended for permanent habitation.

Although the original USBR hydrologic and hydraulic modeling was conducted assuming KBRA flows, it is reasonable to conclude that the likely adverse impacts to structures in the 100-year floodplain downstream of Iron Gate Dam and the timing of downstream flood peaks would be similar under the 2013 BiOp flow regime because: (1) the 2013 BiOp and KBRA flows are similar, and (2) there is no change to flood operations under the 2013 BiOp flows versus the KBRA flows (see also Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*).

An estimated three river crossings in this downstream reach could also be affected by the increase in flood depths: two pedestrian bridges and the Central Oregon and Pacific Railroad Bridge (Appendix B: *Definite Plan*). Both pedestrian bridges are below the existing 100-year flood elevation, and there is a potential increase in scour depth at the railroad bridge. Pedestrian Bridge #1 is dilapidated and is not structurally safe. Pedestrian Bridge #2 and the railroad bridge are in good condition. The KRRC proposes to remove Pedestrian Bridge #1, with the owner's permission. The KRRC proposes to consult with the owner of Pedestrian Bridge #2 during the detailed design phase to determine whether this bridge should be removed or replaced, at the KRRC's expense. The KRRC proposes to perform more analysis during the detailed design phase to confirm the effects of scour on the railroad bridge, as it may have sufficient footing and foundation depths to accommodate the increased scour potential but may need additional scour protection. The KRRC would make any needed improvements.

The change to the 100-year floodplain inundation area between Iron Gate Dam (RM 193) and Humbug Creek (RM 174) due to dam removal would result in exposing approximately two additional habitable structures to a substantial risk of damage due to flooding and is considered a significant impact. To address this potential impact, the Proposed Project includes implementation of the Downstream Flood Control Project Component (Project Component), as described in Section 2.7.8.4 *Downstream Flood Control* and in Appendix B: *Definite Plan*. This Project Component replaces Mitigation Measure H-2 from the 2012 KHSA EIS/EIR.

The KRRC proposes to work with willing landowners to implement a plan to address the significant flood risk for the 36 habitable structures (including permanent and temporary residences) located in the altered 100-year floodplain between Iron Gate Dam and Humbug Creek following dam removal. The KRRC would work with the owners to move or elevate the habitable structures in place before dam removal, where feasible, to reduce the risks of exposing people and/or structures to damage, loss, injury, or death due to flooding. However, flood damage and/or loss of structures that are not feasible to move or elevate would be a significant impact. Final determination of the future 100-year floodplain after dam removal would be made by FEMA. The KRRC is coordinating with FEMA to initiate the map revision process (Appendix B: *Definite Plan*). The Project Component would also evaluate the river crossings that could be affected by a substantial risk of damage due to flooding.

When a large flood event is predicted, the National Weather Service (NWS) River Forecast Center provides river stage forecasts and flood warnings for the Klamath River for the USGS gages at Seiad Valley, Orleans, and Klamath. The River Forecast Center is the Federal agency that provides official public warning of floods. They currently do not publish a forecast for river stage at the Iron Gate gage, however, they work with PacifiCorp to issue flood warnings to Siskiyou County.

Under the Proposed Project, the KRRC's Emergency Response Plan would include informing the NWS River Forecast Center of a planned major hydraulic change (i.e., removal of four dams) to the Klamath River that could potentially affect the timing and magnitude of flooding downstream of Iron Gate Dam (Appendix B: *Definite Plan*). The Emergency Response Plan replaces Mitigation Measure H-1 from the 2012 KHSA EIS/EIR. As needed, the River Forecast Center would update their hydrologic and hydraulic modeling of the Klamath River so that changes to the timing and magnitude of flood peaks would be included in their forecasts. The Proposed Project would not affect the River Forecast Center's practice of publicly posting flood forecasts and flood warnings for use by federal, state, county, tribal, and local agencies, as well as the public, so timely decisions regarding evacuation or emergency response can be made.

As described in the Definite Plan (Appendix B), the KRRC would also inform FEMA of the planned major hydraulic change to the Klamath River (i.e., dam removal) that could affect the 100-year floodplain. This would be done through a conditional letter of map revision (CLOMR) report, submitted to FEMA during the detailed design phase. Subsequently, the KRRC would submit a letter of map revision (LOMR) to FEMA to provide recent hydrologic and hydraulic modeling, and updates to the land elevation mapping so FEMA can update its 100-year floodplain maps downstream from Iron Gate Dam, as needed. These updates would provide critical information regarding real-estate disclosures, zoning decisions, and insurance requirements such that short- and long-term flood risks are evaluated and responded to by agencies, the private sector, and the public.

Overseeing development and implementation of the Downstream Flood Control Project Component and the Emergency Response Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to work with willing landowners to implement a plan to address the significant flood risk and has initiated a process with FEMA to reach enforceable good citizen agreements that will be finalized and implemented, at this time these elements of the Proposed Project are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the Downstream Flood Control Project Component and the Emergency Response Plan, and any modifications developed through the FERC process that provide the same or better level of protection against flood damage, would reduce impacts to less than significant, because the State Water Board cannot ensure their implementation, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance

Significant and unavoidable for exposing structures to a substantial risk of damage due to flooding

No significant impact related to exposing people and/or structures to a substantial risk of flooding related to flood forecasting

Potential Impact 3.6-4 The FEMA 100-year floodplain inundation extent downstream from J.C. Boyle Dam could change between the California-Oregon state line and Copco No. 1 Reservoir, potentially exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.

As part of prior flood-inundation hydrologic and hydraulic modeling conducted for dam removal analyses, USBR (2012) ignored the potential effect of removing J.C. Boyle Dam on floodplain inundation downstream of the Hydroelectric Reach because this dam is approximately 35 miles upstream of Iron Gate Dam and is significantly smaller than either Iron Gate or Copco No. 1 dams. Within the Hydroelectric Reach, USBR (2012) did not conduct 100-yr floodplain mapping; however, FEMA (2016) mapping includes a 100-yr floodplain boundary for existing conditions on the Klamath River, including the Hydroelectric Reach (Appendix K).

Because J.C. Boyle Reservoir provides no storage and the dam typically operates in spill mode at flows above plant capacity (i.e., approximately 6,000 cfs; Table 2-1 in USBR 2012), existing conditions peak flows in the Hydroelectric Reach are not attenuated as a result of J.C. Boyle Dam. More specifically, the estimated spillway capacity of J.C. Boyle Dam at water surface elevation 3,793 feet amsl with all three gates open is 14,850 cfs

(USBR 2012), while the 100-yr estimated peak flow event in the Klamath River downstream of J.C. Boyle Power Plant is slightly lower, at 14,518 cfs (Table 3.6-11).

Therefore, under the Proposed Project the 100-yr flood inundation extent on the Klamath River from the Oregon-California state line downstream to Copco No. 1 Reservoir would not change from existing conditions (see also Appendix K).

Significance

No significant impact

Potential Impact 3.6-5 The release of sediment stored behind the Lower Klamath Project dams and resulting downstream sediment deposition under the Proposed Project could result in potentially exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.

Depending on hydrologic conditions during drawdown and dam removal, approximately 90,000 to 170,000 U.S. tons of sediment behind J.C. Boyle Dam, 950,000 to 1,590,000 U.S. tons of sediment behind Copco No. 1 Dam, and 420,000 to 550,000 U.S. tons of sediment behind Iron Gate Dam would be eroded and flushed down the Klamath River during dam removal activities (USBR 2012) (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). After dam removal, the remaining sediment would be left in place above the active channel. USBR conducted an analysis of future geomorphology and sediment transport during and after dam removal for dry, average, and wet start year scenarios. Most of the erosion would occur during the drawdown period from January 1 to March 15 of the drawdown year and afterwards the river bed in the reservoir reaches is expected to stabilize. Minor deposition would occur in some of the reaches downstream from dam removal activities, however none is expected downstream of the Shasta River confluence (USBR 2012). The Geology and Soils analysis considers the effects of sediment deposition in more detail (see Section 3.11.5 *[Soils, Geology, and Mineral Resources] Potential Impacts and Mitigation* of this EIR). Sedimentation would occur downstream from the Lower Klamath Project, but the quantity would vary depending on water year type. The magnitude of sediment deposition is relatively small compared to sediment loading from other existing sources along the Klamath River. The only measurable sedimentation would occur in the reach from Bogus Creek to Cottonwood Creek. In the short term (i.e., 2 years following dam removal), there is anticipated to be approximately 1.2 feet of deposition between Bogus Creek (RM 192.6) and Cottonwood Creek (RM 185.1) (Figure 3.11-12). This estimate is based on two successive median water years following dam removal. The predicted bed elevation changes under other modeled scenarios (i.e., two successive wet water year types and two successive dry water year types) are both less than the median water year scenario (USBR 2012). In the long term, average bed elevation is predicted to increase by approximately 1.5 feet in the reach from Bogus to Willow Creek and less than one foot downstream of Willow Creek. Additionally, the sedimentation is anticipated to occur primarily in pools and not in the riffle and bedrock sections that tend to control water surface elevations. Because the sediment deposition would be relatively small in comparison with the existing channel bed and bar sediment conditions, it would not affect stream characteristics in a way that would substantively alter flood inundation or flood risks and would therefore be a less than significant impact. Note that even though the effects of sediment deposition would be less than significant with respect to flooding risk, increases in bed elevations due to sedimentation were included in mapping the 100-year floodplain inundation areas downstream of Iron Gate Dam as described above.

Significance
No significant impact

3.6.5.3 Risks of Dam Failure

Potential Impact 3.6-6 Dam failure could flood areas downstream of the Lower Klamath Project.
Removing the Lower Klamath Project dams could reduce the risks of downstream flooding associated with a dam failure. The Lower Klamath Project dams store over 169,000 acre-feet of water that could inundate a portion of the watershed if the dams failed (Siskiyou County Web Site 2011). The dams are inspected regularly and the probability for failure has been found to be low. Removing the Lower Klamath Project dams would eliminate the potential for dam failure and subsequent flood damages and would therefore be beneficial.

The reservoir drawdown and dam removal processes are specifically designed to reduce the potential for dam failure during dam demolition that could result in downstream flooding. Dam embankment excavation at each site would not take place until after the reservoir was completely drawn down (Appendix B: *Definite Plan*). This approach precludes the possibility of dam demolition activities increasing the risk for failure and subsequent downstream flooding.

Copco No. 1 Dam is a concrete gravity arch structure that would require drilling and blasting during the dam removal phase (Appendix B: *Definite Plan*). Copco No. 1 Dam is thicker and wider at its base, which makes it very strong and less prone to risk of failure as the dam crest is lowered through demolition. With minimal water behind the dam due to reservoir drawdown, there would be little hydrostatic pressure against the remaining sections of the dam that could cause dam failure. Additionally, overtopping flows would not cause dam failure as is evidenced by the lack of deterioration to the stepped face on the downstream side of the dam. High flows have poured over the downstream side of the dam for over 100 years with no scour to the concrete. Seismic loading cannot be controlled by the Proposed Project, but as the dam is lowered, the strength of the remaining gravity structure increases, and therefore, the risk of seismic-induced failure would go down for a given event. Thus, there are no likely failure modes created by the removal process even if water did enter the drained reservoir during a late spring storm, and risk of a failure from the removal process is insignificant (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., November 2018). FERC requires a potential failure modes analysis, and the KRRC will be revisiting this topic in more detail prior to dam removal. FERC dam safety experts would have to approve the final dam removal analysis before a license surrender order could be issued.

See Potential Impact 3.6-1 for further discussion of reservoir drawdown and dam removal details.

Significance
Beneficial following dam removal

No significant impact during reservoir drawdown and dam removal

3.7 Groundwater

This section describes the potential effects of the Proposed Project on groundwater levels, recharge, and availability. Potential effects of the Proposed Project related to water quality are described in Section 3.2 *Water Quality* and potential effects related to geology are described in Section 3.11 *Geology and Soils*.

Multiple comments were received during the NOP public scoping process relating to groundwater (Appendix A). These comments were primarily concerned with the potential effects of dam and reservoir removal on groundwater wells adjacent to the Lower Klamath Project reservoirs. Examples of specific concerns include the potential for groundwater levels to lower and/or well production to diminish. See Appendix A for further summary of the groundwater comments received during the NOP public scoping process, as well as the individual comments themselves.

3.7.1 Area of Analysis

The Area of Analysis for groundwater impacts includes the area within 2.5 miles of Copco No. 1, Copco No. 2, and Iron Gate reservoirs (Figure 3.7-1), which encompasses the area immediately adjacent to the reservoirs where the likelihood of groundwater well impacts due to the Proposed Project is greatest, as well as areas further from the reservoirs where regional groundwater flow data are generally available (Figure 3.7-2). The Area of Analysis lies within Siskiyou County, California and portions of Jackson and Klamath counties, Oregon. Portions of the Area of Analysis within Oregon are considered to the extent that they are likely to influence potential impacts to groundwater resources in California, rather than for potential impacts in Oregon.

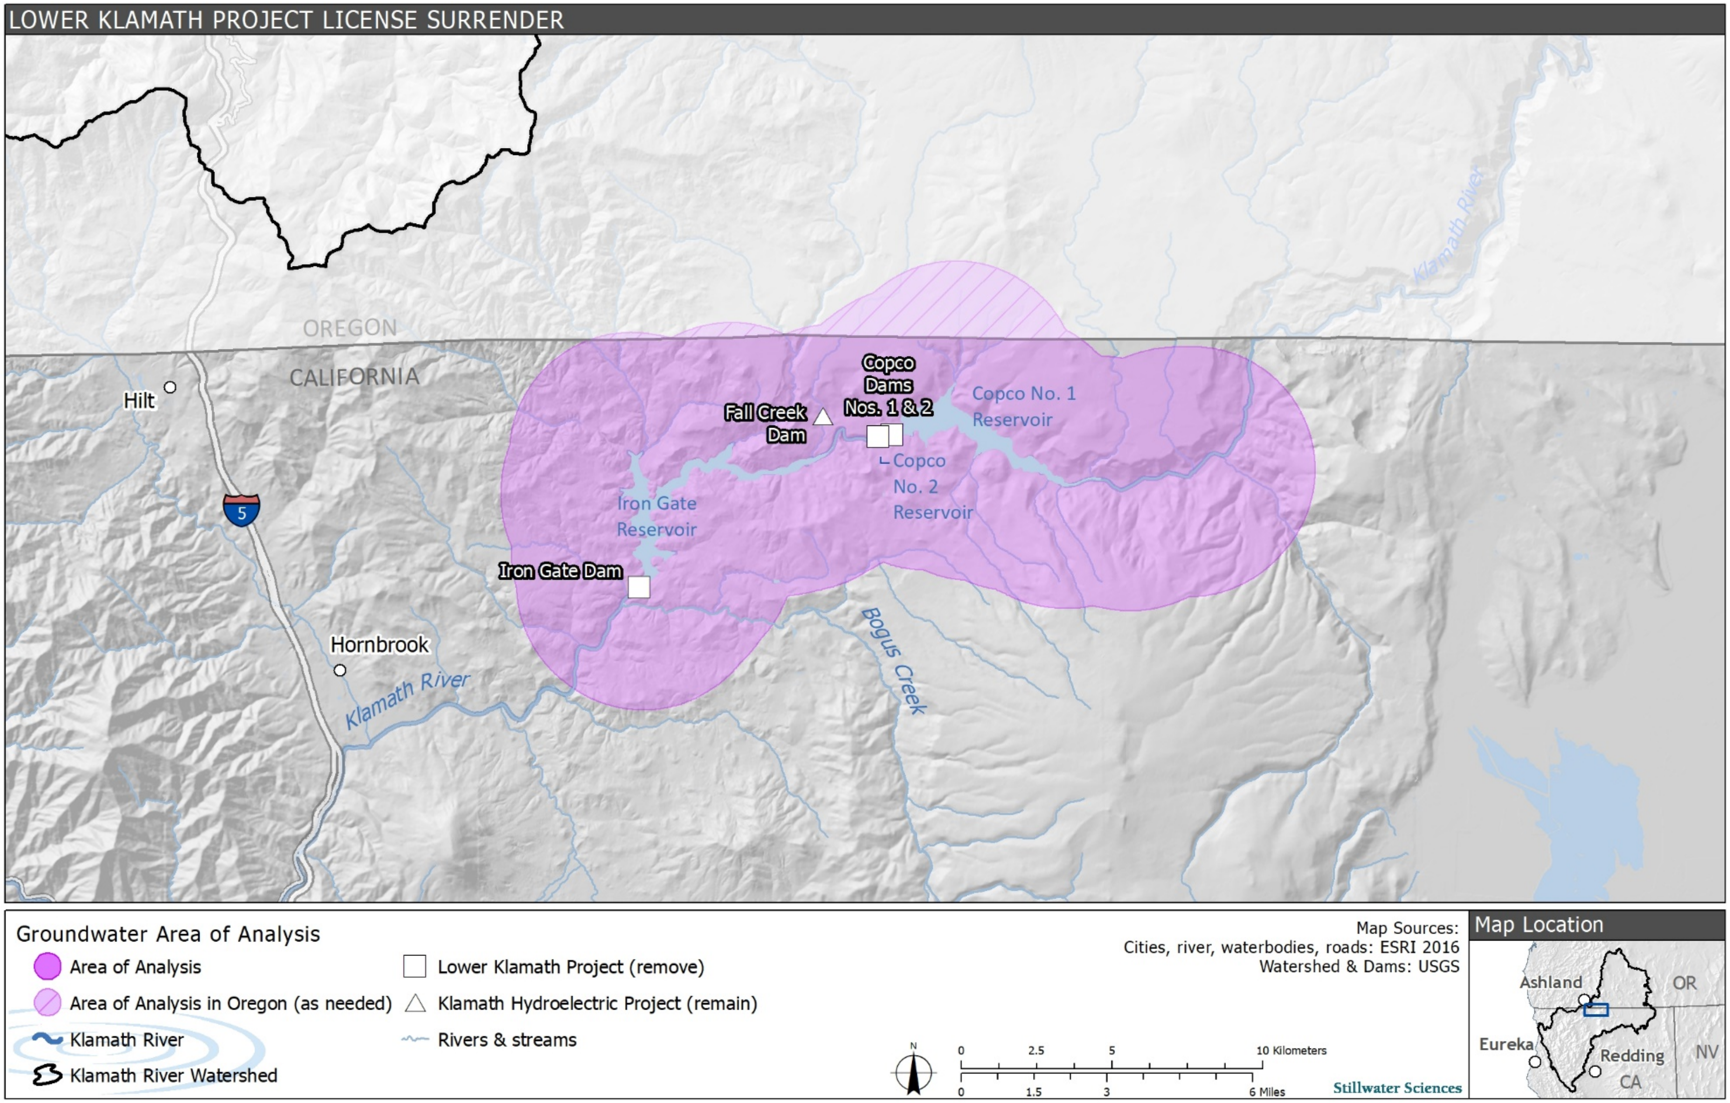

Figure 3.7-1. Groundwater Area of Analysis.

3.7.2 Environmental Setting

This section provides a description of the environmental setting for groundwater resources, including a brief overview of regional groundwater conditions and more specific groundwater information in the Area of Analysis.

3.7.2.1 Regional Groundwater Conditions

There are limited groundwater well data to support characterization of regional groundwater conditions in the Area of Analysis. Gannett et al. (2007) completed the most recent and comprehensive attempt to estimate the groundwater level gradients and flow patterns within the regional area upstream and downstream from each of the four Lower Klamath Project reservoirs. Figure 3.7-2 shows a generalized groundwater flow map for the Hydroelectric Reach of the Klamath Basin (i.e., from Iron Gate Reservoir to Upper Klamath Lake) and portions of the Lower Klamath Basin. Figure 3.7-2 suggests that the regional groundwater flow patterns along the Klamath River downstream from Keno Dam are generally from the higher elevations (upland areas, mountain ranges, hills, etc.) toward the Klamath River, and from Keno Dam toward Iron Gate Dam (USBR 2011). Figure 3.7-2 shows a very steep groundwater head gradient between Keno Dam and J.C. Boyle Reservoir. This steep head gradient suggests the presence of a groundwater barrier and is also roughly correlative with the mapped trace of the Sky Lakes fault zone (Personius et al. 2003). A groundwater barrier at this location implies that the groundwater system upstream of Keno Dam is separate from the groundwater system downstream of Keno Dam.

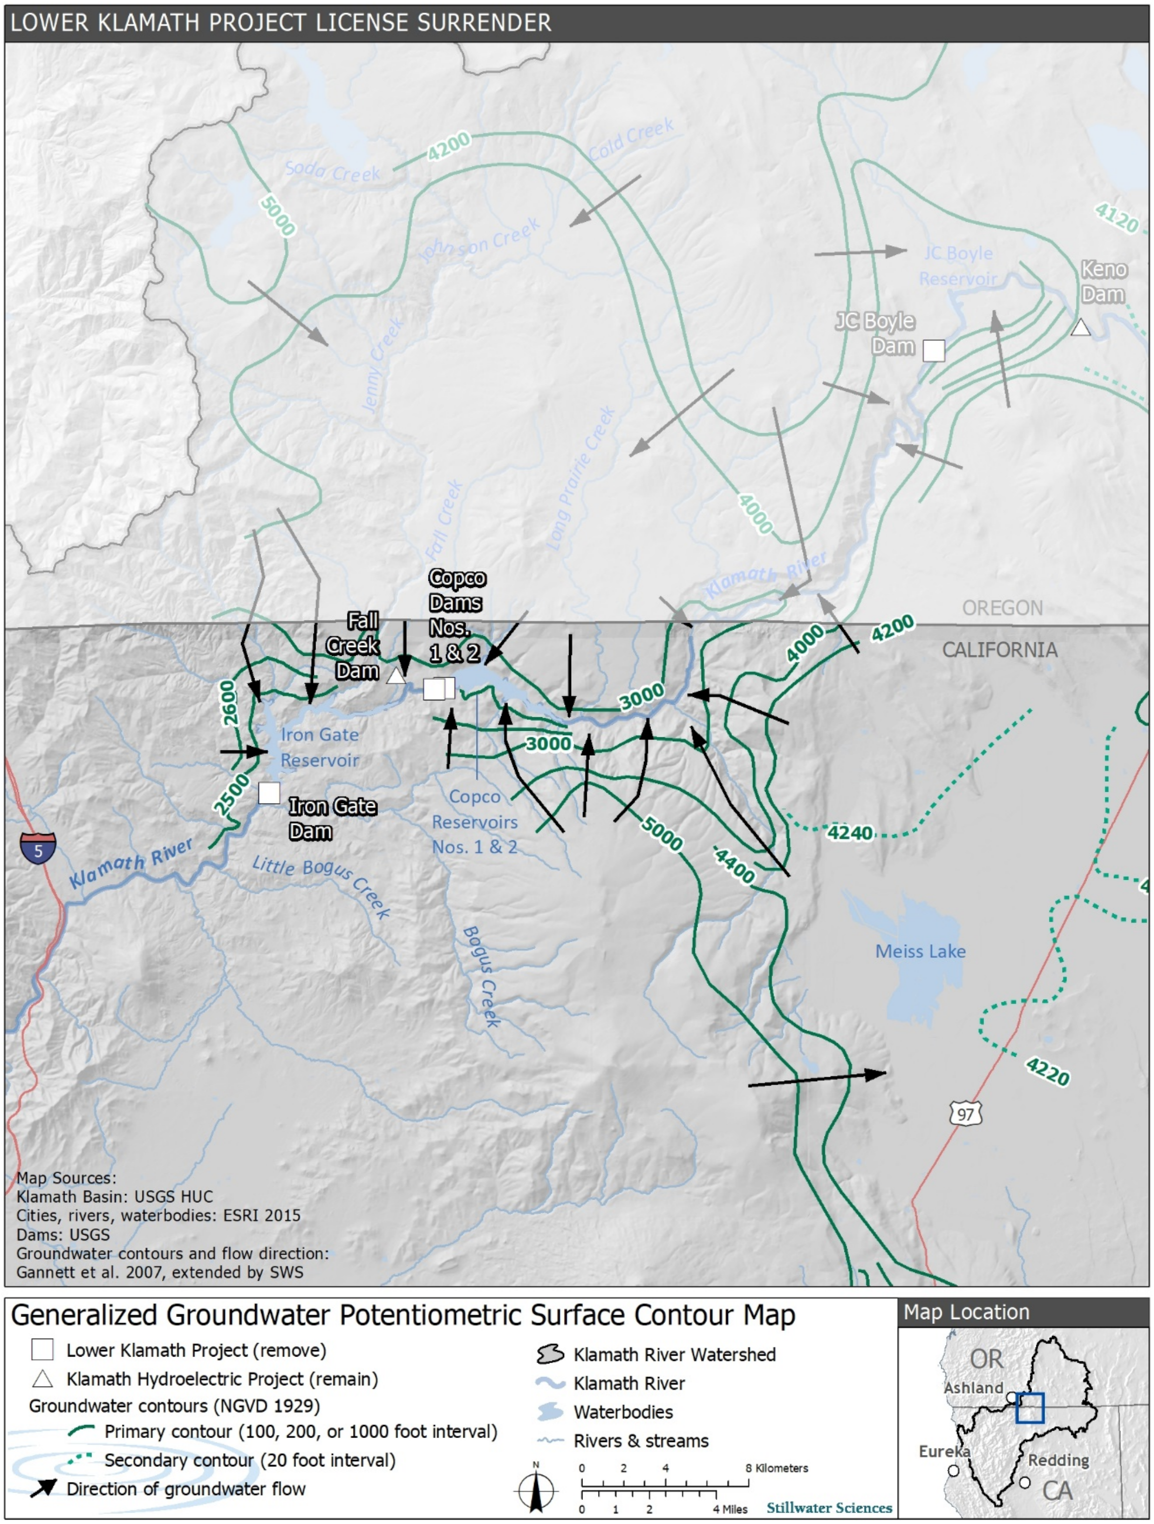

Figure 3.7-2. Regional Groundwater Map (modified from Gannett et al. 2007).

Closer to the Lower Klamath Project Reservoirs but still at the regional scale, USBR (2012) reviewed the area around the Iron Gate and Copco No. 1 reservoirs on USGS topographic 7½-minute quadrangle maps (Iron Gate and Copco No. 1 Quadrangles). Numerous springs, where groundwater discharges to the surface, occur in the area surrounding Iron Gate Reservoir. These springs occur at elevations from less than 50 feet to more than 300 feet above the reservoir level (USBR 2012). The maps also show springs around Copco No. 1 and Copco No. 2 reservoirs. These springs are similarly less than 50 feet to more than 800 feet above the reservoir levels (USBR 2012). The USGS maps also indicate a number of the small drainages that empty into Copco No. 1 Reservoir possess a spring at the headwater of the drainage, again at elevations hundreds of feet above reservoir surface water levels. The presence of numerous groundwater springs in the Area of Analysis indicates that regional conditions support a groundwater table that is near the ground surface, and also suggests that local groundwater systems are not likely to be receiving water directly from the reservoirs (USBR 2012). That is, at the regional scale, water discharging from groundwater springs in the Area of Analysis is not likely to be reservoir water (USBR 2012). Local groundwater conditions (i.e., immediately adjacent to the Lower Klamath Project reservoirs) are discussed in detail in Section 3.7.2.2 *Local Groundwater Conditions*.

Sources of Groundwater in the Area of Analysis

At the regional scale, groundwater in the Area of Analysis is likely fed by the infiltration of surface water and by precipitation and subsequent percolation through the sub-surface soil and bedrock units (Gannett et al. 2007). In the absence of barriers to vertical flow, surface water infiltration is a common source of recharge to groundwater systems. Rivers, lakes and other surface water bodies are common sources of site-specific infiltration recharge. Aerial precipitation is more of a dispersed source of infiltration recharge. As Figure 3.7-2 shows, at a regional scale, groundwater flows into the Area of Analysis from upland areas toward the Klamath River and the Lower Klamath Project reservoirs. Given a regional groundwater flow direction toward the river and reservoirs in the groundwater Area of Analysis (Figure 3.7-2), it is generally assumed that groundwater levels are supported by the regional groundwater system (USBR 2012).

At the local scale, wells immediately adjacent (potentially extending up to a mile from the reservoirs under certain conditions) to the reservoirs are more likely influenced by local site-specific variability in subsurface porosity and permeability. Where current groundwater levels in wells immediately adjacent to a reservoir are above the reservoir water surface elevation (e.g., at Iron Gate Reservoir), river and reservoir reaches are more likely to be receiving water from the regional groundwater system. In locations where current groundwater levels immediately adjacent to a reservoir are below the reservoir water surface elevation (e.g., at Copco No. 1 Reservoir), river and reservoir reaches may be receiving groundwater from the reservoir (USBR 2012). Given the existing data from local groundwater wells, these interpretations provide the best available conceptual characterization of regional and local groundwater resources in the Area of Analysis. Local groundwater conditions (i.e., immediately adjacent to the Lower Klamath Project reservoirs) in the Area of Analysis are discussed in more detail in Section 3.7.2.2 *Local Groundwater Conditions*.

Further upstream, a spring complex approximately one mile downstream of J.C. Boyle Dam contributes substantial flow to the Klamath River (Gannett et al. 2007). The water discharging at this site likely originates from the regional groundwater system, which, as described above, is generally near the ground surface. The flows could also be influenced by seepage from the reservoir that is flowing around or under J.C. Boyle Dam and coming to the surface at the spring site. It is likely that the flows from this spring complex are influenced by both the regional groundwater system as well as leakage from the reservoir (USBR 2012).

Groundwater Sinks in Area of Analysis

Features that cause a loss of groundwater from the groundwater system are called groundwater "sinks." In areas where surface water levels are lower than the adjacent groundwater level, groundwater can discharge to the surface water (e.g., rivers, streams, and reservoirs), making a groundwater sink. At a regional scale, Gannett et al. (2007) estimate that groundwater flow patterns move toward the Klamath River in the Area of Analysis (Figure 3.7-2). The USGS estimates an average groundwater discharge (sink) of 92 cfs for the reach from the J.C. Boyle Powerhouse downstream to Iron Gate Dam. Based on gage data and changes in reservoir storage, these estimates are calculated for the length of each of these reaches and may include some un-gaged tributary inflows.

Groundwater pumping is also a typical groundwater sink in the Area of Analysis. Domestic and limited irrigation are the primary uses of pumped groundwater in the Area of Analysis. Most domestic wells around the reservoirs are likely seasonal residences (i.e., owner's official address is different than the well location address) and are not expected to be a major groundwater sink in the Area of Analysis (USBR 2012). Average well yields in Siskiyou County, California are just over 19 gpm (USBR 2012). Based on completion dates on well logs for Siskiyou County, an average of five new wells per year have been installed in the Proposed Project area since 1963 (USBR 2012).

3.7.2.2 Local Groundwater Conditions

The California Department of Water Resources (DWR) *Bulletin 118 – Interim Update 2016, California's Groundwater,* delineates groundwater basins and sub-basins throughout the State. The Area of Analysis for the Proposed Project does not fall within one of these delineated basins. The area is defined as a "groundwater source area" by the DWR. A "groundwater source area" is defined as "rocks that are significant in terms of being a local groundwater source, but do not fit the [typical] category of basin or sub-basin" (DWR 2003). The Klamath River from the Oregon-California state line to downstream from Iron Gate Dam is a predominantly non-alluvial river flowing through mountainous terrain. Downstream from Iron Gate Dam, and for most of the river's length to the Pacific Ocean, the river maintains a relatively steep, high-energy, coarse-grained channel frequently confined by bedrock. Section 3.11.2.2 *Geomorphology* describes channel reach geomorphology for the Klamath River in the Area of Analysis and in downstream areas.

USBR (2012) obtained and reviewed groundwater well information from the California DWR and Oregon Water Resources Department (WRD) databases to identify well logs for known domestic and irrigation wells within several miles upstream and downstream from the Lower Klamath Project. Roughly 83 percent of the logs (300 out of 360 logs) included sufficient detail to locate the wells relative to the reservoirs. Of the 300 logs for which reasonable coordinate data could be determined, only 47 wells were within 2.5 miles of one or more of the three reservoirs within California, 25 near Iron Gate Reservoir and 22 near Copco No. 1 and Copco No. 2 reservoirs (USBR 2012).

Using the local topography, reservoir bathymetry, and lithologic descriptions on the well logs, representative cross-sections through the reservoirs and adjacent lands were drawn such that each cross-section intersected at least one known well location. Each cross-section displays the topography, water surface elevation of the reservoir, well log ID, abbreviated well log lithology, and the static water level in the well. Cross-sections aid in understanding the spatial relationship between surface waters, potential water-bearing lithologic units, and groundwater aquifers. The water-bearing units in each well are presented in summary tables for each reservoir (Tables 3.7-1 and 3.7-2).

Copco No. 1 and Copco No. 2 Reservoirs

As described in Section 3.11 *Geology and Soils*, Copco No. 1 and Copco No. 2 reservoirs are located at the contact between the Western Cascade Volcanics and the High Cascade Volcanics geologic provinces. The Western Cascade Volcanics is faulted and intruded by basaltic dikes. Its composition of stratified rocks with low to high permeability results in discrete aquifer units. Based upon the generally shallow depth of known groundwater wells, the groundwater near Copco No. 1 and Copco No. 2 reservoirs is likely from the permeable aquifer units of the High Cascade province or the upper water-bearing units of the Western Cascade province.

The California DWR well database identifies 22 wells within 2.5 miles of Copco No. 1 and Copco No. 2 reservoirs. Figure 3.7-3 shows the locations of the wells. The construction details for these wells are outlined in Appendix L. Five cross-sections that intersected at least one of the 22 wells were developed. Figure 3.7-3 shows the locations of these cross-sections. Figures 3.7-4 through 3.7-8 show the cross-sections and abbreviated descriptions are given in Table 3.7-1. The well parameters used to develop the cross-sections are summarized in Table 3.7-2.

[3] Depth to the bottom of the surface casing or sanitary seal in holes/wells that are open

Key:

AMSL: above mean sea level
bgs: below ground surface
in: inches
ft: feet
gpm: gallons per minute
N/R: Data not recorded

The data for the wells in the cross-sections indicate that the water-bearing units and static water levels are above the bottom of the reservoir. All except one of the wells near Copco No. 1 and Copco No. 2 reservoirs have static water levels that are below the reservoir stage but above the river bed elevation at the dam site. Similarly, all the wells except one have elevations for the top of the water-bearing unit below the reservoir stage and above the river bed elevation at the dam site. The two exceptions are two different wells. The top of the water-bearing unit was not identified on the log for some wells. In this case, the elevation at which water was first encountered in the drilling is used as a substitute for the top of the water-bearing unit.

The average static water level for all wells less than 300 feet from Copco No. 1 and 2 reservoirs is 2,591 feet while the average static water level for all wells more than 400 feet from the reservoir is 2,680 feet (USBR 2012). These levels suggest that there is inward groundwater flow near the reservoir (i.e., groundwater is flowing toward the reservoir). As groundwater is flowing toward the reservoir, water level in Copco No. 1 Reservoir is not expected to have a significant lateral influence on local groundwater levels (USBR 2012).

Iron Gate Reservoir

Like Copco No. 1 and Copco No. 2 reservoirs, Iron Gate Reservoir overlies units of the Western Cascade Volcanics geologic province, which has been faulted and intruded by basaltic dikes (Hammond 1983). Specific groundwater well data provides the best understanding of the occurrence of groundwater in the vicinity of Iron Gate Reservoir.

The identification of wells in the vicinity of Iron Gate Reservoir followed the same methods as for Copco No. 1 and Copco No. 2 reservoirs. The California DWR well database identifies 25 wells within 2.5 miles of Iron Gate Reservoir. Figures 3.7-9 and 3.7-10 show the locations of the wells. The construction details for these wells are outlined in Appendix L. Three cross-sections that intersected at least one of the 25 wells were developed. Figures 3.7-9 and 3.7-10 show the locations of these cross-sections. Figures 3.7-11 through 3.7-13 show the cross-sections. The well parameters used to develop the cross-sections are summarized in Table 3.7-3.

The well data show that the static water level (when recorded) is above the reservoir stage with only two exceptions (wells 781723 and 99834). The static water level for all but one of the wells (well 781723) is also above the elevation of the river bed at the dam site. The data in Appendix L show that the estimated elevation of the top of the water bearing unit (recorded on 13 of the 25 logs) is above the reservoir stage in 10 of the 13 wells. The top of the water-bearing unit is between the reservoir stage and the reservoir bottom in two wells. The top of the water-bearing unit is below the reservoir bottom in only one well (781723).

Wells further away from Iron Gate Reservoir have higher static water levels and generally higher top of water-bearing unit elevations than wells closer to the reservoir. These elevations indicate groundwater flow direction is toward the reservoir and is consistent with regional groundwater gradients (Figure 3.7-2). Wells within 2,000 feet of the reservoir have static water levels very close or above the reservoir stage (with one exception, well 334387) indicating a potential flow direction toward the reservoir. The current well dataset cannot determine conclusively whether Iron Gate Reservoir has any vertically downward or horizontal seepage (USBR 2012).

In summary, based on review of topographic and geologic maps, the Area of Analysis is underlain by permeable and porous rocks of the High Cascade and Western Cascade Provinces, and it contains abundant groundwater springs. Existing information indicates that while regional groundwater flow in the Area of Analysis is toward the Lower Klamath Project reservoirs, local (i.e., immediately adjacent to the reservoirs) groundwater levels exhibit site-specific variability, with the majority of wells exhibiting water levels above reservoir stage (i.e., groundwater flow toward the reservoir) and a small number of groundwater wells immediately adjacent to Copco No.1 Reservoir exhibiting water levels below the reservoir stage (i.e., potential groundwater flow from the reservoir toward the well).

3.7.3 Significance Criteria

Criteria for determining significant impacts on groundwater are based upon Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgment. Effects on groundwater are considered significant if the Proposed Project would result in:

- A substantial decrease of groundwater resources or substantial interference with groundwater recharge, lowering the local groundwater table level so that the production rate of existing nearby wells (i.e., within 2.5 miles of Copco No. 1, Copco No. 2, and Iron Gate reservoirs, see Section 3.7.1 *Area of Analysis*) would drop to an amount that would not support existing uses or planned uses for which permits have been granted.
- Substantially interfering with groundwater levels or groundwater recharge so there would be changes to groundwater/surface water interactions that would adversely affect surface water conditions or related resources.

This EIR does not analyze the potential for land subsidence due to groundwater aquifer collapse because the rock types in the Area of Analysis are not susceptible to collapse. Land subsidence caused by aquifer collapse can be caused by many processes such as the dewatering of fine grained materials (i.e., clays) or collapse of the structure of an aquifer (i.e., through over pumping, dissolution, or piping). The Area of Analysis does not contain areas underlain by extensive clay deposits, so it is not anticipated that the Proposed Project would cause land subsidence (Wagner and Saucedo 1987).

3.7.4 Impacts Analysis Approach

The groundwater impact analysis compares the potential effects of the Proposed Project to existing conditions. This analysis used the groundwater information presented in Section 3.7.2 *Environmental Setting* to evaluate potential effects on existing wells and on groundwater's influence on surface water resources in the Area of Analysis.

The analysis of potential or possible impacts to local wells from the Proposed Project is predicated on the conceptual model that in order to be impacted, the water-bearing unit that each well taps must be hydraulically connected to the reservoir—either by having the water-bearing stratigraphic unit exposed at the ground surface (i.e., daylight) within the reservoir walls or being hydraulically connected to the reservoir through a series of permeable layers between the reservoir and the water-bearing unit. Under the Proposed Project, removal of the Lower Klamath Project reservoirs has the potential to impact water levels in groundwater wells in the Area of Analysis. Other researchers have found that potential groundwater impacts to wells associated with dam removal are strongly controlled by local hydrogeologic characteristics and vary on a site-by-site basis (Berthelote 2013 and Tullos et al. 2016). Furthermore, peer-reviewed published literature addressing groundwater changes resulting from dam removal is extremely limited (Tullos et al. 2016). USBR (2012) concluded that based on local hydrogeologic conditions and well completion reports, potential impacts to groundwater wells in the Area of Analysis likely would only extend up to 0.5 mile from the Lower Klamath Project reservoirs.

The potential for impacts to the wells is further predicated on the relative elevation differences between the static water level in the well(s) and the water surface elevation of the reservoir. Specifically, if the water-bearing unit being tapped by any given well is hydraulically connected to a reservoir, then the static water level in the well should be similar or close to the water surface elevation in the reservoir. If the static water level is higher or lower than the reservoir level, and the water-bearing unit is not exposed along the reservoir walls, then it is likely that the water-bearing unit is reflecting a regional or local aquifer system influence in addition to, or in place of, the reservoir. If the water-bearing unit itself is entirely above the reservoir water levels, or it is substantially deeper (more than three or four intervening impermeable units) than the lowest portion of the reservoir, then it would be unlikely that the water-bearing unit would be in hydraulic connection with the reservoir. It should be noted that the static water level in a well can vary from year to year based on preceding hydrologic conditions (i.e., climatic cycles, wet years vs. dry years).

The following existing local plan is relevant to the Proposed Project:

- Siskiyou County General Plan (Siskiyou County 1980)
  - Chapter 3 Land Use Policies
    - Water Quality Policies: 17.

The aforementioned policy is stated in generalized terms, consistent with its overall intent to protect groundwater resources. By focusing on the potential for impacts to specific groundwater resources within the groundwater Area of Analysis, consideration of the more general local policy listed above is inherently addressed by the specific, individual analyses presented in Section 3.7.5 *[Groundwater] Potential Impacts and Mitigation*, below.

3.7.5 Potential Impacts and Mitigation

Potential Impact 3.7-1 Groundwater levels in existing wells adjacent to the reservoirs could decline in response to the decrease in reservoir surface-water elevations if the dams, and therefore reservoirs, are removed.

The water-bearing units from which most of the existing domestic and/or irrigation wells pump have one of three relationships to the hydroelectric reach: (a) below the elevation of the original river channel, (b) exposed along reservoir walls, or (c) above the reservoir stage. This analysis provides the reasonable inferences regarding the hydraulic connection between these water-bearing units and the reservoirs, as the paucity of measured data precludes more detailed analysis.

The location, underlying hydrogeologic conditions (i.e., how groundwater moves through underlying sediment and rock), and construction characteristics for a groundwater well can influence the potential impact of reservoir removal on well water levels. Some of the water-bearing units tapped by existing domestic and/or irrigation wells (approximately 27 of the 47 wells within the Area of Analysis) lie above the reservoir water surface elevations and are at elevations similar to those of mapped springs. These springs are likely fed by the same water-bearing units supplying the wells and therefore water levels in the wells are not expected to be significantly impacted by the removal of the reservoirs. Domestic and irrigation wells that pump from water-bearing units that are directly connected to the reservoirs (approximately 13 wells) would likely be affected by reservoir removal and the impacts could be significant. Wells that tap water-bearing units below the bottom of the reservoir (approximately 6 wells) are assumed to be maintained by regional groundwater flow patterns that would continue to “sink” toward the restored Klamath River and its alluvial floodplain. Consequently, those wells are unlikely to be affected by the removal of the reservoirs. Ultimately, however, the potential impacts at specific wells would also depend upon local hydrogeologic conditions at the well site location and the well construction characteristics.

Because of limited existing well location data, there could be additional domestic or irrigation wells in water-bearing units that intercept the reservoirs. There are existing domestic and irrigation groundwater wells that could not be reliably located based on the information in the Oregon WRD or California DWR water well databases. In addition to the non-locatable wells in the databases, real estate information suggests the potential for some additional wells. The real estate information presented in the Dam Removal Real Estate Evaluation Report prepared by the DOI in 2011 lists 1,467 potentially impacted parcels near the Copco No. 1, Copco No. 2, and Iron Gate reservoirs. Of those 1,467 parcels, 12 percent (176 parcels) are listed as improved and 88 percent (1,291 parcels) are shown as vacant (Bender Rosenthal, Inc. 2011). The extent of improvements on the 12 percent of parcels is not known. However, it is possible that improvements may have included installation of a groundwater well for domestic and/or irrigation supplies.

In light of the likely connectivity of some wells’ water source with the reservoir, and in light of data gaps, it is possible that removal of the reservoir would cause a substantial decrease of groundwater levels and a corresponding decrease in production rates in existing wells to a degree that interferes with existing or planned uses. This would be a significant impact.

However, the Proposed Project includes implementation of the Groundwater Well Management Plan, as described in Section 2.7.8.7 *Groundwater Well Management Plan* and in Appendix B: *Definite Plan*. The Groundwater Well Management Plan is intended to identify groundwater wells that may be adversely impacted following dam removal and reservoir drawdown and provide sufficient monitoring to understand the effects, if any, on groundwater levels and quality. The Well Management Plan would further identify short and long-term measures to address and mitigate any supply impairments encountered.

Under the Groundwater Well Management Plan, baseline conditions would be determined by monitoring sentinel wells within 2.5 miles of the reservoirs, and ideally within 0.25 miles of the reservoirs. Sentinel wells would include those belonging to volunteer landowners, or if an insufficient number of well owners volunteer to participate in the groundwater monitoring activity, a minimum of ten wells around the three reservoirs on PacifiCorp's Parcel B lands (tentatively, up to four monitoring wells each at Iron Gate and Copco No. 1 reservoirs, and two wells at J.C. Boyle Reservoir). Sentinel wells belonging to participating landowners and any monitoring wells installed by the KRRC would be monitored pre-, during, and post-dam removal to identify seasonal fluctuations in groundwater levels and any groundwater level changes resulting from reservoir removal. Sentinel wells would also be monitored for general water quality parameters including pH, conductivity, and major anions and cations. The KRRC would monitor sentinel wells monthly for a minimum of one year prior to dam removal and monthly for up to one year following dam removal, or until such time that groundwater levels and general water quality parameters have stabilized (no discernable water level declines or changes in quality over a four-month period) or they mirror baseline conditions (Appendix B: *Definite Plan*).

Under the Groundwater Well Management Plan, if groundwater levels in existing wells adjacent to the Lower Klamath Project reservoirs are found to be substantially depleted following dam removal, such that production rates drop to levels that do not support designated domestic or irrigation uses, the KRRC would undertake measures to return the production rates of the affected domestic or irrigation groundwater supply wells to conditions existing prior to dam removal. Short-term measures would include actions providing temporary water supplies until long-term measures such as motor replacement, well deepening, or full well replacement are identified and implemented. The regional and local groundwater pattern of groundwater flow toward the Lower Klamath Project reservoirs suggests that the measures in the Groundwater Well Management Plan would be successful in completely mitigating the identified potential impacts. Because successful implementation of the proposed short-term and long-term measures would return production rates of any affected domestic or irrigation groundwater supply wells to conditions existing prior to dam removal, there would be no significant impact on groundwater levels in existing wells adjacent to the reservoirs.

The State Water Board has issued a draft water quality certification[136] which sets forth monitoring and reporting requirements for groundwater wells surrounding the Lower Klamath Project reservoirs as part of Condition 14.

Significance

No significant impact

Potential Impact 3.7-2 The Proposed Project could interfere with groundwater recharge and adversely affect surface water conditions in the Klamath River.

Because of the underlying geology, removal of the Lower Klamath Project reservoirs is not expected to interfere with groundwater recharge that could potentially affect surface water flows in the Klamath River. Sometimes, removing reservoirs from an area can result in percolation of less surface water to the underlying groundwater aquifers. However, as discussed in Section 3.7.2 *Environmental Setting* the reservoirs generally lie within rock valleys where groundwater recharge is expected to be low. Gannett et al. (2007) concluded that the Klamath River reaches in the Area of Analysis are gaining reaches (i.e., groundwater discharges to the stream). This assessment and the characteristics of the rock surrounding the reservoirs suggest that any surface water that may have infiltrated to groundwater aquifers under the reservoirs would likely discharge back to the river just downstream from the impoundments, rather than increasing aquifer storage. Therefore, there would be a less than significant impact on groundwater recharge and the resulting groundwater/surface water interactions due to the Proposed Project.

Significance

No significant impact

3.8 Water Supply/Water Rights

This section describes the potential effects of the Proposed Project on surface water supply availability for existing water rights.

The potential for water supply impacts is an important concern for local residents in the area of the reservoirs and downstream in the Mid and Lower Klamath basins. Multiple comments were received during the NOP public scoping process relating to water supply and water rights (Appendix A). These comments were primarily concerned with the potential effects of dam and reservoir removal on water supply for water right holders. Specific concerns included: (1) reductions in water supplies for Klamath River diverters; (2) indirect impacts to water users on Klamath River tributaries, through potential higher bypass requirements to meet environmental needs; and (3) adverse impacts to water diversion infrastructure, including wells, downstream diversion facilities, and the City of Yreka's municipal water supply pipeline. See Appendix A for further summary of the water supply and water rights comments received during the NOP public scoping process, as well as the individual comments themselves. Potential impacts to private groundwater wells are addressed in Section 3.7 *Groundwater*.

3.8.1 Area of Analysis

The Area of Analysis for water supply/water rights includes portions of the Upper, Middle, and Lower Klamath River from the California-Oregon border downstream to the river's mouth (Figure 3.8-1). The portion of the Upper Klamath River included in the Area of Analysis is along the Hydroelectric Reach and extends from the California-Oregon border to Iron Gate Dam. The Middle Klamath River extends from Iron Gate Dam downstream to the Trinity River confluence and the Lower Klamath River extends from the Trinity River downstream to the Klamath River's mouth. The Area of Analysis also includes portions of the Upper Klamath Basin located within California that receive water deliveries from the Klamath Irrigation Project (e.g., Tule Lake and Lower Klamath Lake).

Fall Creek is included in the Area of Analysis because the Proposed Project involves restarting hatchery operations there, and has the potential to impact the City of Yreka's Fall Creek diversions for municipal water supply. However, except for Fall Creek, the Area of Analysis does not include water rights on tributary rivers because water supply availability in these rivers is not affected by ceasing the non-consumptive hydroelectric power use under the Proposed Project, or by the Proposed Project's discharges.

Residents in the Scott and Shasta river basins raised concerns that removal of the hydroelectric facilities would reduce the water supply available for environmental purposes in the Klamath River mainstem, and that as a result, water diverters in tributaries to the Klamath will be curtailed to increase mainstem surface water flows. Please see Potential Impact 3.8-2 for a discussion of the limited use of hydroelectric project water to assist the USBR in meeting environmental flow obligations. Because the USBR maintains its biological opinion obligations regardless of the existence of the Lower Klamath Project, dam removal would not alter the amount of water available for environmental purposes, or the source of that water. Thus, there would be no water availability impact to tributaries to the mainstem Klamath River from implementation of the Proposed Project.

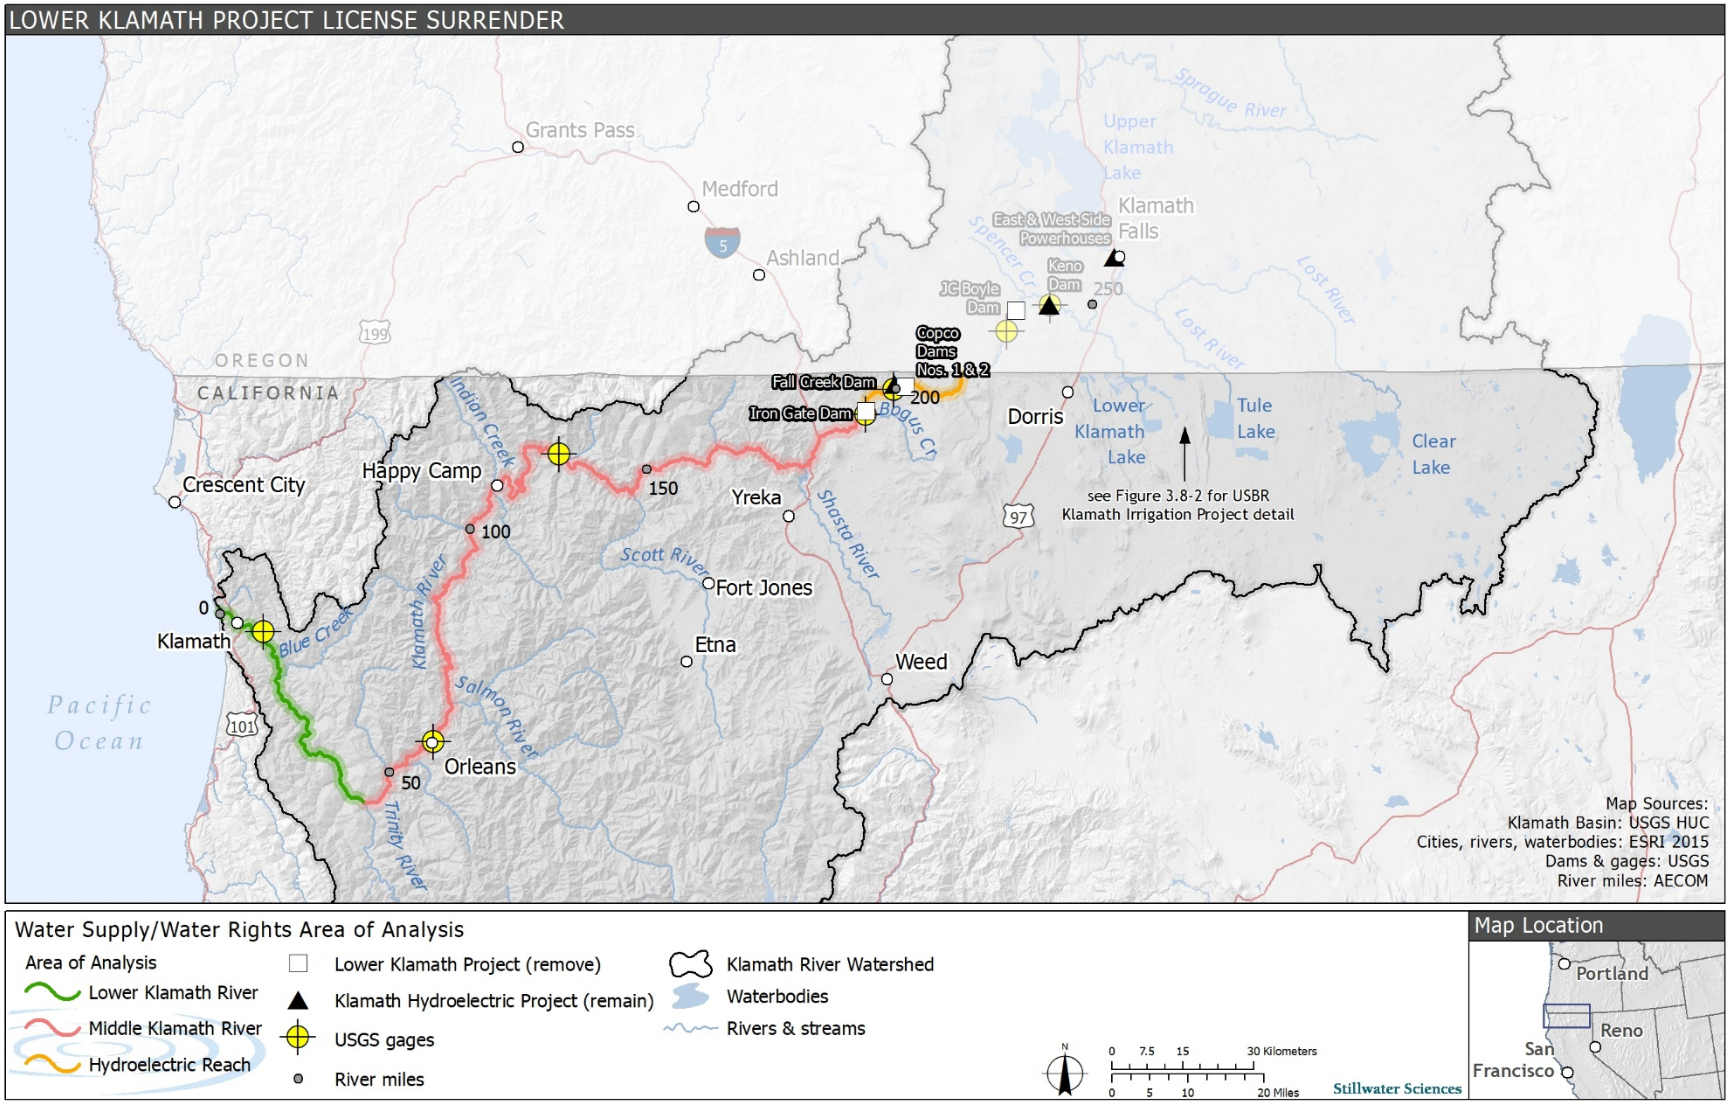

Figure 3.8-1. Water Supply/Water Rights Area of Analysis.

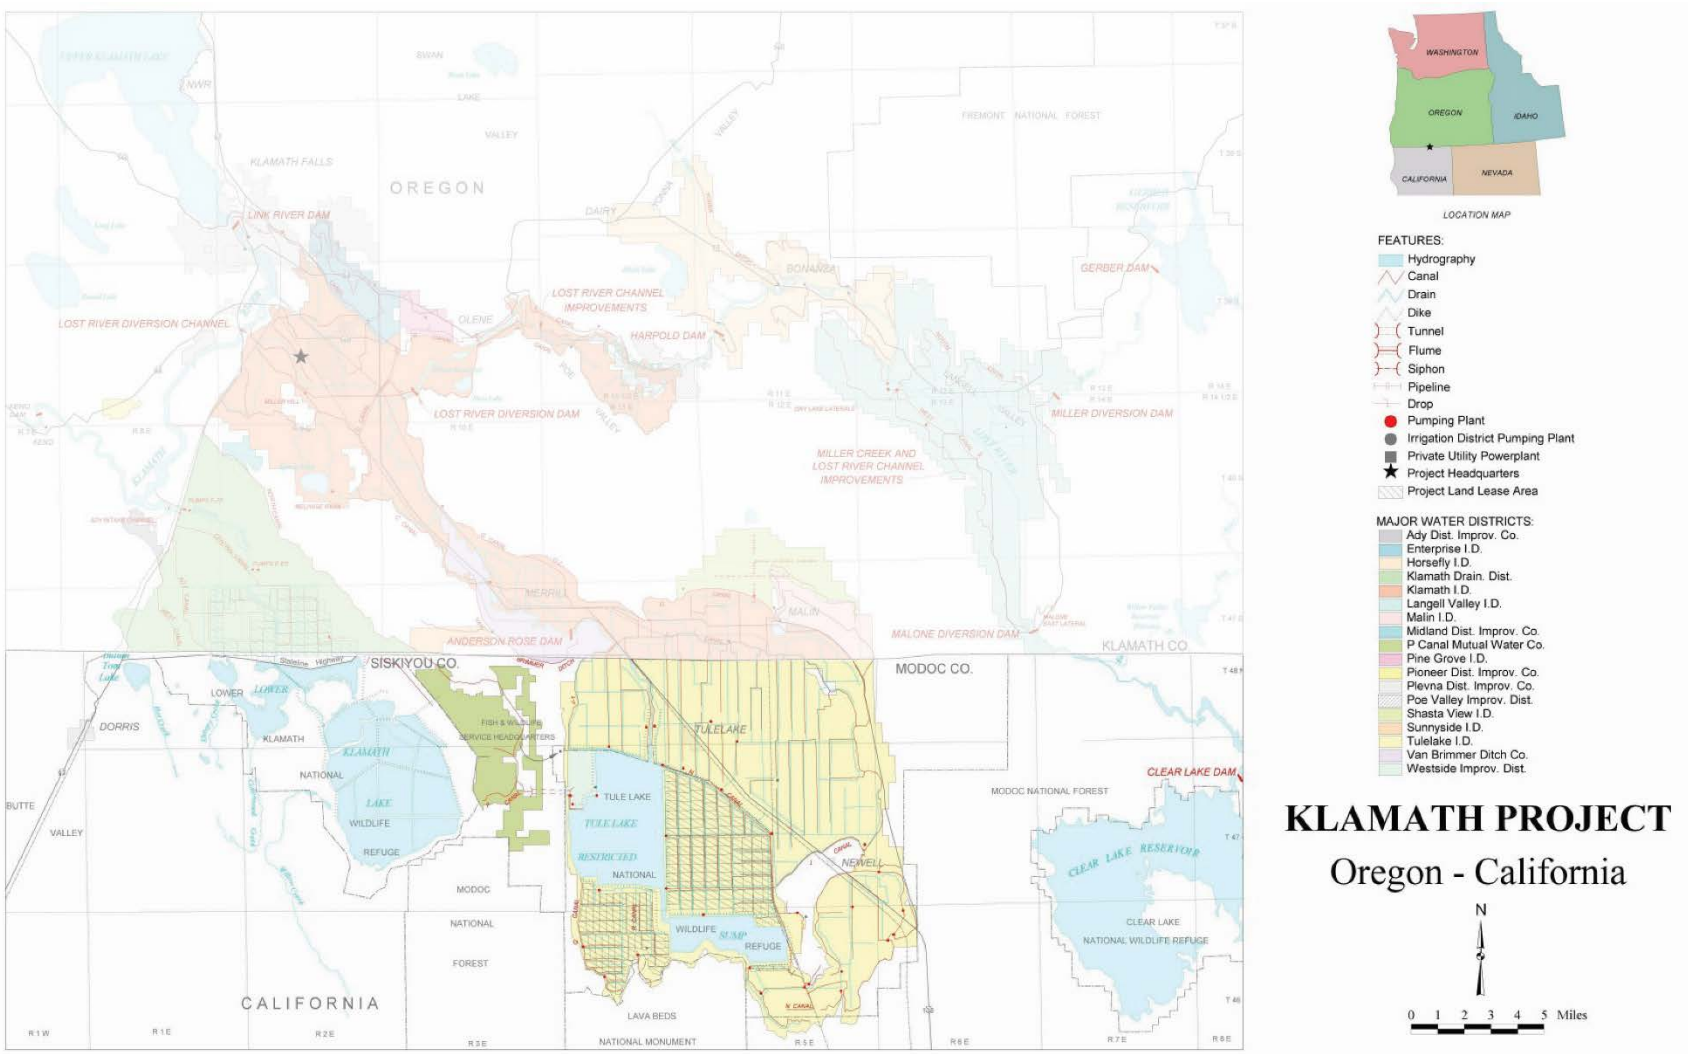

Figure 3.8-2. Water Supply/Water Rights Area of Analysis includes portions of the Klamath Irrigation Project within California. Source: USBR.

3.8.2 Environmental Setting

This section describes information related to existing water supply and water rights in the Area of Analysis. It also includes a brief introduction to the Upper Klamath Basin and the Klamath Irrigation Project, which delivers water from Oregon diversions to portions of California in the Upper Klamath Basin (e.g., Tule Lake and Lower Klamath Lake). This section includes a description of reservoir capacities, Biological Opinion (BiOp)-related water storage and release criteria, municipal water supply for the City of Yreka, and other water right holders along the Klamath River in the Area of Analysis.

3.8.2.1 Upper Klamath Basin

The Corrected Findings of Fact and Order of Determination in the Klamath River Basin General Stream Adjudication (Oregon Department of Water Resources 2014), sets forth the water rights in the Upper Klamath Basin diverted in Oregon. The highest priority water rights in the adjudication are those of the Klamath Tribes', who maintain water rights with a time-immemorial priority to support hunting, gathering, and fishing on their reservation. The USBR's Klamath Irrigation Project stores and delivers a significant amount of water in a water supply project that includes Upper Klamath Lake, Lake Ewauna, Keno Dam, and a host of irrigation canals that connect the Upper Klamath River with the Lost River systems. Average annual Project supply as reported in 2000, prior to BiOp-related storage and flow release criteria, was approximately 350,000 acre-feet (USBR 2000). Project supply is now controlled by BiOp criteria and varies on a yearly basis. In 2017 Project supply was 340,000 acre-feet, and 310,000 acre-feet in 2018 (USBR 2018b). The Klamath Irrigation Project provides irrigation water to approximately 230,000 acres of agricultural land in southern Oregon and northern California, and also supplies water to the Lower Klamath and Tule Lake National Wildlife refuges in California and Oregon (Figure 3.8-2) (USBR 2018b). The USFWS "walking wetlands" program is currently in use in the Lower Klamath National Wildlife Refuge and involves rotating areas of agricultural production with areas of marsh or treatment wetlands on refuge lands to maintain both higher crop yields with lower inputs of fertilizers and pesticides and high-quality wetlands for wildlife (Stillwater Sciences et al. 2013).

The 2013 Joint Biological Opinion (2013 BiOp) for operation of USBR's Klamath Irrigation Project sets minimum lake and river hydrologic conditions to avoid jeopardizing the continued existence of ESA-listed species and adverse modification of designated critical habitat, while providing for delivery of water for irrigation purposes consistent with historical operations, subject to water availability. The 2013 BiOp includes two distinct operational approaches for water management for the fall/winter (October through February) and spring/summer (March through September) time periods (see sections 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and 3.6.2.2 *Basin Hydrology* for further details).

Lower Klamath Project

In addition to natural flows, flows through the Lower Klamath Project depend on water releases from Upper Klamath Lake by USBR, flows diverted to and returned from USBR's Klamath Irrigation Project's operations, the relatively small storage capacities of the Lower Klamath Project developments, and releases from Iron Gate Dam (FERC 2007). Approximately 98 percent of the available active surface water storage along the Klamath River is provided by Upper Klamath Lake behind Link River Dam. Keno, J.C.

Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoirs combined provide approximately two percent of the available active storage on the river. The State of Oregon has issued non-consumptive, hydropower water rights for J.C. Boyle reservoir. California has issued a water right license for diversion at Iron Gate Dam for power generation (1,800 cfs), hatchery operations (50 cfs), and refill of regulatory storage (3,300 cfs). PacifiCorp has filed statements of water diversion and use for pre-1914 direct diversion hydropower water rights for operation of the Copco No. 1 and Copco No. 2 facilities. Thus, none of the Lower Klamath Project facilities' water rights are for seasonal water storage or irrigation purposes. Appendix M contains more details and maps that display the water right locations.

Fall Creek Water Rights

Four water rights are located on Fall Creek: two non-consumptive rights for hydropower generation at PacifiCorp's Fall Creek powerhouse, which is not part of the Proposed Project, one for the City of Yreka's municipal water supply, and one for fish propagation at the Fall Creek Hatchery (see Appendix M).

City of Yreka

The City of Yreka receives its municipal water supply from Fall Creek, a tributary to the Klamath River in the Upper Klamath Basin that is approximately 23 miles northeast of the city (see also Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*). California Water Rights Permit 15379 allocates to Yreka up to 15 cfs, not to exceed 6,300 acre-feet per year from Fall Creek, year round. During the diversion period, the City of Yreka must ensure a minimum flow of 15 cfs, or the natural flow of Fall Creek whenever it is less than 15 cfs, measured by a gage approximately 1,000 feet upstream of Daggett Road. The priority of this water right dates from August 12, 1966. Yreka's Fall Creek diversion was completed in 1969 and the municipal water systems facilities include: 1) two impoundments; 2) an intake structure with fish screens, a pump, and pre-treatment facility; 3) a cathodic protection field at the Fall Creek Campground and Day Use Boat Ramp; and 4) a 24-inch pipeline that crosses on the eastern upstream end of Iron Gate Reservoir.

Fall Creek Hatchery

The California Oregon Power Company (COPCO; now PacifiCorp) built Fall Creek Hatchery (FCH) in 1919 as compensation for lost spawning grounds due to construction of Copco No. 1 Dam. Six of the original rearing ponds remain and they were last used from 1979 through 2003. California State Water Board License 11681 authorizes CDFW to divert up to10 cfs for non-consumptive, fish propagation use at Fall Creek Hatchery between March 15 and December 15 each year, not to exceed 5,465 acre-feet per year. The hatchery diverted 2 cfs during March through December from 2012 to 2017. The priority of this water right dates from January 5, 1979.

3.8.2.2 Mid and Lower Klamath Basins

The Area of Analysis in the Middle and Lower Klamath rivers includes only the mainstem of the Klamath River through these reaches (see Figure 3.8-1).

Generally, tributary discharge to the Klamath River increases substantially with distance downstream within the Mid and Lower Klamath basins, as described in Section 3.6.2.2 *Basin Hydrology*. The long-term average annual flow rate at Iron Gate Dam is approximately 1,970 cfs and is approximately 17,020 cfs at the mouth of the Klamath

River (USGS 2017). Like most rain and snow-pack-influenced basins in the western United State, the months of July through October generally have much lower flow than the winter and spring runoff months. Historical stream flows for the Klamath River are discussed in Section 3.6.2.2 *Basin Hydrology*.

Klamath River Water Rights

In California, water diverters are required to file annual reports or statements of diversion and use with the State Water Board, which are accessible, *inter alia*, through the Electronic Water Rights Information Management System (eWRIMS). In addition to the hydropower water rights discussed above, a query of eWRIMS provided 44 water right records that list the Klamath River or a California Lower Klamath Project reservoir (i.e., Iron Gate, Copco No. 1, and Copco No. 2 reservoirs) as their water source. 41 water right listings are located downstream of Iron Gate Dam and three are located upstream of Iron Gate Dam (Table 3.8-1). Appendix M contains the query results and maps that display the documented locations.

Table 3.8-1. Summary of Water Right Listings from California's Electronic Water Rights Information Management System (eWRIMS) that list the Klamath River or One of the California Lower Klamath Project Reservoirs as the Water Source.

Type of Water Right Listings[1]	Number of Claims
Statements of Diversion and Use	
Active Claims (Claimed)	23
Inactive	9
Post-1914 Appropriative	
Licensed	3
Permitted	1
Small Domestic Registrations	2
State Filing Applications (Unassigned)	10

Source: California Electronic Water rights information Management System (eWRIMS) (State Water Board 2017)

Notes:

[1] Status Definitions:

Active Claims (Claimed): Riparian and pre-1914 appropriative rights predate the Water Commission Act that established the water rights permitting system, and the precursor to the State Water Board. Riparian rights exist due to ownership of parcels abutting a watercourse. Entities that hold either of these rights are not required to obtain a permit from the State Water Board.

Inactive: Claimed riparian or pre-1914 right that are currently unexercised.

Licensed: A license indicates that the conditions of development of the project is complete and diversion and use has occurred, as contemplated under the permit.

Permitted: A permit is an authorization that allows for the development of a project to divert and use water with due diligence, under permitted conditions.

Registered: Entities can register to divert and use a small amount of water from a stream for domestic purposes or the use of a small amount of water for livestock. In such cases, the use is registered with the State Water Board and must follow conditions set by the CDFW to protect fish and wildlife.

State filing applications: State filing applications are made by the State Water Board in trust for the people of California, in order to preserve water for future use and development consistent with a coordinated plan such as the State's Water Plan or a County General Plan. If "assignment" of the state filing application is requested and approved, an applicant to develop a water right may use the water right priority of the state filing, allowing the new project to be senior to certain existing diverters.

A total of 32 Statements of Diversion and Use, including the hydropower rights for Copco No. 1 and No. 2, of water were filed with the State Water Board; nine of which are currently inactive. Of these 32 rights, 18 belong to individuals, 13 to corporations, and one with an incomplete record. Statements of Diversion and Use include claims to riparian water rights as well as claimed pre-1914 appropriative water rights. The requirements for filing Statements of Diversion and Use apply to federal agencies, but do not apply to rights that do not involve a diversion, such as federal reserved rights for instream flow.

There are three licensed appropriative water rights in the Area of Analysis: one for PacifiCorp at Iron Gate Dam (1957); one for the Klamath River Country Estates Owners Association Inc. (1960); and one for an individual. The Klamath Community Services District holds one permitted appropriative water right from 1968, and there is one private Small Domestic Registration water right from 2006.

It is expected that each of the active water rights listings discussed above would, and some of the inactive listings could, have associated intake facilities to draw water from the Klamath River; however, the specific type, location, and layout of each of these intake facilities is unknown.

There are ten state filed applications on the mainstem Klamath River, four in Humboldt County and six in Siskiyou County. Such state filings are to preserve water for future use and development consistent with a coordinated plan such as the State's Water Plan or a County General Plan. State filings hold water in reserve for future needs, and have a priority based on the date of filing. The state filings on the Klamath River all have priority dates of 1956. The ten state filing applications have not been "assigned" yet, meaning that no one has proposed developing water under the rights and received permission to use the 1956 date of priority.

Two of the state filings in Siskiyou County are for storage and later application to beneficial use of 60,000 acre-feet per year at the current location of Iron Gate Dam. One is for power production, while the other is for irrigation, industrial, domestic, municipal, recreational, and fish and wildlife use in the Shasta Valley. No diversion infrastructure exists, or is planned for construction, involving these state-filed applications.

There is also a transient non-community public water system at the Randolph E. Collier rest area on Interstate 5, near the town of Hornbrook. This water system is regulated by the State Division of Drinking Water.

The Proposed Project would not affect the water supplies for these state filings or non-community public water system.

Federal Reserved Rights for Native American Tribes

Hoopa Valley Tribe and Yurok Tribe

The Klamath River Reservation, consisting of a strip of land beginning at the Pacific Ocean and extending one mile in width on each side of the Klamath River for a distance of approximately 20 miles, was established by Executive Order in 1855. The Klamath River Reservation was established on Yurok ancestral lands. In 1876, a second executive order established the Hoopa Valley Indian Reservation, a 12-mile square area southeast of the Klamath River Reservation, beginning at the confluence of the Klamath and Trinity Rivers, and bisected by the Trinity River. A third executive order in 1891 created an extended Hoopa Valley Reservation, which encompassed the original Hoopa Valley Indian Reservation, the Klamath River Reservation, and a strip down the Klamath River from the Klamath-Trinity confluence connecting the two original reservations. In 1988, Congress passed the Hoopa-Yurok Settlement Act, 25 U.S.C. 1300i et seq., which partitioned the extended reservation between the Hoopa Valley Tribe and Yurok Tribe, with the Yurok Reservation comprising the original Klamath River Reservation and the connecting strip, and the Hoopa Reservation comprising the original 12-mile square area. The federal courts have confirmed that the United States reserved fishing rights for the Hoopa Valley and Yurok tribes when it set aside reservations along the Klamath and Trinity Rivers. The Department of the Interior has found that the original orders setting aside the Hoopa Valley and Yurok reservations also reserved rights for instream flows sufficient to sustain fish within the reservations. Although there has been no formal adjudication to quantify and determine the priority of the Yurok and Hoopa Valley tribes' fishing-related water rights, the recognition of such rights is consistent with the federal precedent set in *United States v. Adair*.

3.8.3 Significance Criteria

Impacts to water supply and/or water rights would be considered significant if they result in the following:

- Causing unreasonable injury to existing water rights[137].
- Decreasing water supplies beyond what is needed for public health and safety (human consumption, cooking, and sanitation) for the current population.

In determining the criteria for significance, the lead agency looked to applications of the No Injury Rule and the reasonableness standard in California water law, to the California Constitution Article X, section 2, and to human right to water (Water Code, section 106.3). The assessment of the Proposed Project's effects on Safe Drinking Water Act requirements is presented in Section 3.2 *Water Quality*. The assessment of the effects of the Proposed Project on fire suppression is presented in Section 3.17 *Public Services* and Section 3.21 *Hazards and Hazardous Materials*.

3.8.4 Impacts Analysis Approach

The impacts analysis of water supply and water rights discusses the potential impacts of the Proposed Project to river flows and water diversions throughout the Area of Analysis, and whether these impacts could affect existing water rights or water supplies. The analysis is based on flow rates and water supply delivery data from the hydraulic modeling completed by USBR (2012), along with the methods and assumptions that were utilized in the model. USBR applied a one-dimensional HEC-RAS model using historical flow data as input to the model. The modeling compared river flow rates, assuming KBRA flows, for the Proposed Project and the No Project Alternative. The model's average daily instream flow data help describe how the flows would change under each alternative. USBR used these data to assess whether changes to instream flows as a result of the Proposed Project would be adequate to meet water rights and

[137] An existing water right is one that was in existence at the time of the Notice of Preparation.

water supply requirements. USBR (2012) also compared water supply diversions to baseline conditions and water rights to determine impact significance.

The 2013 BiOp changed the flow regime under which dam removal would occur (i.e., KBRA flows are no longer anticipated). However, the differences in hydrology between KBRA and 2013 BiOp flows are minor (see Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, for further details regarding KBRA and 2013 BiOp flows) and thus do not affect the analysis of future water supply or water rights under the Proposed Project.

Evaporation from the surface of the Lower Klamath Project reservoirs under existing conditions is approximately 11,000 acre-feet/year, and after dam removal evapotranspiration in the same reaches is expected to be approximately 4,800 acre-feet/year, resulting in a gain in flow to the Klamath River of approximately 6,200 acre-feet/year (USBR 2012). The increase in flow is equal to approximately 8.5 cfs on average over a year or approximately 0.4 percent of the average annual Klamath River flow measured downstream of Iron Gate Dam (USGS Gage No. 11516530) between 1961 and 2017. At this point it is speculative where this additional water will be available in the basin. If no change were to be made to the 2013 BiOp for the Klamath Irrigation Project, the additional water would become available to Klamath Irrigation Project operations, and not impact downstream flows. However, the 2013 BiOp is currently under review, and is scheduled for additional review upon implementation of the Proposed Project. It is unclear whether ongoing or planned revisions to the BiOp will change streamflow requirements in light of this additional water availability, and where the measured points of compliance for river flow will be absent Iron Gate Dam (making it unclear whether the additional water will accrue to the system above or below such compliance points). Therefore, while noting the anticipated increase in available water, this EIR does not apply the additional water being made available to any particular use or reach.

The following sources were assessed to determine the scope of existing local plans and policies relevant to the Proposed Project:

- Del Norte County General Plan (Mintier & Associates et al. 2003):
  - Section 1 Natural Resources/Conservation
    - Water Resources Policies: 1.B.5,
  - Section 7 Public Facilities and Services
    - Water Supply and Delivery Policies: 7.B.1, 7.B.3, 7.B.4, 7.B.5, 7.B.8
- Humboldt County General Plan for Areas Outside of the Coastal Zone (Humboldt County 2017):
  - Chapter 11 Water Resources Element
    - Water Resources and Land Use Policies: WR-P1, WR-P2, WR-P3, WR-P4, WR-P5, WR-P6, WR-P7, WR-P8, WR-P9, WR-P10, WR-P11, WR-P12, WR-P14, WR-P18, WR-P21
    - Watershed Planning Policies: WR-P22, WR-P23, WR-P24, WR-P25
    - Public Water Supply Policies: WR-P26, WR-P27
    - Water Exports Policies: WR-P29, WR-P32, WR-P33, WR-P34
    - Water Resources and Land Use Standards: WR-S1, WR-S2, WR-S3, WR-S5

    - Water Exports Standards: WR-S12
- Siskiyou County General Plan (Siskiyou County 1980)
  - Chapter 3 Land Use Policies
    - Wildfire Hazard Policies: 30

Most of the aforementioned policies and standards are stated in generalized terms, consistent with their overall intent to protect water supply resources and water rights. By focusing on the potential for impacts to specific water supply and water rights issues within the water supply/water rights Area of Analysis, consideration of the more general local policies listed above is inherently addressed by the specific, individual analyses presented in Section 3.8.5 *Potential Impact and Mitigation;* and the more general local policies are not discussed further.

3.8.5 Potential Impacts and Mitigation

Potential Impact 3.8-1 Dam removal could change the amount of surface water flow available for diversion under existing water rights in the mainstem Klamath River within the Hydroelectric Reach and downstream from Iron Gate Dam.

Hydroelectric Reach

PacifiCorp has three water rights on the Klamath mainstem upstream of Copco No. 1 Reservoir for irrigation and stock watering.

As noted above, there are five water rights associated with the Lower Klamath Project. Three PacifiCorp Statements of Water Diversion and Use are associated with hydropower and associated reservoirs at Copco No. 1 and Copco No. 2 facilities. PacifiCorp has a water right license at Iron Gate Dam for diversions from the Klamath River that include 1,800 cfs for power generation, 50 cfs for fish propagation facilities, and 3,300 cfs to refill regulatory storage space in Iron Gate Reservoir. Additionally, PacifiCorp has a Statement of Diversion and Use at Iron Gate Dam of 48 cfs for fish culture. Under the Proposed Project, power generation and associated water storage at Copco No. 1, Copco No. 2, and Iron Gate reservoirs would cease, such that the prior water supply requirements for these activities would no longer be needed. Because hydropower water rights are non-consumptive, ceasing to use the water for power production purposes would not have a water supply availability impact for downstream users.

As part of the Proposed Project, the Reservoir Area Management Plan includes restoration actions that would utilize Klamath River water for short-term (i.e., during dam removal year 2 and 1−5 years following dam removal) irrigation of riparian revegetation areas in the Lower Klamath Project reservoir footprints (Appendix B: *Definite Plan-Appendix H* and Section 2.7.4 *Restoration Within the Reservoir Footprint*). The water supply to meet irrigation needs would be the short-term exercise of riparian rights available to the KRRC as the owner of the property at the time of the diversion. Evapotranspiration (ET) of the planted riparian species represents the consumptive water loss associated with revegetation irrigation. Evapotranspiration data from a regional USBR AgriMet station (USBR 2018a), correlated to the Iron Gate and Copco No. 1 reservoirs area using a local weather station, provide a range of reasonable ET rates (i.e., 0.075 to 0.142 ft/day) for riparian species proposed for planting. Based on this calculation, an equivalent of up to approximately 2-4 cfs would be lost due to ET in the irrigated riparian revegetation areas at Iron Gate and Copco No. 1 reservoirs during the April through October irrigation season. This loss due to ET represents a 0.22 to 0.44 percent reduction in water supply available to water right holders downstream of Iron Gate Dam, and therefore would not be a significant impact.

Water supply for fish propagation and fish culture would continue to be required for eight years following dam removal, but would require changes in diversions due to the removal of Iron Gate Reservoir. Currently 50 cfs is diverted from Iron Gate Reservoir for use at the Iron Gate Hatchery. Under the Proposed Project, up to 8.75 cfs of water would be diverted from Bogus Creek to operate Iron Gate Hatchery at reduced production levels. Up to 9.25 cfs of water would be diverted from Fall Creek (downstream of the City of Yreka's intake) to reopen and operate Fall Creek Hatchery (Section 2.7.6 *Hatchery Operations*). The diverted water would be returned to Fall Creek either at a proposed new settling pond location or at the fish ladder on the downstream side of the hatchery. Water diverted from Bogus Creek would be under riparian rights (Appendix B: *Definite Plan*). The Fall Creek Hatchery diversion would be under CDFW's existing appropriative water right for 10 cfs and riparian rights. The water diverted for hatchery use is non-consumptive, and therefore would not change the amount of water available for diversion downstream of the point of return for the waters. For either hatchery diversion, there are no other water users between the point of diversion and the point of return.

Middle and Lower Klamath River

Using historical flow data to create a set of flows under future operational prescriptions, USBR (2012) compared modeled surface water flow rates at Iron Gate Dam under the Proposed Project to a dams-in scenario. Modeling results indicate that under the Proposed Project, average monthly flows in the Klamath River just downstream of Iron Gate Dam would only slightly increase or decrease (typically less than approximately 15 percent) depending on month and water year type, compared to existing conditions. The anticipated small relative changes in Klamath Rivers flows are due to the fact that the Lower Klamath Project reservoirs were not designed, nor are they operated, as seasonal storage reservoirs for maintaining downstream flows for irrigation or drinking water diversions. As a whole, the Lower Klamath Project is primarily operated as a run-of-the-river operation, with inflows essentially matching outflows below Iron Gate Dam. Thus, the Lower Klamath Project has only a small effect on daily, monthly, seasonal, or annual flow conditions downstream of Iron Gate Dam. USBR (2012) modeling results indicate that at Seiad Valley, approximately 62 river miles downstream of Iron Gate Dam, surface water flow rates under the Proposed Project would be nearly identical to those under existing conditions.

Under existing conditions, flow rates just downstream from Iron Gate Dam are the lowest within the Middle and Lower Klamath River and therefore provide a conservative estimate of available water supply when comparing to downstream diversion amounts. The monthly diversion flow rate associated with all of the active and inactive water rights in the Middle and Lower Klamath River, aside from the reserved (but unassigned) state filings and PacifiCorp's Iron Gate power diversion water rights, is approximately 69 cfs (based on water right information in Appendix M). The vast majority of water is diverted in the reach between Iron Gate Dam and Seiad Valley, where during summer months (i.e., July−August), usage typically doubles[138], resulting in an estimated peak short-term diversion of approximately 138 cfs if all users doubled their water diversion rate during the same period. This estimate of peak flow diversion would likely be lower during wetter water years, since not all users would be likely to divert the maximum amount during summer months. Comparing the peak potential diversion flow (138 cfs) to the low-flow condition of a dry water year type immediately downstream of Iron Gate Dam (900 cfs, or a 90 percent exceedance flow per the 2013 BiOp), the diversions would represent approximately 15 percent of Klamath River flows in the upstream portion of this reach under the Proposed Project. Because the amount of flow diverted for water rights users between Iron Gate Dam and Seiad Valley would be relatively small (i.e., approximately 15 percent of the flow in the Klamath River in the upstream portions of this reach during dry years with low-flow conditions), water right users are not likely to be injured. Additionally, there would be no lack of water availability for public health purposes due to limited flow diversion capacity resulting from flow changes as part of the Proposed Project.

Note that the USBR (2012) modeling effort assumed KBRA flows, rather than the 2013 BiOp flows under which the upstream Klamath Irrigation Project (and hence the Lower Klamath Project) currently operates. Compared to KBRA flows, the 2013 BiOp slightly increases the annual average water supply by about 9,000 acre feet. During summer months (July and August) in dry years, the 2013 BiOp requires a higher minimum flow of 900 cfs at Iron Gate Dam, compared to 824 cfs under KBRA (see also Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*). Overall, the hydrologic differences between KBRA flows and those implemented under the 2013 BiOp are small, decrease the relative effect of other diversion in the river in summer, and do not change the assessment of Proposed Project impacts on surface water flows available for diversion under existing water rights in the Klamath River downstream of the Oregon-California border. Furthermore, under the No Project alternative, flow releases would still be controlled by the 2013 BiOp, and therefore, the same quantity of Klamath River flow would be available for downstream water rights.

During the extreme drought of 2014−2016, PacifiCorp coordinated late-2014 releases from Iron Gate and Copco No. 1 dams (see also Potential Impact 3.8-2), which provided a small degree of flexibility for managing irrigation water in the Upper Klamath Basin by allowing USBR to postpone releasing water for environmental purposes at Keno Dam (USBR 2018c). This had the effect of making approximately 15,400 acre-feet of additional irrigation water available for water users in the Klamath Irrigation Project, including users in California (although the diversions themselves occur in Oregon). A comparable water borrowing arrangement between PacifiCorp and USBR for approximately 20,000 acre-feet also occurred in 2018. It is unclear if comparable water borrowing would occur in the future due to multiple constraints detailed by USBR (2018c), and further discussed below in Potential Impact 3.8-2. However, and as previously stated in Section 3.8.1 *Area of Analysis*, removal of the Lower Klamath Project dams would not affect USBR's central role in providing BiOp flows to the Klamath River and would not place flow obligations on small agricultural diverters in tributaries to the Klamath River.

[138] The increase during July and August is an average based on permitted diversion amounts and reported values on Statement Diversion and Use forms available on eWRIMS for the Klamath River.

Significance
No significant impact

Potential Impact 3.8-2 Dam removal could change the amount of surface water flow available for diversion from Upper Klamath Lake and/or Keno Reservoir to California water users in the USBR Klamath Irrigation Project.
As described in Potential Impact 3.8-1 and Section 3.8.2 *Environmental Setting*, PacifiCorp has claimed pre-1914 water rights for hydropower production at Copco No. 1 and Copco No. 2 dams, and a water right license for diversion at Iron Gate Dam for hydropower, fish propagation, fish culture, and refilling regulatory storage space. Neither the Statements of Diversion and Use nor the Iron Gate Dam license include seasonal storage or irrigation use. However, two times in recent years, PacifiCorp has agreed to operate its hydropower projects in a manner that supports increased irrigation deliveries to the Klamath Irrigation Project.

In the fall of 2014, PacifiCorp agreed to release approximately 15,400 acre-feet of water from Iron Gate and Copco No. 1 reservoirs to assist USBR in meeting requirements of the 2013 BiOp (USBR 2014). This water was then repaid from storage in Upper Klamath Lake in February and November of 2015. Release of the 15,400 acre-feet from Iron Gate and Copco No. 1 reservoirs extended irrigation water supply to Klamath Irrigation Project water users during severe drought conditions (USBR 2014).

In April 2018, USBR coordinated with NMFS, USFWS, PacifiCorp, Klamath Basin Tribes, water users, and other stakeholders regarding the temporary release of approximately 10,000 acre-feet from the Lower Klamath Project reservoirs, in order to enable charging of Klamath Irrigation Project irrigation canals in late April and May without violating 2013 BiOp requirements for Upper Klamath Lake elevation or Klamath River flow below Iron Gate Dam. An additional 10,000 acre-feet was released from the Lower Klamath Project reservoirs in late-May to allow for continued Klamath Irrigation Project deliveries without violating 2013 BiOp requirements (USBR 2018c).

The aforementioned releases did not result in a change to Klamath River flows or water supply downstream of Iron Gate Dam since USBR is obligated under the 2013 BiOp to release the water into the Klamath River. If PacifiCorp had not released the flows from Iron Gate and Copco No. 1 reservoirs in the fall of 2014 and spring of 2018, then USBR would have released the flows at Keno Dam and the water would have traveled downstream through the Lower Klamath Project reservoirs to be discharged at Iron Gate Dam, regardless.

Ultimately, precipitation, irrigation needs, and the 2013 BiOp flow requirements determine the amount of surface water flow available for diversion from Upper Klamath Lake and/or Keno Reservoir to the USBR Klamath Irrigation Project. During extreme dry years, any reduction in available water for existing water rights would result in additional water being drawn from Upper Klamath Lake until lake levels drop to 4,137.72 feet (1,261.5 meters), at which point USBR would adjust water deliveries to the Klamath Irrigation Project to prevent the lake elevation from dropping below that value (NMFS and USFWS 2013). Decreased water supply caused by such an adjustment would potentially result in reduced deliveries to Klamath Irrigation Project water users (irrigators and wildlife refuges in Oregon and California).

The Lower Klamath Project has no obligation to apply the water stored in its reservoirs to meeting USBR's 2013 BiOp requirements, and PacifiCorp has indicated that any future borrowing of water from Lower Klamath Project reservoirs would be predicated upon a definitive, rapid refill schedule, and compensation to PacifiCorp for the value of lost power generation due to reduced Lower Klamath Project reservoir capacity, both of which limit the benefit to USBR of borrowing water from the Lower Klamath Project. This places uncertainty as to whether the water-borrowing operation that has occurred in two years since implementation of the 2013 BiOp will continue. Additional uncertainty comes from potential necessary changes to water rights to accommodate more than sporadic emergency use of the reservoirs for other than hydroelectric purposes. Despite the stated limitations of borrowing water from the Lower Klamath Project reservoirs, and the uncertainty of what, if any, permissions would be necessary to affect regular implementation of the operations, dam removal under the Proposed Project would preclude the potential option of utilizing the Lower Klamath Project reservoir water supply to help meet 2013 BiOp flow requirements and thereby extend the available water supply to the USBR Klamath Irrigation Project.

Most Klamath Irrigation Project deliveries are to users in Oregon; however, some users, including agricultural users, wildlife refuges, and a combination of these two users in the "walking wetlands" program, are in California. There could be times in which users in California—agricultural users, wildlife refuges, or both—are next in line for the water in a year that Lower Klamath Project operators could make it available under a comparable water borrowing operation as described above. Additionally, users in California benefit from runoff from Klamath Irrigation Project deliveries in Oregon portions of the Lost River Sub-Basin. Water users in California often turn to groundwater pumping in times of surface water shortages. The Tulelake Basin is designated a medium priority basin under the Sustainable Groundwater Management Act (SGMA), in part because of declining groundwater levels and high volume groundwater extractions (DWR 2014). Under SGMA, the basin must be managed under a groundwater sustainability plan by January 31, 2022 (Wat. Code, § 10720.7, subd. (a)(2)). Thus, groundwater may become limited as an alternative source in the future, as the basin adjusts to sustainable pumping levels. Additionally, dry year groundwater pumping may be financially infeasible for wildlife refuges and some farms. Therefore, for some California users in some years in which Lower Klamath Project owners could have chosen to coordinate supplies, there may be less water available with dam removal than otherwise. Despite this minor chance of a reduction, there would be no legal injury to the Klamath Irrigation Project users because the Lower Klamath Project operators are not required to temporarily supplement water deliveries, per the 2013 BiOp flow requirements. Additionally, there is no indication that water would not be available for public health purposes, absent supplementation of Klamath Irrigation Project available water.

Significance

No significant impact

Potential Impact 3.8-3 Release of stored sediment during reservoir drawdown could change Klamath River geomorphology and affect water intake pumps downstream from Iron Gate Dam.

Reservoir drawdown would release the sediment stored behind the Lower Klamath Project dams into downstream reaches of the Klamath River. Reservoir drawdown activities would begin on January 1 of the drawdown year at J.C. Boyle, Copco No. 2, and Iron Gate dams and on November 1 of the year prior at Copco No. 1 Dam (see

Section 2.7.2 *Reservoir Drawdown*). During this period, individual downstream intake facilities could be affected by fine sediment deposits, causing operational problems. USBR (2012) conducted modeling of the reservoir drawdown and erosion of reservoir sediment. The released sediment would likely exceed the carrying capacity of the river during some water year types, and would result in sedimentation and particle settling in slow-moving downstream areas. However, the fine fraction of the released sediment (silt and clay) would not be expected to deposit in substantial amounts in the river channel. The majority of this material would be transported to the ocean and would not interact substantially with the river bed (see also Section 3.11.5 *[Soils, Geology, and Mineral Resources] Potential Impacts and Mitigation*)

If drawdown occurred in a dry year, deposition of sands and coarser sediment would be expected in the reach from Iron Gate Dam to as much as eight miles downstream from the dam, near the confluence with Cottonwood Creek (see also Potential Impact 3.11-5). The amount of sediment deposition would decrease with distance from Iron Gate Dam. Little to no sediment deposition is expected in the reach between J.C. Boyle Dam and Copco No.1 Reservoir (USBR 2012). There are 15 water rights registered on the reach from Iron Gate Dam to Cottonwood Creek: five are listed as inactive, two are state filings with the State Water Board, and two are associated with PacifiCorp's Iron Gate Dam facility and fish hatchery. There are no facilities for the state filings, and the Iron Gate Dam diversions would cease under the Proposed Project. The remaining six water rights are associated with domestic, irrigation, and/or fire protection use. There is the potential for intake facilities for the active and inactive water right diversions to be affected by sediment deposition, although there is insufficient information on exact intake facility configuration and too much uncertainty in the modeling to determine whether any particular diversion will be affected.

The analysis of potential sediment impacts to water intake pumps considered the results of detailed hydraulic, hydrologic, and sediment transport modeling (USBR 2012); however, even small deviations in localized sediment deposition at a site could affect the ability to use diversion facilities, which could result in injury to an existing water right or decrease water supplies beyond what is needed for public health and safety. This would be a significant impact. Implementation of Mitigation Measure WSWR-1 would reduce the potential for this impact to occur because it requires identification of impacts reported by water rights holders following dam removal and replacement of affected water supplies.

Mitigation Measure WSWR-1 – Water Supply Monitoring and Management
The KRRC shall identify all points of diversion on the Klamath River listed in the Electronic Water Rights Information Management System (eWRIMS). The KRRC shall contact all water rights holders with points of diversion on the Klamath River prior to drawdown of the reservoirs to determine whether the water right holder is interested in working with the KRRC to evaluate potential Proposed Project impacts to the water right holder. If potential impacts are identified, the KRRC shall provide temporary accommodations (e.g., replacement water, settling basins, etc.) to address them. During and following dam removal, the KRRC shall investigate any impacts reported by a water right holder. If the investigation confirms an adverse impact has occurred as a result of dam removal, the KRRC shall immediately provide any necessary replacement of water for health and safety for domestic or municipal diversions, and promptly implement measures to reduce impacts and allow the water right holder to divert water in the same manner (e.g., amounts, suitable quality, and timing) as before dam removal.

Prior to and annually for the first two years following drawdown, the KRRC shall submit a report to the State Water Board on implementation of the activities described above.

Significance

No significant impact with mitigation

Potential Impact 3.8-4 Relocation of the City of Yreka water supply pipeline after drawdown of Iron Gate Reservoir could affect water supply.

The existing water supply pipeline for the City of Yreka passes under the Iron Gate Reservoir and would have to be relocated prior to the decommissioning of the reservoir to prevent damage from deconstruction activities or increased water velocities once the reservoir has been drawn down. Three alternatives have been developed for proposed modifications to the pipeline (see Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*). The alternatives all include a new pipeline that would be tunneled under the river bed, suspended along an existing road bridge, or suspended along a new utility bridge. The KRRC would determine the preferred alternative in consultation with the City of Yreka (Appendix B: *Definite Plan*). Based on the Detailed Plan for Dam Removal (USBR 2012a), the existing flat panel fish screens for the water supply intakes at Dams A and B on Fall Creek may not meet current regulatory agency screen criteria for anadromous fish. While the fish screens have recently been updated, their compliance to NMFS, USFWS, and CDFW screen criteria for anadromous fish still needs to be confirmed. These fish screens would require updates, if found to be non-compliant (Appendix B: *Definite Plan*). Regardless, the water quantity and quality diverted from Fall Creek would not change. During connection of the new pipeline, the KRRC anticipates that the existing pipeline would be disconnected for less than 12 hours during the winter season. The available water in storage is able to supply the City of Yreka for up to 60 hours during the winter (see also Appendix B: *Definite Plan*). However, because the exact plans for pipeline re-routing are incomplete, it is not possible to determine the reasonableness of the assumed timeframe for pipeline disconnection. If the disconnection were to cause a supply interruption, this would constitute a significant impact Implementation of Mitigation Measure WSWR-2 would reduce this potential impact to less than significant.

Mitigation Measure WSWR-2 – City of Yreka Water Supply.

Prior to initiating drawdown of the Lower Klamath Project reservoirs, the KRRC shall construct a new, fully operational replacement pipe for the City of Yreka's current water supply pipeline for the section of pipe that crosses Iron Gate Reservoir. The new replacement pipeline section shall be connected to the existing City of Yreka water supply pipeline and installed in a location that prevents river flows during and after drawdown from affecting the City of Yreka's water supply.

Any work the KRRC undertakes to ensure that the City of Yreka water supply intakes' screens comply with fish screen criteria shall be completed within the water delivery outage period specified above.

Except as provided in this Mitigation Measure, the KRRC shall ensure uninterrupted water supply during replacement of the pipeline section, any required intake screen modifications, and throughout Project implementation. A short water delivery outage is necessary to make the final connections following construction of the new pipeline. The KRRC shall limit the water delivery outage to a maximum of 12 hours, unless the KRRC receives prior approval for a longer outage from the State Water Board, based on detailed information that the outage proposed will not interfere with City of Yreka's ability to supply water. The KRRC shall coordinate the water delivery outage period with the City of Yreka to ensure the City of Yreka has an adequate supply of water stored to cover the maximum water delivery outage period, with adequate buffer.

Significance

No significant impact with mitigation

Potential Impact 3.8-5 Removal and potential replacement of recreational facilities currently located on the banks of the existing reservoirs could affect water supply and/or water rights.

The existing recreational facilities provide camping, fishing, and boating access for recreational users of the reservoirs and currently do not use surface water supplies. Once the reservoirs are drawn down, these facilities would be removed. The Proposed Project (Appendix B: *Definite Plan – Section 7.6.5*) includes the potential for new whitewater boating put-in/take-out sites and fishing access sites. Since these uses are similar to the sites being removed, they are likely also not to require surface water supplies. To the extent that there was water provided for public use at the recreational sites, such use would likely be *de minimus*.

Significance

No significant impact

3.9 Air Quality

This section focuses on potential air quality impacts from implementing the Proposed Project. Section 3.10 of this EIR discusses greenhouse gas emissions. The State Water Board did not receive comments related to air quality during the NOP public scoping process (Appendix A).

3.9.1 Area of Analysis

Criteria air pollutants and toxic air contaminants (TACs) typically have localized air quality effects and relatively short atmospheric lifetimes (approximately one day). For this reason, the Area of Analysis for air quality includes areas within and adjacent to the Proposed Project Limits of Work (Figure 3.9-1), where construction activities would occur, which are located in Siskiyou County, California. As pollutants can travel on air currents away from the place of generation, the Area of Analysis includes Siskiyou County as a whole, along with Klamath County, Oregon where construction activity related to the removal of J.C. Boyle Dam would occur (Figure 3.9-1). Note that the portion of Proposed Project Limits of Work in Oregon is only being considered to the extent that conditions in this area influence air quality in Siskiyou County, California.

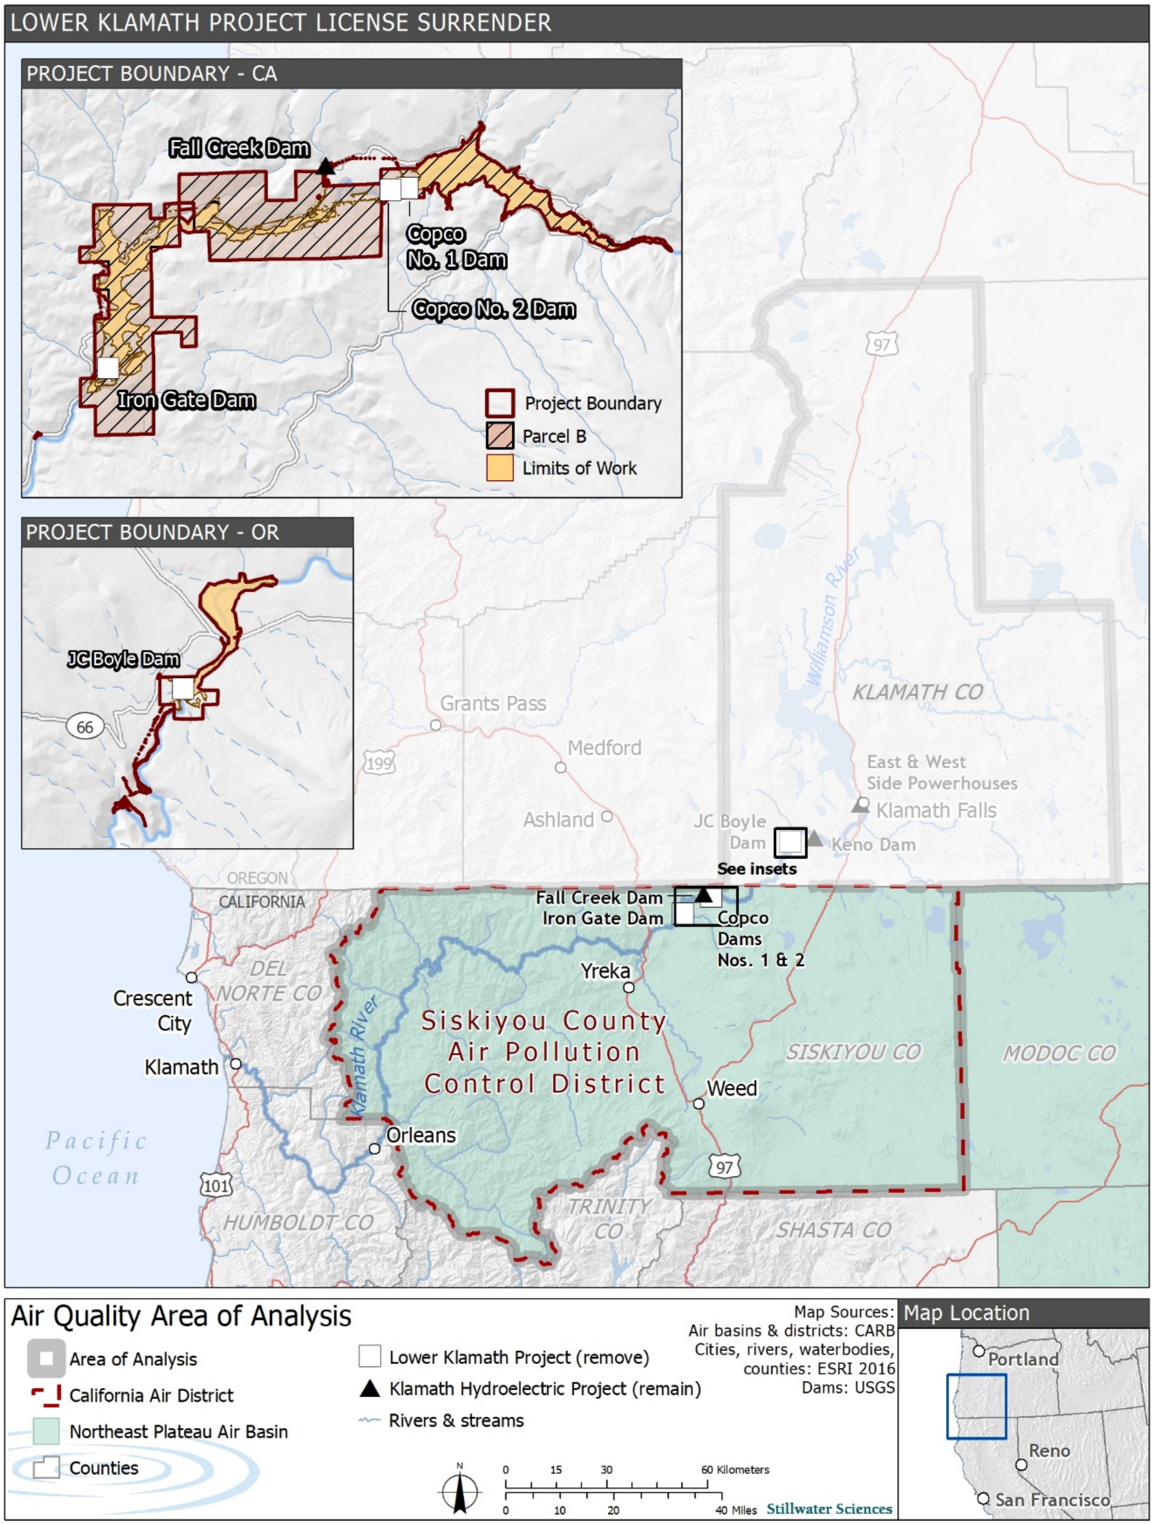

Figure 3.9-1. Area of Analysis for Air Quality.

3.9.2 Environmental Setting

This section provides a description of the environmental setting for air quality in the Area of Analysis, including a brief overview of existing air quality conditions in the portion of the Klamath Basin in California to set the stage for subsequent impact analyses. As Proposed Project construction activities in California would occur in Siskiyou County, this section focuses on the environmental setting in this county.

Ambient concentrations of air pollutant emissions are determined by the amount of emissions released by various sources and the atmosphere's ability to transport and dilute such emissions. In Siskiyou County, the terrain is dominated by volcanic peaks (e.g., Mount Shasta) and forested mountains, with agricultural activities (including rangeland) primarily in areas that are not wooded. Natural factors that affect transport and dilution of air pollutant emissions include terrain, wind, atmospheric stability, and sunlight. Also, air quality is influenced by natural factors, such as topography, meteorology, and climate, in addition to the amount of emissions released by existing air pollutant sources, as discussed separately in this section. The climate of Siskiyou County generally features hot summer days with cool nights and mild winters in the low valleys while the mountainous areas have cool summers and severe winters.

3.9.2.1 Meteorology

The climate in Siskiyou County is characterized by moderately wet winters and dry summers. Approximately 75 percent of the annual total rainfall occurs between November and April. Between June and September, normal rainfall typically is less than one inch per month. Temperatures in Siskiyou County average approximately 60 degrees Fahrenheit (°F) annually, with summer highs in the low 90°F and winter lows in the mid 40°F. Precipitation averages approximately 20 inches per year, although annual precipitation varies markedly from year to year (World Climate 2016). Annual average wind speeds in Siskiyou County are approximately 6.1 miles per hour and predominantly blow from the south. The average wind speed ranges from a low of 5.0 miles per hour in the fall to a high of 7.7 miles per hour in the spring (Western Regional Climate Center 2016).

3.9.2.2 Criteria Air Pollutants

The Clean Air Act requires the U.S. Environmental Protection Agency (USEPA) to set National Ambient Air Quality Standards (NAAQS) for six common air pollutants (also known as "criteria air pollutants") (USEPA 2018). Concentrations of criteria air pollutants are used as indicators of ambient air quality conditions. A brief description of each criteria air pollutant (i.e., source types, health effects, and future trends) is provided below, followed by Section 3.9.2 *Environmental Setting* which describes the air pollutant standards, and subsequent sections that describe whether Siskiyou County complies with the standards.

Ozone

Ozone (O_3) is a photochemical oxidant - a substance whose oxygen combines chemically with another substance in the presence of sunlight. In the lower atmosphere, ozone is the primary component of smog. Ozone is not emitted directly into the air but is formed through complex chemical reactions between certain emissions, known as "precursor emissions," in the presence of sunlight. The precursor emissions for ozone are reactive organic gases (ROG) and nitrogen oxides (NO_X). ROGs are volatile organic compounds that are photochemically reactive. ROG emissions result primarily from incomplete combustion and the evaporation of chemical solvents and fuels. Common sources of ROG emissions include solvents, pesticides, the burning of fuels, and organic wastes. NO_X is a group of gaseous compounds of nitrogen and oxygen that result from the combustion of fuels. Common sources of NOx emissions include emissions from burning of fuel in cars, trucks, buses, power plants, and off-road equipment (USEPA 2018).

Ozone located in the upper atmosphere (stratosphere) shields the earth from harmful ultraviolet radiation emitted by the sun. However, ozone located in the lower atmosphere (troposphere) is a major health and environmental concern. As described below, breathing ozone can trigger a variety of health problems, particularly for children, elderly, and people of all ages who have lung disease such as asthma. Ground level ozone can also have harmful effects on sensitive vegetation and ecosystems, including forests, parks, wildlife refuges, and wilderness areas. Ozone can especially cause damage during the growing season (USEPA 2018).

The adverse health effects associated with exposure to ozone pertain primarily to the respiratory system. Scientific evidence indicates that ambient levels of ozone affect not only sensitive receptors, such as people with asthma and children, but healthy adults as well. Exposure to ambient levels of ozone ranging from 0.10 to 0.40 parts per million (ppm) for one or two hours has been found to substantially alter lung function by increasing respiratory rate and pulmonary resistance, decreasing tidal volume, and impairing respiratory mechanics. Ambient levels of ozone above 0.12 ppm are linked to symptomatic responses that include such symptoms as throat dryness, chest tightness, headache, and nausea. In addition to these adverse health effects, ozone exposure can cause an increase in the permeability of respiratory epithelia (i.e., the thin tissue forming the outer layer of the body's respiratory system); such increased permeability leads to an increase in the respiratory system's responsiveness to challenges and the inhibition of the immune system's ability to defend against infection (Godish 2004).

Meteorology and terrain play a major role in ozone formation in the troposphere (i.e., at ground level). Generally, low wind speeds or stagnant air coupled with warm temperatures and clear skies provide the optimum conditions for formation; therefore, summer generally is the peak ozone season. Peak ozone concentrations often occur far downwind from the precursor emissions due to the time it takes for reactions to complete. Therefore, ozone is a regional pollutant that often affects large areas. In general, ozone concentrations over or near urban and rural areas reflect an interplay of emissions of ozone precursors, transport, meteorology, and atmospheric chemistry.

Carbon Monoxide

Carbon monoxide (CO) is a colorless, odorless, and poisonous gas, produced by incomplete burning of carbon in fuels, primarily from internal-combustion engines used for transportation. In fact, 77 percent of nationwide CO emissions are from transportation. The other 23 percent of emissions are from wood-burning stoves, incinerators, and industrial sources.

CO enters the bloodstream through the lungs by combining with hemoglobin, a component of red blood cells, which normally carries oxygen to the red blood cells. CO combines with hemoglobin much more readily than oxygen does, resulting in a drastic reduction in the amount of oxygen available to the cells. Adverse health effects associated with exposure to CO concentrations include symptoms such as dizziness, headaches, and fatigue. CO exposure is especially harmful to individuals who suffer from cardiovascular and respiratory diseases (USEPA 2018).

The highest CO concentrations generally are associated with the cold, stagnant weather conditions that occur in winter. In contrast to ozone, which tends to be a regional pollutant, CO tends to cause localized problems.

Nitrogen Dioxide

Nitrogen Dioxide (NO_2) is a brownish, highly reactive gas that is present in all urban environments. The major human-made sources of NO_2 are combustion devices, such as boilers, gas turbines, and reciprocating internal-combustion engines (mobile as well as stationary). Combustion devices emit primarily nitric oxide (NO), which reacts with oxygen in the atmosphere to form NO_2 (USEPA 2018). The combined emissions of NO and NO_2 are referred to as NO_X, which is reported as equivalent NO_2. Since NO_2 is formed and depleted by reactions associated with photochemical smog (ozone), the NO_2 concentration in a particular geographical area may not be representative of the local NO_X emission sources.

Inhalation is the most common form of exposure to NO_2, with the principal site of toxicity being the lower respiratory tract. The severity of adverse health effects depends primarily on the concentration of NO_2 inhaled rather than the duration of exposure. An individual may experience a variety of acute symptoms, including coughing, difficulty with breathing, vomiting, headache, and eye irritation, during or shortly after exposure. After approximately 4 to 12 hours of exposure, an individual may experience chemical pneumonitis or pulmonary edema, with breathing abnormalities, cough, cyanosis, chest pain, and rapid heartbeat. Severe, symptomatic NO_2 intoxication after acute exposure has been linked on occasion with prolonged respiratory impairment, including symptoms such as chronic bronchitis and decreased lung function.

Sulfur Dioxide

Sulfur dioxide (SO_2) is produced by stationary sources like coal and oil combustion, steel mills, refineries, and pulp and paper mills. The major adverse health effects associated with SO_2 exposure relate to the upper respiratory tract. SO_2 is a respiratory irritant, with constriction of the bronchioles occurring with inhalation of SO_2 at 5 ppm or more. On contact with the moist mucous membranes, SO_2 produces sulfurous acid, which is a direct irritant. Concentration rather than duration of the exposure is the most important determinant of respiratory effects. Exposure to high SO_2 concentrations may result in edema of the lungs or glottis and respiratory paralysis (USEPA 2018).

Particulate Matter

Particulate matter (PM) is a mixture of solid particles and liquid droplets found in air. PM that is small enough to be inhaled has a diameter of 10 microns or less is referred to as PM_{10}. PM_{10} consists of particulate matter emitted directly into the air, such as fugitive dust, soot, and smoke from mobile and stationary sources, construction operations, fires, natural windblown dust, and can be formed in the atmosphere by condensation or transformation of SO_2 and ROG (USEPA 2018). $PM_{2.5}$ includes a subgroup of finer particles that have a diameter of 2.5 microns or less.

Generally, adverse health effects associated with PM_{10} may result from both short-term and long-term exposure to elevated concentrations, and may include breathing and respiratory symptoms, aggravation of existing respiratory and cardiovascular diseases, alterations to the immune system, carcinogenesis, and premature death (USEPA 2018). The adverse health effects associated with PM_{10} depend on the specific composition of the particulate matter. For example, health effects may be associated with adsorption of metals, polycyclic aromatic hydrocarbons, and other toxic substances onto fine particulate matter (referred to as the "piggybacking effect"), or with fine dust particles of silica or asbestos. $PM_{2.5}$ poses an increased health risk when compared to PM_{10} because the particles can deposit deep in the lungs and are more likely to contain substances that are particularly harmful to human health.

Lead

Lead is a metal found naturally in the environment as well as in manufactured products. The major sources of lead emissions historically have been mobile and industrial sources. Due to the phase-out of leaded gasoline, as discussed in detail in this section, metal processing currently is the primary source of lead emissions. The highest levels of lead in the atmosphere generally are found near lead smelters. Other stationary sources include waste incinerators, utilities, and lead-acid battery manufacturers.

Twenty years ago, mobile sources (e.g., motor vehicles using leaded fuel) were the main contributor to ambient lead concentrations in the air. In the early 1970s, the United States Environmental Protection Agency (USEPA) established national regulations to gradually reduce the lead content in gasoline. In 1975, unleaded gasoline was introduced for motor vehicles equipped with catalytic converters. USEPA banned the use of leaded gasoline in highway vehicles in December 1995 (USEPA 2018).

Due to USEPA's regulatory efforts to remove lead from gasoline, emissions of lead from the transportation sector declined by 95 percent between 1980 and 1999, and levels of lead in the air decreased by 94 percent between 1980 and 1999. Transportation sources, primarily airplanes, now contribute to only 13 percent of lead emissions. A recent National Health and Nutrition Examination Survey reported a 78 percent decrease in the levels of lead in people's blood between 1976 and 1991. This dramatic decline can be attributed to the move from leaded to unleaded gasoline (USEPA 2018).

Similarly, lead emissions and ambient lead concentrations have decreased dramatically in California over the past 25 years. The phase-out of lead in gasoline began during the 1970s, and subsequent California Air Resources Board (CARB) regulations have eliminated virtually all lead from gasoline now sold in California. All areas of the state currently are designated as attainment for state lead standard (USEPA does not designate areas for the national lead standard). Although the ambient lead standards are no longer violated, lead emissions from stationary sources still pose "hot spot" problems in some areas. Therefore, CARB has identified lead as a toxic air contaminant (TAC).

3.9.2.3 Monitoring-Station Data and Attainment-Area Designations

Concentrations of criteria air pollutants are measured at an ambient air quality monitoring station in Yreka (located at 525 South Foothill Drive), which is the closest monitoring station to the Proposed Project in the Northeast Plateau Air Basin (NPAB). This monitoring station is centrally located in Siskiyou County and is the main station that measures criteria air pollutants in the County. As such, this monitoring station is considered representative of air quality in Siskiyou County. The most recent three years of available information on air quality data is provided in Table 3.9-1. As noted below, carbon monoxide (CO) and nitrogen dioxide (NOx) are not measured at the Yreka monitoring station. Data for CO and NOx in Table 3.9-1 was obtained from the closest monitoring station to Yreka, which is the Eureka-Jacobs monitoring station in Eureka, CA. The most recent data available for CO from the Eureka-Jacobs monitoring station is 2012-2014.

Table 3.9-1. Summary of Annual Ambient Air Quality Data (2014–2016).

	2014	2015	2016
Ozone			
Maximum concentration (1-hour/8-hour average, ppm)	0.082/0.065	0.076/0.066	0.092/0.068
Number of days state standard exceeded (1-hour)	0	0	0
Number of days 8-hour standard exceeded (National/California)	0/0	0/0	0/0
Carbon Monoxide[1]			
Maximum concentration (8-hour, ppm)	0.70	*	*
Number of days state standard exceeded	0	0	0
Number of days national standard exceeded	0	0	0
Nitrogen Dioxide [1]			
Maximum concentration (1-hour, ppb)	26.9	35.9	35.1
Number of days state standard exceeded	0	0	0
Annual average (ppm)	2	3	2
Fine Particulate Matter ($PM_{2.5}$)			
Maximum concentration (ug/m^3) (National/California)	71.9/71.9	51.0/51.0	25.1/25.1
Number of days national standard exceeded (estimated/measured)	*/2	*/2	0.0/0
Annual average (ug/m^3) (National/California)	*/*	*/*	4.9/*
Respirable Particulate Matter (PM_{10})			
Maximum concentration (ug/m^3) (National/California)	90.6/82.9	65.5/59.6	*/*
Number of days state standard exceeded (estimated/measured)	*/3	6.1/1	*/0
Number of days national standard exceeded (estimated/measured)	0.0/0	0.0/0	*/0
Annual average (ug/m^3) (California)	*	12.9	*

Source: CARB 2017

Notes:

ug/m^3 = micrograms per cubic meter

$PM_{2.5}$ = particulate matter less than or equal to 2.5 microns in diameter

PM_{10} = particulate matter less than or equal to 10 microns in diameter

ppm = parts per million

ppb = parts per billion

* Insufficient data available to determine the value.

[1] Carbon monoxide and nitrogen dioxide are not measured at any monitoring station in the NPAB. The data shown in the table were obtained from the Eureka-Jacobs monitoring station in Eureka, California, which is approximately 135 miles southwest of the Proposed Project. The most current data available for carbon monoxide from this monitoring station were for the years 2012–2014.

Both CARB and USEPA use this type of monitoring data to designate areas according to their attainment status for criteria air pollutants. The purpose of these designations is to identify areas with air quality problems, and initiate planning efforts for improvement. The three basic designation categories are “non-attainment,” “attainment,” and “unclassified.” The attainment designation means that an area meets the national or state ambient air quality standards for a given criteria air pollutant. The non-attainment designation means that an area exceeds the national or state ambient air quality standards for a given criteria air pollutant. The unclassified designation is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards. In addition, the California designations include a subcategory of the non-attainment designation, called “non-attainment-transitional.” The non-attainment-transitional designation is given to non-attainment areas that are progressing and nearing attainment.

Table 3.9-2 shows the attainment status of Siskiyou County with respect to national ambient air quality standards (NAAQS) (CARB 2016b) and California ambient air quality standards (CAAQS) (CARB 2016b). As indicated in Table 3.9-2, Siskiyou County is designated as attainment or unclassified for all federal and state ambient air quality standards.

Table 3.9-2. Attainment Status Summary, Siskiyou County.

Criteria Pollutant	Federal Designation	State Designation
Ozone (O_3) (1-hour)	(no federal standard)	Attainment
Ozone (O_3) (8-hour)	Unclassified/Attainment*	Attainment
Nitrogen Dioxide (NO_2)	Unclassified/Attainment*	Attainment
Sulfur Dioxide (SO_2)	Unclassified*	Attainment
Carbon Monoxide (CO)	Unclassified/Attainment*	Unclassified*
Particulates (as PM_{10})	Unclassified*	Attainment
Particulates (as $PM_{2.5}$)	Unclassified/Attainment*	Attainment
Lead (Pb)	Unclassified/Attainment*	Attainment
Sulfates (as SO_4)	(no federal standard)	Attainment
Hydrogen Sulfide (H_2S)	(no federal standard)	Unclassified*
Vinyl Chloride (C_2H_3Cl)	(no federal standard)	n/d
Visibility Reducing Particles	(no federal standard)	Unclassified*

Source: CARB 2015a
Notes:
* At the time of designation, if the available data does not support a designation of attainment or non-attainment, the area is designated as unclassified.
n/d—no data/information available

Appendix N provides a summary of the existing emission sources and monitoring data, detailed emission calculation methodologies, and detailed emission inventories.

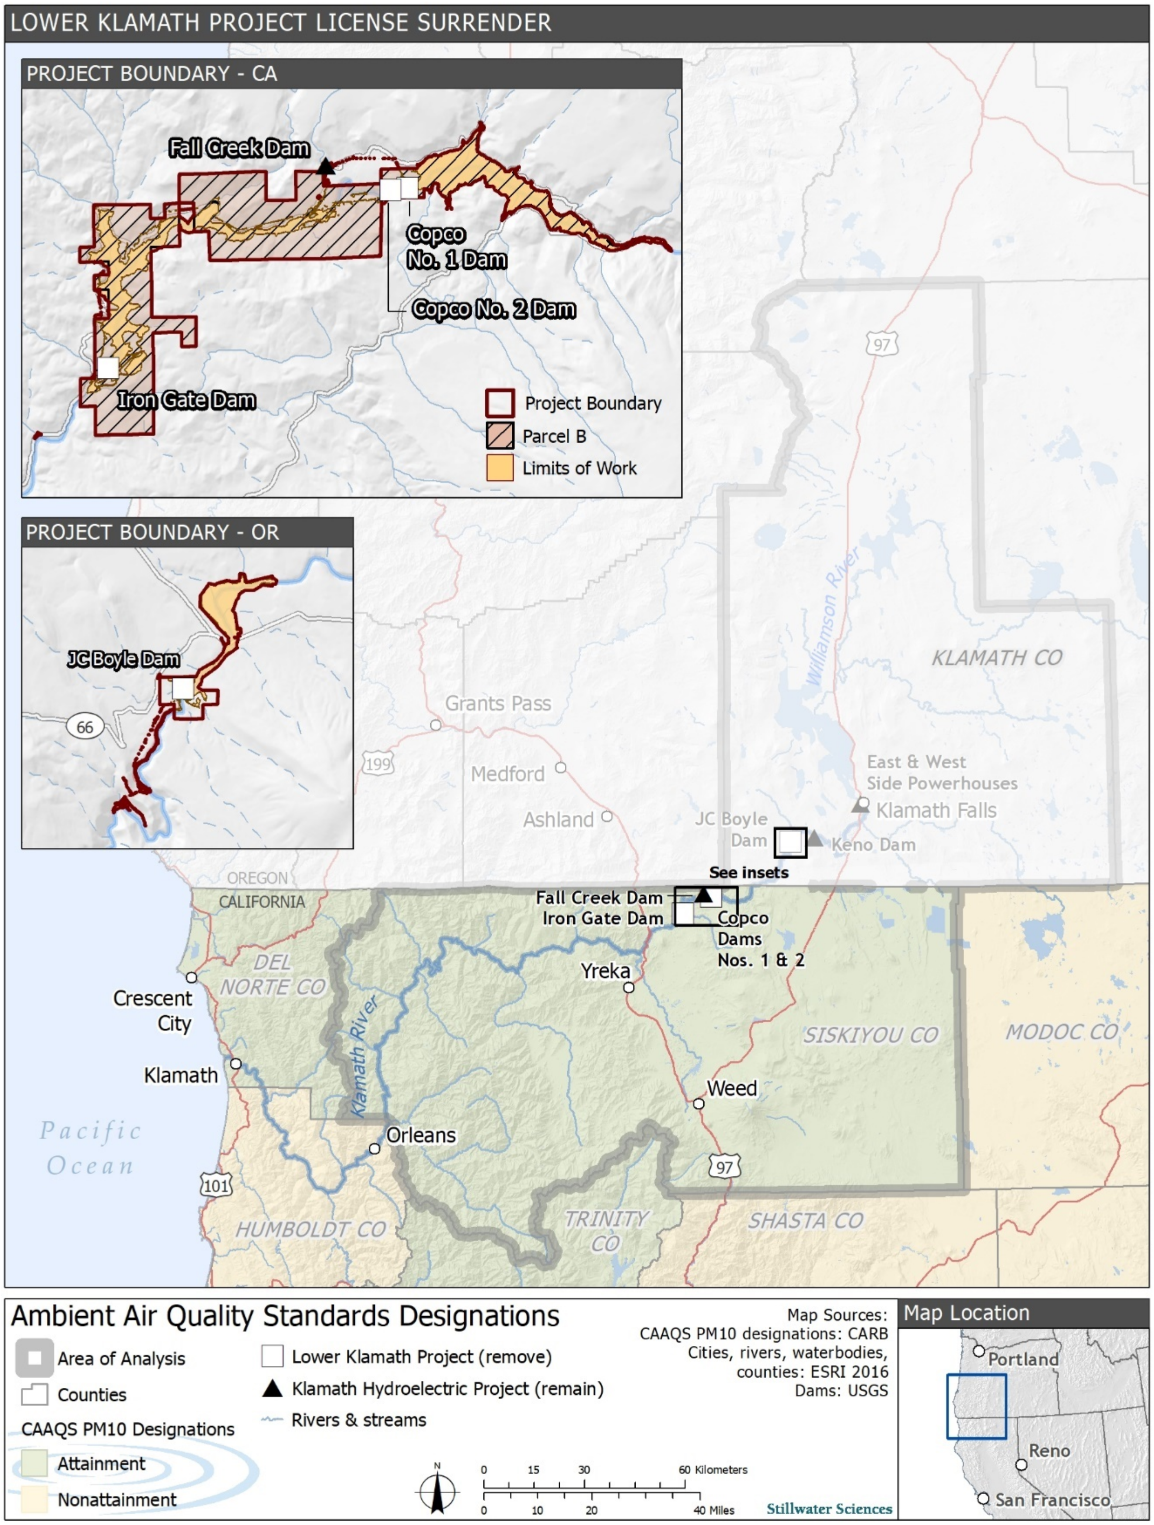

Figure 3.9-2. Particulate Matter (PM_{10}) California Ambient Air Quality Standards (CAAQS) Designations.

3.9.2.4 Air Quality Conditions

Sources of criteria air pollutant emissions in Siskiyou County include stationary, area-wide, and mobile sources. These sources are summarized in Table 3.9-3. According to Siskiyou County's emissions inventory, stationary sources provide a relatively small contribution to total emissions. Area-wide sources, which include emissions spread over a wide area such as consumer products, fire places, road dust, and farming operations, account for approximately 94 percent and 78 percent of the county's total PM_{10} and $PM_{2.5}$ emissions respectively, and 66 percent of total ROG emissions. Mobile sources are the largest contributor to the estimated annual average air pollutant levels of NO_X, accounting for approximately 94 percent of the total emissions. Mobile sources also account for approximately 27 percent of the total ROG emissions for the county.

Table 3.9-3. Summary of 2015 Estimated Emissions Inventory for Siskiyou County.

Source Type/Category	Estimated Annual Average Emissions (Tons per Day)			
	ROG	NO_X	PM_{10}	$PM_{2.5}$
Stationary Sources				
Fuel Combustion	0.09	0.33	0.25	0.24
Waste Disposal	0.00	0.00	0.00	0.00
Cleaning and Surface Coating	0.19	-	-	-
Petroleum Production and Marketing	0.40	-	-	-
Industrial Processes	0.14	-	0.35	0.15
Subtotal (Stationary Sources)	**0.82**	**0.33**	**0.61**	**0.39**
Area wide Sources				
Solvent Evaporation	4.63	-	-	-
Miscellaneous Processes	3.89	0.70	17.05	4.80
Subtotal (Area-wide Sources)	**8.52**	**0.70**	**17.05**	**4.80**
Mobile Sources				
On-Road Motor Vehicles	1.74	4.96	0.24	0.13
Other Mobile Sources	0.90	2.40	0.11	0.10
Subtotal (Mobile Sources)	**2.64**	**7.36**	**0.36**	**0.23**
Grand Total for Siskiyou County	**11.98**	**8.39**	**18.01**	**5.42**

Source: CARB 2015b
Notes: "-" = less than 0.1 ton per day
Totals shown in this table are rounded, and therefore may not appear to add exactly.

3.9.2.5 Local Emission Sources

Land uses surrounding the Limits of Work for the Proposed Project include mainly open space and recreational land. Sources of criteria air pollutants are primarily area-wide and mobile sources. Mobile sources include road motor vehicles, such as trucks and passenger vehicles. Area-wide sources include road dust, farming operations, and fire places.

3.9.2.6 Air Quality—Toxic Air Contaminants

Toxic Air Contaminants (TACs) are air pollutants that may cause or contribute to an increase in mortality or serious illness or pose a hazard to human health. TACs usually are present in small quantities in the ambient air. However, in some cases, their high toxicity or health risk may pose a threat to public health even at low concentrations. Of the TACs for which data are available in California, diesel PM, benzene, 1,3-butadiene, acetaldehyde, carbon tetrachloride, hexavalent chromium, para-dichlorobenzene, formaldehyde, methylene chloride, and perchloroethylene pose the greatest ambient risks.

According to CARB, the majority of the estimated health risk from TACs can be attributed to relatively few compounds, the most important being particulate matter from diesel-fueled engines (diesel PM) (CARB 2013). Diesel PM differs from other TACs in that it is not a single substance but rather a complex mixture of hundreds of substances. Although diesel PM is emitted by diesel-fueled, internal combustion engines, the composition of the emissions varies depending on engine type, operating conditions, fuel composition, lubricating oil, and whether an emission control system is present. Other sources of particulate matter emissions are discussed in Section 3.9.2.2 *Criteria Air Pollutants*.

Statewide, diesel PM emissions account for approximately two percent of the annual average for on-road emissions, while other diesel PM emissions from off-road mobile sources (e.g., construction and agricultural equipment) account for an additional three percent (CARB 2013). Statewide diesel PM emissions decreased approximately 37 percent from year 2000 to 2010, primarily from implementation of more stringent federal emission standards and cleaner burning diesel fuel (CARB 2013). CARB anticipates that diesel PM emissions from on-road and other mobile sources (e.g., construction and agricultural equipment) will continue to decrease into 2035. This decrease would also be attributed to more stringent emissions standards and the introduction of cleaner burning diesel fuel.

3.9.2.7 Sensitive Land Uses

As noted above, high concentrations of criteria air pollutants and toxic air contaminants can result in adverse health effects to humans. Some population groups are considered more sensitive to air pollution and odors than others; in particular, children, elderly, and acutely ill and chronically ill persons, especially those with cardio-respiratory diseases, such as asthma and bronchitis. Sensitive land uses are facilities that generally house more sensitive people (e.g., schools, hospitals, nursing homes, residences, etc.).

The areas surrounding Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam are sparsely populated with few sensitive land uses. The nearest sensitive land uses are recreational facilities, located along the Copco No. 1 Reservoir and Iron Gate Reservoir, along with hiking trails around the Fall Creek development (see Section 3.20 *Recreation* for more details). The next closest sensitive land uses include scattered residences that are located along the Klamath River. The closest homes to construction sites are located over 2,000 feet from Copco No. 1 Dam, over 3,500 feet from Copco No. 2 Dam, and over 4,000 feet from Iron Gate Dam. There are also several modular homes located at Copco Village that are currently occupied by PacifiCorp staff. These homes are located within the Limits of Work and range from 850 feet to 2,200 feet west of the Copco No. 2 Powerhouse (Figure 2.7-2). Prior to the beginning of dam deconstruction activities, these homes would be vacated. The nearest licensed daycare providers and hospitals are located in Yreka, approximately 15 miles southwest of Iron Gate Dam. The nearest schools are more than 5 miles from Iron Gate Dam (Bogus Elementary is approximately 5.3 miles; Willow Creek Elementary School is approximately 5.5 miles; Hornbrook Elementary School is more than 6 miles).

3.9.2.8 Characteristics of Odors

Odors generally are regarded as a nuisance rather than a health hazard. However, manifestations of a person's reaction to foul odors can range from psychological (e.g., anger or anxiety) to physiological (e.g., circulatory and respiratory effects, nausea, vomiting, or headache).

The ability to detect odors varies considerably among the population and the odor interpretation is subjective. Some individuals have the ability to smell small quantities of specific substances. Others may not have the same sensitivity but may have sensitivities to odors of other substances. In addition, people may have different reactions to the same odor. An odor that is offensive to one person (e.g., from a fast food restaurant) may be perfectly acceptable to another. Unfamiliar odors are detected more easily than familiar odors and are more likely to be offensive.

Quality and intensity are two properties present in any odor. The quality of an odor indicates the nature of the smell experience. For instance, if a person describes an odor as flowery or sweet, then the person is describing the quality of the odor. Intensity refers to the strength of the odor. Odor intensity depends on the odorant concentration in the air. When an odorous sample is progressively diluted, the odorant concentration decreases. As this occurs, the intensity of the odor weakens and eventually becomes so low that detection or recognition of the odor is difficult. At some point during dilution, the concentration of the odorant reaches a detection threshold. An odorant concentration below the detection threshold means that the concentration in the air is not detectable by the average person (Siskiyou County 2017).

Odors currently present on a periodic basis in areas within and adjacent to the Proposed Project Limits of Work are generated from livestock, agricultural crop production, wood burning, wildfires, on-site wastewater treatment systems, and algal blooms in Iron Gate Reservoir and Copco No. 1 Reservoir.

3.9.3 Significance Criteria

Criteria for determining significant impacts on air quality are based upon Appendix G the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and best professional judgement. Effects on air quality are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

1. Conflict with or obstruct implementation of the California Regional Haze Plan.
2. Exceed the Siskiyou County Air Pollution Control District emissions thresholds in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).
3. Result in a cumulatively considerable net increase of any criteria pollutant for which the Siskiyou County Air Pollution Control District is in non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors).
4. Expose sensitive receptors to substantial toxic air contaminant concentrations during project construction.
5. Create objectionable odors affecting a substantial number of people during project construction.

For areas that are designated as non-attainment for criteria air pollutants, some of the air districts in California have developed air quality plans that contain measures designed to reduce the sources of these air pollutants. As noted in Table 3.9-2 (Attainment Status Summary, Siskiyou County), Siskiyou County is designated as attainment or unclassified for all federal and state ambient air quality standards. As such, the Siskiyou County Air Pollution Control District has not developed any air quality plans relevant to the Proposed Project. As noted above, the construction emissions in Oregon are only being considered to the extent that these emissions would influence air quality in Siskiyou County, California. As such, consistency with air quality plans relevant to Klamath County, Oregon are not considered in this section.

To protect visibility in Class 1 federal lands (e.g., national parks and scenic areas), the USEPA adopted the Regional Haze Rule in 1999. The Rule lays out specific requirements to ensure improvements in the anthropogenic components of visibility at 156 of the largest national parks and wilderness areas across the United States. The vast majority of these areas are in the West (118), with 29 in California, including such national treasures as Yosemite and Sequoia National Parks. Good visibility is essential to the enjoyment of national parks and scenic areas. Across the United States, regional haze has decreased the visual range in these pristine areas from 140 miles to 35–90 miles in the West, and from 90 miles to 15–25 miles in the East. This haze is composed of small particles that absorb and scatter light, affecting the clarity and color of what humans see in a vista. The pollutants (also called *haze species*) that create haze are measurable as sulfates, nitrates, organic carbon, elemental carbon, fine soil, sea salt, and coarse mass. Anthropogenic sources of haze include industry, motor vehicles, agricultural and forestry burning, and dust from soils disturbed by human activities. Pollutants from these sources, in concentrations much lower than those which affect public health, can impair visibility anywhere.

To comply with the Regional Haze Rule, CARB developed a Regional Haze Plan (CARB 2009) which sets out a long-term path towards attaining improved visibility in national parks and other scenic areas, with the goal of achieving visibility which reflects natural conditions by year 2064. An air quality impact would be significant if the construction emissions from the Proposed Project would substantially conflict with or obstruct implementation of the Regional Haze Plan.

Siskiyou County is in attainment or unclassified for all criteria air pollutants and the Siskiyou County Air Pollution Control District (SCAPCD) has not adopted thresholds of significance for conducting an air quality analysis under CEQA. However, the SCAPCD Rule 6.1 (Construction Permit Standards for Criteria Pollutants) contains thresholds for operational emissions from new stationary sources (CARB 2016a). Criteria air pollutants from the operation of stationary sources are considered significant if they exceed the following thresholds.

- 250 pounds per day for NO_x, volatile organic compounds (VOC), PM_{10}, $PM_{2.5}$, sulfur oxides (SO_x)
- 2,500 pounds per day for CO

Since the project proposes construction activity related to the decommissioning of the Lower Klamath Project facilities that would be completed at the end of 2021, it does not include long-term operational emissions. Unlike operational emissions, construction emissions do not occur continuously over the lifetime of a project. Rather, construction emissions are temporary emissions that are spread out over the construction period. Therefore, the application of the SCAPCD stationary source operational emissions significance threshold for construction emissions from the Proposed Project is conservative because these emissions are limited in duration. As such, an air quality standard would be violated, and a significant air quality impact would result, if the construction emissions from the Proposed Project exceed the thresholds in SCAPCD Rule 6.1.

An air quality impact would be significant if project construction would expose sensitive receptors to substantial pollutant concentrations. As noted above, population groups including children, elderly, and acutely ill and chronically ill persons, are considered more sensitive to air pollution than others. Sensitive land uses are facilities that generally house more sensitive people (e.g., schools, hospitals, nursing homes, residences, etc.). Sensitive receptors within a quarter-mile of construction activities would be at the greatest risk for exposure to fugitive dust and heavy equipment emission diesel exhaust during construction. According to the USEPA, the majority of fugitive dust generally settles out of the atmosphere within 300 feet of the source, with larger particles traveling less distance and smaller particles traveling a longer distance (USEPA 1995). According to the CARB, concentrations of mobile-source diesel particulate matter emissions are typically reduced by 70 percent at a distance of approximately 500 feet (CARB 2005).

There are several sources of odors that could result from the Proposed Project including odors from exposed sediments and odors from construction equipment emissions. These potential sources of odors are discussed below along with a determination of whether substantial numbers of people could be impacted by these sources of odors.

3.9.4 Impact Analysis Approach

Within the Area of Analysis, potential air quality impacts due to construction activities related to the removal of the Lower Klamath Project facilities were quantitatively assessed for Siskiyou County, California and Klamath County, Oregon. The quantitative assessment focused on these counties because that is where direct air quality impacts from construction activity would occur. Construction emissions estimates were developed for dam and powerhouse deconstruction, restoration activities, the relocation and demolition of recreation facilities, and the Yreka supply pipeline relocation. As noted above, the construction emissions in Oregon are only being considered to the extent that these emissions would influence air quality in Siskiyou County, California.

No changes in operational sources are part of the Proposed Project; therefore, this analysis considers only construction-related air quality impacts. Operational emissions for the reduced operation of Iron Gate Fish Hatchery combined with the re-instated operation of Fall Creek Hatchery were assumed to be the same as existing operation conditions at Iron Gate Hatchery for eight years following dam removal. This is due to the fact that the existing functions at the Iron Gate Hatchery that would be eliminated as part of dam removal activities, would be replaced by the reopening and operation of the Fall Creek Hatchery and by making improvements to the Iron Gate Hatchery (Section 2.7.6 *Hatchery Operations*).

The construction emissions estimates used for this EIR (Appendix N) were developed in 2011 as part of the 2012 KHSA EIS/EIR analysis. Although there have since been modifications to the Proposed Project schedule (Table 2.7-1), the 2011 emissions modeling is still relevant as the construction-related activities and their associated emissions for the Proposed Project are materially similar to those modeled in 2011. Minor changes in proposed construction activities between the 2012 KHSA EIS/EIR analysis and the Proposed Project are primarily due to the timing associated with removing each dam (Table 2.7.1). The exceptions to this are discussed below. The Proposed Project and the data modeled as part of the 2012 KHSA EIS/EIR are compared to the thresholds noted in Section 3.9.3 *Significance Criteria* and analyzed in Section 3.9.5 *[Air Quality] Potential Impacts and Mitigation*.

As noted in Appendix N, the estimates of earthen material waste that would require on-site disposal has decreased by approximately 80,000 cubic yards under the current project proposal (Appendix B: *Definite Plan*). As such, there is the potential to generate fewer equipment engine exhaust, haul truck engine exhaust, and fugitive dust emissions during the excavation and on-site disposal of earthen materials from the dams. However, the estimates of building waste that would require off-site disposal has increased by approximately 2,600 cubic yards under the current project proposal (Appendix B: *Definite Plan*). As such, there is the potential to generate greater equipment engine exhaust, haul truck engine exhaust, and fugitive dust emissions during the demolition and off-site disposal of building waste.

The decrease in emissions from the excavation and hauling of earthen material waste would partially off-set the increase in emissions from the demolition and hauling of building waste. However, the building waste would require disposal at off-site locations that range from 22 to 28 miles (44 to 56 miles round-trip) from the dams. The earthen material waste would be disposed of at on-site locations that range from 0.25 to 4 miles (0.5 to 8 miles round-trip) from the dams. As such, it is anticipated that the emissions from dam removal activities under the current proposal (Appendix B: *Definite Plan*) would be greater than the emissions estimates calculated for the 2012 KHSA EIS/EIR. This increase would primarily be due to haul truck engine exhaust because of the hauling distance required for the off-site disposal of building waste. This issue is addressed further under Potential Impact 3.9-2.

Quantification of Criteria Air Pollutants

This EIR's air quality analysis calculated estimates of emissions for construction activities related to dam demolition, including heavy equipment use, hauling of demolition debris to landfills, and worker transportation. Appendix N describes the methodology used to develop the emissions inventories related to construction activities. The emissions estimates are derived from the following emissions models and spreadsheet calculations:

- CARB Urban Emissions model, Version 9.2.4 (fugitive dust calculations from construction equipment, cut/fill activities, and building demolition);
- CARB Emissions Factor (EMFAC) 2007 model (on-road vehicle emissions factor model for California);
- USEPA MOBILE6.2[139] (on-road vehicle emissions factor model for Oregon), as applicable;
- CARB OFFROAD2007 (off-road vehicle emissions factor model for California);
- USEPA NONROAD2008a (off-road vehicle emissions factor model for Oregon), as applicable;
- Midwest Research Institute (1996), Improvement of Specific Emission Factors (paved road dust emissions);
- Compilation of Air Pollutant Emission Factors (AP-42) (USEPA 2006).

A combination of techniques was used to estimate emissions from the restoration activities. Emissions from landing and takeoff operations associated with aerial seed application were estimated using the Federal Aviation Administration's Emissions and Dispersion Modeling System. Emissions from hydroseeding barges were estimated using the following sources:

- Analysis of Commercial Marine Vessels Emissions and Fuel Consumption Data (USEPA 2000);
- AP-42, Chapter 3.3: Gasoline and Diesel Industrial Emissions (USEPA 1996);
- Title 17 California Code of Regulations, Section 93115.7: Air Toxic Control Measure for Stationary Compression Ignition Engines—Stationary Prime Diesel-Fueled Compression Ignition Engine (>50 bhp) Emission Standards;
- Title 13 California Code of Regulations, Section 2423: Exhaust Emission Standards and Test Procedures—Off-Road Compression-Ignition Engine.

Emissions from ground support equipment were estimated using the emission factors for off-road engines identified above and EMFAC for on-road motor vehicle emissions.

[139] Although the USEPA recently developed the Motor Vehicle Emission Simulator (MOVES) to replace MOBILE6.2, MOVES has only been approved for use in SIPs and Transportation Conformity (75 FR 9411) (USEPA 2010). As it has not yet been approved for project-level analyses, MOBILE6.2 was used to estimate emissions from on-road vehicles in Oregon.

The California Emissions Estimator Model (CalEEMod), Version 2011.1.1, was used to estimate exhaust emissions that would occur from grading activities associated with restoring parking lots associated with recreational facilities proposed for removal and restoration. The California Emissions Estimator Model makes general assumptions about the quantity and types of construction equipment needed to grade a site based on its size (acreage).

The Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model, Version 6.3.2 (2009), was used to estimate exhaust emission factors associated with relocation of the Yreka water supply pipeline. The Siskiyou County Air Pollution Control District does not have a comparable model to estimate emissions from linear projects like the proposed pipeline relocation action.

Appendix N contains an estimate of "uncontrolled emissions" and an estimate of emissions after implementation of mitigation measures that were proposed as part of the analysis in the 2012 KHSA EIS/EIR. These included Mitigation Measures Air Quality (AQ)-1 (Off-road construction equipment), AQ-2 (On-road construction equipment), AQ-3 (trucks used to transport materials), and AQ-4 (Dust control measures). Mitigation Measures AQ-1 through AQ-3 required off-road construction equipment and on-road construction equipment and trucks to be equipped with engines that meet certain model year emissions standards. Mitigation Measure AQ-4 required dust control measures to minimize fugitive dust emissions during construction activity. With the implementation of these mitigation measures, the 2012 KHSA EIS/EIR determined construction emissions from the Proposed Project would still result in significant and unavoidable impacts from NO_x and PM_{10}.

The current proposal for the Proposed Project lacks sufficient detail concerning construction activities and it is too speculative to determine whether the mitigation measures proposed in the 2012 KHSA EIS/EIR are feasible and enforceable. As such, the analysis in this section does not include mitigation to minimize impacts from construction emissions generated by the Proposed Project activities. Since similar minimization measures may be implemented during project construction, it is assumed that the emissions generated by the Proposed Project would fall somewhere in the range between the uncontrolled and mitigated emissions estimates contained in Appendix N.

3.9.5 Potential Impacts and Mitigation

Potential Impact 3.9-1 Conflict with or obstruct implementation of the California Regional Haze Plan.

As noted in Table 3.9-2 (Attainment Status Summary, Siskiyou County), Siskiyou County is designated as attainment or unclassified for all federal and state ambient air quality standards. As such, the Siskiyou County Air Pollution Control District has not developed any air quality plans relevant to the Proposed Project. As noted above, the construction emissions in Oregon are only being considered to the extent that these emissions would influence air quality in Siskiyou County, California. As such, consistency with air quality plans relevant to Klamath County, Oregon are not considered in this section.

In 1999, the USEPA adopted the Regional Haze Rule, which requires states to establish a series of interim goals to ensure continued progress towards improving visibility in Class 1 federal lands (e.g., national parks and other scenic areas). To comply with the

Regional Haze Rule, CARB developed a Regional Haze Plan (CARB 2009), which sets out a long-term path towards attaining improved visibility in Class 1 federal lands, with the goal of achieving visibility which reflects natural conditions by year 2064. The closest Class 1 areas near the Proposed Project include the Marble Mountain Wilderness and Lava Beds National Monument. Sources of haze in this area of northern California include, but are not limited to, rural land uses, traffic on Interstate 5, railroad freight traffic, wildfires, and natural biogenic emissions from plants (CARB 2009).

Since the Proposed Project involves construction activity related to the decommissioning of the Lower Klamath Project facilities that would be completed at the end of 2021, and the Proposed Project would not have long-term operational emissions, the potential for the project to conflict with the California Regional Haze Plan is limited. In addition, CARB has adopted regulations designed to reduce diesel emissions from off-road vehicles, which includes construction equipment that may be used for the Proposed Project.

In July 2007, ARB adopted a pioneering regulation aimed at reducing diesel and NO_x emissions from the State's estimated 180,000 off-road vehicles used in construction, mining, airport ground support and other industries. The Regional Haze Plan indicates that CARB's In-Use Off-Road Diesel Vehicle Regulation (adopted on July 26, 2007) would reduce particulate matter and NO_x emissions by 74 percent and 32 percent, respectively, from current levels. Off-road diesel vehicles (25 horsepower or greater) and most two-engine vehicles (except on-road two-engine sweepers) used for construction activities related to the Proposed Project would be required to comply with this regulation (CARB 2016c). Adhering to this CARB regulation for off-road diesel vehicles would reduce potential visibility impacts from construction activities related to the Proposed Project and provide consistency with the Regional Haze Plan.

Therefore, the proposed project would not conflict with or obstruct implementation of the California Regional Haze Plan.

Significance

No significant impact

Potential Impact 3.9-2 Exceedance of the Siskiyou County Air Pollution Control District emissions thresholds in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).

Summary

Table 3.9-4 summarizes the uncontrolled emissions associated with the Proposed Project activities including dam and powerhouse deconstruction, restoration activities, and the relocation and demolition of recreational facilities. Since these project activities have the potential to overlap, their daily emissions are combined and compared to emissions thresholds in the SCAPCD's Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants). Since the Yreka water pipeline relocation would occur prior to initiating drawdown of the Iron Gate Reservoir, the construction emissions from this project activity is analyzed separately.

The daily emissions estimates in Table 3.9-4 also includes construction activity related to the removal of J.C. Boyle Dam in Oregon. Due to the potential for the emissions generated from construction activity in Oregon to have air quality impacts in Siskiyou County, California, the emissions from construction activity in Oregon are conservatively added to the emissions from construction activity in California and compared to the SCAPCD's significance thresholds.

Table 3.9-4. Uncontrolled Emissions Inventories for the Proposed Project.

Phase	Peak Daily Emissions (pounds per day)[1]					
	VOC	**CO**	**NO_x**	**SO_2**	**PM_{10}**	**$PM_{2.5}$[2]**
Dam and Powerhouse Deconstruction	131	584	650	9	503	248
Restoration Activities	19	62	168	20	3	3
Recreation Facilities	12	77	85	0	17	7
Maximum Daily	162	723	**903**	29	**523**	**258**
Significance Criterion[2]	250	2,500	250	250	250	250

Source: Appendix N
Notes:
[1] Values shown in **bold** exceed the Siskiyou County Air Pollution Control District's (SCAPCD) thresholds of significance in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).
Key:
VOC = volatile organic compounds
CO = carbon monoxide
NO_x = nitrogen oxides
SO_2 = sulfur dioxide
PM_{10} = inhalable particulate matter
$PM_{2.5}$ = fine particulate matter

As shown in Table 3.9-4, total daily emissions from the Proposed Project are estimated to exceed the SCAPCD's significance thresholds for NO_x, PM_{10}, and $PM_{2.5}$. As such, the construction emissions from the Proposed Project would be significant.

As discussed above in Section 3.9.4 *Impact Analysis Approach*, it is anticipated that the emissions from dam removal activities under the current proposal (Appendix B: *Definite Plan*) would be greater than the emissions estimates calculated for the 2012 KHSA EIS/EIR. This increase would primarily be due to haul truck engine exhaust because of the hauling distance required for the off-site disposal of building waste. As such, it is anticipated that these additional emissions would contribute to the finding of significant impacts for the emissions of NOx, PM_{10}, and $PM_{2.5}$ from the Proposed Project. It is not anticipated that these additional emissions would cause the Proposed Project to exceed the significance thresholds for VOC, CO, or SOx for the following reasons: (1) the emissions of these criteria air pollutants from the Proposed Project are well below the SCAPCD's significance thresholds (Table 3.9-4); and (2) the hauling of waste from dam removal activities only constitutes a small portion of the emissions of these criteria air pollutants (Appendix N).

As discussed above, mitigation measures were included for the Proposed Project as part of the analysis in the 2012 KHSA EIS/EIR. The mitigation measures required on and off-road construction equipment and trucks to be equipped with engines that meet certain model year emissions standards and various dust control measures. With the implementation of these mitigation measures, the 2012 KHSA EIS/EIR determined construction emissions from the Proposed Project would still result in significant and unavoidable impacts from NO_x and PM_{10}.

As noted above, the current proposal for the Proposed Project lacks sufficient detail concerning construction activities and it is too speculative to determine whether the mitigation measures proposed in the 2012 KHSA EIS/EIR are feasible and enforceable. As such, the analysis in this section does not include mitigation to minimize impacts from construction emissions generated by the Proposed Project activities. Since similar minimization measures may be implemented during project construction, it is assumed that the emissions generated by the Proposed Project would fall somewhere in the range between the uncontrolled and mitigated emissions estimates contained in Appendix N. Due to this uncertainty, the emissions of NOx, PM_{10}, and $PM_{2.5}$ from the Proposed Project are found to be significant and unavoidable.

The discussion below provides more detailed information about the emissions from the various project activities.

Dam and Powerhouse Deconstruction

Vehicle exhaust and fugitive dust emissions from dam removal activities would generate emissions of VOC, NO_x, CO, SO_2, PM_{10}, and $PM_{2.5}$ during the dam deconstruction period. The emission sources would include exhaust emissions from off-road construction equipment, on-road trucks, construction worker employee commuting vehicles, fugitive dust emissions from unpaved roads, blasting activities, and general earth-moving activities. Activities that could generate fugitive dust include on-site operation of construction equipment and removal and placement of excavated materials (cut/fill activities).

Predicted uncontrolled peak daily emission rates for VOC, NO_x, CO, SO_2, PM_{10}, and $PM_{2.5}$ for the Proposed Project are summarized in Table 3.9-5. This analysis uses the conservative assumption that the peak day of construction could occur at the same time for each dam; therefore, the peak daily emissions are additive.

Table 3.9-5. Uncontrolled Emissions Inventories for Dam and Powerhouse Deconstruction**.**

Location	Peak Daily Emissions (pounds per day)[1]					
	VOC	CO	NO_x	SO_2	PM_{10}	$PM_{2.5}$ [2]
Iron Gate	67	272	**348**	2	210	50
Copco No. 1	27	176	129	1	174	165
Copco No. 2	22	83	113	1	17	6
J.C. Boyle	15	54	60	5	103	27
Grand Total	131	584	**650**	9	**503**	248
California Total[3]	116	531	**590**	4	**401**	221
Oregon Total	15	54	60	5	103	27
Significance Criterion[1]	250	2,500	250	250	250	250

Source: Appendix N

Notes:

1 Values shown in **bold** exceed the Siskiyou County Air Pollution Control District's (SCAPCD) thresholds of significance in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).

2 Where emission factors were only provided for PM_{10}, appropriate PM size profiles were used to estimate $PM_{2.5}$ emissions.

3 Appendix N - California total includes emissions for activities at Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam.

As Table 3.9-5 shows, emissions from deconstruction of the dams would exceed the significance criteria for NOx and PM_{10}. The greatest source of NO_x emissions from each of the dams would be off-road construction equipment, followed by on-road trucks, and then employee commuting vehicles. The major sources of PM_{10} emissions would be fugitive dust from unpaved roads and then cut/fill activities. As indicated in Table 3.9-4, deconstruction of the dams would produce the majority of construction emissions that would occur from the Proposed Project.

Cofferdams would be constructed during deconstruction activities from concrete rubble, rock, and earthen materials that would come from the dam removal activities, as possible. As the cofferdams would be constructed from materials salvaged from the dam demolition activities, emissions associated with cofferdam construction would already be included in the emissions inventory. Additional emissions could occur when the cofferdams are later demolished. Due to the limited size of these structures and the fact that much of the material used to construct the coffer dams would be disposed of in close proximity to the dam sites, it is not anticipated that the additional emissions from this activity would result in a change to the significance determinations.

Following drawdown of the reservoirs and prior to the establishment of ground vegetation from reseeding, there is the potential for windblown dust to be generated from the exposed sediment deposits remaining in the reservoirs. Once reseeding occurs, it typically takes a minimum of four weeks for vegetation to be established to reduce the potential for windblown dust. Considering that reservoir drawdown would occur in the winter months (January to March), it is anticipated that the seasonally wet conditions would substantially reduce the potential for windblown dust until the establishment of vegetation. However, there is the potential for short-term impacts from windblown dust not accounted for in the particulate matter emission estimates in Table 3.9-5 and Appendix N, Table M-19. As such, this additional source of particulate matter emissions would contribute to the finding of significant and unavoidable impacts for particulate matter emissions from the Proposed Project.

Restoration Activities

Restoration actions included in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) could result in short-term increases in criteria pollutant emissions from vehicles exhaust and fugitive dust from the use of helicopters or other small aircraft, trucks, and barges. Following drawdown of the reservoirs, revegetation efforts would be initiated to support establishment of native wetland, riparian, and upland species on newly exposed riverbank sediment and surrounding areas. Additional fall seeding may be necessary to supplement areas where spring hydroseeding was unsuccessful (Appendix B: *Definite Plan*).

Emissions from ground support equipment were estimated using the emission factors for off-road engines identified above and EMFAC model for on-road motor vehicle emissions. The majority of peak daily emissions that would be generated by the restoration activities would occur from the use of barges or aircraft for reseeding during and following reservoir drawdown. As the use of barges would cease when reservoir levels become too low (by March of dam removal year 2), there would not be an overlap between the use of the barges and the peak construction activities related to dam removal (May through September of dam removal year 2) (Table 2.7-1). Overlap that could occur between the restoration activities and peak construction activities related to dam removal, would include the use of ground and aerial equipment for reseeding (Table 3.9-4). Table 3.9-6 summarizes emissions from restoration activities.

Table 3.9-6. Uncontrolled Emissions from Restoration Activities .

Phase	Peak Daily Emissions (pounds per day)					
	VOC	CO	NO_x	SO_2	PM_{10}	$PM_{2.5}$[2]
Ground Equipment	3	8	15	2	0	0
Barges	16	54	153	18	3	3
Air craft	15	39	3	1	0	0
Maximum Daily[1]	19	62	168	20	3	3

Source: Appendix N
Notes:
[1] Barge and aerial application would not happen simultaneously; therefore, maximum daily emissions summarizes the peak day that consists of ground equipment and barges operating at the same time.

Recreation Facilities

Relocation and demolition of various recreation facilities would produce criteria pollutant emissions from vehicle exhaust and fugitive dust. The demolition of the Lower Klamath Project recreation facilities would change recreation opportunities from lake-based recreation to river-based recreation. This change would require several recreation facilities to be reconstructed or demolished. On- and off-road construction equipment would be used to complete these activities, which would occur after the dam demolition actions.

Emissions from relocation and demolition of the various recreation facilities were estimated using the CalEEMod emissions model. As the relocation and demolition of recreational facilities could occur during dam demolition, it is assumed there would be an overlap with the peak construction activities related to dam removal (Table 3.9-4). Table 3.9-7 summarizes emissions from the relocation and demolition of recreation facilities.

Table 3.9-7. Uncontrolled Emissions from Relocation and Demolition of Recreation Facilities.

Location	Peak Daily Emissions (pounds per day)					
	VOC	CO	NO_x	SO_2	PM_{10}	$PM_{2.5}$[2]
J.C. Boyle	4	32	31	0	4	1
Copco No. 1 Reservoir	2	13	16	0	4	2
Iron Gate Reservoir	6	32	38	0	9	4
Total Emissions	12	77	85	0	17	7

Source: Appendix N

City of Yreka Water Supply Pipeline Relocation

Construction of a new water supply pipeline for Yreka would produce criteria pollutant emissions from vehicle exhaust and fugitive dust. On- and off-road construction equipment would be used to complete the relocation and construction of the Yreka water supply pipeline. Construction of the pipeline would occur prior to initiating drawdown of the Iron Gate Reservoir. It is estimated the replacement of the water supply pipeline would last approximately one month. As such, emissions from this project activity would not overlap with peak daily emissions due to dam removal construction activities (Table 2.7-1) (Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*). The Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model (2009) was used to estimate emissions associated with grubbing/land clearing, grading/excavation, and other phases. Table 3.9-8 summarizes emissions from replacement of the Yreka water supply pipeline.

Table 3.9-8. Uncontrolled Emissions from Construction of the Yreka Water Supply Pipeline.

Phase	Peak Daily Emissions (pounds per day)					
	VOC	CO	NO_x	SO_2	PM_{10}	$PM_{2.5}$
Grubbing/Land Clearing	2.3	9.3	16.4	--	10.1	2.6
Grading/Excavation	2.8	16.5	18.4	--	10.3	2.7
Drainage/Utilities/Sub-Grade	2.2	11.3	14.4	--	10.2	2.6
Maximum	2.8	16.5	18.4	--	10.3	2.7
Significance Criterion	250	2,500	250	250	250	250

Source: Appendix N

As shown in Table 3.9-8, emissions from replacement of the Yreka water supply pipeline would not exceed the SCAPCD's significance thresholds. Therefore, emissions from construction of the Yreka water supply pipeline would be less than significant.

Other Project Components

Construction activities associated with implementation of the Other Project Components identified in Section 7 of the Definite Plan, would produce additional emissions from vehicle exhaust and fugitive dust. These activities include, but are not limited to, improvements to roads, bridges and culverts that would be affected by the Proposed Project, relocation or elevation of structures that would be subject to flood risk after removal of the dams, and the modification of downstream water intakes to protect them from passing sediment after removal of the dams. On- and off-road construction equipment would be used to complete the necessary construction.

Due to the limited nature of these additional project components, they are anticipated to produce minor emissions compared to the dam and powerhouse demolition activities. The emissions estimates for the relocation of the Yreka water supply pipeline are considered to be representative of the emissions that would be generated by these project components.

Most of these project components are planned to take place before or after primary construction and deconstruction associated with the Proposed Project. As such, they would not overlap with the peak construction activity related to the dam and powerhouse deconstruction, restoration activities, and the relocation and demolition of recreation facilities. However, there is the potential that some of these project components may overlap with the peak construction activity. To the extent that this occurs, the additional emissions produced by these project components would contribute to the significant and unavoidable significance determination related to emissions of NOx, PM_{10}, and $PM_{2.5}$ generated during peak construction activity.

Therefore, air quality impacts from the implementation of the other project components would be significant and unavoidable.

Significance
Significant and unavoidable impact

Potential Impact 3.9-3 Short-term cumulative increase in criteria pollutants for which the Siskiyou County Air Pollution Control District is non-attainment.
Direct air quality impacts from construction activities occurring during the Proposed Project would be limited to Siskiyou County, California, which is designated as attainment or unclassified for all federal and state ambient air quality standards (Table 3.9-2). As such, the Proposed Project would not result in a cumulatively considerable net increase of any criteria air pollutant for which Siskiyou County is non-attainment (including releasing emissions which exceed quantitative thresholds for ozone precursors).

Significance
No significant impact

Potential Impact 3.9-4 Short-term exposure of sensitive receptors to substantial toxic air contaminant concentrations.
The area surrounding Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam is sparsely populated with few sensitive land uses. The nearest sensitive land uses are recreational facilities located at Copco No. 1 and Iron Gate reservoirs, along with hiking trails around the Fall Creek development (Section 3.20 *Recreation*). The next closest sensitive land uses include scattered residences that are located along the Klamath River. The closest homes to construction sites are located over 2,000 feet from Copco No. 1 Dam, over 3,500 feet from Copco No. 2 Dam, and over 4,000 feet from Iron Gate Dam. As noted above, there are also several modular homes located at Copco Village that are currently occupied by PacifiCorp staff. These homes are located within the Limits of Work and range from 850 feet to 2,200 feet west of the Copco No. 2 Powerhouse (Figure 2.7-2). Prior to the beginning of dam deconstruction activities, these homes would be vacated.

The Proposed Project has the potential to create a significant hazard to sensitive receptors (e.g., residents and recreationists) near the construction sites through exposure to substantial pollutant concentrations such as ROG, NO_X and particulate matter and/or other toxic air contaminants during construction activities. Construction activities would involve the use of a variety of gasoline or diesel-powered equipment that emits exhaust fumes. Sensitive receptors in the vicinity of the construction sites would potentially be exposed to nuisance dust and heavy equipment emission diesel exhaust during construction. The duration of exposure would be short and exhaust from construction equipment dissipates rapidly. Sensitive receptors within a quarter-mile (1,320 feet) of construction activities would be at the greatest risk for exposure to fugitive dust and diesel exhaust during construction.

Since the recreation facilities near the construction sites would be closed during dam removal activities, it is not anticipated that recreationists would be exposed to substantial pollutant concentrations during construction activity. As noted above, the closest residences are located over 2,000 feet away from the construction sites. According to the USEPA, the majority of fugitive dust generally settles out of the atmosphere within

300 feet of the source, with larger particles traveling less distance and smaller particles traveling a longer distance (USEPA 1995). According to the CARB, concentrations of mobile-source diesel particulate matter emissions are typically reduced by 70 percent at a distance of approximately 500 feet (CARB 2005). Due to the low density of residential uses in the project area, and the fact that the nearest residences are well over a quarter mile (1,320 feet) from the construction sites, it is not anticipated that sensitive receptors residing at the closest residences would be exposed to substantial toxic air contaminant concentrations during construction activities. Therefore, the exposure of sensitive receptors to pollutant concentrations during construction activity is less than significant.

Significance

No significant impact

Potential Impact 3.9-5 Short-term exposure to objectionable odors near construction sites.

The Siskiyou County Air Pollution Control District addresses odor impacts through Rule 4.2 (Nuisance Section 24243), which states "No person shall discharge from any source whatsoever, such quantities of air contaminants or other material which cause injury, detriment, nuisance or annoyance to any considerable number of persons or to the public or which endanger the comfort, repose, health or safety of any such persons or the public or which cause or have a natural tendency to cause injury or damage to business or property." Rule 4.2 does not apply to odors emanating from agricultural operations in the growing of crops or raising of fowl or animals (CARB 2016a).

The following odors could result from the Proposed Project:

- Odors from exposed sediments (including algae) in the reservoir footprints; and
- Odors from construction equipment/vehicle exhaust.

Both of these odor sources would be likely to generate minor odor impacts relative to land use types capable of generating significant odor impacts (e.g., wastewater treatment plant, sanitary landfill, petroleum refinery, rendering plant, food packaging plant) (SMAQMD 2016).

The Proposed Project would ultimately drain Iron Gate, Copco No. 1, and Copco No. 2 reservoirs and expose the underlying sediments. Because the reservoir sediment deposits contain unoxidized organic matter from algal detritus (organic content of the sediments is on average 2.7 to 5.1 percent by mass [GEC 2006]), earthy or sulfide odors (e.g., tidal marsh sediment odors at low tide), may be evident during or immediately following reservoir drawdown while the exposed sediments dry out and new vegetation is established. There is the potential that these odors could temporarily impact nearby land uses such as the closest recreational facilities and residential uses. These odor impacts have the potential to cause nearby recreationists and residents to reduce outdoor activity or take other actions to avoid detection of the odors (e.g., keep windows closed). The level of impact would be dependent on proximity to the reservoirs and wind patterns during and immediately following reservoir drawdown (i.e., winter and spring months). Within a relatively short amount of time (i.e., days to a few weeks), the sediment surfaces would oxidize as they are exposed to air and the organic compounds causing the odors would be broken down. Due to the low density of development in the vicinity of the reservoirs, the relatively low number of recreationists in the vicinity of the Lower Klamath Project reservoirs during winter and spring months) the short-term nature of the anticipated odor impacts (days to a few weeks during dam removal year 2), it is not anticipated that the Proposed Project would create objectionable odors affecting a substantial number of people and thus would not result in a significant impact.

As discussed in Section 3.20 *Recreation*, two-thirds of recreational users of the Klamath River reservoirs that were surveyed responded that the algae blooms in the reservoirs produced bad odors. Reservoir drawdown under the Proposed Project would occur during winter months (January–March) (Table 2.7-1) when intense algae blooms do not typically occur in lakes and reservoirs in general, or in the Lower Klamath Project reservoirs in particular (Section 3.2 *Water Quality* and Section 3.4 *Phytoplankton and Periphyton*). Despite a very low likelihood of occurrence, algae blooms could be present as reservoir drawdown occurs and as the water level lowers in the reservoirs, algae would settle on the exposed sediments. If this does occur, it is anticipated that the algae and underlying sediments would dry out quickly (i.e., within days to weeks), which would substantially reduce any odors generated by decaying algae. Similar to odors from the reservoir sediments, it is not anticipated that a substantial number of people would be impacted due to the low density of development in the area and the short-term nature of the odor impacts. Ultimately, the Proposed Project is anticipated to substantially reduce the annual occurrence of odors from algae blooms since this section of the Klamath River would be restored to a free-flowing condition.

During construction, there is the potential for the generation of objectionable odors in the form of construction equipment/vehicle exhaust in the immediate vicinity of the construction sites at the three dams (Copco No. 1, Copco No. 2, and Iron Gate). However, these emissions would rapidly dissipate and be diluted by the atmosphere downwind of the site. As noted above, CARB estimates that concentrations of mobile-source diesel particulate matter emissions are typically reduced by 70 percent at a distance of approximately 500 feet (CARB 2005). At this distance from the construction sites, there would also be a substantial reduction in odors generated by exhaust emissions. The nearest residences to the dam construction sites are over 2,000 feet away, which would provide adequate distance for the dissipation of odors from construction activity. Due to the low density of development in the areas within and adjacent to the Limits of Work, intervening topography and vegetation, and the rapid dissipation of odors from construction activity, it is not anticipated that these odors would impact a substantial number of people.

Significance
No significant impact

3.10 Greenhouse Gas Emissions

This section focuses on potential greenhouse gas (GHG) and energy effects due to implementation of the Proposed Project. Section 3.9 *Air Quality* of the Lower Klamath Project EIR discusses air quality.

3.10.1 Area of Analysis

Global climate change is not confined to a particular project area and is generally accepted as the consequence of global industrialization over the last 200 years. A typical project, even a very large one, does not generate enough greenhouse gas emissions on its own to influence global climate change significantly; hence, the issue of global climate change is, by definition, a cumulative environmental impact. For this reason, the Area of Analysis for GHG emissions and energy effects includes areas within California and Oregon where construction activities related to removal of the Lower Klamath Project dam complexes would occur (Figure 3.10-1). In addition, these areas may experience impacts from GHG emissions as a result of replacing hydroelectric power produced at the Lower Klamath Project dams on an interim basis with power that may be produced from fossil fuels through other regional sources.

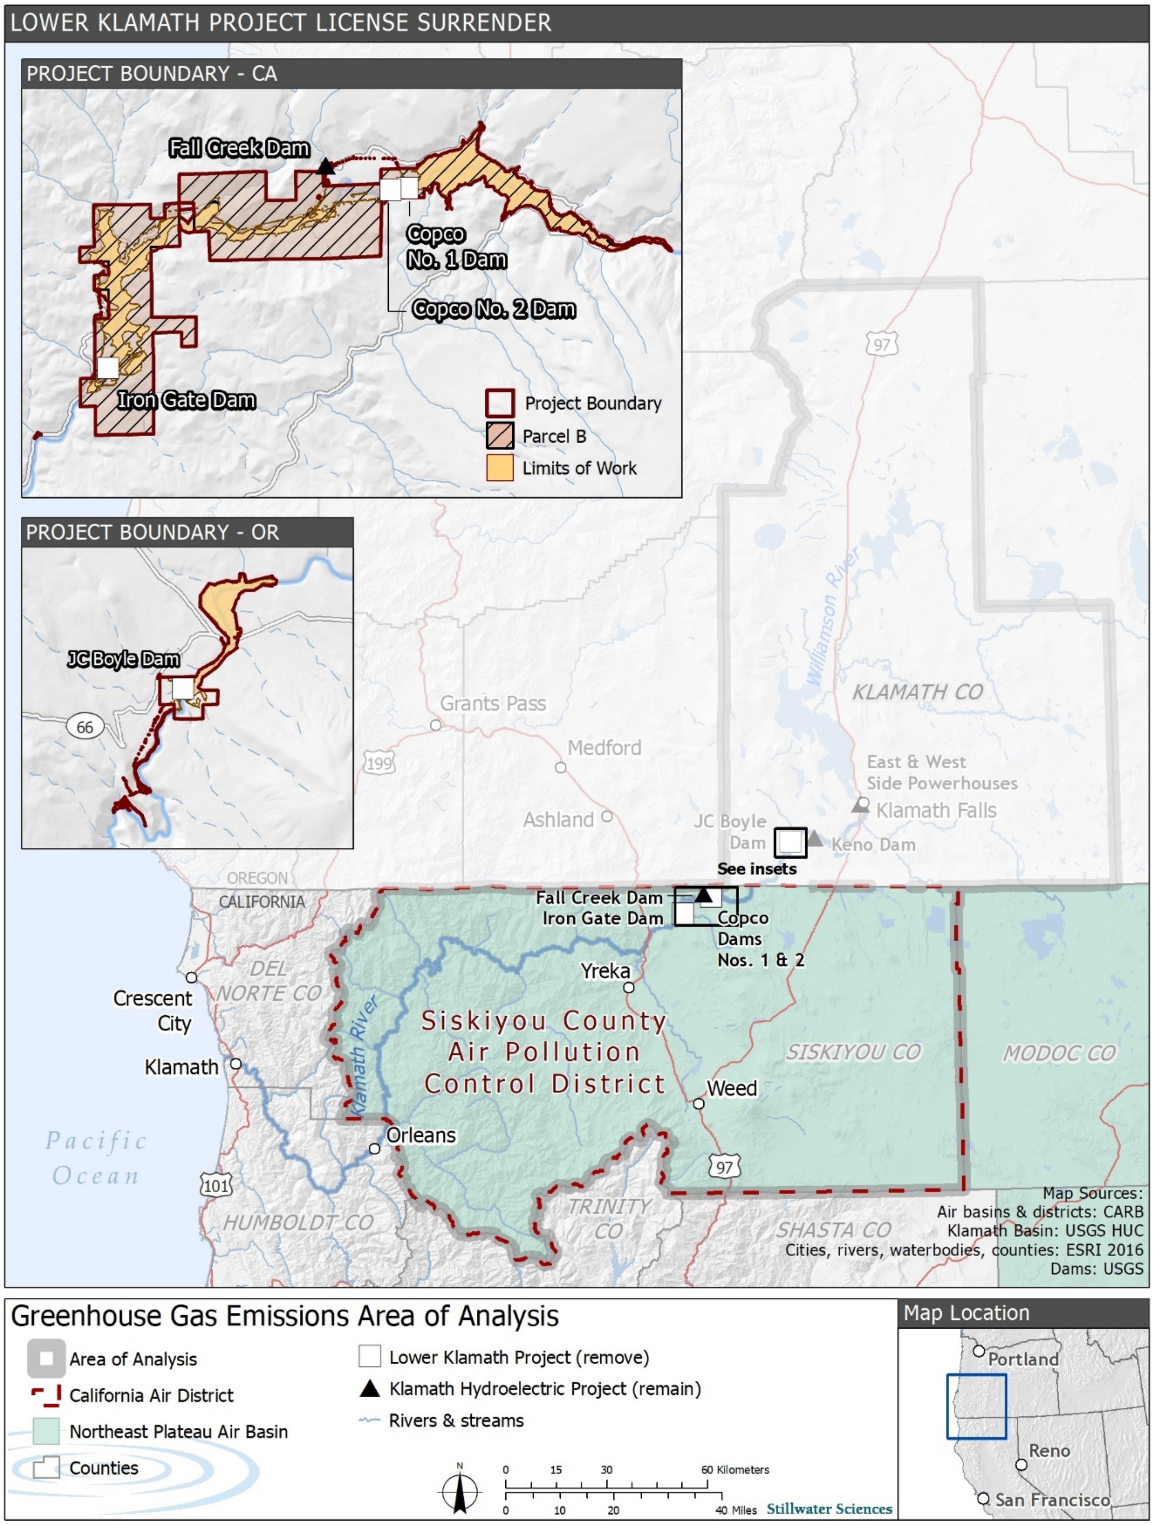

Figure 3.10-1. Area of Analysis for Greenhouse Gas Emissions.

3.10.2 Environmental Setting

3.10.2.1 Greenhouse Gas Emissions

Summary information regarding anticipated global, state, and regional effects of climate change are provided below, as well as a discussion of GHG emissions generated in California and the potential influence of the Lower Klamath Project dam complexes on GHG emissions.

Although Proposed Project-related emissions would be restricted to the Area of Analysis described above, data characterizing existing GHG emissions are only available at the state-level for California (California Air Resources Board [CARB] 2017a). As a result, the GHG environmental setting uses a larger region than that of the Area of Analysis for GHG emissions to establish existing conditions.

Global Climate Change

Radiation from the sun is the Earth's primary source of energy. As solar radiation enters the Earth's atmosphere, a portion is reflected back towards space; a portion is absorbed by the upper atmosphere; and a portion is absorbed by the Earth's surface. The radiation absorbed by the Earth heats the surface, which is then emitted as infrared radiation. As Earth has a much lower temperature than the sun, the Earth emits longer-wavelength radiation[140]. Certain gases in the Earth's atmosphere, classified as GHGs, play a critical role in determining the Earth's surface temperature. GHGs have strong absorption properties at wavelengths that are emitted by the Earth. As a result, radiation that otherwise would have escaped back into space is instead trapped, resulting in a warming of the atmosphere. This phenomenon, known as "the greenhouse effect", is responsible for maintaining a habitable climate on Earth.

Anthropogenic emissions of GHGs, leading to atmospheric levels in excess of natural ambient concentrations, are responsible for intensifying the greenhouse effect, and have led to a trend of unnatural warming of the Earth's atmosphere and oceans, with corresponding effects on global circulation patterns and climate (Stocker 2014). Prominent GHGs contributing to the greenhouse effect are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6).

HFCs, PFCs, and SF_6 are considered high global warming-potential (GWP) GHGs. GWP is a concept developed to compare the ability of each GHG to trap heat in the atmosphere relative to another gas. GWP is based on several factors, including the relative effectiveness of a gas absorbing infrared radiation, and length of time that the gas remains in the atmosphere ("atmospheric lifetime"). The GWP of each gas is measured relative to CO_2, the most abundant GHG. The concept of CO_2-equivalency (CO_2e) is used to account for the different GWP potentials of GHGs to absorb infrared radiation.

Climate change is a global problem because GHGs are global pollutants, unlike criteria air pollutants and toxic air contaminants (TACs), which are pollutants of regional and local concern (see Section 3.9 *Air Quality* for more information on criteria air pollutants and TACs). Whereas pollutants with localized air quality effects have relatively short atmospheric lifetimes (approximately one day), GHGs have long atmospheric lifetimes

[140] The wavelength at which a body emits radiation is proportional to the temperature of the body.

(one year to several thousand years). GHGs persist in the atmosphere for enough time to be dispersed around the globe. The quantity of CO_2e that will ultimately result in measurable climate change is enormous; no single project could measurably contribute to a noticeable incremental change in the global average temperature, or to global, local, or micro-climate change.

Greenhouse Gas Emission and Inventory

As the second largest emitter of GHGs in the United States, and 20th largest in the world, California contributes a significant quantity of GHGs to the atmosphere (CARB 2017a). Emissions of CO_2, CH_4, and N_2O are byproducts of fossil-fuel combustion, and are attributed in large part to human activities associated with transportation, industry/manufacturing, electricity generation and natural gas consumption, and agriculture (CARB 2017a). In California, the transportation sector is the largest emitter of GHGs, followed by industrial activities (CARB 2015) (see Figure 3.10-2).

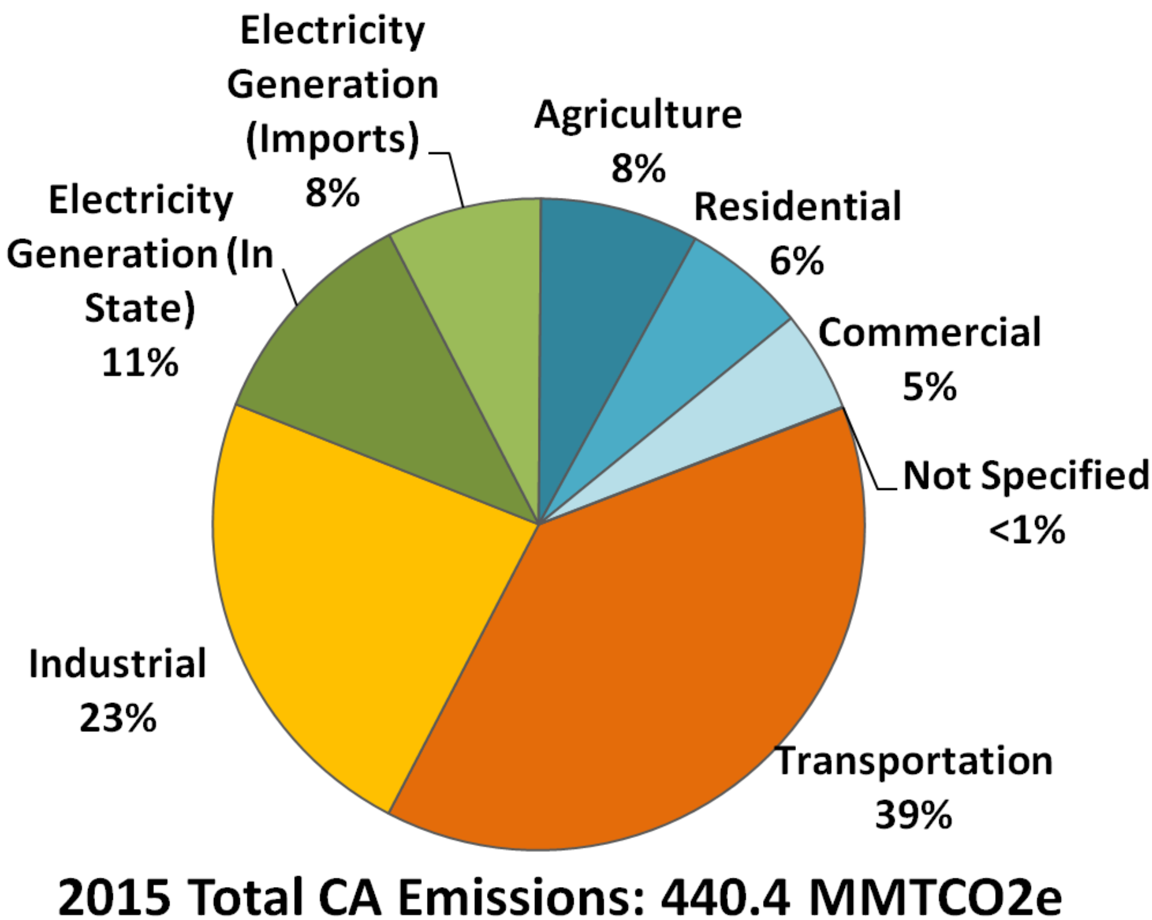

Figure 3.10-2. California GHC Emission Sources, in Million Metric Tons of CO_2e (as of 2015). Source: CARB 2015.

Statewide Effects of Climate Change

Climate change is anticipated to affect environmental conditions in California through a variety of mechanisms. One effect of climate change is sea-level rise. Sea levels along the California coast rose approximately 7 inches during the last century (CEC 2006a), and are predicted to rise an additional 7 to 22 inches by year 2100, depending on the future levels of GHG emissions (Stocker 2014). However, the Governor-appointed Delta Vision Blue Ribbon Task Force has recommended that California plan for a scenario of 16 inches of sea-level rise by year 2050, and 55 inches by year 2100 (CNRA 2008). Effects of sea-level rise could include increased coastal flooding, saltwater intrusion in the low-lying areas, and disruption of wetlands (CEC 2006a).

As the California climate changes over time, the range of various plant and wildlife species could shift or be reduced, depending on the favored temperature and moisture regimes of each species. In the worst cases, some species would become extinct if suitable conditions are no longer available. Additional concerns associated with climate change are a reduction in the snowpack, leading to less overall water storage in the mountains (the largest "reservoir" in the State), and increased risk of wildfire caused by changes in rainfall patterns and plant communities (CEC 2006a).

Regional Effects of Climate Change

Projected changes in climate conditions are expected to result in a wide variety of effects in the Pacific Northwest[141] and the Klamath Basin. The most relevant consequences related to the Area of Analysis for GHGs include changes to stream flow, temperature, precipitation, groundwater, and vegetation changes. In general, climate model projections include:

- Increased average ambient air and water temperature
- Increased number of extreme heat days
- Changes to annual and seasonal precipitation, including increased frequency and length of drought, less winter snow and more winter rain, and changes in water quality
- Increased heavy precipitation
- Reduced snow pack and snow melt, resulting in less runoff during the late spring through early autumn
- Vegetation changes
- Groundwater hydrology changes
- Changes to annual stream flow

Lower Klamath Project Facility Influence on GHG Emissions

The hydroelectric power that is generated by the Lower Klamath Project dam complexes is considered a renewable source of energy that produces significantly reduced GHG emissions relative to other non-renewable energy sources in the region that burn fossil fuels. GHG emissions generated by hydroelectric facilities are primarily from power plant operations and maintenance. In addition, there is also the potential for plant matter to decay in the reservoirs which can cause the buildup and release of methane. As discussed in Appendix N, the Karuk Tribe (2006) estimated the total amount of methane released from Keno, J.C. Boyle, Copco, and Iron Gate reservoirs in its comments on the

[141] The Pacific Northwest is defined by the U.S. Global Change Research Program (USGCRP) as Washington, Oregon, Idaho, and western Montana. Although the USGCRP "Pacific Northwest" region does not include California, it has the climate most representative of the Klamath Basin. The USGCRP region that contains California is the "Southwest" climate region, which includes California, Nevada, Arizona, Utah, and parts of New Mexico, Colorado, and Texas. The Southwest data represent primarily desert climates, which are less similar to the Klamath Basin.

Draft Environmental Impact Statement for relicensing and/or decommissioning of the Klamath Hydroelectric Project. The emissions estimation method presented by the Karuk Tribe was adapted for the analysis in Appendix N to estimate emissions from the water impounded in the reservoirs associated with the Lower Klamath Project dam complexes. According to Table O-2 in Appendix N, it is estimated that the methane produced by the Lower Klamath Project dam complexes ranges from 4,000 to 14,000 metric tons of CO2e annually.

As Section 3.2 *Water Quality* and Section 3.4 *Phytoplankton and Periphyton* describe in detail, the Klamath River produces significant concentrations of algae, particularly in the Copco No. 1 and Iron Gate reservoirs. The primary types of algae found in these reservoirs have been diatoms (prevalent throughout the Klamath River system) and two types of cyanobacteria: *Aphanizomenon flos-aquae* and *Microcystis aeruginosa*. As with other forms of biomass, algae sequester GHGs during photosynthesis that would otherwise be in the atmosphere.

Algal production in the Lower Klamath Project reservoirs can result in temporary sequestration of CO_2 as carbon present in algal cells. When algae die at the end of their life and sink to the bottom of the Lower Klamath Project reservoirs, the temporarily sequestered carbon can be released back to the atmosphere during microbial decomposition. However, in the anoxic (lacking oxygen) environment of the Lower Klamath Project reservoir sediments, algal biomass can resist decomposition and continue to sequester carbon until disturbed and exposed to an oxygenated environment. For example, when sediments comprised of dead algae are released to downstream reaches of the Klamath River, they are subjected to oxygenated conditions and aerobic bacterial decomposition of the sediments would release sequestered carbon.

3.10.2.2 Energy

The Lower Klamath Project includes four hydroelectric developments along the mainstem of the Klamath River between river mile (RM) 193.1 and 229.8. As shown in Table 3.10-1, the installed generating capacity of the existing Lower Klamath Project is approximately 163 megawatts (MW) and, on average, the Lower Klamath Project generates 686,000 megawatt-hours (MWh) of electricity annually (PacifiCorp 2016).

Table 3.10-1. Lower Klamath Project Dam Complexes.

Dam Complex Name	Generating Facility	Total Authorized Generating Capacity (MW)	Average Annual Generation (MWh)	Location	River Mile
Copco No. 1 Dam and Reservoir	Copco No. 1 Powerhouse	20.0	106,000	California	201.8 to 208.3
Copco No. 2 Dam and Reservoir	Copco No. 2 Powerhouse	27.0	135,000	California	201.5 (Dam) and 200 (Powerhouse)
Iron Gate Dam and Reservoir	Iron Gate Powerhouse	18.0	116,000	California	193.1 to 200.0
J.C. Boyle Dam and Reservoir	J.C. Boyle Powerhouse	97.98	329,000	Oregon	229.8 (Dam) and 225.2 (Powerhouse)
Total	**--**	**162.98**	**686,000**	**--**	**--**

Source: FERC 2007, river miles updated based on Appendix B: *Definite Plan*.

The Lower Klamath Project in California includes Copco No. 1, Copco No. 2, and Iron Gate facilities. As shown in Table 3.10-1, these developments have a generation capacity of approximately 65 MW of electricity and produce an average of 357,000 MWh of electricity annually. This accounts for approximately 52 percent of the Lower Klamath Project total generation.

Although the J.C. Boyle dam complex is located in Oregon, it is being considered in this section since removal of this dam is related to the Proposed Project and the emissions of greenhouse gases are inherently a cumulative impact.

3.10.3 Significance Criteria

Criteria for determining significant impacts of GHGs and energy are based upon Appendices F and G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and best professional judgment. Effects of GHGs and changes in energy production are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

1. Generation of GHG emissions, either directly or indirectly, that would exceed 10,000 MT CO_2e.
2. Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing the emissions of greenhouse gases.

Significance Thresholds

The nature of the GHG emissions from the Proposed Project differs from most projects considered highest priority for curbing emissions either on a statewide or regional basis. Typical emission sources considered for quantitative thresholds of significance involve construction and ongoing operational emissions from stationary industrial projects with high rates of combustion emissions (e.g., refineries, power plants, other processing that uses industrial boilers) or the construction and increased power and transportation needs from newly constructed residential or commercial projects.

The Siskiyou County Air Pollution Control District (SCAPCD) has not adopted quantitative thresholds for determining the significance of greenhouse gas emissions. In the absence of quantitative significance thresholds for GHG emissions in the SCAPCD, the calculated GHG emissions from the Proposed Project are compared to quantitative thresholds of significance adopted by other air districts in California. The South Coast Air Quality Management District (SCAQMD) and the Bay Area Air Quality Management District have adopted numerical CEQA thresholds of significance for GHG emissions from the operation of industrial projects. Both districts use a threshold of 10,000 metric tons (MT) CO_2e per year for industrial projects that would capture 90 percent of all operational GHG emissions from stationary sources in each air basin (BAAQMD 2017, SCAQMD 2008).

Since the project proposes construction activity related to the decommissioning of the Lower Klamath Project dam complexes that would be completed at the end of 2021, it does not include long-term operational emissions. Unlike operational emissions, construction emissions do not occur continuously over the lifetime of a project. Rather, construction emissions are temporary emissions that are spread out over the construction period. Therefore, the application of the 10,000 $MTCO_2$e operational GHG emissions significance threshold for construction emissions from the Proposed Project is conservative because these emissions are limited in duration. As such, a GHG impact would be significant if the construction emissions from the Proposed Project exceed the 10,000 $MTCO_2$e threshold.

A GHG impact would be significant if GHG emissions from the Proposed Project would substantially obstruct compliance with the GHG emission reduction goals in Assembly Bill (AB 32), Senate Bill 32 (SB 32), and Executive Order S-3-05 (EO S-3-05). In addition, an impact would be significant if the removal of the Lower Klamath Project hydroelectric facilities would conflict with the California Renewable Portfolio Standard (RPS) (S-14-08, SB X1-2, and SB 350). AB 32 established the goal for the reduction of California's GHG emissions to 1990 levels by 2020. SB 32 established the goal of reducing emissions 40 percent under 1990 levels by 2030. Executive Order S-3-05 established the goal of reducing emissions 80 percent under 1990 levels by 2050. The California RPS established the goals of requiring retail sellers of electricity to provide a power mix that includes 33 percent renewable sources by 2020 and 50 percent renewable sources by 2030.

Following the passage of AB 32, some of the regional air districts in the state, such as the SCAQMD and BAAQMD, based their planning and regulations on the requirements of AB 32. These air districts set forth GHG significance thresholds specifically to meet AB 32 requirements, and so plans and projects that meet those thresholds can be assumed to meet the requirements of AB 32 (BAAQMD 2017). This includes the 10,000 $MTCO_2$e threshold for industrial projects that is compared to the construction emissions from the Proposed Project. If the Proposed Project will generate construction emissions that are less than this threshold, then it would not conflict with the AB 32 goal of reducing GHG emissions to 1990 levels by 2020.

Prior to the adoption of AB 32, EO S-3-05 established the goal of reducing California's emissions 80 percent under 1990 levels by 2050. In 2016, SB 32 was signed into law, establishing the state's mid-term target for 2030 emissions to be 40 percent below the 1990 emissions. The plan outlined in Senate Bill 32, involves increasing renewable energy use, putting more electric cars on the road, improving energy efficiency, and curbing emissions from key industries. Adopted regulations that correspond to elements of the Scoping Plan include the Renewable Portfolio Standard, the Cap-and-Trade Program, and the Low Carbon Fuel Standard (CARB 2017b). Since the Proposed Project involves construction activity related to the decommissioning of the Lower Klamath Project dam complexes that will be completed at the end of 2021, and the Proposed Project will not have long-term operational emissions, the potential for the project to conflict with the goals in EO S-3-05 and SB 32 is limited. Despite this, a discussion of the Proposed Project's compliance with existing regulatory requirements (e.g., low carbon fuel standards) and the California RPS is included under Potential Impact 3.10-2 to assess whether the Proposed Project will conflict with the GHG reduction goals in EO S-3-05 and SB 32.

In 2002, California established an RPS that requires a retail seller of electricity to include in its resource portfolio a certain amount of electricity from renewable energy sources, such as wind, geothermal, and solar energy. The retailer can satisfy this obligation by using renewable energy from its own facilities, purchasing renewable energy from another supplier's facilities, using Renewable Energy Credits (RECs) that certify renewable energy has been created, or a combination of all of these. California's RPS requirements have been accelerated and expanded a number of times since its inception. Most recently, Governor Jerry Brown signed into law Senate Bill (SB) 350 in October 2015, which requires utilities to procure 50 percent of their electricity from renewables by 2030. SB 350 also requires California utilities to develop integrated resource plans that incorporate a greenhouse gas emission reduction planning component. Compliance with the California RPS requires PacifiCorp to develop and implement an integrated resource plan that demonstrates they are on schedule to comply with the goals of providing 33 percent renewable sources by 2020 and 50 percent renewable sources by 2050.

3.10.4 Impact Analysis Approach

The quantification of direct GHG emissions was performed similarly to that of the Lower Klamath Project air quality analysis (Section 3.9 *Air Quality*) with a few exceptions (see discussion below). Project-related construction emissions were compared to applicable thresholds of significance to evaluate environmental impacts from GHGs. Direct short-term GHG emissions include those associated with on- and off-site construction equipment, construction worker commuting, and haul truck emissions. For this analysis, direct GHG emissions associated with the reduced operation of Iron Gate Fish Hatchery combined with the re-instated operation of Fall Creek Hatchery were set at the same as existing operation conditions at Iron Gate Hatchery for eight years following dam removal. This is due to the fact that the existing functions at the Iron Gate Hatchery that will be eliminated as part of dam removal activities, will be replaced by the reopening and operation of the Fall Creek Hatchery and by making improvements to the Iron Gate Hatchery (Section 2.7.6 *Hatchery Operations*).

Indirect GHG emissions were qualitatively analyzed, which includes potential GHG emissions associated with non-renewable power sources that could potentially be used to replace the hydropower associated with the Lower Klamath Project dam complexes on an interim basis.

The construction GHG emissions estimates used for this Lower Klamath Project EIR (Appendices N and O) were developed in 2011 as part of 2012 EIS/EIR analysis.

Although there have since been modifications to the Proposed Project schedule (Table 2.7-1), the 2011 GHG emissions modeling is still relevant as the construction-related activities and their associated emissions for the Proposed Project are materially similar to those modeled in 2011. Minor changes in proposed construction activities between the 2012 EIS/EIR analysis and the Proposed Project are primarily due to the timing associated with removing Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam. The Proposed Project and the data modeled as part of the 2012 EIS/EIR are compared to the thresholds noted in Section 3.10.3 *Significance Criteria* and analyzed in Section 3.10.5 *[Greenhouse Gas Emissions] Potential Impacts and Mitigation*.

Greenhouse Gas Emissions Quantification

The Lower Klamath Project GHG analysis evaluated the following three pollutants: carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). Emissions of CO_2, CH_4, and N_2O were estimated for on- and off-site combustion sources, including mobile and stationary sources. The other two pollutants commonly evaluated in various mandatory and voluntary reporting protocols, hydrofluorocarbons and perfluorocarbons, are not expected to be emitted in large quantities and are not discussed further in this section. It is likely that sulfur hexafluoride (SF_6) would be released during deconstruction because the circuit breakers from the power facilities would be emptied. Although SF_6 has a relatively high GWP, sufficient data was not available at the time of this writing to quantify emissions.

Each GHG contributes to climate change differently, as expressed by its GWP. GHG emissions are discussed in terms of carbon dioxide equivalent (CO_2e) emissions, which express, for a given mixture of GHG, the amount of CO_2 that would have the same GWP over a specific timescale. CO_2e is determined by multiplying the mass of each GHG by its GWP[142]. This analysis uses the GWP from the Intergovernmental Panel on Climate Change's (IPCC) Second Assessment Report (IPCC 1996) for a 100-year period to estimate CO_2e. Although subsequent assessment reports have been published by the IPCC, the international standard, as reflected in various federal, state, and voluntary reporting programs, is to use GWPs from the Second Assessment Report.

Direct GHG emissions were calculated for construction activities related to dam demolition including heavy equipment use, hauling of demolition debris to landfills, and worker transportation. Detailed calculations for the Proposed Project are provided in Appendices N (Air Quality Supplemental Methodology Information and Detailed Impact Analyses) and O (Greenhouse Gas Emissions Impacts).

If a United States Environmental Protection Agency (USEPA)-approved emissions factor model (e.g., EMFAC2007, MOBILE6.2, OFFROAD, or NONROAD) does not estimate emissions of a particular pollutant, then emission factors were obtained, if possible, from the Federal Mandatory Reporting of Greenhouse Gases Rule (40 CFR Part 98).

A combination of techniques was used to estimate emissions from reservoir restoration activities. Emissions from landing and takeoff operations associated with aerial seed application were estimated using the Federal Aviation Administration's Emissions and

[142] As an example, CH_4 has a GWP of 21, as specified in the Intergovernmental Panel on Climate Change's (IPCC) Second Assessment Report (1996). One metric ton of CH_4 is equal to 21 metric tons of CO_2e (1 metric ton x 21).

Dispersion Modeling System. Emissions from hydroseeding barges were estimated using the following sources listed below.

- Analysis of Commercial Marine Vessels Emissions and Fuel Consumption Data (USEPA 2000)
- AP-42, Chapter 3.3: Gasoline and Diesel Industrial Emissions (USEPA 1995)
- Title 17 California Code of Regulations, Section 93115.7: Air Toxic Control Measure for Stationary Compression Ignition Engines – Stationary Prime Diesel-Fueled Compression Ignition Engine (>50 bhp) Emission Standards
- Title 13 California Code of Regulations, Section 2423: Exhaust Emission Standards and Test Procedures—Off-Road Compression-Ignition Engine

Emissions from ground support equipment were estimated using the emission factors for off-road engines identified above and EMFAC for on-road motor vehicle emissions.

The California Emissions Estimator Model, Version 2011.1.1, was used to estimate exhaust emissions that would occur from grading activities associated with restoring parking lots associated with recreational facilities proposed for removal and restoration. The California Emissions Estimator Model makes general assumptions about the quantity and types of construction equipment needed to grade a site based on its size (acreage).

The Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model, Version 6.3.2 (2009), was used to estimate exhaust emission factors associated with relocation of the Yreka water supply pipeline. The Siskiyou County Air Pollution Control District does not have a comparable model to estimate emissions from linear projects like the proposed pipeline relocation action.

Energy Conservation

Appendix F of the *State CEQA Guidelines* requires that an EIR shall include a "discussion of the potential energy impacts of proposed projects, with particular emphasis on avoiding or reducing inefficient, wasteful, and unnecessary consumption of energy."

There are no unusual project characteristics that would necessitate the use of construction equipment or practices that would be less energy efficient than at comparable construction sites in the region or State. Therefore, it is expected that construction energy consumption associated with the Proposed Project would not be any more inefficient, wasteful, or unnecessary than other similar construction projects of this nature. Therefore, this issue is not further addressed in this section.

This project proposes the removal of the Lower Klamath Project dam complexes and would not result in long-term energy use. For this analysis, energy use associated with the reduced operation of Iron Gate Fish Hatchery combined with the re-instated operation of Fall Creek Hatchery was set to be the same as existing conditions operations at Iron Gate Hatchery for the eight years following dam removal. This is due to the fact that the existing functions at the Iron Gate Hatchery that will be eliminated as part of dam removal activities, will be replaced by the reopening and operation of the Fall Creek Hatchery and by making improvements to the Iron Gate Hatchery (Section 2.7.6 *Hatchery Operations*). As such, the issue of energy conservation during long-term operation is not further addressed in this section.

CEQA Guidelines Appendix F indicates that "increasing reliance on renewable energy sources" is one of the means of achieving the goal of energy conservation (see Appendix F [I][3] and [II][D][4]). The Proposed Project will result in the decommissioning of the Lower Klamath Project hydroelectric facilities in California, which have a generation capacity of approximately 65 MW of electricity and produce an average of 357,000 MWh of electricity annually. As described in the PacifiCorp Integrated Resource Plan (IRP), PacifiCorp plans to transition to additional renewable energy sources, or purchase RECs, to provide a power mix that complies with the California Renewable Portfolio Standard (RPS). Although, the Proposed Project would result in the loss of a renewable energy source, overall PacifiCorp will be increasing the percentage of renewable energy sources in its power mix to comply with the California RPS.

3.10.5 Potential Impacts and Mitigation

Potential Impact 3.10-1 Generation of greenhouse gas emissions, either directly or indirectly, that would exceed 10,000 MT CO_2e.

The nature of the GHG emissions from the Proposed Project differs from most projects considered highest priority for curbing emissions either on a statewide or regional basis. Typical emission sources considered for quantitative thresholds of significance involve construction and ongoing operational emissions from stationary industrial projects with high rates of combustion emissions (e.g., refineries, power plants, other processing that uses industrial boilers) or the construction and increased power and transportation needs from newly constructed residential or commercial projects. In these cases ongoing emissions from combustion and transportation are likely to be cumulatively considerable.

For the Proposed Project, there are few direct operational GHG emissions. As noted above, direct GHG emissions associated with operation of the Iron Gate Hatchery and Fall Creek Hatchery are assumed to be the same as existing baseline GHG emissions associated with current hatchery operations. Appreciable direct GHG emissions would occur only for a limited time as a result of construction related to dam deconstruction, restoration, relocation and demolition of recreational facilities, and Yreka supply pipeline relocation.

However, the Proposed Project has the potential to indirectly produce GHG emissions through conversion from the hydroelectric energy produced by the Lower Klamath Project to regional power from a mixture of sources likely including GHG-emitting fossil fuels.

Summary

Table 3.10-2 summarizes the total uncontrolled emissions associated with the Proposed Project activities including dam and powerhouse deconstruction, restoration activities, relocation and demolition of recreational facilities, and the Yreka supply pipeline relocation. The GHG emissions estimates in Table 3.10-2 include construction activity related to the removal of J.C. Boyle Dam in Oregon. Due to the cumulative nature of GHG emissions, the emissions from construction activity in Oregon are conservatively added to the emissions from construction activity in California and compared to the SCAQMD's 10,000 $MTCO_2$e significance threshold.

Table 3.10-2. Uncontrolled Direct GHG Emissions Inventories for the Proposed Project.

Project Activity	Emissions ($MTCO_2e$)
Dam and Powerhouse Deconstruction	8,558
Restoration Activities	704
Recreation Facilities	160
Yreka Supply Pipeline Relocation	33
Total Emissions	**9,455**

Source: Appendix N

As shown in Table 3.10-2, total GHG emissions from the Proposed Project are estimated to be approximately 9,455 $MTCO_2e$, which is below the SCAQMD's 10,000 $MTCO_2e$ significance threshold. As such, the construction GHG emissions from the Proposed Project would be less than significant. The discussion below provides more detailed information about the emissions from the various project activities.

Dam and Powerhouse Deconstruction

Vehicle and equipment exhaust from dam removal activities would produce GHG emissions during the dam deconstruction period. The emission sources would include off-road construction equipment, on-road trucks, and construction worker commuting vehicles (Section 2.7.1 *Dam and Powerhouse Deconstruction*). Table 3.10-3 summarizes uncontrolled emissions associated with dam and powerhouse deconstruction.

Table 3.10-3. Uncontrolled Direct GHG Emissions Inventories for Dam and Powerhouse Deconstruction.

Location	Project Emissions ($MTCO_2E$)			
	CO_2	CH_4	N_2O	Total
Iron Gate	4,106	4	0	4,110
Copco No. 1	1,459	1	0	1,461
Copco No. 2	970	1	0	971
J.C. Boyle	2,016	<1	0	2,016
Total Emissions	**8,551**	**6**	**0**	**8,558**
California Total	6,535	6	0	6,542
Oregon Total	2,016	n/a	0	2,016

Source: Appendix N

As Table 3.10-3 shows, deconstruction of the dams would contribute approximately 8,558 $MTCO_2e$ of GHG emissions during the deconstruction period. As indicated in Table 3.10-2, deconstruction of the dams would produce the majority of construction emissions that would occur from the Proposed Project.

Cofferdams would be constructed at the Lower Klamath Project during deconstruction activities from concrete rubble, rock, and earthen materials that would come from the dam removal activities, as possible. Construction of the cofferdams from materials salvaged from the dam demolition activities would reduce the need for importing new construction materials. As the cofferdams would be constructed from materials salvaged from the dam demolition activities, GHG emissions associated with cofferdam construction would already be included in the emissions inventory. Additional emissions could occur when the cofferdams are later demolished. Due to the limited size of these structures and the fact that much of the material used to construct the coffer dams would be disposed of in close proximity to the dam sites, it is not anticipated that the additional emissions from this activity would result in a change to the significance determination.

Restoration Activities

Restoration actions included in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) would produce GHG emissions from the use of helicopters, trucks, and barges. Following drawdown of the reservoirs, revegetation efforts would be initiated to support establishment of native wetland, riparian, and upland species on newly exposed sediment. Additional fall seeding may be necessary to supplement areas where spring hydroseeding was unsuccessful. Table 3.10-4 summarizes GHG emissions from restoration activities.

Table 3.10-4. Uncontrolled Direct GHG Emissions Inventories for Restoration (Seeding).

Location	Project Emissions ($MTCO_2E$)			
	Ground Equipment	Barges	Aerial	Total
Iron Gate	29	88	149	266
Copco No. 1 and Copco No. 2	32	88	298	419
J.C. Boyle	19	n/a	n/a	19
Total Emissions	**80**	**177**	**447**	**704**

Source: Appendix N

As shown in Table 3.10-4, total GHG emissions from restoration activities are estimated to be approximately 704 $MTCO_2e$. As indicated in Table 3.10-2, next to deconstruction of the dams, restoration activities would be the second largest contributor of the construction emissions that would occur from the Proposed Project.

Recreation Facilities

Relocation and demolition of various recreation facilities (Section 2.7.8.3 *Recreation Facilities Management*) would produce GHG emissions from vehicle exhaust. The demolition of the Lower Klamath Project recreation facilities would change recreation opportunities from reservoir-based recreation to river-based recreation. This change would require several recreation facilities to be relocated or demolished. On- and off-road construction equipment would be used to complete these activities. GHG emissions from recreation facilities removal and construction were estimated using the California Emissions Estimator Model (CalEEMod). Approximately 160 $MTCO_2e$ would be emitted during relocation and demolition of the recreation facilities (Appendix N).

City of Yreka Water Supply Pipeline Relocation

Construction of a new Yreka water supply pipeline (Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*) would produce GHG emissions from vehicle exhaust. On- and off-road construction equipment would be used to complete the relocation and construction of the water supply pipeline. Construction of the pipeline is to occur prior to initiating drawdown of the Iron Gate Reservoir. It is estimated the replacement of the water supply pipeline would last approximately one month. The Sacramento Metropolitan Air Quality Management District's Road Construction Emissions Model (2009) was used to estimate emissions associated with grubbing/land clearing, grading/excavation, and other phases of construction. The Road Construction Emissions Model estimated that approximately 33 $MTCO_2e$ would be emitted.

Replacement of Hydroelectric Energy

Removing a renewable source of energy by removing the dams has the potential to result in increased GHG emissions from possible non-renewable alternate sources of power. GHG emissions could occur in the event that the renewable source of power represented by the Lower Klamath Project was replaced by other regional power sources, which in part, could be generated from fossil fuels.

As described above, the average annual electricity generation from the Lower Klamath Project is 686,000 MWh (Table 3.10-1). This includes generation from the following developments: Copco No. 1 Dam, Copco No. 2 Dam, Iron Gate Dam, and J.C. Boyle Dam. The Lower Klamath Project dam complexes in California (Copco No. 1, Copco No. 2, and Iron Gate) have a generation capacity of approximately 65 MW of electricity and produce an average of 357,000 MWh of electricity annually. This accounts for approximately 52 percent of the Lower Klamath Project total electrical production.

The 2015 electricity generation resource mix for PacifiCorp's Power Control Area (PCA), which is a region of the power grid in which all power plants are centrally dispatched, is dominated by coal (62 percent), natural gas (15.4 percent), wind (7.1 percent), and hydroelectricity (5.2 percent) (PacifiCorp 2017a). Electricity produced from the Lower Klamath Project, if removed, would likely be replaced with another source within the PacifiCorp PCA because the amount of electricity provided by the Lower Klamath Project is only approximately two percent of PacifiCorp's total generation capacity (CEC 2006b).

In 2017, PacifiCorp issued an Integrated Resource Plan (IRP) identifying the preferred power generation portfolio over the next 20 years. The IRP indicates that PacifiCorp plans to meet new energy resource needs primarily through new renewable resources and demand management (e.g., energy efficiency measures) over the 20-year (2017–2036) planning horizon. The IRP includes the anticipated loss of Lower Klamath Project hydroelectric generation beginning in 2020. The preferred portfolio also identified a reduction in coal capacity of 3,650 MW through the end of 2036. PacifiCorp projects that between 2017 and 2036 its average annual CO_2 emissions would be reduced by 24.5 percent falling from 43.8 million tons in 2017 to 33.1 million tons in 2036 representing an annual average reduction in CO_2 emissions of 10.7 million tons (PacifiCorp 2017b).

Removal of the reservoirs associated with the Lower Klamath Project dam complexes would also result in a reduction in methane (CH_4) production. As previously described, CH_4 emissions from the reservoirs range from 4,000 to 14,000 $MTCO_2e$ per year. Under the Proposed Project, these CH_4 emissions would cease to be a factor and would further reduce GHG emissions beyond the projections in the PacifiCorp 2017 IRP.

Since it is planned in the 2017 IRP for PacifiCorp to add new sources of renewable power or purchase RECs to comply with the California RPS, and removal of the reservoirs would result in a reduction in methane production, it is not anticipated that the replacement of the hydroelectric energy from the Lower Klamath Project dam complexes would result in an increase in GHG emissions from non-renewable power sources. As such, GHG impacts from replacement of the hydroelectric energy from the Lower Klamath Project dam complexes is determined to be less than significant.

Significance
No significant impact

Potential Impact 3.10-2 Conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing GHG emissions.
Climate change is a cumulative phenomenon, and it is not possible to link a single project to specific climatological changes. The Proposed Project would result in temporary direct GHG emissions from construction and restoration related activities, but would not include direct operational GHG emissions. However, the Proposed Project could result in additional indirect emissions from non-renewable replacement power that could potentially be provided until PacifiCorp adds new sources of renewable power that would replace the removed dams.

For the purposes of this analysis, the Proposed Project is analyzed for compliance with the following applicable plans, policies, and regulations:

- Assembly Bill 32 (AB 32)
- Executive Order S-3-05 (EO S-3-05) and Senate Bill 32 (SB 32)
- Renewable Portfolio Standard (RPS) (S-14-08, SB X1-2, and SB 350)

Assembly Bill 32 (AB 32)
The Global Warming Solutions Act of 2006 (AB 32) directed the CARB to develop the Climate Change Scoping Plan (Scoping Plan), which outlines a set of actions to achieve the AB 32 goal of reducing GHG emissions to 1990 levels by 2020 (CARB 2008). CARB approved the Scoping Plan in 2008 and updated it in May 2014 and November 2017.

As discussed under Potential Impact 3.10-1, the construction emissions from the Proposed Project would fall below the 10,000 $MTCO_2e$ significance threshold developed by the SCAQMD and BAAQMD to provide consistency with AB 32. Since the project's GHG emissions would be below a GHG threshold developed to provide consistency with AB 32, the Proposed Project would not conflict with AB 32.

In addition, It is noted that CARB announced in July 2018, that the State has already met the AB 32 goal of reducing emissions to 1990 levels by 2020 approximately four years early. As stated in the Executive Summary of the 2018 Edition of the California Greenhouse Gas Emissions Inventory: 2000–2016 (CARB 2018):

> "The inventory for 2016 shows that California's GHG emissions continue to decrease, a trend observed since 2007. In 2016, emissions from routine GHG

emitting activities statewide were 429 million metric tons of CO2 equivalent (MMTCO2e), 12 MMTCO2e lower than 2015 levels. This puts total emissions just below the 2020 target of 431 million metric tons. Emissions vary from year-to-year depending on the weather and other factors, but California will continue to implement its greenhouse gas reductions program to ensure the state remains on track to meet its climate targets in 2020 and beyond."

Executive Order S-3-05 (EO S-3-05) and Senate Bill 32 (SB 32)
Since the Proposed Project involves construction activity related to the decommissioning of the Lower Klamath Project dam complexes that would be completed at the end of 2021, and the Proposed Project would not have long-term operational emissions, the potential for the project to conflict with the goals in EO S-3-05 and SB 32 is limited. However, a discussion of the Proposed Project's compliance with existing regulatory requirements (e.g., low carbon fuel standards) and the California RPS is included below to assess whether the project would conflict with the GHG reduction goals in EO S-3-05 and SB 32.

In 2016, the CARB released the updated Mobile Source Strategy, which addresses the current and proposed programs for reducing mobile source emissions, including GHG emissions. The Mobile Source Strategy identifies programs that the state and federal government have or would adopt, which further the goals of the Scoping Plan. Some programs provide incentives to facilitate increased purchase of new, lower emission light-, medium-, and heavy- duty vehicles to aid the state in achieving emission reduction goals. Other programs require certain engine years to upgrade the engine to newer, cleaner engines by specific dates or strict performance standards for specific model years. These programs for more stringent emission are required by state and federal law and are monitored by CARB or USEPA (CARB 2016). As such, the vehicles used during construction of the Proposed Project are required to comply with the applicable GHG reduction programs. KRRC or the construction contractor are required to provide verification of compliance to CARB or USEPA under state and federal law.

As described below, PacifiCorp plans to add new sources of renewable power or purchase RECs to comply with the California RPS. As such, the power mix provided by PacifiCorp after removal of the Lower Klamath Project dam complexes would comply with regulations that support the goals identified in S-3-05 and SB 32.

Therefore, the Proposed Project and the power mix that would be provided by PacifiCorp after removal of the Lower Klamath Project dam complexes, would conform with relevant actions and programs detailed in the Scoping Plan and Mobile Source Strategy. As such, the Proposed Project would not conflict with EO S-3-05 and SB 32.

Renewable Portfolio Standard (RPS) (S-14-08, SB X1-2, and SB 350)
In 2017, PacifiCorp issued an Integrated Resource Plan (IRP) identifying the preferred power generation portfolio over the next 20 years that "reflects a cost-conscious transition to a cleaner energy future". The IRP indicates that PacifiCorp plans to meet new energy resource needs primarily through new renewable resources and demand management (e.g., energy efficiency measures) over the 20-year (2017–2036) planning horizon by adding approximately 4,000 MW of wind and solar resources and 2,100 MW through energy efficiency and load control. The IRP includes the anticipated loss of Lower Klamath Project hydroelectric generation beginning in 2020. The preferred portfolio also identified a reduction in coal capacity of 3,650 MW through the end of

2036. As it relates to compliance with the California RPS, the PacifiCorp IRP concludes that the California RPS compliance position is improved by the addition of repowered wind, new renewable resources and transmission in the 2017 IRP preferred portfolio and would require the purchase of under 150,000 RECs per year to achieve compliance through the planning horizon.

Although the Proposed Project would result in the loss of a renewable energy source, overall PacifiCorp would be increasing the percentage of renewable energy sources in its power mix to comply with the California RPS. Since it is planned in the 2017 IRP for PacifiCorp to add new sources of renewable power or purchase RECs to comply with the California RPS, the Proposed Project would not conflict with the State's RPS.

As such, the Proposed Project would not conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing the emissions of greenhouse gases.

3.11 Geology, Soils, and Mineral Resources

3.11.1 Area of Analysis

This section analyzes potential impacts on geology, soils, and mineral resources related to implementation of the Proposed Project. The Area of Analysis for geology, soils, and mineral resources includes the riverbed and reservoir slopes at the sites of the Iron Gate, Copco No. 1, and Copco No. 2 dam complexes; as well as the Klamath River bed and banks from the California-Oregon state line to the Pacific Ocean, including the Klamath River Estuary. Areas of the Upper Klamath Basin in Oregon are discussed in this section only to the extent they pertain to potential impacts to geology, soils, and mineral resources in California.

The assessment of potential impacts to geology, soils, and mineral resources includes the following reaches of the Klamath River defined by changes in physiography, presence of the developments included in the Lower Klamath Project, and tidal influence (Figure 3.11-1):

1. Hydroelectric Reach (from the upstream extent of J.C. Boyle Reservoir to Iron Gate Dam), including the following:
   a. J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoirs
   b. J.C. Boyle Bypass and Peaking reaches
   c. Copco No. 2 Bypass Channel;
2. Klamath River downstream of Iron Gate Dam to the Pacific Ocean;
3. Klamath River Estuary; and
4. Pacific Ocean nearshore environment.

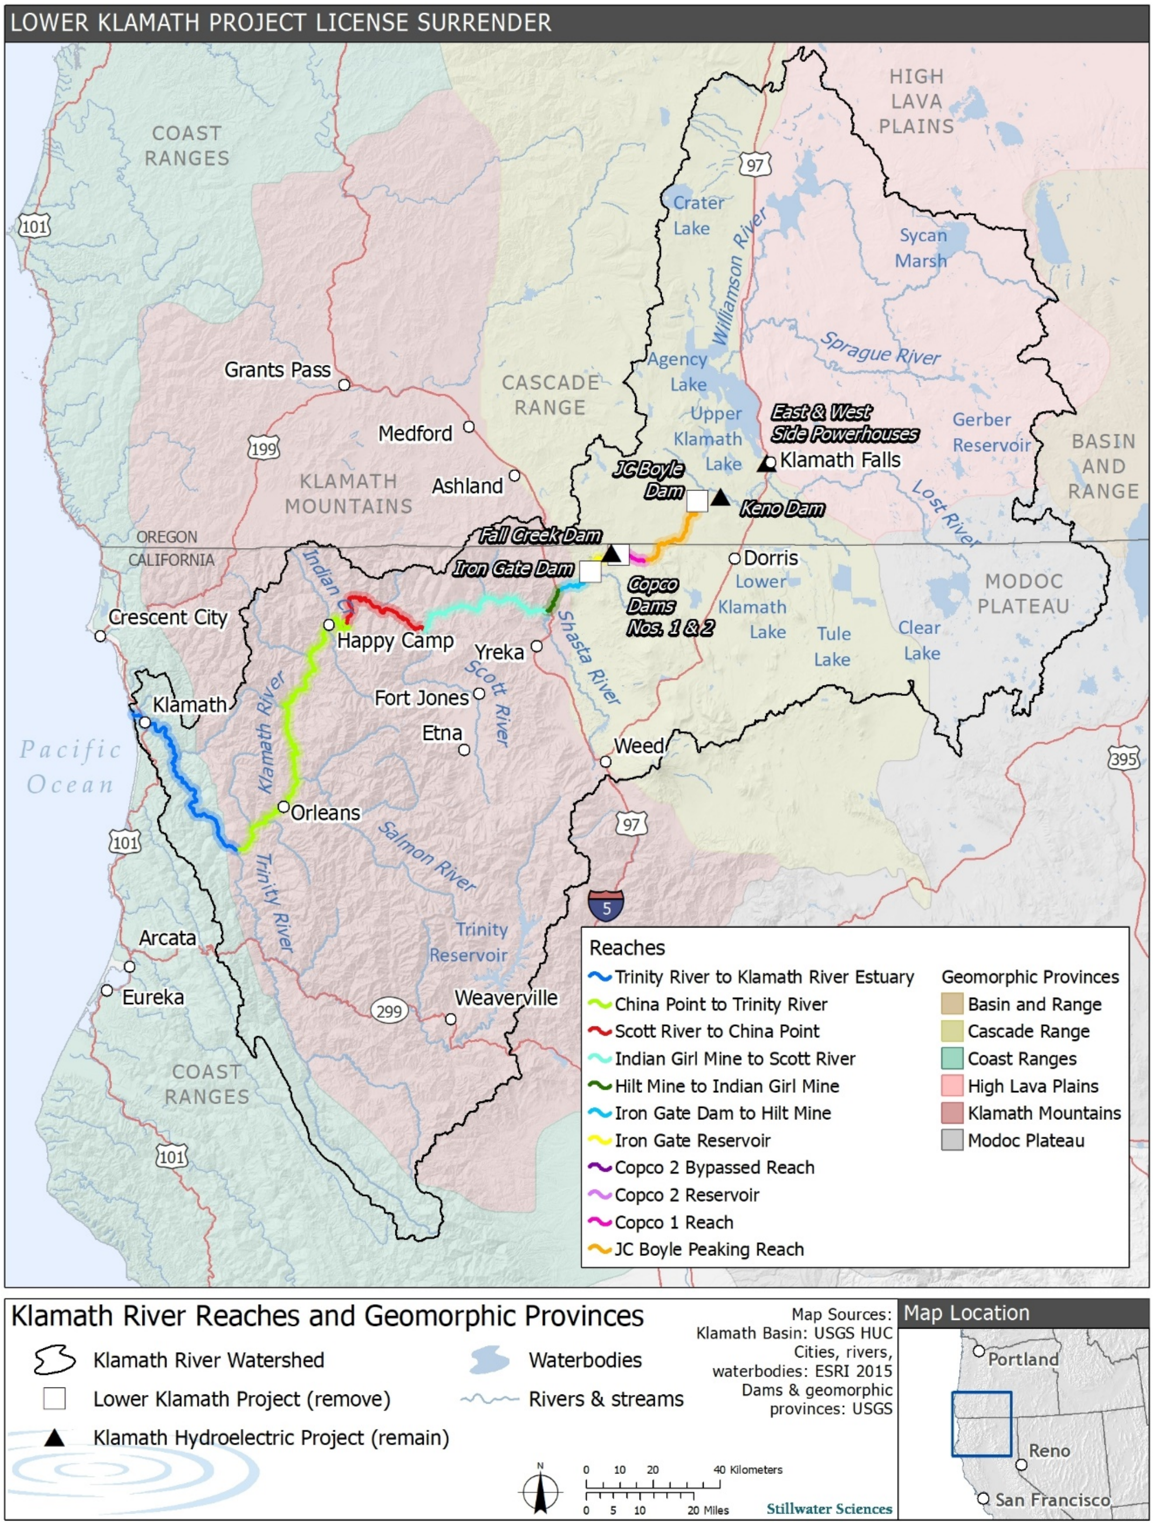

Figure 3.11-1. Geomorphic Provinces in the Klamath Basin and Geomorphic Reaches within the Area of Analysis for Geology and Soils.

3.11.2 Environmental Setting

The Proposed Project would erode sediment from reservoir deposits and transport this sediment to downstream reaches of the Klamath River. The following description of the geology and soils environmental setting therefore focuses primarily on the geology and geomorphology of the reservoir, channel, and floodplain environments directly and indirectly affected by dam removal and the associated release of stored sediment to downstream reaches of the Klamath River.

The Klamath River traverses approximately 260 river miles (approximately 214 river miles in California and 46 river miles in Oregon), originating in Upper Klamath Lake in southern Oregon and cutting southwest through the Klamath Mountains and northern California Coast Range to the Pacific Ocean near Requa. With a watershed area of approximately 15,722 mi^2, the Klamath River produces the second largest average annual runoff (Kruse and Scholz 2006) and sediment flux (Willis and Griggs 2003) of California's rivers.

The USBR refers to areas upstream of Iron Gate Dam as the Upper Klamath Basin and areas downstream of Iron Gate Dam as the Lower Klamath Basin (USBR 2012). These generalized basin areas are further subdivided based on geomorphic terrains with distinctly different geologic, geomorphic, hydrologic, climatic, vegetative, and resulting land use characteristics.

3.11.2.1 Regional Geology

Bedrock Geology

The geologic history of the Klamath River basin follows the interaction of three tectonic plates: the Pacific, the North American, and the Juan de Fuca. As a result, the Klamath River downstream of J.C Boyle Dam flows through three distinct geomorphic provinces: the Cascade Range Province, the Klamath Mountains Province, and the Coast Range Province (Figure 3.11-1) (CGS 2002). Each geomorphic province uniquely influences hydrology; channel morphology; and the supply of water, sediment, nutrients, and wood originating from tributary rivers and streams.

The portion of the Upper Klamath Basin located upstream of Upper Klamath Lake drains two geomorphic provinces: High Lava Plains and Modoc Plateau, composed predominantly of Miocene age basalts. The permeable volcanic rocks and subdued relief in these geomorphic provinces result in low drainage density, low stream gradients, and large internally drained areas that are typically filled with volcaniclastic sediment, alluvial fan deposits, and lake sediment (e.g., Upper Klamath, Lower Klamath, and Tule lakes). The Upper Klamath Basin also lies in the rain shadow of the Klamath and Cascade mountain ranges, and streamflow is largely from relatively steady groundwater flow. Low channel gradients, limited surface runoff, and internal drainage contribute to a muted hydrologic response to storm events and low sediment yield to the Klamath River.

The Lower Klamath Project is located in the Cascade Range Province, comprised predominantly of andesitic volcanic rocks of Cenozoic age. The Cascade Range Province is divided into the Western Cascade Sub-Province and the High Cascades Sub-Province based on the age and style of volcanism (Mertzman and Hazlett 1997, Taylor 1990). The Western Cascade Sub-Province is dominated by calc-alkaline continental margin andesites extruded about 40 million years ago (Mertzman and Hazlett

1997). The High Cascades Sub-Province is younger (Quaternary age) and is distinguished by lava flows, lava shields, pyroclastic flows, tuffs, cinder cones, and classic cone shaped stratovolcanoes.

The Mid-Klamath Basin is a subdivision of the basin located between approximately Iron Gate Dam the Trinity River confluence. The Mid-Klamath Basin occurs predominantly within the Klamath Mountains Province and is underlain by a series of geologic terranes comprised of accreted oceanic lithosphere, volcanic arcs, and mélange (Irwin 1994). The terranes were successively accreted to the convergent margin of western North America through a series of tectonic episodes. Each band of accreted material composing a terrane served as the backstop for the successive accretionary episode. Widespread metamorphism, folding, and faulting occurred in both the continental and accreted rocks during each episode. The complex geologic and geomorphic character of the Klamath Mountains reflects this tectonostratigraphic growth and subsequent plutonic intrusive, metamorphic, and volcanic activity that has occurred since the early Devonian geologic period (Irwin 1994). These rocks are more resistant to weathering and form high-relief terrain with prominent peaks and ridges.

The Lower Klamath Basin occurs farther west within the Coast Range Province and includes 40 miles of the Klamath River from approximately the Trinity River confluence to the Pacific Ocean. The Lower Klamath Basin is underlain mostly by the Eastern Belt of the Franciscan Complex and a narrow band of the Central Belt of the Franciscan Complex along the coast. The Eastern Belt is composed of schist and meta-sedimentary rocks (mostly metagraywacke) with minor amounts of shale, chert, and conglomerate. The Central Belt is principally an argillite-matrix mélange that contains kilometer-sized slabs of greenstone, serpentinite, graywacke, and abundant meter-size blocks of greenstone, graywacke, chert, higher-grade metamorphics, limestone, and lenses of serpentinite. The combination of tectonic deformation and shear, compositionally weak bedrock, and high precipitation rates in the Coast Ranges result in high erosion rates and sediment yields compared to other parts of the Klamath Basin (FERC 2007).

Faulting and Seismicity

The California Geological Survey (CGS) identifies seismic hazard zones according to the Alquist–Priolo Special Studies Zone Act of 1972 (Alquist-Priolo Act). Zone 4 is the highest rating requiring, compliance with the strictest building standards, while Zone 1 represents areas with the lowest probability of a seismic event. CGS has placed Siskiyou County in Seismic Zone 3 due to the presence of nearby active faults capable of surface rupture (CGS 2007).

Review of available fault and earthquake epicenter maps for northern California and southern Oregon show no fault lines or earthquake epicenters beneath Iron Gate Dam, Copco No. 1 Dam, Copco No. 2 Dam, or the Lower Klamath Project reservoirs. The Cedar Mountain fault is located approximately five miles east of the Klamath River in Siskiyou County (Table 3.11-1). The Hat Creek–McAuthur fault zone is located approximately 50 miles southeast of Copco No. 1 Dam. Other faults mapped by USGS, but not zoned under the Alquist–Priolo Act, include the Gillem–Big Crack fault, Pittville fault, Mayfield fault, and Rocky Ledge fault. Faults exist beneath the J.C. Boyle Dam and Reservoir; however, these faults have not moved within the past 1.5 million years and are considered inactive (Personius et al. 2003). No earthquake epicenters are mapped beneath the J.C. Boyle Reservoir, but one of the largest earthquakes recorded in Oregon occurred in 1993, with a magnitude of 6.0, in and around the Klamath Falls area approximately 15 miles north of the J.C. Boyle Reservoir. In California, the nearest active fault to the Lower Klamath Project is the Meiss Lake fault, approximately five miles east of the Klamath River near the California-Oregon State line in Siskiyou County. The next nearest California-zoned active fault in relation to the Lower Klamath Project is the Mahogany Mountain fault zone, approximately six miles east (Jennings and Bryant 2010).

Table 3.11-1. Earthquake and Fault Information.

Fault	Zoned by State of California [a]	Magnitude of Maximum Credible Earthquake (moment magnitude) [b]	Approximate Slip Rate (inches/year)	Approximate Recurrence Interval (years)
Cedar Mountain fault	Yes	6.9	0.04 [c]	3,600[c]
Hat Creek–McArthur faults	Yes	7	0.06 [c]	Unknown, possibly 1,000 to 3,000 [c]
Gillem–Big Crack faults	No	6.6	0.04 [c]	Not available
Pittville fault	No	6.7	less than 0.03 [c]	Not available
Mayfield fault	No	6.5	0.03–0.19 [c]	A few thousand years [c]
Rocky Ledge fault	No	N/A	less than 0.03 [c]	Not available

Sources:
[a] Bryant and Hart 2007
[b] Mualchin 1996
[c] USGS 2006

Based on the USGS earthquake database, the three largest earthquakes that have occurred closest to Copco No. 1, Copco No. 2, and Iron Gate dams were as follows. The first was located approximately 10 miles east of Copco No. 1 Dam and occurred with a magnitude of 3.3 on November 11, 1997. The second was located approximately 20 miles east of Copco No. 1 Dam and occurred with a magnitude of 3.0 on July 17, 1999. The third was located approximately 25 miles south of Iron Gate Dam and occurred with a magnitude of 2.5 on February 21, 2014.

Ground shaking is ground movement caused by seismic activity. Unlike surface rupture, ground shaking propagates into surrounding areas during an earthquake rather than being confined to a fault trace. A review of the CGS database indicates that the largest earthquake nearest the Lower Klamath Project, with the potential to have resulted in ground shaking near the Lower Klamath Project, occurred west of Eureka, California on November 8, 1980 (magnitude 7.3). Numerous earthquakes greater than magnitude 4.0 have occurred offshore west of Eureka (CGS 2007). The potential therefore exists for the soils and geology Area of Analysis to be affected by seismic ground shaking in the future.

Volcanism

Volcanism started in the Lower Klamath Project area approximately 40 million years ago and continued until approximately 10 and 5 million years ago. Volcanic activity shifted eastward, narrowed, and diminished in intensity over time. Estimates of the thickness of the Western Cascades strata range from between 12,000 and 15,000 feet to greater than 20,000 feet (PanGeo 2008). In the vicinity of Copco No. 1 Reservoir, the Klamath River has incised up to half of the Western Cascade strata, exposing inter-bedded tuffs, ash, and lava flows dipping east at approximately 25 degrees. These east-dipping Western Cascades strata are overlain by nearly flat-lying High Cascades strata composed of younger Pliocene lava flows with a cumulative thickness of up to 500 feet. Zones of inter-bedded Western Cascade strata may serve as geothermal reservoirs when coupled with a heat source and sealed by overlying High Cascades lava flows (Hammond 1983).

Volcanism in the vicinity of the Lower Klamath Project includes stratovolcanoes, lava domes, and cinder cones. Quaternary volcanics, including two Pleistocene cinder cones and associated lava flows, occur in the region between the eastern edge of Iron Gate Reservoir and Copco No. 1 Dam (GEC 2006, Wagner and Saucedo 1987). Within the past 10,000 years, Mount Shasta eruptions have occurred on average every 800 years. Over the past 4,500 years, eruptions have occurred on average every 600 years. The last known eruption occurred approximately 200 years ago (Miller 1980).

There are also a series of basaltic volcanoes extending northward from California into Oregon towards Klamath Falls, which have been dissected by subsequent block faulting in the Basin and Range Province (PanGeo 2008). In addition to the large shield volcanoes with their multiple eruptive events, numerous smaller vents and volcanoes are present in the area. The majority of the volcanism in the Upper Klamath Basin consists of single events from a given vent and most of the smaller explosive cones are formed from the interaction of flow material intersecting ground water (hydrovolcanic events). Tephra hazards zones are found in association with vents that have erupted in the last 10,000 years and are thought to be likely sources for future explosive eruptions of fragmental material (Miller 1989). The closest source of potential tephra is Mount Shasta, located approximately 40 miles from Iron Gate Dam. The Klamath River, from the Oregon-California state line to approximately the confluence of Seiad Creek, is within the 85-kilometer radius of an area subject to at least two inches or more of compacted ash (Miller 1989).

Pyroclastic flows are a mixture of hot gas and rocks. During an eruption, pyroclastic flows could travel northwest from Mount Shasta toward the Klamath River (Miller 1989). The farthest potential extent of pyroclastic flows has been delineated to the bank of the Klamath River.

Rapid melting of snow and ice during a volcanic eruption can lead to local flooding. The high sediment concentrations in flood waters generated by volcanic eruptions can be more damaging than flooding from rainfall runoff. The USGS has delineated this hazard downstream of Iron Gate Reservoir (Miller 1989).

Soils

Soils within the Klamath Basin span multiple geologies, terrains, and climates. Soils in the vicinity of the Upper Klamath River surrounding J.C. Boyle Reservoir and along the river south to the Oregon-California state line generally consist of lacustrine and alluvial clay, silt, fine-grained sand, and peat (Priest et al 2008). The primary soil association along both sides of the river is Skookum-rock outcrop-Rubble land complex with 35 to 70 percent slopes. Soils along the Klamath River within the Hydroelectric Reach in

California are less homogenous. Soils along the Klamath River downstream of Iron Gate Dam are generally composed of associations consisting of gravelly clay loam and gravelly sandy loam (Holland-Clallam, Skalan, Weitchpec, and Lithic Mollic Dubakella associations).

Soil types in the Area of Analysis can be grouped generally into those on steeper slopes, floodplain or terrace surfaces, or directly along the Klamath River itself. Soils on steeper slopes are shallow to moderately deep (typically 17 to 40 inches) and comprise a 7- to 8-inch surface horizon of gravelly loam; an underlying horizon of gravelly, clayey loam; and locally a very gravelly clay (FERC 2007). Floodplain or terrace surface soils comprise a deep, well-drained combination of alluvium (and in some places colluvium). These soils, as found within the canyon of the J.C. Boyle Peaking Reach, can be divided typically into a 15-inch very gravelly loam upper horizon, a transitional 6-inch gravelly clay loam layer, and a 39-inch horizon of heavy clay loam underlain by weathered bedrock to 60 inches or more below the surface (FERC 2007). The third soil type, located directly along the river, comprises unconsolidated alluvium, colluvium, and fluvial deposits. These geologically recent alluvial, low terrace, and landslide deposits consist of unconsolidated sand, silt, and gravels.

Mineral Resources

The CGS and the California Department of Conservation State Mining and Geology Board have classified Mineral Resource Zones (MRZs) in accordance with Sections 2761(a) and (b) and 2790 of the California Surface Mining and Reclamation Act of 1975 (SMARA). Lands categorized as MRZ-2 are underlain by "regionally significant" mineral resources that require that the CEQA lead agency's land use decisions be made in accordance with its mineral resource management policies, and that it consider the importance of the mineral resource to the region or the state as a whole. The primary source of information considered in this mineral resources analysis are the "mineral lands classification" maps published by the State pursuant to SMARA. Two comprehensive databases managed by the USGS (Minerals Availability System and Mineral Resource Data System) contain information regarding specific mineral locations.

Economically, the most important minerals that are extracted in the Area of Analysis for geology and soils are sand, gravel, and crushed rock (Figure 3.11-2, Table 3.11-2) (CGS/USGS 2004). Numerous small aggregate production areas are present. Other minerals that could be mined include asbestos, chromium, clay, copper, diatomite, gold, graphite, and mercury. The CGS has not prepared any reports that designate Mineral Resource Zones to be protected in Siskiyou County (Kohler 2002). The Siskiyou County General Plan does not contain a Mineral Resource Element and does not identify any specific areas of mineral resources within the county to be protected (Siskiyou County 1973).

Diatomite deposits surround much of the shoreline of Copco No. 1 Reservoir (PanGeo 2008). Diatomite is a chalk-like, very fine-grained sedimentary rock. It is used principally as a filter aid but has other commercial applications (USGS 2011). Near vertical bluffs have formed in the diatomaceous deposits as a result of undercutting due to wave erosion and failure of the weak material. Because of their location in the reservoir and existing erosion, diatomite resources are currently inaccessible for extraction purposes.

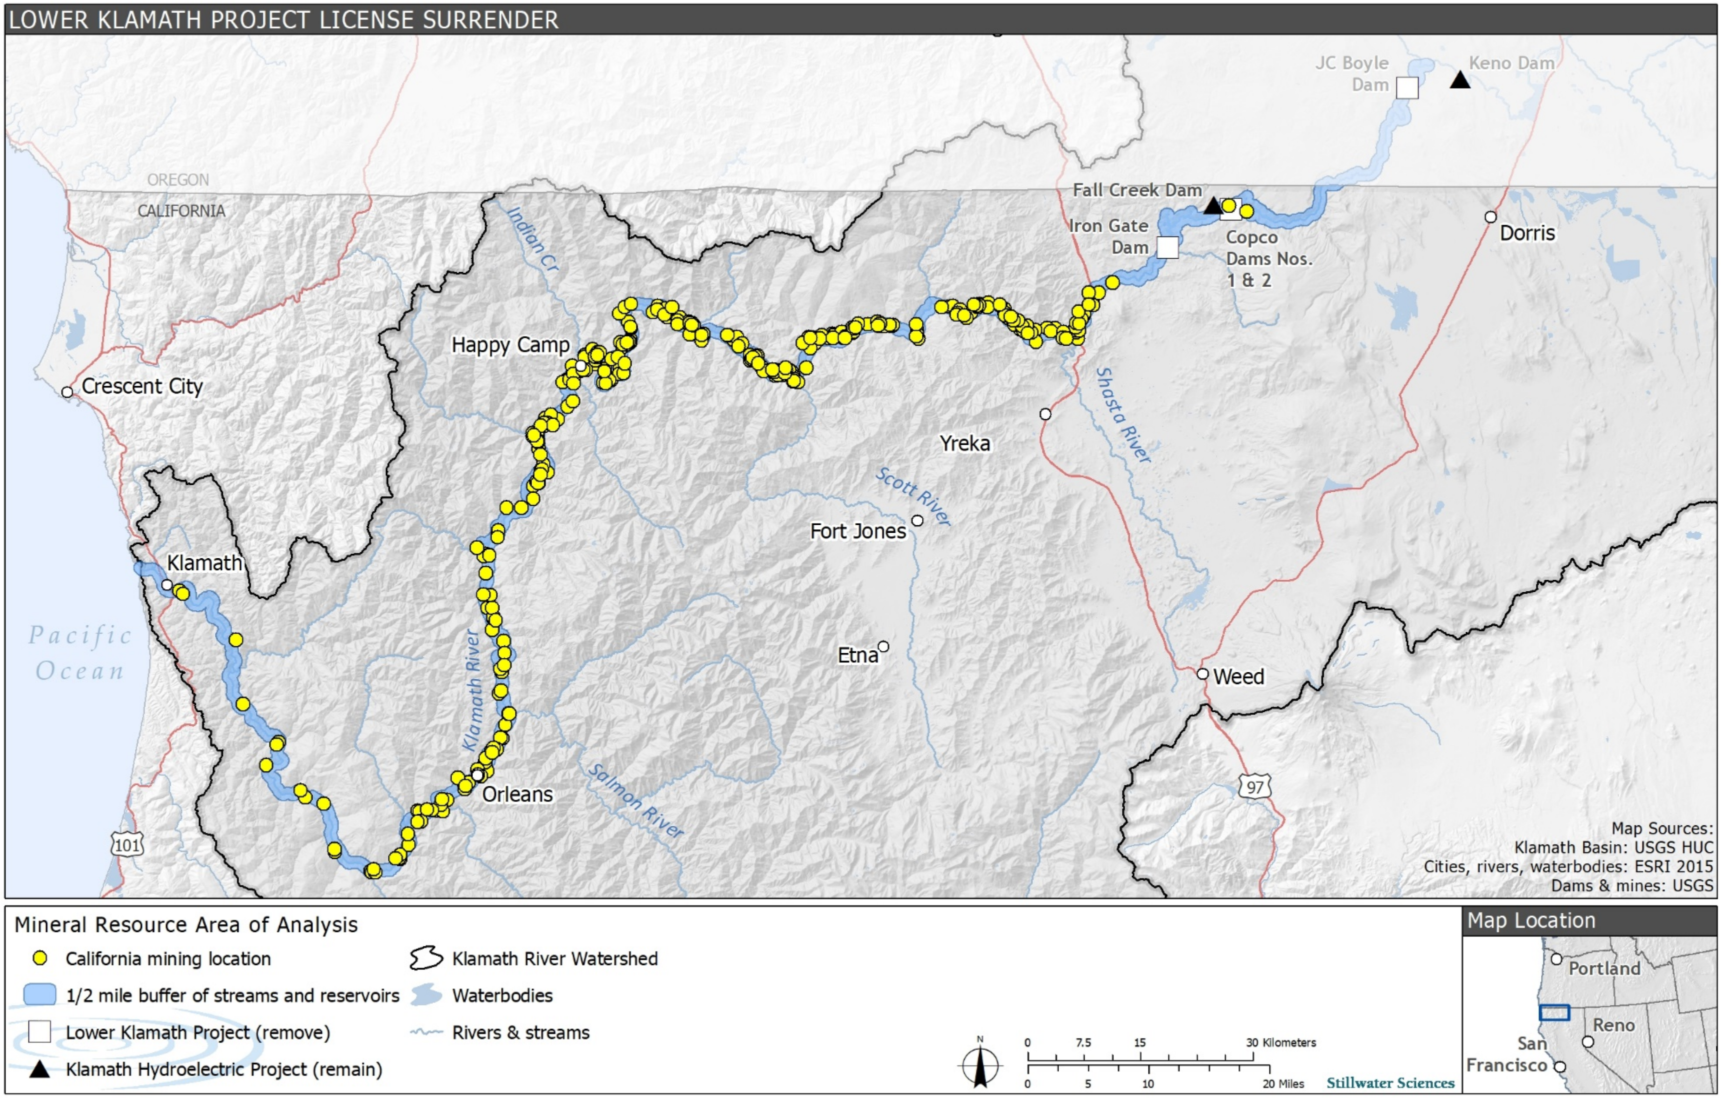

Figure 3.11-2. Mineral Resource Sites within the Area of Analysis for Geology and Soils.

Table 3.11-2. Mineral Resource Sites within the Area of Analysis for Geology and Soils.

Commodity	Occurrence	Past Producer	Producer	Prospect	Unknown	Total
Asbestos	1					1

Sand and Gravel			3		1	4
Crushed Rock					1	1

3.11.2.2 Geomorphology

The geomorphology of the Klamath River in the Area of Analysis reflects the geology, hydrology, climate, and vegetation characteristic of the geomorphic provinces it flows through. The Klamath River within and downstream of the Hydroelectric Reach flows through steep, mountainous terrain and is generally a coarse-grained, bedrock-controlled channel with relatively short alluvial reaches and little floodplain development (Ayres Associates 1999). Channel morphology, degree of confinement, and bed surface grain size distribution are locally controlled by bedrock and by tributary flow and sediment inputs. The following sections provide a detailed description of the geology and geomorphology in channel reaches (Figure 3.11-1).

J.C. Boyle Reservoir

J.C. Boyle Reservoir (RM 229.8 to RM 233.3) transitions from a relatively wide and shallow upstream end, where the reservoir inundates a formerly low-gradient river valley, to a narrower and deeper downstream end, where the Klamath River incises into a bedrock canyon. The transition occurs at approximately RM 231. The bedrock surrounding and underlying J.C. Boyle Reservoir is principally inter-fingered volcanic deposits that are less than five million years old and are part of the High Cascade sub-province. Common lithologies include resistant basalt and basaltic andesite and less resistant volcaniclastic deposits. An outcrop of diatomite is present along the margin of the reservoir on the north side of the Klamath River by the prominent eastward bend (Appendix B: *Definite Plan*). The outcrop is at least 10 feet high and located at the foot of a rounded hill mapped as glacial material. The diatomite is underlain by black sand and is possibly interbedded with volcaniclastic material. The land surface surrounding the J.C. Boyle Reservoir is generally low gradient and underlain by competent materials. Spencer Creek enters the right bank at the upstream end of the reservoir.

J.C. Boyle Bypass and Peaking Reaches (RM 229.8 to 208.3)

The J.C. Boyle Bypass Reach begins in the Klamath Gorge downstream of J.C. Boyle Dam. Channel gradient in the bypass reach averages 1.4 to 2.3 percent. The channel through the upper portion of the bypass reach is typically composed of boulder and bedrock cascades with intermittent pools. The channel in the lower portion of the bypass reach is characterized by boulder to large cobble-bedded riffles, runs, and pools.

Rock fall from talus cones and block failures from cliff faces are the dominant sediment sources (FERC 2007).

The J.C. Boyle Peaking Reach begins as a wide, plane-bed channel just downstream of the powerhouse. The channel remains steep and boulder-dominated to the USGS gage (RM 224.4), downstream of which the steep (1.7 percent) channel is characterized by cobble-bedded riffles and runs with intermittent pools and gravel bars. Stepped terraces related to the thick lacustrine deposits occur from just downstream of J.C. Boyle Powerhouse to RM 219.1. The river is less steep (0.3 percent) in this segment, allowing for an increase in the size and frequency of finer sediment deposits (e.g., small cobble and gravel). At RM 219.1 the river becomes confined, channel gradient increases to 2 percent, and the channel bed and banks are composed of bedrock and boulders. Channel gradient decreases to approximately 0.8 percent and the river valley widens near the California state line (RM 213.8). Alternating riffles, runs, and pools characterize this section of the reach. A broad terrace within the peaking reach supports a riparian corridor, beyond which irrigated pastures occupy the floodplain. These channel conditions continue for the next five miles, where several side channels occur in conjunction with lateral bars and islands (FERC 2007). Shovel Creek, the largest tributary in this reach, enters the Klamath River from the left bank at RM 211.1.

Copco No. 1 Reservoir and Tributaries (RM 208.3 to 201.8)

Copco No. 1 Reservoir is located at a slope break in the Klamath River valley profile. The upper approximately 80 percent of the reservoir length inundates a low gradient reach of the river valley, while the lower 20 percent of the reservoir closest to the dam inundates a steeper reach. This slope break reflects base level control caused by emplacement of young volcanic deposits (e.g., Pleistocene cinder cones and associated lava flows, air fall tuff, and ash flows) that resulted in valley filling in the lower gradient upstream portion of the river valley. (FERC 2007, PanGeo 2008). Surficial deposits around Copco No.1 Reservoir include talus and rockfall debris, colluvium, alluvium and alluvial fans associated with tributary drainages, and older (likely Quaternary) fluvio-lacustrine terrace deposits (Appendix B: *Definite Plan*) (Figure 3.11-3). Fluvio-lacustrine terrace deposits surround much of the reservoir shoreline, extending to approximately 40 feet above the current reservoir level. These deposits consist of diatomite, fine-grained diatomaceous sediment and dense, coarse-grained alluvial deposits (Appendix B: *Definite Plan*). Lacustrine diatomite deposits also exist below the current range of reservoir levels, and appear as prominent benches in the bathymetry. Along the south shore, this bench is mostly continuous and ranges between 100 and 300 feet wide. Along the north shore, the bench is wider, with large peninsulas extending to the south with very steep to near vertical side slopes (Appendix B: *Definite Plan*). Multiple springs emerge from the hillside above the reservoir northeast of Copco Cove. Long Prairie Creek, Beaver Creek, Deer Creek, and Raymond Gulch drain to Copco No. 1 Reservoir.

Copco No. 2 Reservoir (RM 201.8 to 201.5)

Copco No. 2 Reservoir is a short impoundment (just over 0.25 mile) that lies immediately downstream of Copco No. 1 Dam. The narrow reservoir inundates a confined river valley deeply incised into the same young lava flows and associated volcanic rocks described above for the downstream portion of Copco No. 1 Reservoir.

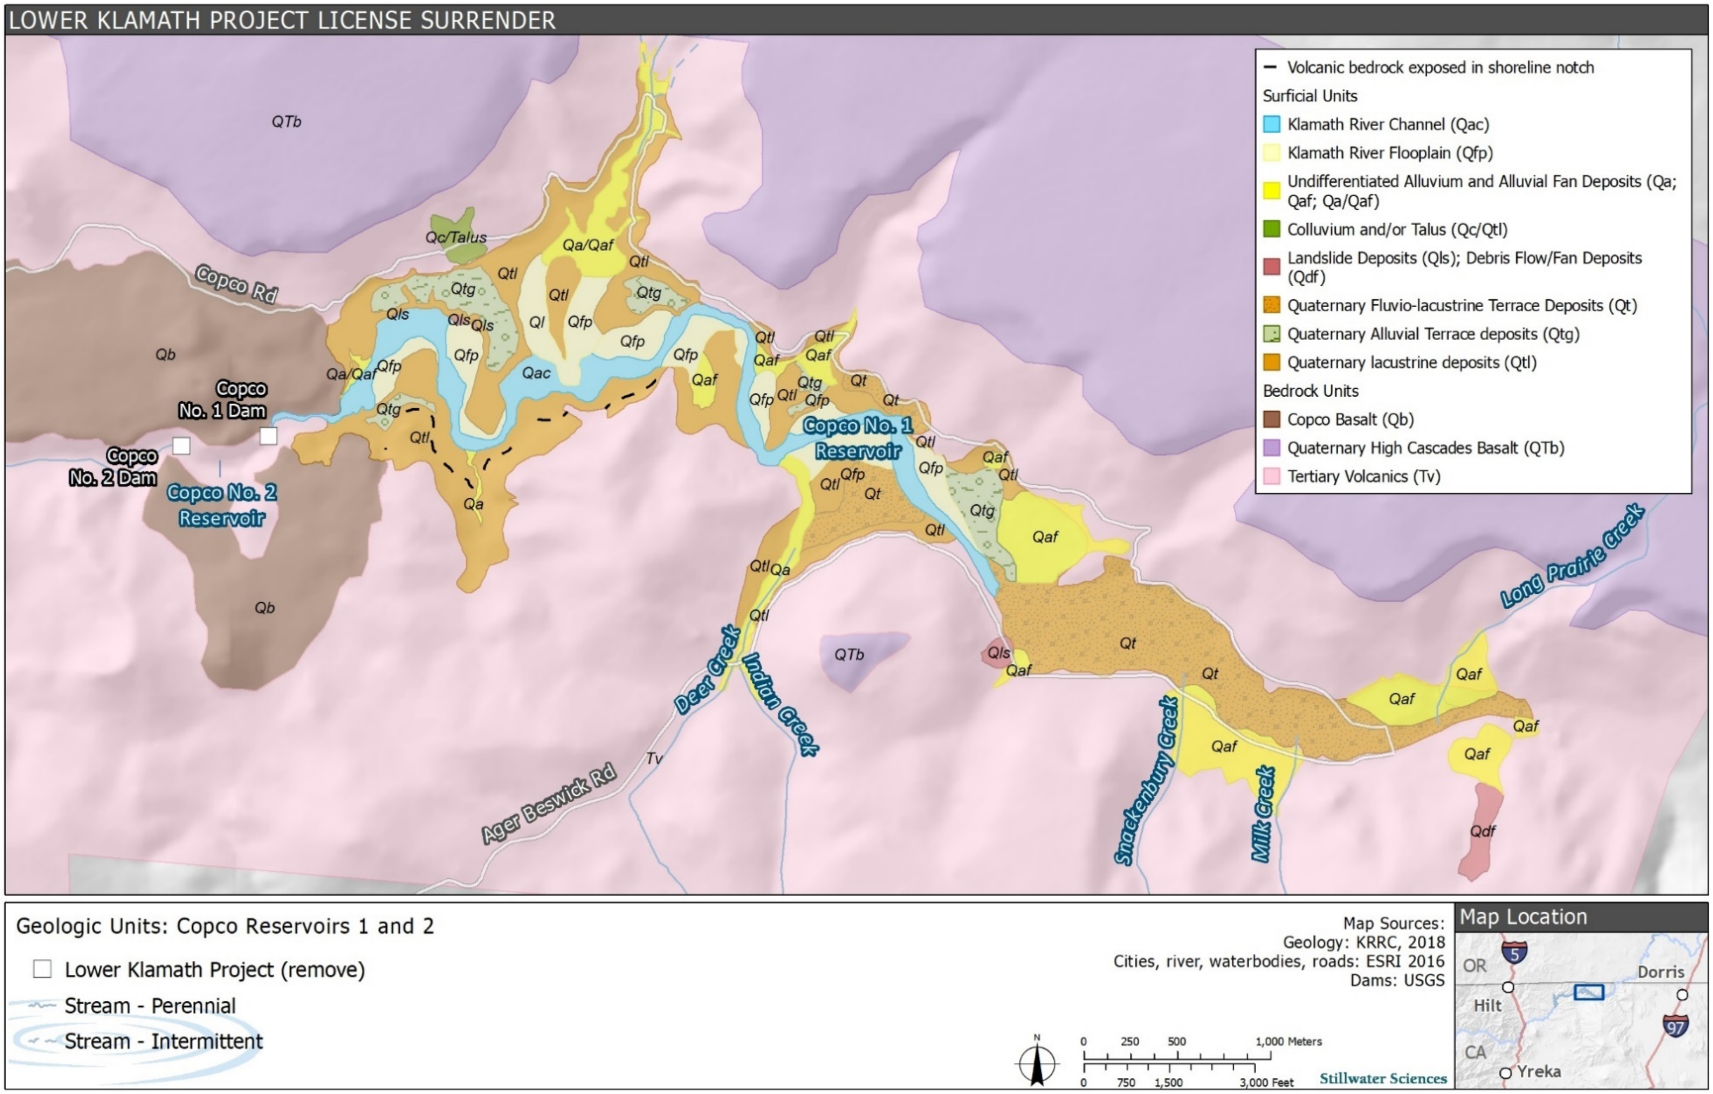

Figure 3.11-3. Surficial geology at Copco No. 1 Reservoir (Appendix B: *Definite Plan*).

Copco No. 2 Bypass Reach (RM 201.5 to 200.0)

Downstream of Copco No. 2 Dam, the Copco No. 2 Bypass Reach is a confined with minimal floodplain area. The average gradient of the bypass reach is about 1.9 percent. Bedrock channel reaches alternate with reaches where boulder-cobble deposits occupy most of the channel area. The Copco No. 2 Powerhouse returns flow to the Klamath River near RM 200.0 at the end of the reach (FERC 2007).

Iron Gate Reservoir and Tributaries (RM 200.0 to 193.1)

Iron Gate Reservoir overlies a slope break in the Klamath River valley profile, where a steeper upstream reach transitions to a lower gradient downstream reach. In this downstream reach, the valley widens and the channel is less confined by basalt flows (FERC 2007). Iron Gate Dam and its reservoir lie within Western Cascades geologic sub-province. Bedrock units include tuffaceous siltstones and sandstones, bouldery volcaniclastics and volcanic breccia, tuff and tuff breccia, and pyroxene flow rocks (Figure 3.11-4). Iron Gate Reservoir is relatively narrow and steep-sided, with numerous tributaries entering from the north (Fall Creek, Jenny Creek, Dutch Creek, Camp Creek, and Scotch Creek). Of these tributaries, Camp Creek and Jenny Creek supply the most sediment to the reservoir.

Iron Gate Dam to Hilt Mine (RM 193.1 to 184.0)

Downstream of Iron Gate Dam, the Klamath River flows through a narrow valley cut into the Western Cascade sub-province geology and sedimentary rocks of the Cretaceous Hornbrook Formation. The average gradient ranges from about 0.2 to 0.4 percent in the first five miles downstream of Iron Gate Dam. A narrow, discontinuous floodplain and extensive high terraces border the channel. The mostly single thread channel contains frequent bedrock outcrops, but the predominantly alluvial reaches have cobble-boulder bars and split flow around mid-channel bars with short side channels. Most of the bars are at least partially vegetated. The main tributaries entering this reach include Brush Creek, Bogus Creek, Little Bogus Creek, Willow Creek, and Cottonwood Creek. With the exception of Cottonwood Creek, these tributaries form relatively small, fine-grained alluvial fans at their confluences with the Klamath River. Cottonwood Creek forms a relatively large alluvial fan at its confluence near RM 185.1. Cottonwood Creek, Bogus Creek, and Little Bogus Creek are the first substantial sources of sediment downstream of Iron Gate Dam (Ayres Associates 1999, Buer 1981).

Hilt Mine to Indian Girl Mine (RM 184.0 to 177.2)

The Klamath River channel in this reach becomes more bedrock-dominated and confined within a narrow canyon. Alluvial bars are limited to the vicinity of the larger tributary confluences, such Williams Creek near RM 182.1 and the Shasta River near RM 179.5. The Shasta River is a source of fine gravel, sand, and finer sediment. However, the lack of substantial sedimentation in the vicinity of its confluence with the Klamath River suggests the Shasta River supplies little coarse sediment (Ayres Associates 1999).

Indian Girl Mine to Scott River (RM 177.2 to 145.1)

The channel in this reach of the Klamath River is mostly meandering and single thread, with valley width ranging from 300 feet to almost 1,200 feet. Sections with larger valley widths typically promote a lower gradient channel, more frequent alluvial features, and more

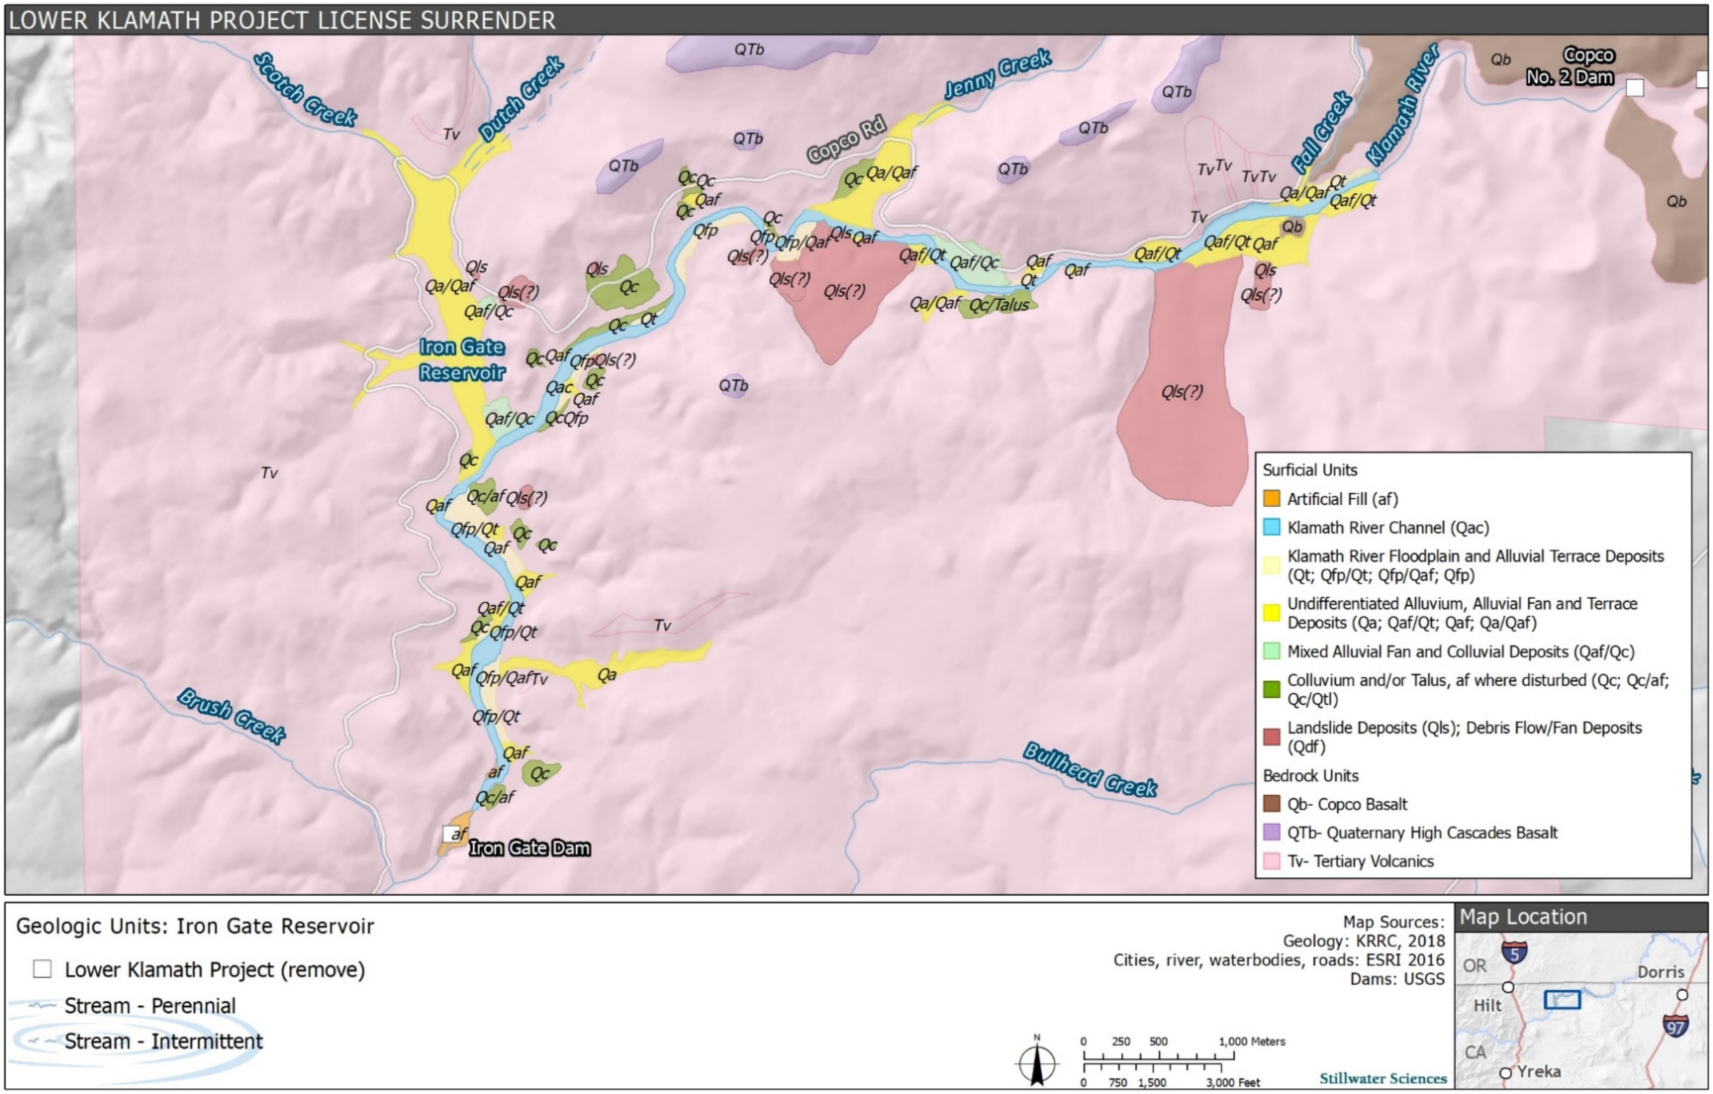

Figure 3.11-4. Surficial geology at Iron Gate Reservoir (Appendix B: *Definite Plan*).

extensive floodplains. Unvegetated point bars at the inside of channel bends, mid-channel bars, and side channel complexes are more prevalent in this reach. Alluvial features are largest in the areas immediately downstream of major tributary confluences and are typically smaller than about 17 acres per mile until after the Scott River confluence at RM 145.1. Terraces have been extensively mined throughout the reach, with tailings piles occurring in some floodplain areas.

From Miller Gulch (RM 163.8) to Horse Creek (near RM 149.7), the river valley broadens and includes terraces and gravel bars. A narrower section from between RM 156.3 and RM 152 is confined by bedrock and by the Kohl Creek alluvial fan. From RM 152 to Horse Creek (RM 149.6), the river valley widens and has been extensively placer mined, resulting in mine tailings and other floodplain disturbance.

From Horse Creek (RM 149.6) to Scott River(RM 145.1), the river valley narrows and is confined by bedrock. Terraces and bars are restricted to the inside of meander bends. Several small tributaries enter in this reach, forming steep alluvial fans at their confluence with the Klamath River. Channel morphology is single thread with few small and unvegetated mid-channel bars and point bars (USBR 2012).

Scott River to China Point (RM 145.1 to 119.8)

The Scott River is a major source of gravel and finer sediment to the Klamath River (Ayres Associates 1999). The prevalence, size, and height of unvegetated gravel bars increases downstream of the Scott River confluence (RM 145.1 to RM 133.8), with discontinuous narrow alluvial terraces forming along the canyon margins. At Seiad Valley (approximately RM 132.8), large alluvial fans from Seiad Creek, Little Grider Creek and Grider Creek form a wider alluvial valley in which terraces are cut on the front edges of the fans and the increased tributary sediment supply results in large bars and riffles. Extensive placer mining has occurred on floodplains and terraces within the Seiad Valley area.

From RM 131.4 to 123.3, the Klamath River flows through a bedrock canyon with unvegetated bars located on the inside of meander bends. Valley terraces and bars with bedrock at shallow depth are prevalent in this reach. From RM 123.3 to China Point (RM 119.8), the canyon narrows as it enters bedrock of the Jurassic Galice Formation. Bedrock benches form along the channel margins. At China Point, an extensive, unvegetated gravel bar lies on the inside of the bend along with a higher alluvial terrace. Tributaries that contribute sediment to the river in this reach include Thompson, Fort Goff, Portuguese, Grider, Walker, O'Neil, and Macks creeks (USBR 2012).

China Point to Trinity River (RM 119.8 to 43.3)

From China Point (RM 119.8) to Deason Flat (RM 106), the channel is narrow with numerous valley terraces that have been extensively mined. Well-developed bars and riffles occur at tributary confluences and meander bends. The lower three miles of this reach contain a greater number of unvegetated bars formed by sediment inputs from Elk and Indian creeks and channel constriction beginning at RM 105.6. Tributaries in this reach deliver large quantities of sediment from landslide sources.

From Deason Flat to Dutch Creek (RM 93), the river flows through a narrow bedrock canyon with low bedrock benches capped by thin gravel deposits. Wider sections interspersed in this reach have small valley terraces that have been extensively mined and have unvegetated gravel bars. This reach also contains notable landslides along the mainstem. Independence and Clear creeks both contribute large amounts of sediment to the Klamath River in this reach.

From Dutch Creek to the Trinity River (RM 43.3), the Klamath River is confined within a narrow bedrock canyon with intermittent alluvial reaches. This reach also includes the wider alluvial valley at Orleans (RM 59). Geomorphic features include valley terraces, alluvial fans, bedrock benches, and alluvial bars. Numerous landslides occur along the Klamath River and interact with the river by delivering sediment and controlling channel position. This reach is the downstream limit of mining on the Klamath River. Tributaries that are major contributors of sediment include Ukonom Creek, Camp Creek, Bluff Creek, and the Salmon River (USBR 2012).

Trinity River to the Pacific Ocean (RM 43.3 to 0)

From the Trinity River (RM 43.3) to Cappell Flat (RM 33), the Klamath River flows through a narrow bedrock canyon with few bars and no floodplain or terraces. The channel is primarily bedrock controlled. Landslides and alluvial fans are less common. The Trinity River is a major source of sediment (Ayres Associates 1999).

From Cappell Flat to Starwein Flat (RM 10), the river flows through a narrow, confined valley with minimal floodplain and terraces. Alternate bars form in straighter reaches and point bars form at meander bends. Split flow channels, mid-channel bars, and riffles commonly form in the vicinity of tributary confluences. Major sediment contributors include Blue, Pecwan, Cappell, Bear, and Tectah creeks.

From Starwein Flat to the mouth (RM10–0), the river transitions into a wide valley with floodplain surfaces and terrace remnants. Well-developed bars of variable height lie along the reach and several large pools and few riffles are present. Turwar Creek is the only major sediment producer in this reach, contributing mostly fine materials to the Klamath River (USBR 2012). The lower seven miles of the Klamath River are relatively narrow and confined, typically between 650 and 800 feet wide, with steeper gradient than in upstream reaches. The channel is up to 1,600 feet wide at large bends and in areas with active erosion and channel migration.

The mouth of the river is characterized by a delta with a large barrier bar parallel to the coastline. Landward of the barrier bar is a shallow estuary about 2,500 feet long by less than 1,000 feet wide. The Klamath River through the estuary is highly dynamic, changing positions during large flood events and transporting most of its suspended sediment load out to the ocean. The relatively small size of the estuary is maintained by ongoing deposition of medium grained sand and silty sand (USBR 2010a).

3.11.2.3 Slope Instability and Mass Wasting

Mass failures and other gravity-driven erosion processes can occur on relatively steep slopes. Such conditions within the soils and geology Area of Analysis exist only within the vicinity of the Klamath River Gorge from the California-Oregon state line to just downstream of Iron Gate Dam. Other areas of potential slope instability include all steep slopes underlain by consolidated volcanic ash (also known as tuff), as well as slopes of deep colluvium or talus that could produce slumps and debris flows. Continuous creep and rapid rockfall occur on and near talus slopes throughout the Klamath River Gorge.

Land surrounding J.C. Boyle Reservoir is generally low gradient and underlain by competent materials (Appendix B: *Definite Plan*). Rock fall from steep talus slopes is prevalent along the Klamath River between J.C. Boyle Dam and Copco No. 1 Reservoir.

Undifferentiated surficial deposits occur around much of Copco No. 1 Reservoir. These deposits include talus and rockfall debris, alluvium and alluvial fans associated with tributary drainages, and alluvial and lacustrine terrace deposits. No large-scale landslides have been identified in either the terrestrial or subaqueous slopes around Copco No. 1 Reservoir (Appendix B: *Definite Plan*), although a large alluvial fan or colluvial deposit on the north side of Copco No. 1 Reservoir may be related to an ancient inactive landslide (PanGEO 2008) (Figure 3.11-3). Wave action at the Copco No. 1 Reservoir shoreline has eroded sand and volcaniclastic tuff beneath diatomite beds, creating up to 10- to 20-ft-high vertical exposures.

PanGEO (2008) identified three possible old landslide-related features that occur on the south rim of Iron Gate Reservoir (Figure 3.11-4). KRRC identified another likely landslide along Copco Road within the peninsula between the east and west arms of Iron Gate Reservoir (Appendix B: *Definite Plan*).

Channel boundaries in the vicinity of the Lower Klamath Project are prominently composed of bedrock, boulders, and cobble, and thus subject to only minor erosion. Bank erosion is therefore not a substantial sediment source.

3.11.2.4 Sediment Load

Sediment is supplied to stream channels through mass wasting (landslides, debris flows, earthflows), sheetwash, gullying, bank failure, fluvial erosion (bank erosion, channel avulsion), dry ravel (loss of cohesion in surface materials), tree throw, wind erosion, animal action (e.g., burrowing), and soil creep. Sediment supply to the Klamath River has been estimated for portions of the Klamath Basin through various methods, including field inventory of sediment sources, interpretation of air photos and other historical information, estimation of reservoir sediment accumulation, and modeling based on empirical sediment delivery rates for specific geomorphic terrains. Primary sources of existing information about sediment delivery to the Klamath Basin include the following:

- Assessment of the quantity and characteristics of sediment stored in Iron Gate, Copco No. 1, and J.C. Boyle reservoirs (GEC 2006, USBR 2012);
- The sediment budget developed by PacifiCorp and submitted to FERC as part of the final license application for the Klamath Hydroelectric Project (FERC No. 2082) (PacifiCorp 2004);
- Sediment source inventories conducted in support of sediment TMDLs in the Scott River, Trinity River, and South Fork Trinity River sub-basins (USEPA 1998, 2001; North Coast Regional Board 2005);
- The Salmon Sub-basin Sediment Analysis (de la Fuente and Haessig 1993);
- Cumulative watershed effects analyses and watershed analyses conducted for federal lands administered by the Forest Service (UDSA Forest Service 2003, 2004, 2005; Elder 2005, 2006); and
- Sediment source inventories conducted on industrial timberlands (Simpson Resource Company 2002).

Existing information on sediment loads delivered to the Klamath River was combined with extrapolated estimates of sediment delivery from data-deficient source areas to derive estimates of cumulative average annual sediment delivery in the Klamath River from Keno Dam (RM 237) to the Pacific Ocean (RM 0) and the proportion of coarse material and fine material within the load (Stillwater Sciences 2010) (Table 3.11-3). Upper Klamath Lake traps most sediment entering the lake, and therefore little sediment is supplied to the Klamath River from the watershed upstream of Keno Dam. The average annual sediment delivery from Keno Dam to Iron Gate Dam was estimated to be approximately 150,000 tons/yr. The Scott River supplies approximately 607,000 tons/yr, the Salmon River 320,000 tons/yr, and the Trinity River 3,300,000 tons/yr. The cumulative average annual sediment delivery from the Klamath River to the ocean was estimated to be 6,237,500 tons/yr. The cumulative average annual delivery of sediment with a particle size greater than 0.063 mm (coarse sediment) was estimated to be 1,970,200 tons/yr. This estimate is within about 20 percent of Willis and Griggs (2003) estimate of average annual coarse sediment flux from the Klamath River to the Pacific Ocean (2,502,200 tons/yr). These estimates are based on various data sources encompassing different time periods and do not account for transfer of sediment to and from storage nor attrition.

Table 3.11-3. Estimated Annual Sediment Delivery to the Klamath River.

Source Area	River Mile	Cumulative delivery[1] (tons/year)		
		Total	≥0.063 mm	≤0.063 mm
Keno Dam to Iron Gate Dam	193.1	151,000	24,160	126,840
Iron Gate Dam to Cottonwood Creek	185.1	160,961	25,754	135,207
Cottonwood Creek	185.1	175,560	30,426	145,135
Cottonwood Creek to Shasta River	179.5	177,715	31,115	146,600
Shasta River	179.5	199,259	38,009	161,250
Shasta River to Beaver Creek	163.4	231,710	48,393	183,316
Beaver Creek	163.4	279,869	63,804	216,065
Beaver Creek to Scott River	145.1	373,073	93,630	279,443
Scott River	145.1	980,393	287,972	692,421
Scott River to Grider Creek	132.1	1,048,860	309,881	738,978
Grider Creek to Indian Creek	108.3	1,099,934	326,225	773,709
Indian Creek	108.3	1,173,246	349,685	823,561
Elk Creek	107.1	1,211,930	362,064	849,866
Clear Creek	100.1	1,253,972	375,517	878,454
Dillon Creek	85.4	1,282,389	384,611	897,778
Indian Creek to Dillon Creek	85.4	1,354,759	407,769	946,990
Dillon Creek to Salmon River	66.3	1,440,282	435,137	1,005,146
Salmon River	66.3	1,760,904	537,736	1,223,169
Salmon River to Camp Creek	57.3	1,785,769	545,693	1,240,077
Camp Creek	57.3	1,923,108	589,641	1,333,467

Source Area	River Mile	Cumulative delivery[1] (tons/year)		
		Total	≥0.063 mm	≤0.063 mm
Camp Creek to Red Cap Creek	52.9	1,946,606	597,160	1,349,446
Red Cap Creek	52.9	2,063,374	634,526	1,428,848
Red Cap Creek to Bluff Creek	49.7	2,079,504	639,687	1,439,816
Bluff Creek	49.7	2,417,974	747,998	1,669,976
Bluff Creek to Trinity River	43.3	2,439,210	754,793	1,684,416
Trinity River	43.3	5,756,544	1,816,340	3,940,204
Blue Creek	16.2	5,859,351	1,849,239	4,010,112
Trinity River to Mouth	0.0	6,237,471	1,970,237	4,267,234

Source: Adapted from Stillwater Sciences 2010.
[1] Cumulative sediment delivery is reported for the downstream endpoint of the corresponding source area identified in the first column. Mass is reported in US short tons and assumes a density of 1.5 tons/yd^3. Above Cottonwood Creek, assumes 16 percent of total load is ≥0.063 mm based on grain size distribution of reservoir sediment (Gathard Engineering Consulting 2006). Below Cottonwood Creek, assumes 10 percent of total load is bedload and 24 percent of suspended load is sand ≥0.063 mm.

The sediment load supplied from the watershed in any given year will vary from the long-term annual average load based on annual hydrologic conditions and other environmental factors (e.g., mass wasting, wildfire, land use) that control sediment supply and transport. Quantifying the potential annual variations around the estimated average annual sediment supply in the entire Klamath River basin is difficult without long-term data sets describing suspended or total sediment load. However, analyzing historical sediment discharge data from nearby locations provides a reasonable indication of the potential variation and trends in annual sediment supply. Janda and Nolan (1979) summarize sediment discharge data from a variety of USGS gaging stations in Northern California, including the Klamath River watershed. The highest annual sediment yield (Water Year [WY] 1974) in the Klamath River at Orleans was three times greater than the period average (WY 1968–1977). The highest annual sediment yield (WY 1964) in the Trinity River at Hoopa was a factor of seven greater than the period average (WY 1957–1977) and a factor of 14 greater than the estimated long-term annual average (Janda and Nolan 1979). The period of record for the Trinity River at Hoopa includes the large flood of 1964, whereas the period of record for the Klamath River at Orleans does not. Using these observed variations in annual sediment discharge as indicators for the expected range of potential variability in annual background sediment loads, the predicted sediment release from removal of dams on the Klamath River is within the typical range of background conditions at Scott River during years with average sediment delivery and as far upstream as Beaver Creek during years with high sediment delivery.

Additional insight is gained by comparing the average annual basin sediment delivery and the anticipated annual sediment load from dam removal with daily suspended sediment loads observed during large floods. The daily suspended sediment load measured in the Klamath River at Orleans exceeded the estimated cumulative average annual basin sediment delivery at the Salmon River confluence (sediment delivery node nearest Orleans) for five days during the period from WY 1968 to WY 1979. The highest daily suspended sediment load in the Klamath River at Orleans during the January 1974 flood (second largest during the 81 year period of record) was greater than the median estimate of total annual sediment load released by dam removal. Suspended sediment flux in the Trinity River at Hoopa from December 22 to 26, 1964 was approximately 25,400,000 tons, nearly eight times the high estimate of total annual sediment release from dam removal. During three of the days during the 1964 flood, the daily suspended sediment flux exceeded the high estimate of total annual sediment release from dam removal. Observations from these gaging records indicate that the predicted amount of sediment released by removal of dams on the Klamath River could be considered equal or less than the background sediment flux over a single day at the Salmon River confluence during large flood events (e.g., the January 1974 flood).

The coarse sediment deficit resulting from sediment trapping in the Lower Klamath Project developments has resulted in coarsening of the channel bed and a reduction in the size and frequency of mobile coarse sediment deposits in a limited downstream channel extent. Because tributaries downstream of Cottonwood Creek supply most of the coarse sediment to the mainstem Klamath River under both unimpaired and current conditions, the effects of reservoir sediment trapping are most apparent in the reach between J.C. Boyle Reservoir and approximately the Scott River. Reduced coarse sediment delivery to this reach has reduced the amount and quality of spawning gravel deposits and disrupted the geomorphic processes that create and maintain aquatic habitats (Buer 1981, PacifiCorp 2004). In response to this condition, the California Department of Water Resources developed (but never implemented) gravel augmentation programs for spawning gravel downstream from Iron Gate Dam (Buer 1981). Per the interim operations of the Klamath Hydroelectric Project HCP (PacifiCorp 2012), PacifiCorp developed and implemented a plan to augment gravel immediately downstream of Iron Gate Dam beginning in 2014 (PacifiCorp 2014). Gravel augmentation occurred immediately downstream of Iron Gate Dam in 2014, 2016, and 2017, with approximately 4,600 cubic yards total placed downstream of the dam as of December 2017 (PacifiCorp 2018). The placed gravel has been moved downstream by high flows (PacifiCorp 2018), although additional details on the extent of downstream movement have not been reported. Appendix F assesses the changes to bedload sediment within the soils and geology Area of Analysis for existing conditions and for the Proposed Project.

USBR (2010b) used reach average hydraulic properties and grain size data from previous studies to estimate the flow magnitude and return period at which sediment mobilization occurs downstream of Iron Gate Dam. The representative particle diameters for all data collected downstream of Iron Gate Dam are given in Figure 3.11-5. The estimates did not include the reach from Iron Gate Dam to Bogus Creek, for which there were no grain size data. USBR (2010b) assumed this reach to be fully armored because reservoir trapping has eliminated coarse sediment supply to the reach during the past 50 years. Flows required to initiate mobilization of the median grain size (D_{50}) in reaches downstream of Bogus Creek are summarized in Figure 3.11-6.

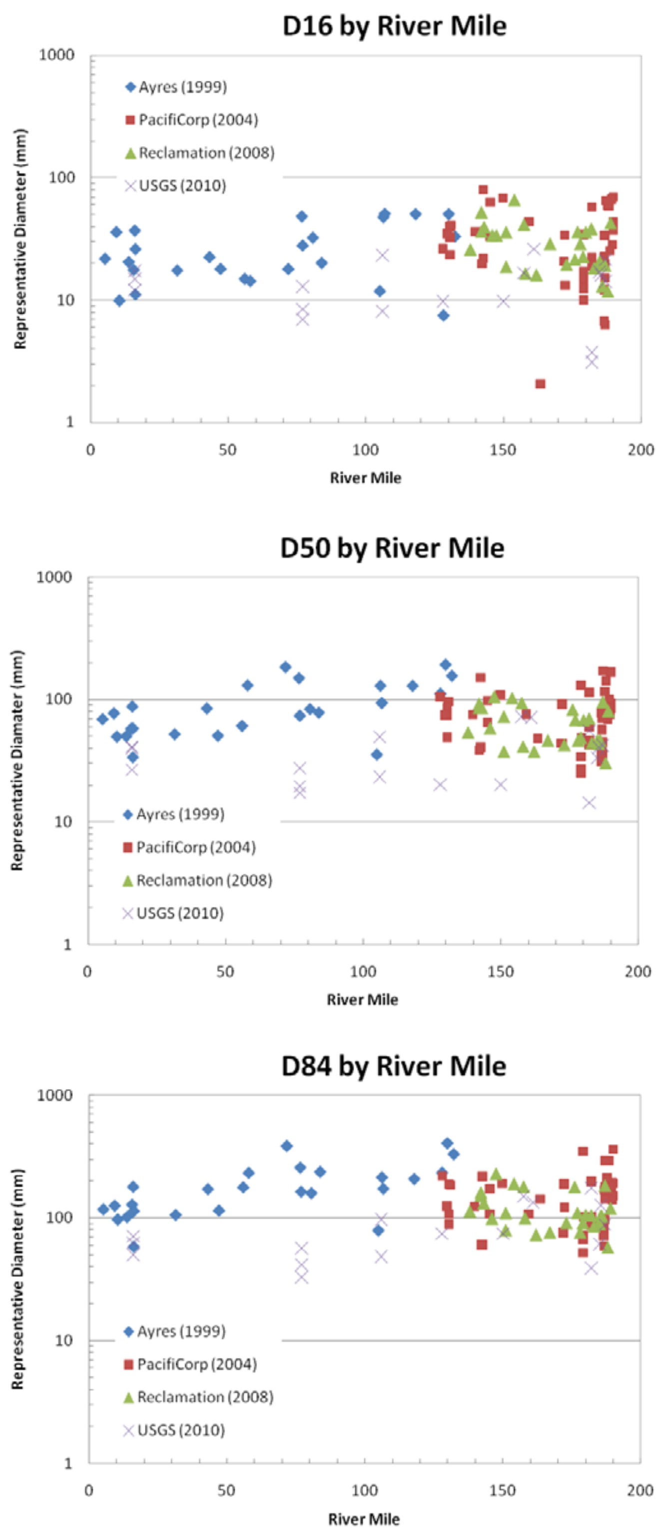

Figure 3.11-5. Particle Size Parameters (D_{16}, D_{50}, and D_{84}) from Pebble Counts of the Klamath River Bed Surface Downstream of Iron Gate Dam (USBR 2012).

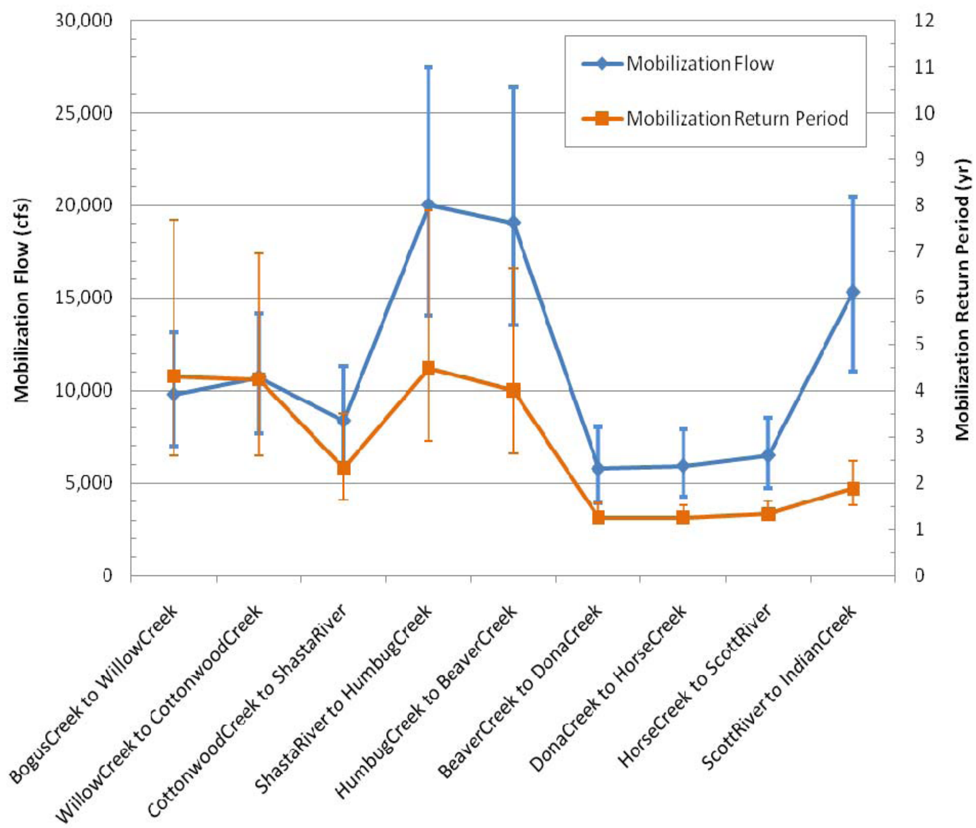

Figure 3.11-6. Flow and Corresponding Return Period at which Bed Mobilization Begins Under Existing Conditions (USBR 2012).

Suspended sediment data were collected by USGS at its gauges on the Shasta River near Yreka from 1957 to 1960, and on the Klamath River at Orleans from 1957 to 1979 and at Klamath from 1974 to 1995. The data show that suspended sediment concentrations commonly exceed 1,000 mg/L at Orleans, even at flows as low as 20,000 cfs (USBR 2012). Suspended sediment concentrations in the Klamath River upstream and downstream of Iron Gate Dam under existing conditions are summarized in Section 3.2.2.3 *Suspended Sediments* and in Appendix C.

The Scott River, mainstem Trinity River, South Fork Trinity River, and Klamath River downstream of the Trinity River confluence at Weitchpec are listed as sediment impaired under Section 303(d) of the federal CWA. Sediment source analyses, TMDL allocations for sediment, and sediment TMDL implementation plans have been completed for the Scott River, Trinity River, and South Fork Trinity River basins. A sediment source analysis and sediment TMDL have not been completed for the Klamath River downstream of the Trinity River confluence. The North Coast Regional Water Quality Control Board (North Coast Regional Board) adopted a regional sediment TMDL implementation policy for the Klamath River downstream of the Trinity River (Resolution R1-2004-0087 on 29 November 2004), and no additional sediment sources analyses are scheduled to be conducted in the basin.

3.11.2.5 Reservoir Sediment Storage and Composition

The four Lower Klamath Project reservoirs currently store approximately 13.15 million cubic yards (yd^3) of sediment (USBR 2012). The volume and weight of sediment stored in each reservoir is given in Table 3.11-4. The distribution of sediment deposits varies within each of the reservoirs. In J.C. Boyle Reservoir, sediment primarily resides in the area nearest to the dam, with thicknesses up to 20 ft (Figure 3.11-7). Both Copco No. 1 and Iron Gate reservoirs have generally even distributions of sediment with thicknesses increasing towards the dams (Figure 3.11-8 and Figure 3.11-9). The maximum thickness of the Copco No. 1 Reservoir sediment is approximately 10 ft. The maximum deposition within the thalweg of Iron Gate Reservoir is around 5 ft, with nearly 10 ft of deposition in the Jenny Creek arm of the reservoir. Copco No. 2 Reservoir inundates a small area extending to the base of Copco No. 1 Dam has no sediment sources, and does not retain appreciable amounts of sediment (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

Table 3.11-4. Sediment stored in Lower Klamath Project reservoirs, Fall 2009.

Reservoir	Total Sediment Volume[1] (yd^3)		Total Sediment Mass[2,3] (tons)	Fine Sediment Mass[2,4] (tons)	Sand Sediment Mass[2,5] (tons)	Percent Fine Sediment by Mass[7]	Percent Sand Sediment by Mass[7]
J.C. Boyle	990,000	+/- 300,000	290,000	190,000	100,000	66 percent	34 percent
Copco No. 1[6]	7,440,000	+/- 1,500,000	1,880,000	1,630,000	260,000	86 percent	14 percent
Iron Gate[6]	4,710,000	+/- 1,300,000	1,430,000	1,210,000	230,000	84 percent	16 percent
Total[6]	13,150,000	+/- 2,000,000	3,600,000	3,020,000[6]	590,000	84 percent	16 percent
Total Copco No. 1 and Iron Gate[6]	12,150,000	+/- 2,000,000	3,320,000	2,830,000[6]	490,000	85 percent	15 percent

Source: Modified from USBR 2012a, as noted in the below footnotes.
1 Uncertainty resulted from interpolation between drill holes and is calculated as a volume with a +/- amount shown in the table (USBR 2012a).
2 Amount of sediment with a diameter greater than 2 millimeters is negligible (< 0.5 percent) for all the reservoirs and within the uncertainty of the sediment estimates. Ton is defined as equal to 2,000 pounds (dry weight).
3 Average dry densities vary between reservoirs and within the reservoir depending upon compaction and grain size distribution. The dry unit weight varies between 44.4 and 16.3 lb/ft^3 (USBR 2012a).
4 Fine sediment is sediment with a diameter less than 0.063 millimeters
5 Sand sediment is sediment with a diameter between 0.063 and 2 millimeters
6 Amounts of sediment (volumes and masses) from individual reservoirs may not equal the total amounts indicated because all volumes and masses taken from USBR (2012a) were rounded to the nearest 10,000 yd^3 (volume) or 10,000 tons, dry weight (mass). Copco No. 2 Reservoir does not retain measurable amounts of sediment and therefore is not included in the estimates of total stored sediment.
7 Percent sediments are calculated from the masses listed in the table and rounded so the percent fine sediment and the percent sand sediment sum to 100 percent.

Sediment in the Lower Klamath Project reservoirs is primarily composed of elastic silt and clay (fine sediment), including silt-size particles of organic material such as algae and diatoms, with lesser amounts of cobble and gravel (coarse sediment) (Table 3.11-5) (USBR 2012). The fine-grained sediment has low cohesion and is erodible (USBR 2010a).

Source: USBR 2010a, 2012.

[1] Clay = 0 to 0.005 mm; Silt and very fine sand = 0.005 to 0.075 mm; Sand = #200 to #4 sieve; Gravel = #4 to 3 inch. Note that while organic material such as algae and diatoms would be associated with the clay and/or silt classes in the reservoir sediments, the standard method used for size separation (ASTM D22) in USBR (2012) would remove a small fraction of these during sample drying at 110ºC.

Key:
yd³: cubic yards
lb/ft: pounds per foot

3.11.3 Significance Criteria

For the Lower Klamath Project EIR, impacts to geology and soils would be considered significant if Proposed Project implementation would result in any of the following:

- Substantial soil erosion from upland areas into the reservoirs or the Klamath River due to project construction activities.
- New or exacerbated mass wasting around the rim of the reservoirs during drawdown.
- Substantial deposition of sediment in the Klamath River channel or Klamath estuary due to erosion of reservoir sediment deposits.
- Long-term removal of access to mineral resources for extraction.
- Exposure of people or structures to adverse effects resulting from rupture of a known earthquake fault, strong seismic ground shaking, volcanic activity, or large-scale slope instability.

For the purposes of this EIR, substantial is defined as "of considerable importance to public health and safety, water quality, and/or physical conditions supporting aquatic resources as these resources pertain to geology and soils." Additional criteria related to geology and soils associated effect to other resources is addressed in Section 3.2 *Water Quality*, Section 3.3 *Aquatic Resources*, and Section 3.6 *Flood Hydrology* of this EIR.

3.11.4 Impacts Analysis Approach

The assessment of the environmental impacts on geology and soils focuses on whether changes to geomorphology and sediment transport resulting from implementation of the Proposed Project would substantially increase erosion or mass wasting, or result in substantial sediment deposition which could adversely affect other associated resources within the soils and geology Area of Analysis. The soils and geology impact analysis uses results from the analyses described below to determine changes in bed elevation, substrate composition, and fine sediment deposition under the Proposed Project. Potential geomorphic changes associated with dam removal activities are described qualitatively.

Bedload transport in the area upstream of the influence of J.C. Boyle Reservoir is not anticipated to be affected by the Proposed Project (i.e., dam removal), is not within California, and is not evaluated further in this document. Link and Keno dams would remain in place and would continue to affect hydrology and sediment transport as occurs under existing conditions.

The following sources were assessed to determine the scope of existing local policies relevant to the Proposed Project:

- Del Norte County General Plan (Mintier & Associates et al. 2003):
  - Soil Resources, Policy 1.D.5
- Humboldt County General Plan for Areas Outside of the Coastal Zone (Humboldt County 2017):
  - Chapter 10.3.4, Policies BR-S8 and BR-S9
  - Chapter 11, Policies WR-P10, WR-P42, WR-P42, WR-S7, WR-IM3, WR-IM32

- Klamath County Comprehensive Plan (Klamath County 2010):
  - Goal 5 (Open Space, Scenic, and Historic Area and Natural Resources), Policy 16
- Siskiyou County General Plan (Siskiyou County 1980):
  - Geologic Hazard, Policies 1, 2, 3, 5, and 6
  - Erosion Hazard, Policy 7

Most of the aforementioned policies (and objectives) are stated in generalized terms, consistent with their overall intent to protect geologic and soil resources. By focusing on the potential for impacts to geologic and soil resources within the Area of Analysis, consideration of the more general local policies listed above is inherently addressed by the specific, individual analyses presented in Section 3.11.5 *[Geology, Soils, and Mineral Resources] Potential Impacts and Mitigation*. The more general local policies are not discussed further.

3.11.4.1 Flows

Flows under the Proposed Project were modeled assuming Klamath River hydrology defined by KBRA operations of the Klamath Irrigation Project (USBR 2012). As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, the KBRA has expired, and hydrology under the Proposed Project would be pursuant to the 2013 BiOp (NMFS and USFWS 2013). As detailed in Section 3.1.6, the 2013 BiOp provides similar flow releases to KBRA, and does not alter the key hydrological factors that drive model results, including timing, frequency, and magnitude of flows released during winter and spring.

3.11.4.2 Suspended Sediment

USBR (2012) analyzed the potential effects of the Proposed Project on suspended sediment concentration (SSC) using output from the One Dimension Version (2.4) of the Sedimentation and River Hydraulics sediment transport model (SRH-1D). SRH-1D provided estimates of daily average SSCs at different points in the river (Huang and Greimann 2010, as summarized in USBR 2012) (see also Appendix E of this EIR). Existing conditions were also simulated using the SRH-1D model, to provide a comparison of what SSCs would be under existing conditions or under the Proposed Project in the years 2020 and 2021. Modeling assumed the Proposed Project occurred within the 48-year period beginning in 1961.

3.11.4.3 Bedload Sediment

USBR (2012) also analyzed potential changes to bedload sediment using output from the SRH-1D model (Huang and Greimann 2010, USBR 2012) (see also Appendix F of this EIR). Short-term (2-year) and long-term (5-, 10-, 25-, 50-year) changes in bedload were evaluated for a range of hydrologic conditions using representative flows taken from historical hydrology. A long-term simulation was not conducted for the Klamath River upstream of Iron Gate Dam under the assumption that short-term bedload sediment conditions (i.e., at the end of 2 years) are representative of long-term bedload sediment conditions (USBR 2012).

3.11.5 Potential Impacts and Mitigation

Potential Impact 3.11-1 Reservoir drawdown could result in changes to geologic hazards, such as seismic or volcanic activity.
As described in Section 3.11.2 *Environmental Setting*, the Lower Klamath Project is within an area that has historically been seismically active. The nearest active fault is approximately five miles from the dams proposed for removal. These faults are reported not to have moved within the past 1.5 million years and, therefore, are considered inactive (Personius et al. 2003). Under the Proposed Project, the four developments within the Lower Klamath Project would be removed as described in Section 2 *Proposed Project*. Sediment currently held behind the dams would be released during the same period. Although reservoir filling can induce seismicity, drawdown of reservoirs of this size is not expected to induce seismicity. Reservoir draining is also not expected to cause volcanic activity due to the distance from volcanic hazards (e.g., Mount Shasta). No new structures would be constructed in the Area of Analysis for geology and soils following removal of the four developments, thus there would be little to no immediate risks from changes to geologic hazards to people and infrastructure.

Significance
No significant impact

Potential Impact 3.11-2 Soil disturbance associated with heavy vehicle use, excavation, and grading could result in erosion during removal activities.
Soil disturbance associated with heavy vehicle use, excavation, and grading could result in erosion during removal activities at Iron Gate and J.C. Boyle reservoirs and could exacerbate existing erosion at Copco No. 1 Reservoir. Prior to demolition, coverage under the General Stormwater National Pollution Discharge Elimination System Permit for Construction Activities in both Oregon and California would be required as per Section 402 of the Clean Water Act. Coverage under this permit requires the development and implementation of an Erosion Control Plan prior to deconstruction that describes BMPs to prevent erosion during demolition activities. These BMPs would be implemented in accordance with the approved Storm Water Pollution Prevention Plan (SWPPP) and Erosion Control Plan (Appendix B: *Definite Plan*). Implementation of these BMPs under the Proposed Project would minimize the potential for erosion and sediment delivery into the reservoir areas.

Significance
No significant impact

Potential Impact 3.11-3 Reservoir drawdown could result in hillslope instability in reservoir rim areas.
The KRRC proposes drawdown of J.C. Boyle, Copco No. 1, and Iron Gate reservoirs would take place between November 1 of dam removal year 1 and March 15 of dam removal year 2 as detailed in the proposed Reservoir Drawdown and Diversion Plan (Appendix B: *Definite Plan*). For all reservoirs, the minimum drawdown rate would be 2 feet per day and the maximum drawdown rate would be 5 feet per day, until drained. Although the new gates at Copco No. 1 and Iron Gate dams would be able to accommodate higher drawdown rates, the maximum drawdown rate of 5 feet per day is recommended by KRRC as a conservative value based upon slope stability analyses conducted for each of the Lower Klamath Project reservoirs.

The area surrounding J.C. Boyle Reservoir is generally low gradient and underlain by competent materials. Review of topographic data and reconnaissance of the reservoir slopes indicate that no landslides occur adjacent to the reservoir. For these reasons, the stability of the J.C. Boyle Reservoir slopes would be unaffected by the reservoir drawdown and there would be no impact due to the Proposed Project.

No large scale landslides have been identified in the terrestrial or subaqueous slopes around Copco No. 1 Reservoir. Diatomaceous deposits along the rim and below the reservoir water level present the greatest potential for slope instability during drawdown (Appendix B: *Definite Plan*). Where the toe of the diatomite deposit lies above the current high lake level, slope response to rapid drawdown is determined by the properties and geometry of the underlying volcanic and volcaniclastic strata. Where the toe of the diatomite deposit lies below the current high lake level, slope response to rapid reservoir drawdown is determined by the properties and thickness of the diatomite deposits and the underlying material. Based on the low diatomite permeability, the proposed drawdown rate (2 to 5 feet per day) would have minimal effect on its stability. KRRC is therefore not proposing to limit the drawdown rate of Copco No. 1 Reservoir.

The geologic assessment and slope stability analysis conducted by KRRC (Appendix B: *Definite Plan*) indicated that certain segments along the Copco No. 1 Reservoir rim have a potential for slope failure that could impact existing roads and/or private property (Figure 3.11-10). These areas include approximately 3,700 linear feet of slopes along Copco Road and approximately 2,800 linear feet of slope adjacent to private property (Appendix B: *Definite Plan*). Up to eight parcels in these areas have existing habitable structures that could potentially be impacted. KRRC has proposed to complete additional field geologic investigation and laboratory testing of material properties to better understand the potential for slope instability in these areas.

As part of the Proposed Project, KRRC would consider the following actions to offset potential impacts in reservoir rim areas where there is a high probability of slope failure (Appendix B: *Definite Plan*):

1. For segments along Copco Road:
    a. Re-align road segment away from rim slope
    b. Engineer structural slope improvements (e.g., drilled shafts or other structural elements that could be installed to resist slope movement)
2. For segments adjacent to property or structure:
    a. Move structure or purchase property
    b. Engineer structural slope improvements (e.g., drilled shafts or other structural elements that could be installed to resist slope movement)

While the proposed actions is designed to reduce the potential for new or exacerbated mass wasting around the rim of the reservoirs associated with drawdown, the proposed actions do not explicitly address potential impacts resulting from hillslope instability outside of those areas currently identified as having a high probability of slope failure or commit KRRC to implementation of their aforementioned proposed actions. Therefore, the impact of the project on hillslope instability in reservoir rim areas would be significant.

Implementation of Mitigation Measure GEO-1 would reduce the impact of slope failure in reservoir areas to less than significant. If instability of these deposits exposes cultural resources, then the impact may be significant and mitigation may be required (see Section 3.12.5 *[Historical Resources and Tribal Cultural Resources] Potential Impacts and Mitigation*).

The extent and morphology of bedrock outcrops and general lack of surficial deposits around Iron Gate Reservoir suggest stable reservoir slopes under rapid drawdown conditions (Appendix B: *Definite Plan*). There may be potential for drawdown to induce block sliding where hard, strong volcanic flow rocks are underlain by saturated tuffaceous beds and bedding dips into the valley (PanGEO 2008). Hammond (1983) reports several low to moderate dip angles of volcaniclastic beds into the valley, but there is no evidence of previous slope instability at these locations. Historical aerial photographs indicate that the three possible old landslide-related features that occur on the south rim of Iron Gate Reservoir have been stable and unaffected by historical reservoir drawdowns and have a low risk of instability during future drawdown (Appendix B: *Definite Plan*). Shallower slides are likely to occur in the shallow surficial deposits around the reservoir rim and on the reservoir slopes that are currently below the reservoir surface (Appendix B: *Definite Plan*). Small, shallow soil failures in the more deeply weathered volcaniclastic beds and in colluvial deposits present a minor hazard to Copco Road where the road is immediately adjacent to the shore (Appendix B: *Definite Plan*). These slope failures are likely to be shallow and local and therefore, if they were to occur, would constitute a less than significant impact.

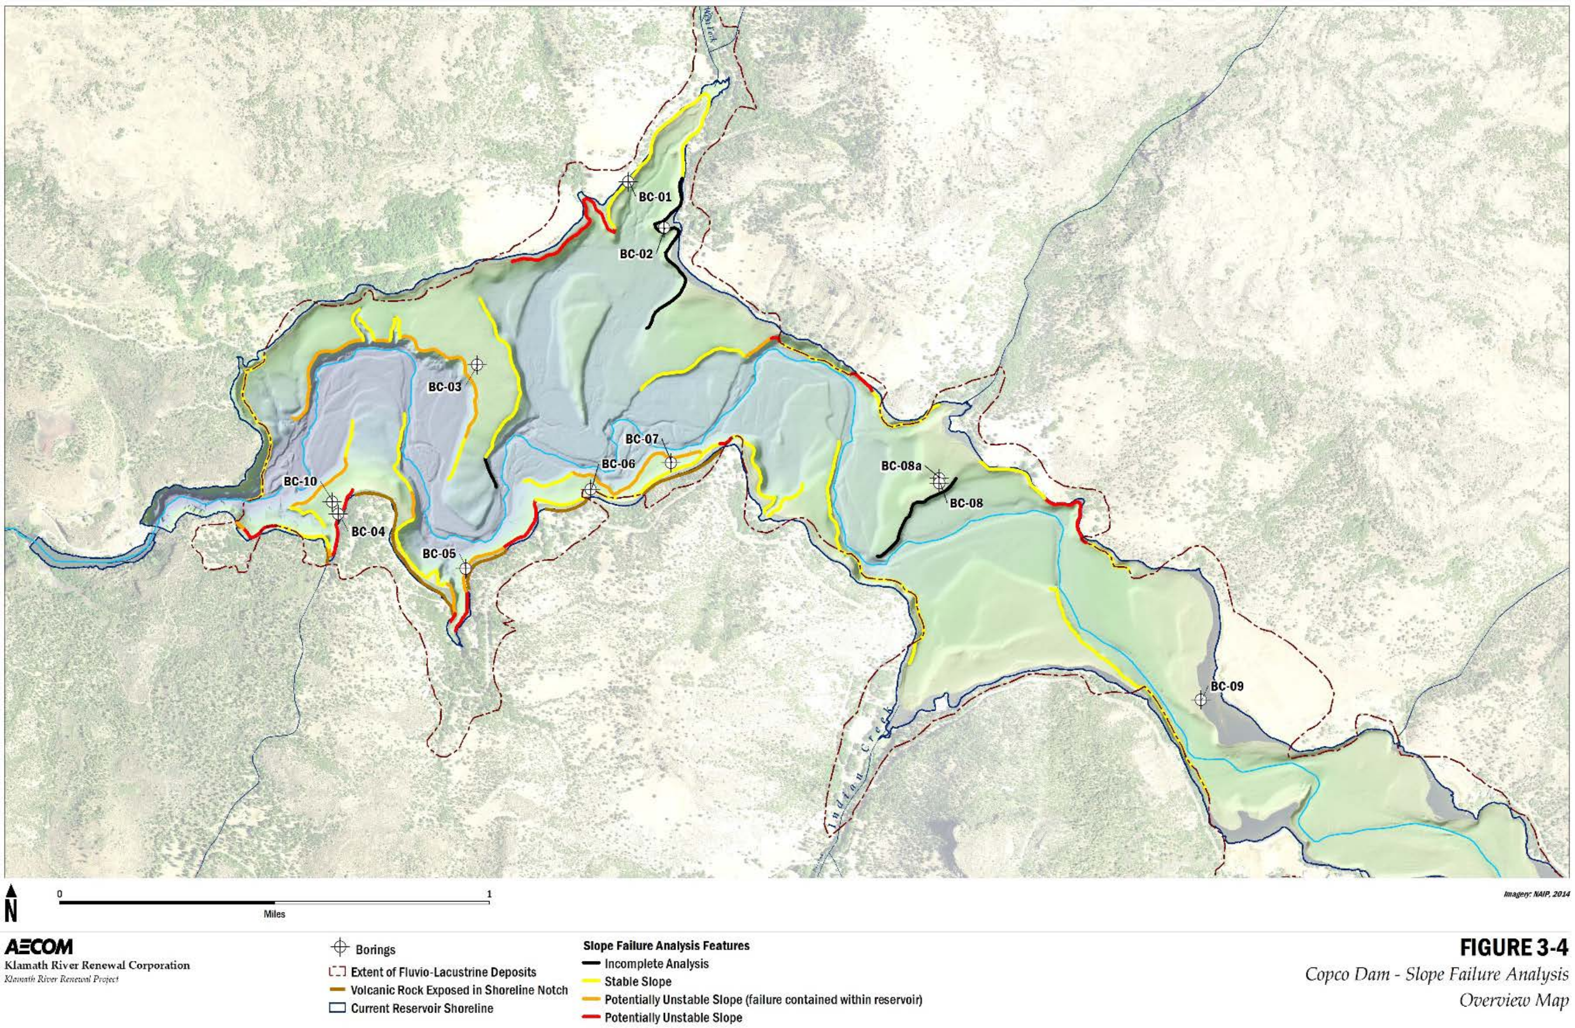

Figure 3.11-10. Results of slope failure analysis at Copco No. 1 Reservoir (Appendix B: *Definite Plan*).

Mitigation Measure GEO-1 – Slope Stabilization.
KRRC will visually monitor large, potentially unstable areas within the Copco No. 1 Reservoir footprint for the duration of reservoir drawdown and for two weeks following drawdown. Depending on the location, monitoring may involve tribal monitors (see also Mitigation Measures TCR-1, TCR-2, and TCR-3). If slope failure is observed, an exclusion zone will be established around the unstable area and the KRRC will monitor the unstable area.

Following drawdown activities, and once the areas are safe to inspect, the KRRC shall inspect any slope failures and implement slope stabilization measures, as appropriate. For any large slope failure that occurs during drawdown or the year following drawdown, KRRC will offset potential impacts by implementing the following actions:

1. Move affected structures or purchase affected property,
2. Re-align affected road segments,
3. Engineer structural slope improvements (e.g., drilled shafts or other structural elements that could be installed to resist slope movement), and
4. Revegetate affected areas.

Significance
No significant impact at Iron Gate Reservoir and J.C. Boyle Reservoir

No significant impact with mitigation for diatomaceous deposits along the rim and below the Copco No. 1 Reservoir water level

Potential Impact 3.11-4 Reservoir drawdown could result in short-term instability of embankments at the earthen dams (Iron Gate and J.C. Boyle).
Analyses of embankment stability during drawdown at the earthen dams (i.e., Iron Gate Dam and J.C. Boyle Dam) indicate factors of safety greater than the selected minimum factor of safety of 1.3. The analyses indicate that the proposed reservoir drawdown rates would not result in substantial embankment instability (Appendix B: *Definite Plan*). While there is a potential for small, shallow slumping along the upstream embankment slopes due to the potential strength loss of surficial materials during drawdown, this degree of slumping would not threaten the structural integrity of the embankments or deliver a substantial amount of sediment. The impact would be a less than significant in the short term (less than two years following dam removal). Copco No. 1 and No. 2 dams are concrete structures that would be unaffected by reservoir drawdown rate.

Significance
No significant impact

Potential Impact 3.11-5 Reservoir drawdown could result in substantial short-term sediment deposition in the Klamath River downstream of Iron Gate Dam due to erosion of reservoir sediment deposits and a long-term change in sediment supply and transport due to dam removal.
Based on average annual sediment deposition rates, approximately 15.1 million yd3 (4.16 million tons) of sediment would be deposited behind the dams by 2020 (USBR 2012) (Table 3.11-6). Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual

sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable to the Proposed Project.

Table 3.11-6. Estimated Amount of Sediment in the Lower Klamath Project Reservoirs in 2020 (Source: USBR 2012).

Reservoir	Estimated 2020 Total			
	Total Volume (yd^3)	Total Sediment (tons)[1]	Fine Sediment[2] (tons)	Sand[3] (tons)
J.C. Boyle	1,190,000	340,000	220,000	120,000
Copco No. 1	8,250,000	2,090,000	1,800,000	290,000
Iron Gate	5,690,000	1,730,000	1,460,000	280,000
Total[4]	**15,130,000**	**4,160,000**	**3,480,000**	**680,000**
Total Copco No. 1 and Iron Gate	**13,940,000**	**3,820,000**	**3,260,000**	**560,000**

[1] Ton is defined as equal to 2,000 pounds (dry weight).
[2] Fine sediment is sediment with a diameter less than 0.063 millimeters.
[3] Sand is sediment with a diameter between 0.063 and 2 millimeters.
[4] Sediment volumes and weights from individual reservoirs from USBR (2012) were rounded to the nearest 10,000th unit. Copco No. 2 Reservoir does not retain measurable amounts of sediment and therefore is not included in the estimates of total stored sediment.

Reservoir sediment consists primarily of silts and clays that would be easily eroded during drawdown. Approximately 36 to 57 percent of the total sediment stored in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs by 2021 would be eroded and transported downstream during the drawdown period and the year following dam removal (i.e., short-term), or an estimated 5.4 to 8.6 million yd^3 (1.2 to 2.3 million tons) (Table 3.11-7, Figure 3.11-11). Approximately 15 percent of this sediment eroded from reservoir areas during the first year following dam removal would be transported farther downstream as bedload.

The rate of reservoir drawdown would affect the amount of erosion of the sediment deposit. A faster drawdown rate would reduce the time of interaction between the flow and reservoir sediment deposits, thus reducing the overall amount of sediment erosion, whereas a slower drawdown rate would increase the time of interaction between the flow and reservoir sediment deposits, thus increasing the overall amount of sediment erosion. It is expected that increasing the previously modeled maximum drawdown rate of 2.25 to 3 feet per day (USBR 2012b) to the Proposed Project maximum drawdown rate of 5 feet per day (Appendix B: *Definite Plan – Appendix P*) would slightly decrease the total amount of sediment erosion that occurs during drawdown. The previously modeled maximum drawdown rate would result in erosion of 36 to 57 percent of the reservoir sediment deposits (Table 2.7-11). Increasing the drawdown rate to 5 feet per day would most likely result in less erosion than previously modeled.

Erosion and transport of sediment deposits within Copco No. 1 and Iron Gate reservoirs during drawdown would be assisted by using barge-mounted pressure sprayers to jet water onto newly exposed reservoir sediment deposits as the water level drops (a process referred to as sediment jetting). Sediment jetting would maximize erosion of reservoir sediment deposits in historical floodplain areas (especially the historical two-year floodplain) during drawdown and minimize the potential for future erosion of reservoir sediment deposits after the drawdown period. Additionally, removal of reservoir sediment deposits with sediment jetting would promote riparian bank and floodplain connectivity by increasing river inundation on the historical floodplain during high flow events and minimize manual excavation and grading of sediments from proposed restoration sites after completing drawdown. Sediment jetting would be focused in the six areas where restoration actions are proposed within the Copco No. 1 Reservoir footprint (Figure 2.7-9) and the three areas where restoration actions are proposed within the Iron Gate Reservoir footprint (Figure 2.7-10).

While the anticipated amount of sediment that will be eroded varies by reservoir, approximately 36 to 57 percent (5.4 to 8.6 million yd^3 [1.2 to 2.3 million tons]) of the total 2020 reservoir sediment volume is expected to erode and be transported downstream during the drawdown period (Table 2.7-1). Large quantities of sediment would remain in place after dam removal in each of the former reservoirs, primarily in areas above the active channel. The remaining sediments would consolidate (dry out and decrease in thickness). Studies of the existing sediments in J.C. Boyle Reservoir show an anticipated change in sediment depth of up to 61 percent of original depth (USBR 2012a). A higher degree of shrinkage of the sediment layers is expected in Copco No. 1 and Iron Gate reservoirs due to the increased organic matter content in these sediment deposits.

The range in the estimated volume of sediment eroded from each reservoir is primarily dependent upon whether the prevailing hydrology during reservoir drawdown corresponds to a dry hydrologic year or a wet hydrologic year. The majority of the erosion would occur during the reservoir drawdown process and would be a combination of direct erosion of sediment by moving water, slumping of the fine sediment along the reservoir sides toward the river, and sediment jetting of some areas of reservoir-deposited sediments during drawdown. In a dry hydrologic year, reservoir pool levels can be drawn down steadily and relatively quickly, resulting in a shorter period of interaction between the flow and sediment deposits, and thus less overall sediment erosion. In a wet hydrologic year, the reservoir pool may experience cycles of drawdown followed by periods of refilling during high flow events, resulting in longer period of interaction between the flow and the sediment deposits, and thus more overall sediment erosion.

Table 3.11-7. Estimated Amount of Sediment Erodible with Dam Removal (Source: USBR 2012).

Reservoir	Percent Erosion[1]		Fine Sediment Erosion		Sand Erosion	
	Minimum Erosion (percent)	Maximum Erosion (percent)	Minimum (tons)	Maximum (tons)	Minimum (tons)	Maximum (tons)
J.C. Boyle	27	51	60,000	110,000	30,000	60,000
Copco No. 1	45	76	820,000	1,370,000	130,000	220,000
Iron Gate	24	32	350,000	460,000	70,000	90,000
Total	36	57	1,230,000	1,950,000	230,000	370,000
Total Copco No. 1 and Iron Gate	36	56	1,170,000	1,830,000	200,000	300,000

1 The erosion rates are based on hydrologic conditions recorded for the March to June flow volume at Keno gage on the Klamath River from water year 2001(90 percent exceedance) and 1984 (10 percent exceedance). Erosion would primarily occur during the drawdown period. Additional erosion and sediment transport could occur in the following year that would be indistinguishable from the background sediment regime.

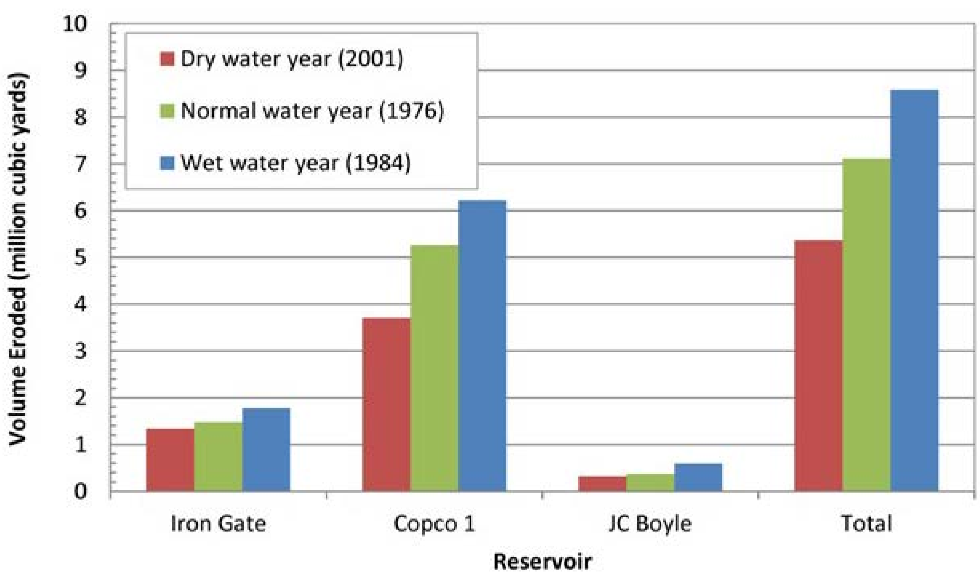

Figure 3.11-11. Volume of Sediment Eroded from Reservoirs in the Hydroelectric Reach During 2020 Drawdown Beginning in January (USBR 2012).

Model simulations indicate that 43 percent to 64 percent of the sediment stored in the reservoirs would remain in place following the year after dam removal (i.e., long-term), primarily as a relatively thin wedge in areas above the active channel. The remaining sediment would consolidate (i.e., harden, dry, shrink in volume, and decrease in thickness) following reservoir drawdown (USBR 2012). Studies of the existing sediment in Lower Klamath Project reservoirs indicate an anticipated change in sediment thickness in J.C. Boyle Reservoir of up to 61 percent due to consolidation (USBR 2012). A higher degree of shrinkage of the sediment layers is expected for Copco No. 1 and Iron Gate reservoirs due to the increased organic matter content in the sediment deposits contained within these reservoirs. Sediment deposits remaining in the reservoir footprints following reservoir drawdown would erode slowly, or potentially not at all due to consolidation. Secondary erosion of residual reservoir deposits would be affected by increases in shear strength with desiccation, the prevalence of cracks, and disintegration in response to wetting and drying cycles. The prevalence of cracking would encourage gully erosion as lower infiltration rates intensify surface runoff and concentrate flow in cracks. Gullies would incise and widen with time. The availability of coarse sediment (i.e., sand and larger) to abrade fine-grained deposits may be an important factor encouraging gully erosion. Gullies closer to coarse sediment sources (e.g., near the steep hillslopes at Copco No. 1 and Iron Gate reservoirs) may have more effective secondary erosion than areas lacking those sediment sources (e.g., Upstream Reach of J.C. Boyle Reservoir) (Appendix B: *Definite Plan*). As riverine conditions return within the reservoir footprints, any additional erosion and transport of reservoir sediment farther downstream would be indistinguishable from background rates within the watershed. Overall, this degree of long-term erosion would be a less than significant impact. Future construction activities (e.g., access road construction, recreation facilities) would need to consider the potential instability and erodibility of sediment remaining within the reservoir footprints.

Anticipated erosion volume due to dam removal into the context of annual basin-wide sediment discharge are estimated to average an annual total sediment supply from the Klamath River to the Pacific Ocean of approximately 5.8 million tons (4 million tons/yr of fine sediment and 1.8 million tons/yr of sand and larger sediment (Stillwater Sciences (2010). Farnsworth and Warrick (2007) estimate that the average annual silt and clay discharge is 1.2 million tons/yr. The considerable uncertainty in the annual average sediment load estimates is related to the different approaches to estimation, the large variation in the measurement of SSCs, the lack of a unique relationship between flow and SSC, and the large annual variation in sediment loads. In dry years the supply of sediment to the ocean could be less than 1 million tons/yr (Figure 3.11-12). Given these estimates, it is expected that the amount of sediment released during the year of drawdown and dam removal would be similar to that transported by the Klamath River to the Pacific Ocean in a year with average flow, much less than that transported by the Klamath River in a wet year, and greater than that transported by the Klamath River in a dry year.

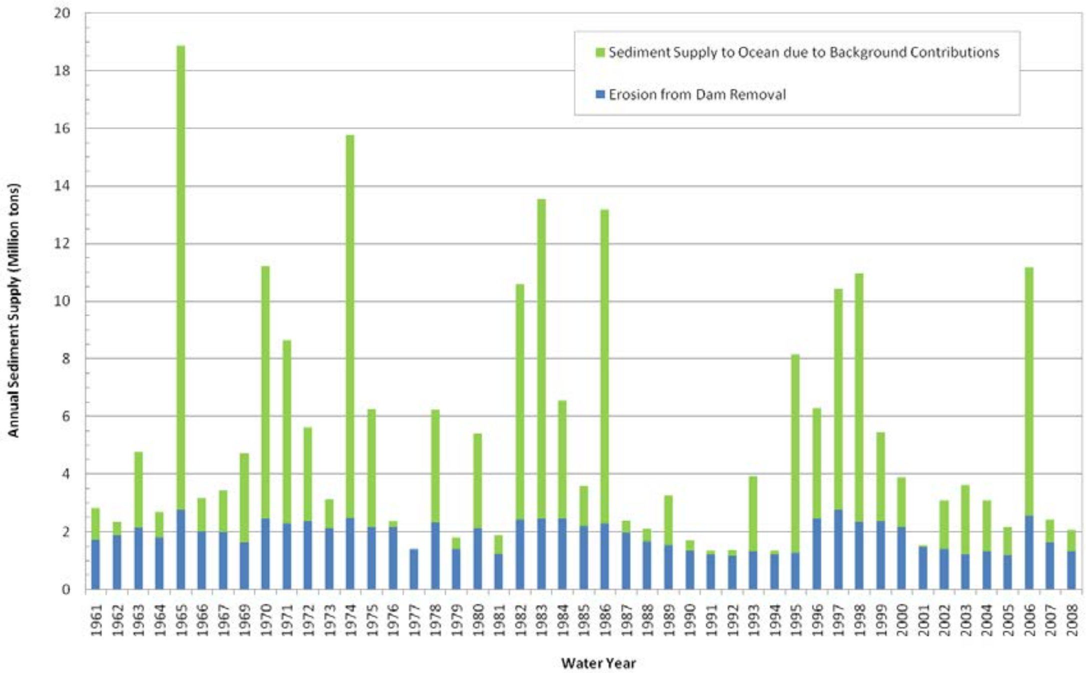

Figure 3.11-12. Annual predicted sediment delivery to the Pacific Ocean under the Proposed Project and existing conditions ("Background Contributions") by water year. Model results are only valid for the year of dam removal, and no significant increase in sediment loads is predicted in years following dam removal (Source: USBR 2012).

Channel Response in the Hydroelectric Reach

SRH-1D modeling results indicate channel bed elevations would decrease and median channel substrate size would increase within the reservoir reaches during drawdown (January to May of the drawdown year) (Figure 3.11-13, Figure 3.11-14). The proportion of fine sediment would decrease to near zero within two months after drawdown; the proportion of sand would initially increase to 30 to 50 percent then decrease to 10 to 25 percent; the proportion of gravel would change (mostly increase) to 20 to 35 percent; and the proportion of cobble would increase to 50 to 70 percent. The estimated changes depend on the reservoir and simulation water year type (i.e., wet, median, or dry). These changes would stabilize within six months as the bed within the historical river channel reaches pre-dam elevations (USBR 2012). After dam removal, channels currently inundated by reservoirs would likely vary from narrow, single-threaded to wide and sinuous with the potential to form complex features, such as meander cut-offs and vegetated islands (USBR 2012).

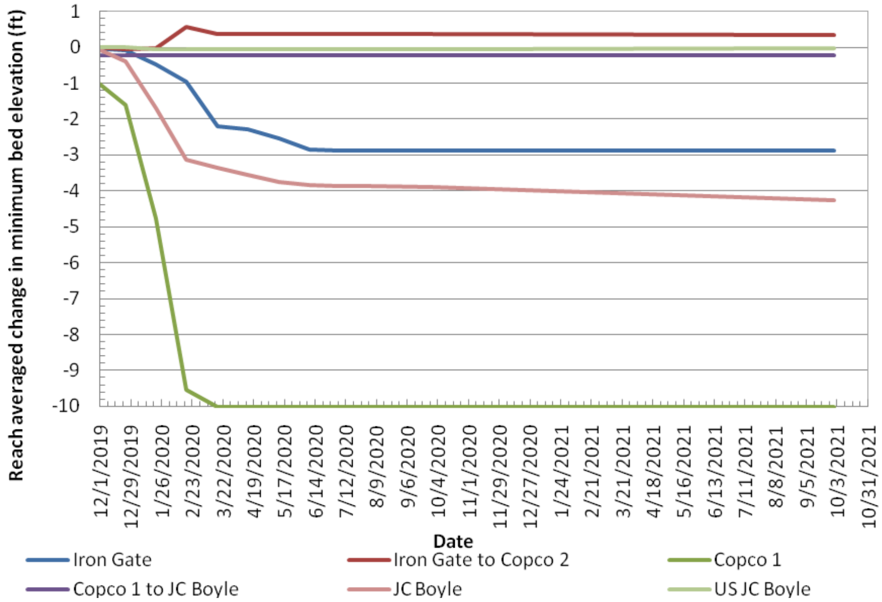

Figure 3.11-13. Reach-Averaged Erosion in the Hydroelectric Reach during a Representative Wet Water Year (USBR 2012).

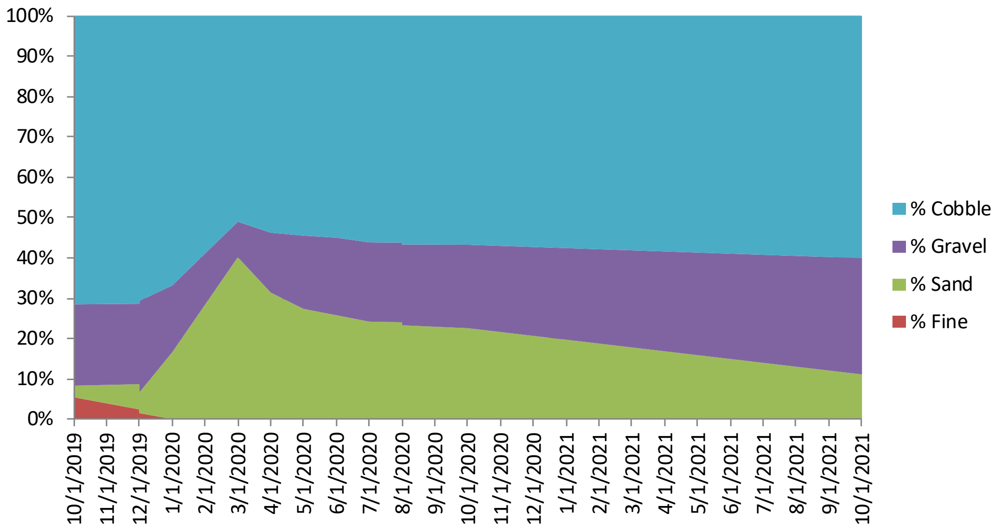

Figure 3.11-14. Simulated Bed Composition from Copco No. 2 to Iron Gate Reservoirs during Two Successive Representative Dry Water Years During and After Drawdown (Based on simulation results provided by USBR, March 2012).

The river reaches upstream of J.C. Boyle Reservoir and from Copco No. 1 Reservoir to J.C. Boyle Dam would experience little change in bed composition or median substrate size during drawdown (USBR 2012). Currently, these reaches are predominantly cobble (90 percent) with small fractions of gravel and sand. Modeling of the Copco No. 2 Dam to Iron Gate Reservoir reach shows decreases in the combined proportion of sand and fines, with the dry simulations showing decreases to approximately 35 percent of sand and fines two years after drawdown.

Channel Response in the Klamath River Downstream of Iron Gate Dam

The short-term (i.e., two years following dam removal) effects of the Proposed Project on dam-released sediment and sediment resupply would likely extend from Iron Gate Dam to approximately Cottonwood Creek (USBR 2012). Because approximately 85 percent of the sediment stored within the reservoirs is fine (silt and clay), most sediment eroded from the reservoirs would be fine. Fine sediment transport rates would increase downstream of Iron Gate Dam during the short-term, but a large portion of this fine sediment would be transported to the ocean as suspended sediment shortly after being eroded (Stillwater Sciences 2010, USBR 2012). Coarse sediment (i.e., sand and larger) transport would occur more slowly depending on the frequency and magnitude of mobilization flows and attenuation by channel storage.

Short-term (2-year) SRH-1D model simulations indicate up to about 0.9 feet of reach-averaged deposition between Bogus Creek and Willow Creek (RM 188.0), and up to about 0.4 feet of deposition from Willow Creek to Cottonwood Creek (USBR 2012) (Figure 3.11-15). Model simulations indicate that reaches located farther downstream will change little (< 0.5 ft). Eight miles of the Klamath River mainstem channel could potentially be affected by sediment release and resupply, representing 4 percent of the total mainstem channel length downstream of Iron Gate Dam (190 miles).

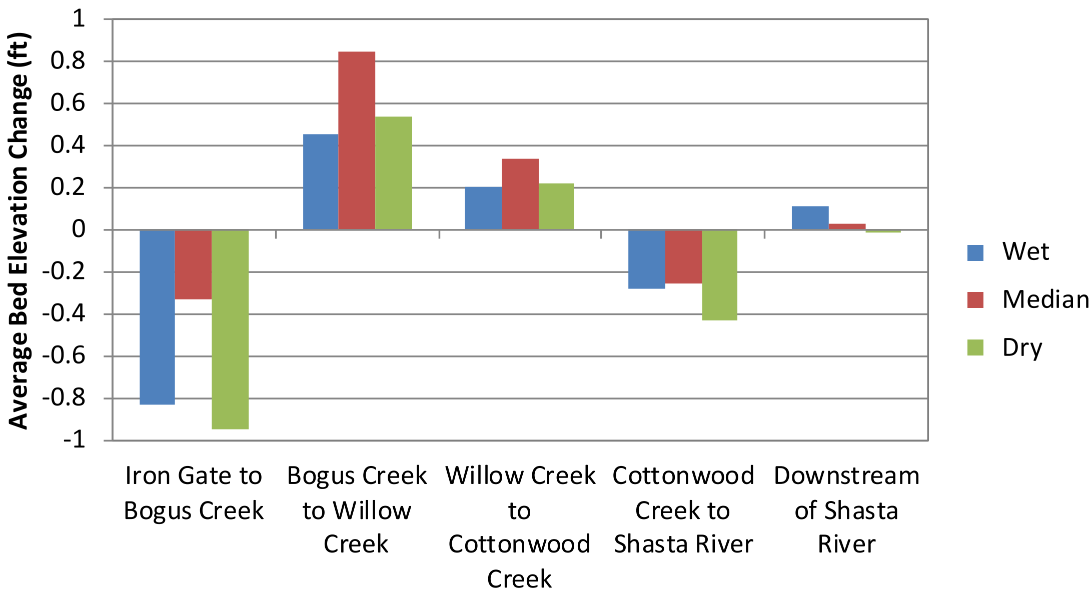

Figure 3.11-15. Reach Averaged Bed Elevation Change for Two Successive Wet, Median, or Dry Water Years Following Reservoir Drawdown (Based on simulation results provided by USBR, March 2012).

It is not possible to accurately predict short-term deposition patterns in the mainstem river channel at a fine spatial scale (e.g., individual pools or other slack-water areas) under the Proposed Project using 1D sediment transport models. However, the general short-term sediment transport and depositional patterns can be reasonably surmised based on patterns observed in the Klamath River and other analogous river channels. Dam-released sediment may temporarily deposit in pools and other slack water areas (e.g., eddies) and at tributary confluences in the reach from Iron Gate Dam to Cottonwood Creek. These transient sediment deposits would be highly erodible during subsequent flow events, leading to a short residence time (i.e., likely one year or less except during dry years). KRRC proposes a channel survey to document pool depths in the Klamath River from Iron Gate Dam to Humbug Creek prior to dam removal, and every year after dam removal for the first 3 years

In the short term, SRH-1D model simulations indicate that dam-released sediment and sediment resupply under the Proposed Project would increase the proportion of sand in the channel bed and decrease median bed substrate size (Figure 3.11-16 and Figure 3.11-17) (USBR 2012). Under wet, median and dry simulations, sand within the bed in the reach from Iron Gate to Bogus Creek would increase to 30 to 35 percent by March to June of the drawdown year, gradually decreasing to 10 to 20 percent by September two years later. Median substrate size (D_{50}) would fluctuate slightly before stabilizing to approximately existing conditions with a D_{50} of 100 mm (Appendix F). Short-term model simulations also indicate a decrease in median grain size (from an initial value of approximately 80 mm down to 40 to 65 mm) and an increase in the proportion of sand (up to 40 percent) in the reach from Bogus Creek to Willow Creek, and an increase in the proportion of sand (up to 35 percent) and a decrease in median grain size (from an initial value of approximately 65 mm down to 38 to 45 mm) in the reach from Willow Creek to Cottonwood Creek (Appendix F).

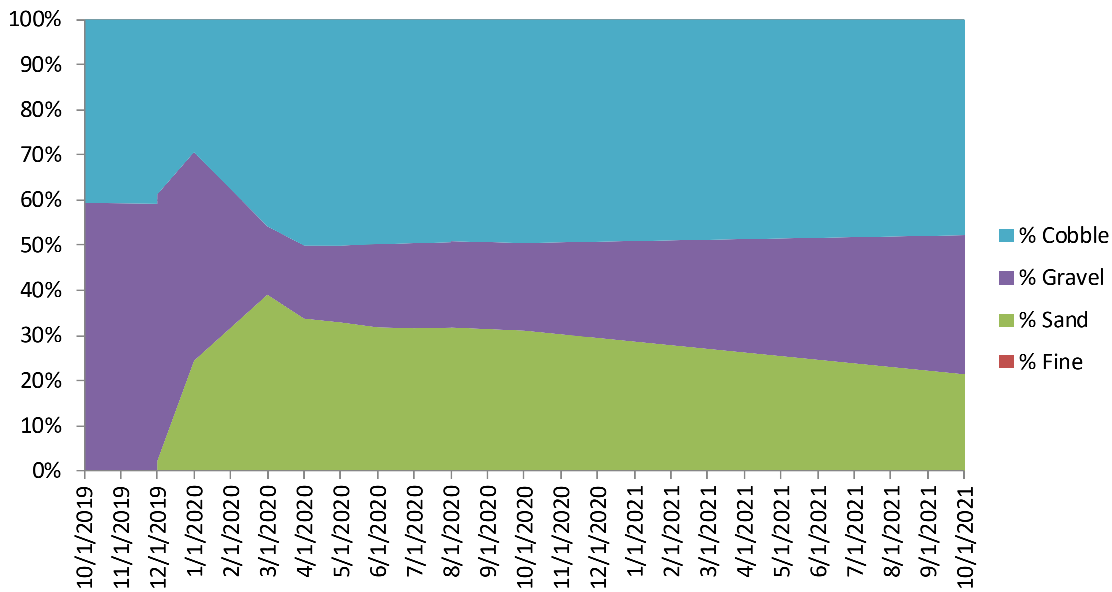

Figure 3.11-16. Simulated Bed Composition from Iron Gate Dam to Bogus Creek during Two Successive Dry Water Years Following Reservoir Drawdown (Based on simulation results provided by USBR, March 2012).

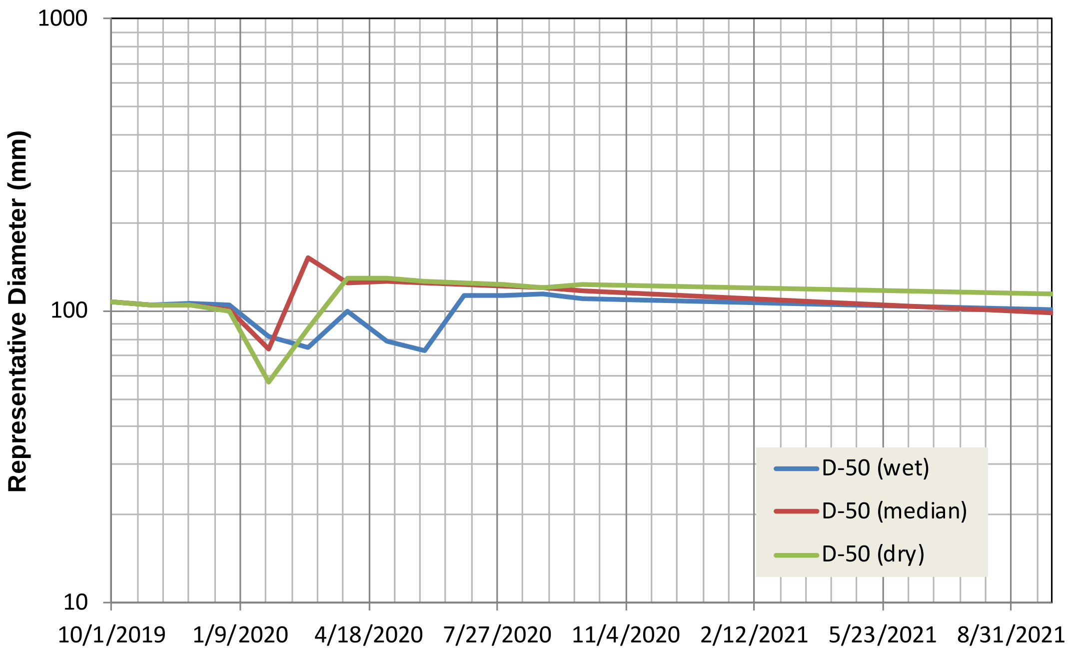

Figure 3.11-17. Simulated D50 (mm) from Iron Gate Dam to Bogus Creek during Successive Wet, Median, and Dry Water Years Following Reservoir Drawdown (Based on simulation results provided by USBR, March 2012).

In general, the Proposed Project would have the beneficial long-term (i.e., 50 years) effects of increasing sediment supply and transport and creating a more dynamic and mobile bed downstream of Iron Gate Dam. During the 50 years following the initial release of sediment by the Proposed Project, bed elevations would adjust to a new equilibrium in response to sediment supplied by upstream tributaries within the Hydroelectric Reach. While 0.8 to 1.7 feet of aggradation could result from the Proposed Project between Iron Gate Dam and Cottonwood Creek (i.e., simulations based on a median start year), no long-term sediment deposition is expected downstream of Cottonwood Creek (USBR 2012). Long-term (5 to 50 year) simulations indicate that after 5 years, the Proposed Project would increase the proportion of sand in the bed to 5 to 22 percent and decrease the D_{50} to approximately 50 to 55 mm (Appendix F). These changes would stabilize and continue through to Year 50. Fining of the bed surface would reduce the flow required to mobilize the channel bed from approximately 10,000 cfs to 6,000 cfs in the reach from Bogus Creek to Willow Creek (RM 192.6 to RM 188) and from 11,000 cfs to 6,000 cfs in the reach from Willow Creek to Cottonwood Creek (RM 188 to RM 185.1) (USBR 2012). The corresponding return period for a bed-mobilizing flow in the reach from Iron Gate Dam to Cottonwood Creek (USGS RM 193.1 to RM 185.1) would decrease from 4 years to approximately 2 years.

Channel Response in the Klamath River Estuary

The majority of the fine sediment (silts, clays, and organics) released by dam removal would be transported to the ocean. The fine material is unlikely to deposit in significant quantities in the estuary, evidenced by the lack of a large sandbar within the mouth of the Klamath River under existing conditions. There are currently high concentrations of silt and clay transported through the estuary, and sediment sampling by USBR (2010) documented the absence of fine material in the estuary except in the backwater and vegetated areas. If dam removal occurs during a low flow year, there may be relatively small volumes of sediment deposited in these areas.

Pacific Ocean Nearshore Environment

Because of the complexities of the transport processes, the area and depth of fine sediment deposition in the Pacific Ocean nearshore environment resulting from the Proposed Project cannot be precisely predicted. A considerable amount of fine sediment is anticipated to initially deposit on the seafloor shoreward of the 196-feet isobath along the coast, with greater quantities depositing in close proximity to the mouth of the Klamath River. After fine sediment loading onto the continental shelf during river floods, fluid-mud gravity flows typically transport fine sediment offshore. Summer coastal upwelling naturally re-suspends some of the river sediments that are transported to the nearshore environment and deposited on the continental shelf, especially those from the previous winter (Ryan et al. 2005; Chase et al. 2007; see Potential Impact 3.2-7). Along with the background river sediments transported annually by the Klamath River and deposited on the continental shelf, a portion of the sediment deposited on the continental shelf following dam removal would also have the potential to be re-suspended during the summer coastal upwelling. Any sedimentation of the nearshore seafloor resulting from the Proposed Project would likely be transported farther offshore to the mid-shelf and into deeper water depths off-shelf. The short-term (less than two years following dam removal) and long-term (2–50 years following dam removal) effects of the Proposed Project on sediment delivery to the Pacific Ocean would be less-than-significant, given the relatively small amount of total sediment input from reservoir sediment release in comparison to the total annual naturally occurring sediment inputs to the nearshore environment.

Bedload sediment effects related to coarse sediment released by the Proposed Project or sediment re-supply likely would not extend downstream of the Cottonwood Creek confluence (RM 185.1). Therefore, there would be no bedload-related effects in the Klamath River Estuary or Pacific Ocean nearshore environment under the Proposed Project.

Significance

Significant and unavoidable in Middle Klamath River from Iron Gate Dam to Cottonwood Creek in the short term

No significant impact in the Middle Klamath River downstream of Cottonwood Creek, Lower Klamath River, and Klamath River Estuary in the short term

Beneficial for Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary in the long term

No significant impact in Pacific Ocean nearshore environment in the short term and long term.

Potential Impact 3.11-6 Reservoir drawdown could result in increased bank erosion in the Klamath River downstream of Iron Gate Dam.

Reservoir drawdown could increase bank erosion in downstream reaches if, as a result of the Proposed Project, river discharge increases such that higher stages exert more force on erodible banks over a longer period of time. Under the Proposed Project, drawdown of the four reservoirs would occur simultaneously beginning in January of the drawdown year (Copco No. 1 Reservoir would also experience early drawdown starting November of the year prior to drawdown, at a lower rate [maximum of 2 feet per day]), see also Section 2.7.2 *Reservoir Drawdown*). Section 3.6 *Flood Hydrology* discusses historical flow rates and discharge statistics for each of the reservoirs. The proposed drawdown rates are consistent with the historical discharge rates from the reservoirs and would be adjusted depending on the water year; therefore, flow rates downstream of the dams are not anticipated to increase substantially above median historical rates, if at all (discharges from the reservoirs would be similar to, or less than, seasonal 10-year flood flows from the reservoirs).

Although some erodible banks have been identified in the Lower Klamath River, based on expected drawdown flow rates which are similar to existing flow rates, substantial amounts of additional bank erosion are not expected to occur downstream of any of the dams during reservoir drawdown. Therefore, bank erosion in downstream reaches due to reservoir drawdown would be a less than significant impact.

Significance
No significant impact

Potential Impact 3.11-7 Reservoir removal could reduce or eliminate the availability of a known mineral resource or a locally-important mineral resource recovery site.
Diatomite deposits near the southern downstream shore of Copco No. 1 Reservoir are currently inaccessible for extraction purposes due to their location in the reservoir and existing erosion. Under the Proposed Project, land ownership within the reservoir areas would be transferred to the KRRC and then to California, or to a designated third-party transferee, in the case of Copco No. 1 Reservoir (Section 2.7.10 *Land Disposition and Transfer*). The lands would thereafter be managed for public interest purposes, which could include open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially others. While it is possible that the diatomite deposits would become more available than under the existing condition, it is also possible that they would continue to be inaccessible in the short and long term. Thus, this EIR does not consider the accessibility of diatomite deposits to be a beneficial effect, but rather a continuation of the existing condition.

Significance
No significant impact

3.12 Historical Resources and Tribal Cultural Resources

This section focuses on the potential for impacts to historical and tribal cultural resources due to the Proposed Project. For the purposes of this section of the EIR:

Tribal Cultural Resources: Tribal Cultural Resources (TCRs) are defined consistent with Public Resources Code section 21074(1)(a) which includes sites, features, places, cultural landscapes, sacred places, and objects with cultural value to a California Native American tribe that are either included or determined to be eligible for inclusion in the California Register of Historical Resources, or included in a local register or historical resources, or as determined by the lead agency under the criteria for listing (PRC 210749(1)(a)).

Historical Resources: Historical Resources are defined consistent with Public Resources Code section 21084.1 which includes a resource listed in, or determined to be eligible for listing in, the California Register of Historical Resources, or as determined by the lead agency (PRC 21084.1).

Many comments were received during the NOP public scoping process relating to historical and/or tribal cultural resources (Appendix A). Several commenters expressed a profound personal and tribal connection to the Klamath River, its water quality, and its fishery from a traditional, subsistence, ceremonial, and spiritual viewpoint, and expressed that dam removal would provide an opportunity for river restoration, including the return of a traditional fishery. Other commenters expressed concern regarding low flows and poor water quality that would ensue following dam removal and could preclude certain tribal ceremonies. Several commenters expressed concern regarding dam removal and the potential for impacts to specific known cultural resources associated with ancient Shasta tribal occupation of the landscape and that there may be unknown archaeological resources that could be adversely affected by dam removal. A summary of the historical and/or tribal cultural resources comments received during the NOP public scoping process, as well as the individual comments themselves, are presented in Appendix A.

Assembly Bill 52 (AB52) (Gatto 2014) amended Section 5097.94 of the Public Resources Code to require consideration of tribal cultural resources in CEQA review, and to require certain consultation requirements with California Native American Tribes. AB 52's requirements went into effect on July 1, 2015.

A tribal cultural resource is defined as a site, feature, cultural landscape, sacred place or object with cultural value to a California Native American tribe that is listed or determined to be eligible for listing in the California Register of Historical Resources or under certain local registers, or that the lead agency determines to be significant under the criterial for listing. (Public Resources Code, Section 21074, subdivision (a).).

The Yurok Tribe, the Shasta Indian Nation and the Shasta Nation requested consultation under AB 52, and met with the State Water Board and the KRRC in a series of confidential consultation meetings within the timeframe of February 2017 through October 2018. The consultations with the Yurok Tribe and the Shasta Indian Nation resulted in identification of potentially-impacted resources, articulation of potential impacts, and development of, and agreement on, specific mitigation measures (see Section 3.12.5.1 *Potential Impacts to Tribal Cultural Resources*, TCR-1 through TCR-8).

KRRC has formally committed to implementing the measures as part of concluding AB 52 consultation, and has initiated consultation for development of a Tribal Cultural Resources Management Plan to meet the requirements described in TCR-1 through TCR-4, as well as the requirements of National Historic Preservation Act, Section 106. The TCRMP will be submitted to FERC for implementation.

Consultation with the Shasta Nation has informed the analysis in this EIR, but concluded after the Shasta Nation and the State Water Board acknowledged that it would not be possible to reach agreement on mitigation measures, despite a good faith effort to do so.

In order to support Project development, the KRRC undertook efforts to identify and evaluate historical and tribal cultural resources in the vicinity of the Proposed Project, and these efforts have provided information contributing to the Historical and Tribal Cultural Resources environmental setting, potential impacts and mitigation measures. KRRC has also prepared a Draft Cultural Resources Plan (Appendix B: *Definite Plan – Appendix L*), which provides a framework for understanding the cultural resources studies that KRRC has completed, those that are currently ongoing, and others that KRRC anticipates completing in order to comply with regulatory requirements. The KRRC proposes that the Final Cultural Resources Plan would be available prior to implementation of the Proposed Project.

3.12.1 Area of Analysis

The Area of Analysis for historical and tribal cultural resources is shown in Figure 3.12-1. Within the Area of Analysis, there are four subareas relevant to the analysis of potential historical and tribal cultural resource impacts, as follows:

- *Subarea 1* (Figure 3.12-2)
  - KRRC's Limits of Work for the Proposed Project, which includes the horizontal boundary conforming to the high-water line around the Lower Klamath Project reservoirs, the construction footprint needed for dam and other structure removal, ingress and egress routes, staging and stockpiling areas, disposal areas, and transmissions lines to be removed; and,
  - The inclusive area of known cultural sites that lie partially within and partially outside of the Limits of Work.
- *Subarea 2* (Figure 3.12-3)
  - Post-dam removal altered Federal Emergency Management Agency (FEMA) 100-year floodplain along the 18-river mile stretch of the Middle Klamath River downstream of Iron Gate Dam (RM 193.1) to the confluence with Humbug Creek (RM 174).
- *Subarea 3* (Figure 3.12-4)
  - 0.5-mile buffer on either side of the Hydroelectric Reach, Middle Klamath River, and Lower Klamath River encompassing the existing conditions and post-dam removal altered FEMA 100-year floodplain, which, with the exception of the Middle Klamath River reach described in *Subarea 2*, have the same extent.
- *Subarea 4* (Figure 3.12-5)
  - Parcel B lands immediately surrounding the Lower Klamath Project, which would be transferred from PacifiCorp to the KRRC prior to dam removal and

then transferred to the respective states (i.e., California, Oregon), as applicable, or to a designated third-party transferee, following dam removal. The lands would thereafter be managed for public interest purposes (KHSA Section 7.6.4.A).

To allow for individual impact analyses specific to geographic location (e.g., reservoir footprint, riverside location) and Proposed Project activity timing (e.g., pre-dam removal, reservoir drawdown, restoration activities), the subareas include overlap. The subarea overlap has no bearing on the analysis of any impact, since the subareas are considered independently by impact.

3.12.2 Environmental Setting

The Klamath River flows through several cultural regions in California's Northwest Coast, the Great Basin, and portions of the Columbia Plateau. These unique cultural regions have been used and occupied by Native American peoples for centuries.

3.12.2.1 Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods)

The tribal cultural resources analysis focuses on Shasta, Klamath, Karuk, Modoc, Hupa[177], and Yurok peoples that occupy the territory along and adjacent to the Klamath River in the vicinity of the Proposed Project. These tribes have a long history of occupation along the Klamath River as evidenced by the numerous archaeological and ethnographical resources that are present. Traditional beliefs indicate that these groups have occupied the area for time immemorial.

Over the millennia, native peoples occupied the area along the Klamath River in the vicinity of the Proposed Project, especially the corridor along the Klamath River. Ancient stream terraces—composed of gravel and sand and covered in meadows of grass with mixed oak groves—provided ideal conditions for food supply. Additionally, the area of the Upper and Middle Klamath River provided naturally occurring salt deposits, geothermal hot springs, basalt rock caves, and food such as anadromous and resident fish, seeds, roots, birds, and mammals.

Archaeological investigations have confirmed over 10,000 years of human presence in the Middle and Upper Klamath Basins, which extend beyond the extent of the Klamath River (Balter 2008, Ames et. al 1998, and Aikens and Jenkins 1994). Mammal remains document their use as a food source for native people approximately 7,500 years before the present (BP) (Ames et al., 1998). The presence of milling slabs, mortars, and mullers on the landscape dating back to approximately 6,000 BP, provides evidence for use of bulbs and seeds for subsistence (Mack 1983 and 1991). Use of fish, as a food source, began about 2,600 years BP (Beckham 2006, Daniels 2006, Deur 2011).

Section 3.12 *Tribal Trust* of the 2012 KHSA EIS/EIR is included as Appendix V of this EIR, and includes significant additional context regarding the histories of Native Americans in the basin and the longstanding relationships with various resources. Because this information was developed under auspices of the USBR's trust responsibilities towards federally-recognized Native American tribes, it includes only federally-recognized tribes. Additionally, the subsections of Section 3.12 *Tribal Trust* that address the various potential impacts of the alternatives that were being evaluated in the 2012 KHSA EIS/EIR are not directly applicable to the Proposed Project because they involve similar, but not exactly the same, actions.

Columbia Plateau and Great Basin Culture Areas

The Upper Klamath Basin and Klamath Lakes area exhibits a blend of cultural traits from the Columbia Plateau and Great Basin culture areas. The chronology of the area may be organized into the Paleoarchaic (14,000 to 7,000 BP), Early Archaic (7,000 to 4,500 BP), Middle Archaic (4,500 to 2,500 BP), and Late Archaic/Late Prehistoric (2,500 to 200 BP) periods (Ames et al. 1998; Balter 2008; Aikens and Jenkins 1994; Mack 1983, 1991).

Paleoarchaic (14,000 to 7,000 BP)
During the Paleoarchaic period, the Klamath Basin was occupied by hunter-gatherers that tended to focus on hunting large game animals, but also supplemented their diet with fish, birds, and plant resources. These groups were seasonally mobile and generally small in size (Ames et al. 1998). Two of the oldest sites in the region are Paisley Cave, which is dated at 14,200 BP (Balter 2008) and Fort Rock Cave, which is dated between 13,200 and 10,200 BP (Aikens and Jenkins 1994). The oldest site in the upper Klamath River area is the Klamath Shoal midden site, 35KL21, which yielded a date of 7,700 BP.

Early Archaic (7,000 to 4,500 BP)
Most of the archaeological evidence for early human occupation in the Klamath River Canyon dates to the beginning of the Early Archaic period (Mack 1983 and 1991). Semi-subterranean house pits first appear in the Plateau region during this period suggesting that some people were adopting a less mobile lifestyle. Typical artifacts associated with the Early Archaic include large stemmed, lanceolate, or leaf-shaped projectile points, knives, gravers, scrapers, and some cobble and ground stone tools (e.g., abraders or grinding slabs, mortars, mullers, and stone bowls).

Middle Archaic (4,500 to 2,500 BP)
The Middle Archaic period is characterized by an increase in the exploitation of riverine and marsh environments and food resources such as salmon and various plant roots/tubers. There was also an increase in the use of milling stones and pestles at sites during this period. Typical Middle Archaic artifacts include broad-necked, corner-notched, and side-notched projectile points, many types of ground stone tools, bone and antler tools (e.g., chisels and wedges), and specialized fishing gear (e.g., bone harpoon barbs and net sinkers).

Late Archaic/Late Prehistoric (2,500 to 200 BP)
Several major cultural changes occurred during the Late Period, including: the widespread appearance of pit houses; a shift to a heavy reliance on fishing; the use of storage pits for salmon; camas exploitation; the development of seasonal land use patterns (i.e., use of “winter villages”); the appearance of the bow as evidenced by the presence of small corner- and side-notched projectile points at sites; and the appearance of Olivella shell beads. Extensive trade networks became important across the region by as early as 1,500 years ago, as suggested by tools made from obsidian sources 110 to 120 miles away and the presence of beads made from marine shells.

<u>Ethnography</u>
Klamath Tribes: The Klamath Tribes include the Klamath, Modoc, and Yahooskin Band of Snake Indians. Prior to their placement on a shared reservation, these groups utilized overlapping resource areas in the Upper Klamath Basin. The Klamath and Modoc people occupy the entire Upper Klamath Basin and adjacent interior drainages to the east, living in close association with the marsh and riverine resources of this area (Spier 1930 and Barrett 1910). The Klamath and Modoc tribes were occupying the Upper Klamath Basin prior to Euro-American contact, and also participated in salmon fishing and social gatherings along the Klamath River at least as far downstream as Seiad Valley (Deur 2011). The Yahooskin principally occupy lands east of the Klamath Basin, but did participate in resource harvests, including fish harvests, with Klamath and Modoc on the Sprague River and other Klamath River tributaries (Deur 2011).

Deur (2011) also presents a summary of the ethnography of The Klamath Tribes and their relationship to the Klamath River. Klamath ancestral territory stretches from the southern boundary of the Deschutes River watershed in the north to Shovel Creek drainage in the south (Stern 1998). These encompass the Sprague River and Sycan Rivers, Sycan Marsh, Klamath Lake, and Klamath Marsh (Spier 1930, Berreman 1937). Modoc territory extends from Mount Shasta in the south to an area near the current Oregon-California state line in the north and from the eastern slope of the Cascade Range near Mount Shasta to the area around Goose Lake in the east (Ray 1963). This area encompassed Lower Klamath Lake and Tule Lake.

Klamath and Modoc were both organized in villages that collectively owned productive fishing or other resource (e.g., seed or other plants) gathering areas. Influential heads of households, supported by extended families, assumed leadership roles in the villages (Stern 1998). Villages included various types of structures including semi-subterranean winter lodges for families and extended families. The Klamath and Modoc rebuilt their winter lodges in the fall. Spier (1930) identified five geographic subdivisions of winter villages:

- Klamath Marsh-Williamson River group on the southern margin of Klamath Marsh and the Lower Williamson and Sprague rivers (about 34 villages, plus four to five villages on the upper Sprague and Sycan rivers).
- Agency Lake group on Agency Lake and the northern arm of Klamath Lake (one village and one hamlet).
- Lower Williamson River group close to the mouth of Williamson River (about seven villages).
- Pelican Bay group that includes the Pelican Bay district on the west side of Klamath Lake, Four Mile Creek, and the marsh north of the lake (about eight villages).
- Klamath Falls group: along Klamath Lake south of Modoc Point (about 14 villages).

The permanent winter villages were never fully abandoned during the year. Each group of villages maintained one or more places for cremation of the dead. The ashes of cremated individuals were covered with soil and rocks. Individuals dying away from home might be interred under piles of rocks or cremated and returned to the cremation ground. Particular sweat houses, said to have been built by the legendary *Kemu'kumps*, and a hot spring were used to cleanse mourners.

Fish is the primary resource for the Klamath and Modoc; consequently, settlements clustered near rivers and streams. Runs of fish began in the early spring and lasted into the fall (Spier 1930). Men, with some assistance from women, fished throughout the year from the banks of rivers or streams or from canoes using long-handled dip nets, spears, harpoons, and hook-and-line. During parts of the year, fish drives were also used to harvest fish. Members of the tribe would drive fish toward individuals dragging triangular nets on A-frames or purse nets through the water either on foot or from a canoe. Gill nets drawn between canoes and traps were also used to acquire fish. In addition, stone barriers were constructed on some streams to restrict fish passage and facilitate fishing.

Klamath and Modoc typically left their winter villages in early spring to begin a seasonal round of harvest activities. Spring activities began with harvesting fish from the run of large suckers that took place in Upper Klamath Lake in March. Fish were dried on the branches of pine saplings and sometimes pounded into a meal and bagged for storage. As the spring sucker run subsided, Klamath and Modoc women turned their attention to digging ipos (*Carum oregonum*) roots, gathering waterfowl eggs, and scraping the cambium layers of young ponderosa pines for food. By late spring, women dug camas bulbs in wet meadows, baking them in earth ovens and sun-drying them for storage while men hunted waterfowl and other animals.

Summer was the season when women harvested wocas, the nutritious seeds of the yellow pond lily, at Klamath Marsh, Sycan Marsh, Tule Lake, Lower Klamath Lake, and other water bodies. Wocas were an important food resource and shaman conducted a ceremony at the beginning of the harvest. The seeds were processed for soup and flour. Women also collected cattail roots for drying and grinding into meal. During the summer months men hunted waterfowl and a variety of small mammals.

In fall, Klamath and Modoc gathered chokecherries, serviceberries, Klamath plums, pine nuts, blackberries, and gooseberries. Klamath and Modoc eventually moved into the high country of the western Cascades to harvest huckleberries. Women dried the berries before fires, while men hunted deer and elk and trapped furbearing mammals. Deer hunting methods included stalking and driving the animals into the lakes, rivers, or confined spaces where they could be clubbed by women in canoes or shot with bows and arrows. Whitefish were also harvested in the fall primarily by the use of dip-nets.

Klamath and Modoc sought power by visiting places where they believed that sacred beings resided and sought to gain their power through ritualized activities. Klamath and Modoc parents sent boys and girls on a power quest when they reached puberty. Fathers and mourning kinsmen sometimes sought power at the birth of a child or death of a wife or child (Stern 1998). Seekers of power often sought specific competence such as luck in hunting or fishing, war, love-making, gambling, foot-racing, or curing. Seekers of power went alone into the mountains for 5 days to fast, pile rocks, wrestle with trees, run, perhaps take sweat baths, and climb hills. Power might come in the form of a dream or a visit by a spirit, which would be followed by the seeker waking with blood in his mouth or nose and a personalized spirit song in his ears.

Shamans, mourners, and gamblers also sought power by swimming in deep river eddies. During the day, the seeker sweated and fasted, waiting in the brush until nightfall. At that time the power seeker went to the river and dove to the bottom in search of a spirit. The seeker did not appear to be frightened even if he saw something moving under the water. Similar to other power-seeking events, it is reported that sometimes a seeker surfaced from the bottom of the river unconscious, with blood flowing from his mouth and/or nose (Spier 1930).

Shamans performed important ceremonies in midwinter gatherings, first-fruit rites for wocas gathering, and other occasions. They also cured illnesses and provided spiritual and practical support during warfare. Novice shamans received their initiation as a group at midwinter ceremonies. Helpers worked with shamans over a 5-day period during the ceremonies to call spirits, interpret spirit messages, and lead the audience in singing sacred songs.

Euro American expansion into Klamath and Modoc territory had a dramatic effect on their traditional cultural practices. Regardless, The Klamath Tribes exhibited considerable and well-documented persistence in their ceremonial and social traditions, particularly as they related to site-specific and resource-specific traditions. However, in 1954 Congress terminated the reservation and its trust relationship with The Klamath Tribes. The Klamath Tribes retained some rights to resources, but a majority of the tribal members withdrew from the tribe and received a portion of the tribal holdings. The trust account created for the rest of the members was later liquidated. In addition, in 1974 the Federal Government condemned thousands of forest acres that had been part of the Klamath Reservation so that the forest land could be added to the Winema National Forest (Klamath Tribes 2003).

The Klamath Tribes accomplished restoration of Federal recognition in 1986 and began to rebuild their tribal government, economy, and community. Currently, the tribal Culture and Heritage Department is working to protect, preserve, and enhance traditional cultural values (Klamath Tribes 2003). The Klamath Tribes are also pursuing a variety of economic enterprises through their Economic Self-Sufficiency Plan. (Please refer to 2012 KHSA EIS/EIR Section 3.12 *Tribal Trust* in Appendix V of this EIR for additional information on traditional and current lifeways and the history of Federal recognition.)

Northern Interior California Culture Area

Previous archaeological investigations in the vicinity of the Proposed Project were conducted in response to hydroelectric developments and highway construction projects beginning in the 1940s. These early archaeological investigations contain limited general information on the cultural chronology of lands in the vicinity of the Proposed Project. However, the investigations of Basgall and Hildebrandt (1989) and Cleland (1997a,b) in the northern Sacramento River Canyon do offer information on cultural chronology of lands in the Sacramento River Canyon which can provide additional insights to cultural chronology of lands in the Proposed Project area because it is likely that the subsistence and settlement patterns identify for the Sacramento River Canyon are similar to the patterns along the Klamath River and within the vicinity of the Proposed Project.

Basgall and Hildebrandt (1989) propose a three-phase cultural chronology for the northern Sacramento River Canyon, which is thought to be similar to the prehistory of the Klamath Basin. These are the Pollard Flat Phase (2,700–5,300 BP), the Vollmers Phase (1,700–4,500 BP), and the Mosquito Creek Phase (1,900 BP to contact). The Pollard Flat Phase appears to represent a forager population that occupied residential base camps for extended periods of time, and is characterized by relatively large projectile points, ground stone tools, anvils, mauls, and net weights. The Vollmers Phase represents populations that were more mobile than those of the previous phase, while still maintaining residential camps, and are characterized by medium size projectile points, ground stone tools, anvils, mauls, and net weights. The Mosquito Creek Phase populations consisted of small groups that practiced a pattern of seasonal migration, and have ben archaeologically characterized by small projectile points, ground stone tools, and the absence of hand stones, milling stones, hammer stones, anvils, mauls, and net weights.

Cleland's (1997a,b) chronology for the Lake Britton area is divided into six periods spanning 7,000 years. The six periods include: Paleo-Indian (prior to 7,500 BP; Early Archaic-A (5,000–7,500 BP); Early Archaic-B (3,900–5,000 BP); Middle Archaic-A

(3,000–3,900 BP); Middle Archaic-B (2,000–3,000 BP); Late Archaic (1,000–2,000 BP); and Emergent (150–1,000 BP).

The Paleo-Indian Period is poorly represented at the Area of Analysis and only sporadic use of the area may have been occurring during this time. Early Archaic Period sites along the Pit River and Klamath River, however may be associated with an intensification of use of the area. Sites associated with this period are usually on mid-slope terraces and tend to be situated some distance from rivers. This period reflects increased occupation of the area and freshwater mussel shell midden deposits appear at sites suggesting the exploitation of riverine resources.

The Middle Archaic Period is highlighted by a continued increase in the intensity of use of the area and a diversification of the overall settlement pattern. Occupation of the higher terraces above the river continues, but habitation sites also occur closer to the river. The diversified settlement pattern of the Middle Archaic-A Period continues during the Middle Archaic-B Period, but there is increased occupation of sites near the river. The Late Archaic-A Period is characterized by an increase of more riverine sites. This pattern continues into the Emergent-A Period during which occupation of riverine sites intensifies.

Ethnography

Shasta People

The Shasta People are currently represented by various Native American entities including the Shasta Nation, Shasta Indian Nation, and the Etna Band of Indians otherwise known as the Ruffey Rancheria. During separate consultations between the State Water Board and the Shasta Indian Nation and Shasta Nation, tribal representatives provided various historic accounts related to locations, individuals, and significant events permanent to the specific tribe’s history and culture. These accounts, and specific tribal histories are included in confidential appendixes of this EIR (Confidential Appendix P and Q). Below is the traditional information provided for the Shasta people based on literary research.

Silver (1978) summarizes ethnographic information regarding Shasta collected by Dixon (1907), Voegelin (1942), and Holt (1946). These sources generally agree that traditional Shasta territory extended north to a point about 20 miles north of Ashland, Oregon, and from Clear Creek on the Klamath River east to Mt. Hebron (Silver 1978, Jester 2016) (Figure 3.12-6). Shasta are members of the Hokan language family (Silver 1978).

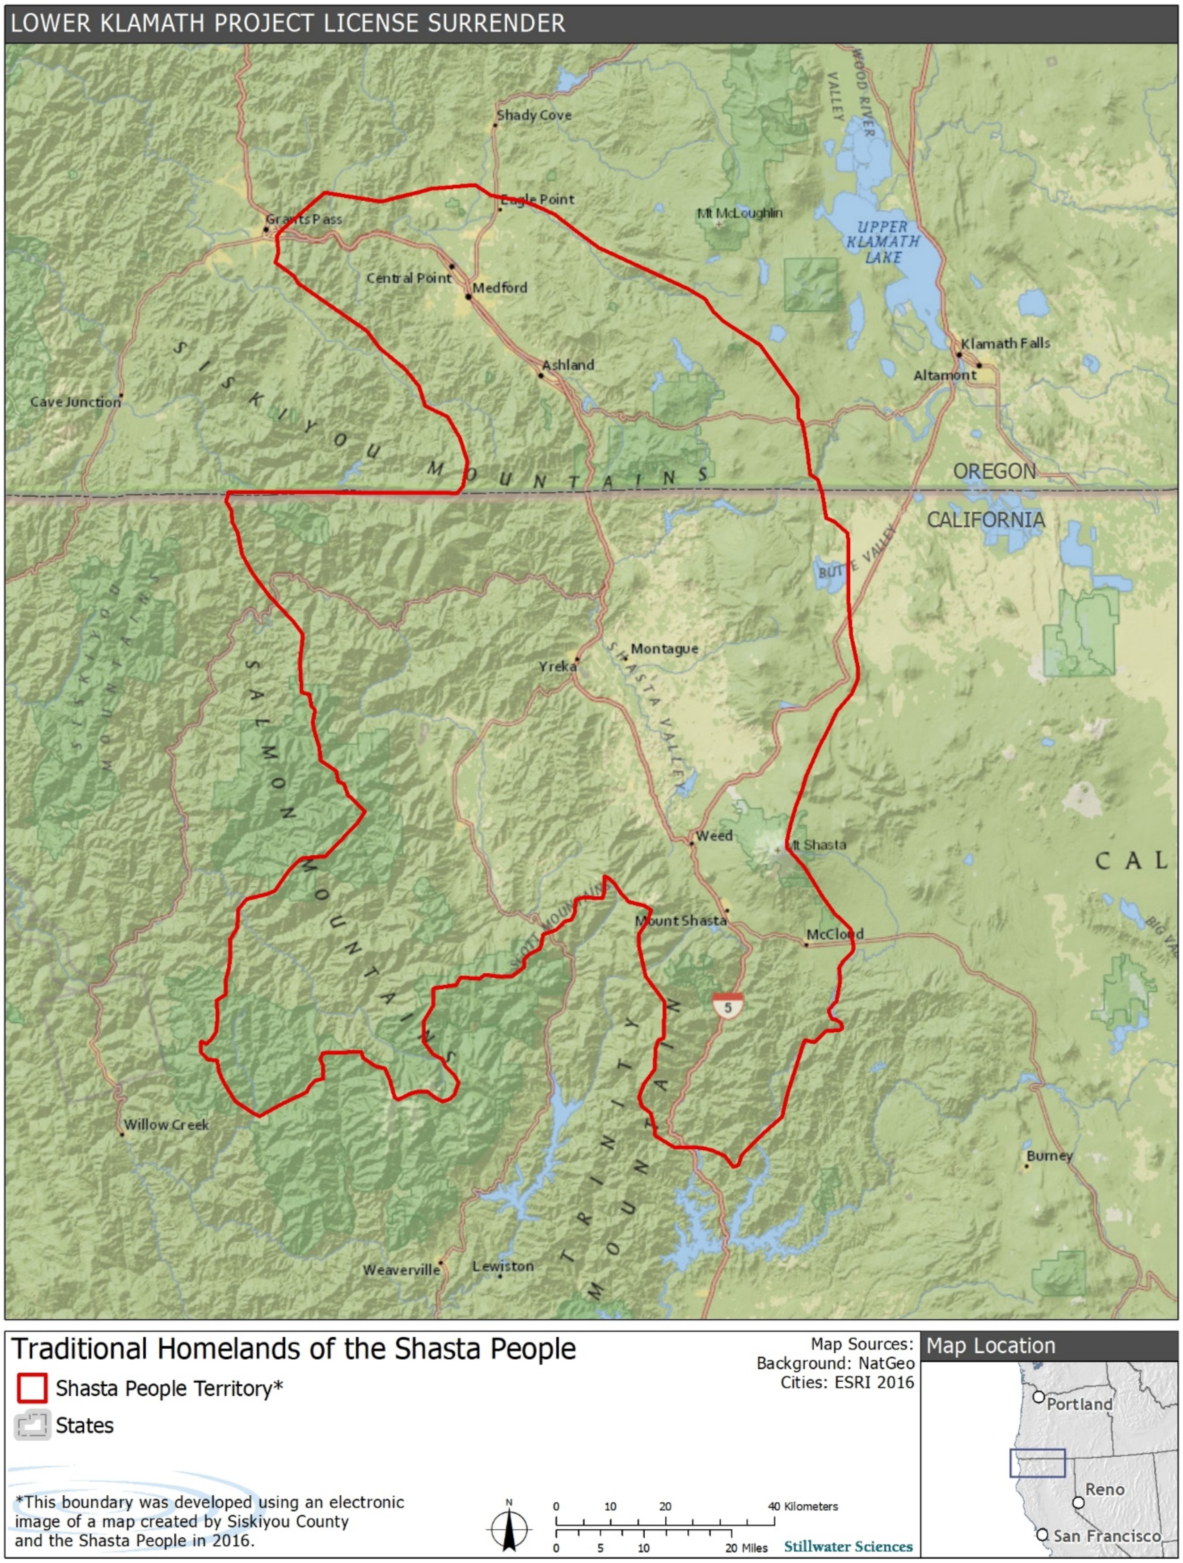

Figure 3.12-6. Traditional Homelands of the Shasta People. Map based on GIS interpretation of traditional Shasta People Homeland map provided by Shasta Nation and Siskiyou County.

There are several groups of Shasta that exhibit different cultural traits. Information presented here focuses on the Klamath River Shasta, called the Wiruhikwaiiruka or Kammatwa (Daniels 2006). Shasta were organized into autonomous tribelets consisting of extended family groups that occupied a group of villages. The family was the basic social unit of the Shasta, with the village being the political and economic unit. Each village had a chief/headman to provide leadership and organize important social, political, and economic events (Silver 1978). Shamans conducted a variety of ceremonies in villages, and the Shasta people considered Mount Shasta to be sacred ground that was used for healing, blessing, and ceremonies. Mount Shasta is a significant part of Shasta traditions and ceremonialism.

Shasta along the Klamath River tended to build their winter villages near the river. Villages had recognized territories with areas for each family, including fishing places with fish weirs along the Klamath. Hunting territories also were held privately over the long term, in contrast to tobacco-growing plots and acorn-gathering trees, which were claimed only for brief periods. Typical villages consisted of brush shelters, bark houses, sweathouses, assembly houses, and winter houses (Silver 1978). The major structures of a Shasta village included the dwelling house (umma), a big house (okwa-umma), the sweat house (wukwu), and the menstrual hut (wapsahumma) (Shasta Indian Nation 2018).

During the spring and summer, Shasta established temporary hunting and gathering camps in the foothills and mountains to make use of seasonally available resources in those ecological zones. Shasta relied on a subsistence pattern emphasizing gathering, hunting, and fishing, and use of a variety of plant and animal resources as they became seasonally available. For example, resources used by the Shasta included deer, brown bear, rabbit, and a variety of small mammals, fish, birds, insects, acorns, buckeye, pine nuts, manzanita berries, and a variety of other plants. Acorns were a staple of the Shasta diet. Regardless of the variety of resources available to the Shasta, the primary components of their diet were deer, Chinook salmon, and acorns (Dixon 1907, Silver 1978).

Individual hunters and communal hunting parties hunted deer using bows and arrows, snares, dogs, and drives (e.g., driving deer over cliffs). Waterfowl and quail were taken using nets, snares, and traps (Moratto 1984). Spring and fall salmon runs were important fishing times for the Shasta. Fishing techniques included a combination of techniques including nets, weirs, spears, and fish drives (Shasta Indian Nation 2018). In the spring, Klamath River Shasta waited to catch salmon until a member of another Shasta Group called the Kammatwa caught the first fish and performed a ritual. Klamath River Shasta could then catch and process the fish for storage but could not eat them until the Karuk performed the White Deerskin Dance ceremony. Salmon and trout were sun dried and stored in baskets for winter consumption (Silver 1978). Women and children also dove for mussels in the Klamath River during the spring.

Shasta traded pine nuts, obsidian blades, and juniper beads with their neighbors for obsidian from the Achumawi; pine nut necklaces from the Wintu; canoes from Karuk and Yurok; acorns, baskets, dentalia shells, haliotis shells, and other shells from the Karuk, Hupa[177], and Yurok; and beads from Wintu (Silver 1978). Shasta also acted as a middleman for the Achumawi, who acquired dentalia shells from groups in the Columbia River area. In addition, Shasta occasionally attended Karuk, Hupa, and Yurok dances.

Euro American settlement into Shasta lands accelerated as a result of the Gold Rush. Conflicts between Indian Tribes and Euro Americans resulted in the Rogue River Indian Wars of 1850–1857 that pushed Shasta from their traditional fishing, hunting, and village sites. A treaty in 1851 established a reservation in Scott Valley for Shasta, but conflict between Euro Americans and Shasta persisted. Consequently, in the 1870s Shasta welcomed cultural revivalist movements such as the Ghost Dance. From the 1870s through the 1940s most Shasta in the vicinity of the Proposed Project lived at the Frain Ranch or Bogus Tom Smith's Rancheria (Daniels 2006) and continued to practice their traditional subsistence activities. Currently, Shasta are represented in the Shasta Nation, Shasta Indian Nation, and the Etna Band of Indians otherwise known as the Ruffey Rancheria. Along with working on federal recognition, through the Ruffey Rancheria Restoration Act (HR 3535, La Malfa 2017), the Shasta people continue to preserve, protect, and maintain traditional cultural practices, including sites associated with those practices.

Northwest California Culture Area

King et al. (2016) identified six patterns or modes of adaptation (i.e., Post, Borax Lake, Berkeley, Mendocino, Tuluwat, and Augustine Patterns) for northwest California and the North Coast Ranges and assigned them to six time periods: Paleo-Indian (10,000–6,000 B.C.); Lower, Middle, and Upper Archaic (6,000 B.C.–A.D. 500); and Upper and Lower Emergent (A.D. 500–1800) periods. The patterns applicable to northwest California are the Post, Borax Lake, Mendocino, and Tuluwat (formerly Gunther).

The Post Pattern (12,000–8,000 BP) represents the earliest occupation of the area and is characterized by fluted, concave-base projectile points and crescents. Regardless, archaeological sites with well-defined assemblage of typical Post Pattern artifacts are not well represented in northwest California.

The Borax Lake Pattern (8,000–2,500 BP) represents a generalized hunting and gathering subsistence pattern. It is characterized by heavy, wide-stemmed points with indented bases, serrated bifaces, ovoid tools, hand stones, and milling slabs (King et al. 2016). The Borax Lake Pattern is identified at sites across a wide variety of environments in Humboldt and Trinity counties along Pilot Ridge and South Fork Mountain and along a river terrace adjacent to the Trinity River. One archaeological site has a house floor and post holes dated over 7,000 BP (Fitzgerald and Hildebrandt 2001).

The Mendocino Pattern (5,000–1,500 BP) appears to represent a hunting and gathering subsistence pattern that is well adapted to local environments and typically exploits seasonally available resources across different ecological zones. It is characterized by side-notched, corner-notched, and concave base dart points, hand stones, milling slabs, and in some cases small numbers of cobble mortar and pestles. The Mendocino Pattern is not clearly defined in northwestern California, but it has been identified at sites on Point St. George, and along the Smith River, in Humboldt Bay, and in the northern mountains of Humboldt County (King et al. 2016).

The Tuluwat Pattern (beginning about 1,500 years BP) appears to be associated with the exploitation of marine and riverine resources. It is characterized by barbed projectile points, concave based points used for composite harpoons, spears, hooks ground and polished stone artifacts, flanged pestles, notched net sinkers, and steatite bowls.

Sites representing this settlement pattern are associated with exploitation of marine mammals and fish and include locations in Del Norte and Humboldt Counties (King et al. 2016). The pattern appears to represent the earliest evidence of subsistence patterns associated with the exploitation of marine mammals and fish that is typical of the Yurok, Hupa, and Karuk that currently inhabit northwest California and the Klamath Basin.

Ethnography

Karuk: Bright (1978) summarizes ethnographic information regarding Karuk primarily from information presented by Gifford (1939a,b; 1940) and Kroeber and Barrett (1910). Karuk occupy territory west of the Shasta, which stretches along the Middle Klamath River near the western boundary of Siskiyou County from Seiad to Bluff Creek just west of Orleans (Bright 1978). The Karuk Tribe has been federally recognized since 1979 and occupies territory along the Middle Klamath River. Karuk are members of the Hokan language family (Bright 1978). Karuk share similar cultural traits with the Yurok and Hupa and regularly interact with each other.

Karuk were organized in villages with a relatively loose political structure. The acquisition of wealth is an important part of Karuk culture, and wealthy men assumed leadership roles because of their prestige. Villages varied in size and consisted of rectangular cedar plank houses and sweat houses. Karuk focused on the use of fish and aquatic resources, but other terrestrial resources were also important supplements to their diet. Karuk also harvested acorns and hunted in upland areas around the Klamath River for deer, elk, birds, and fur bearing mammals. The hides of mammals were used for a variety of clothing and bird feathers and pelts were used for ceremonial regalia.

Plentiful fish resources facilitated the occupation of numerous villages along the Klamath and Salmon Rivers (i.e., Salter [2003] reports that 100 villages existed along the two rivers). The villages were in advantageous locations on bends of the Klamath River and bluffs above it, such as near the mouths of Camp Creek (Tishawnik), the Salmon River (Mashuashav), and Clear Creek (Inam).

Archaeologically, Karuk tools reflect their emphasis on the acquisition of fish and other aquatic resources and include harpoons, nets, and hooks. Facilities constructed to harvest fish include weirs, dams, and fishing platforms. Karuk also constructed canoes from hollowed out logs for fishing and transportation along the Klamath River and its tributaries. Transportation along the river and streams was essential to Karuk ceremonial activity. Indeed, Karuk traditions state that the Klamath River was created to facilitate their interaction with Yurok and Hupa and with salmon.

The political and social organization and material cultural of the Karuk are important topics, but their religious and ceremonial practices highlight their relationship to the Klamath River and its associated resources. Of particular importance are world renewal ceremonies and ceremonies for bountiful harvests of fish and other resources (Bright 1978). World renewal ceremonies include the White Deerskin and Jump ceremonies at which the earth and the creator are honored for providing food and facilitating the prosperity of the tribes. These ceremonies were and continue to be conducted at sites along the Klamath River such as Panamnik (Drucker 1936, Verwayen and Hillman 2010). Ceremonies to insure harvests of fish include the First Fish, First Salmon, and Fish Dam ceremonies. Other ceremonies related to world renewal and curing are the

Boat Dance and the Brush Dance. Karuk, Hupa, and Yurok regularly attend each other's ceremonies and the ceremonies are conducted for the benefit of all the groups.

The White Deerskin and Jump ceremonies honor the earth and the creator for providing food resources and maintaining the tribes. The White Deerskin ceremony is held from late August into September, depending on the river and its waters. The Jump ceremony is conducted after the conclusion of the White Deerskin ceremony and is also held for the "good" of the world. Both the White Deerskin and the Jump ceremonies depend on a healthy Klamath River system for fish, basket materials, and bathing. The First Fish ceremony is conducted in spring and the Fish Dam ceremony is conducted to in mid-summer to celebrate the harvesting of fish and to pray for continuing prosperity and access to subsistence resources, primarily fish resources. The Boat ceremony forms part of the White Deerskin ceremony, celebrating the flows and health of the rivers. The Brush Dance is held to cure the sick, particularly children.

Euro American settlement in the Area of Analysis for historical and tribal cultural resources accelerated as a result of the California Gold Rush. Conflicts between Indian Tribes and Euro Americans were commonplace across Karuk territory. Consequently, Karuk welcomed cultural revivalist movements in the 1870s such as the Ghost Dance, but traditional cultural practices and numbers of Karuk continued to decline. Regardless, the Karuk persisted and contemporary Karuk continue to practice their traditional activities and are actively engaged in programs related to improving the health of the Klamath River and its fishery.

Quartz Valley Indian Community

The Quartz Valley Community is a federally recognized tribe mainly representing people of Karuk and Shasta ancestry, with 174 acres of reservation lands in the Scott Valley, near Fort Jones, California. Their cultural history is similar to that described for the Karuk, as most members are of Karuk ancestry (Appendix V – 2012 KHSA EIS/EIR *Section 3.12 Tribal Trust*). The Quartz Valley Indian Community's reservation lands are located near the community of Fort Jones. The Quartz Valley Indian Community initially filed their constitution and bylaws with the Office of Indian Affairs in 1939 (DOI 1939).

Yurok

Pilling (1978) summarizes ethnographic information regarding Yurok collected by Waterman (1920), Waterman and Kroeber (1934), and others. Sloan (2003, 2011) also presents a summary of the ethnography of the Yurok and the relationship to the tribe to the Klamath River. Yurok are members of the Algonquian language family. Yurok ancestral territory extends along the Pacific coast of California from Crescent City in the north to Trinidad in the south and along the Klamath River from the coast to a point near the confluence of the Klamath and Trinity Rivers and the town of Weitchpec (Pilling 1978). The Yurok Tribe's reservation currently consists of a strip of land beginning at the Pacific Ocean and extending a mile along each side of the Klamath River approximately 45 miles.

The Yurok life, language, ceremonies, society, and economy are linked with the Klamath River. There are Yurok stories that reinforce the Yurok belief that the River was created in a distinct way in order to provide Yurok people with the best of worlds (Sloan 2003, 2011). Yurok refer to the river as HeL kik a wroi or "watercourse coming from way back in the mountains." Contemporary Yurok often refer to the Klamath River as the "Yurok Highway" emphasizing its comparison to a blood vessel that provides the main flow of sustenance. Karuk, Yurok, and Hupa share similar cultural traits and traditional stories state that the Klamath River was created to facilitate their interaction with each other and with salmon.

The Yurok had permanent settlements with substantial architectural features including houses, smokehouses, and storage facilities (Kroeber and Barrett 1910, Pilling 1978). Pilling (1978) cites 44 villages, 97 fishing spots, 82 significant cultural places (e.g., places used for ceremonies, gathering, and hunting), and 41 places of cultural significance along the Klamath River in Yurok territory.

The Yurok represent a socially complex hunter-gatherer population in California (Fredrickson 1984, Kroeber 1925) that used marine and salmon resources. Organizing labor to capture the short-duration salmon runs, preserving fish by smoking, then packing and storing the fish suggests a high degree of sociopolitical differentiation. There is also evidence of a maritime expression to Yurok culture involving marine mammal hunting more than 10 miles offshore. The most telling argument for an open-ocean maritime adaptation comes from the presence of the large amount of northern fur seal fauna in the Stone Lagoon midden. Jones and Hildebrandt (1995) argued that pinnipeds were extirpated early on shore by Native Americans, who then developed watercraft to hunt offshore.

The material culture of the Yurok people includes, to this day, dugout redwood canoes, split-plank houses, storage boxes, sweathouse pillows and stools, many fishing devices, baskets and leather, shell, straw and feather garments and ceremonial regalia.

Transportation along the rivers and streams is essential to Yurok ceremonial activity. One of the most important aspects of Yurok technology was the river- and ocean-going canoe or yoch, which were carved from selected redwood trees (Sloan 2003, 2011). There are historic accounts of expeditions traveling up to 180 miles along the coast (Sloan 2003, 2011). A typical river canoe measured 16 to 20 feet in length and 3 to 4 feet in width. River canoes were customarily paddled and/or pushed with a long pole. Yurok technology and facilities do not only serve utilitarian functions, but also include ceremonial aspects of Yurok culture. For example, facilities, such as fishing weirs, were created specifically to signify the time of sacred ceremonies (e.g., the White Deerskin and Jump ceremonies).

Fishing places along the Klamath River are owned by individuals, families, or groups of individuals. Fishing places can be borrowed, leased, inherited, or bought and sold (Sloan 2003, 2011). Some ownership rights at fishing places depended on species of fish caught at the site, while others depended on the water level (i.e., individuals owned the right to fish at a place if the river was below or above a certain level). Yurok still recognize this traditional form of resource management and use of the river. Families and individuals continue to use and own rights to fishing places on the Klamath River.

Like the Karuk, the religious and ceremonial practices highlight the Yurok relationship to the Klamath River and its associated resources. Of particular importance were the Jump, White Deerskin, Boat, and Brush ceremonies. The Jump and White Deerskin ceremonies were held in late fall to give thanks for food resources abundance collected during the year and to insure a continued abundance of food resources for the next year (Sloan 2003, 2011). Affluent individuals and religious leaders conduct most ceremonies, and wealthy individuals were expected to feed salmon to everyone attending the ceremonies.

The Boat Ceremony is part of the White Deerskin Ceremony. In this ceremony, several boats filled with participants travel down the Klamath River. The participants thank the river for continuing to flow and provide resources. The Brush Ceremony unfolds over a four-day period and highlights the importance of Klamath River resources to Yurok. For example, baskets made of plant materials collected at the water's edge are used to hold food and ceremonial medicine; acorns are cooked in the baskets using cooking stones gathered at specific river bars; ceremonial regalia is made from various plant and animals that live along the river; ceremonial bathing is performed; and participants listen to the sounds made by the Klamath River (King 2004).

The social and ceremonial significance of the Klamath River is evident in and reinforced by Yurok traditions. For example, there are at least 77 Yurok stories that make direct reference to the Klamath River (Sloan 2003, 2011). These Yurok stories reinforce the belief that the Klamath River was created to provide Yurok with a very good place to live.

Spanish explorers and vessels traveling from the Philippines may have interacted with Yurok along the coast in the late 1700s. Other explorers such as Peter Skene Odgen and Jedediah Smith certainly encountered Yurok along the Klamath River in the early 1800s. Regardless, Euro American settlement and use of Yurok territory did not begin until after the discovery of gold in California in early 1850. With strikes along the Klamath and Trinity rivers, gold prospectors inundated the region affecting Yurok traditional culture (Pilling 1978).

In 1851 a "Treaty of Peace and Friendship" was signed between the United States Government and the Klamath River Indians, but the United States Congress did not ratify this treaty. Subsequently, on November 16, 1855, the Klamath River Reserve, also known as the Klamath Indian Reservation, was established by Executive Order. The Order designated the reservation lands from the mouth of the Klamath River, one mile on each side extending approximately 20 miles upriver to Tectah Creek (Sloan 2003, 2011).

Escalating conflict between Yurok and Euro Americans during the 1860s and 1870s over encroachment onto the Klamath Indian Reservation resulted in the gradual displacement of Lower Klamath Indians further upriver (Sloan 2003, 2011). Euro Americans on the reserve resisted attempts to remove them, including eviction in 1879 by the United States Army (Sloan 2003, 2011). After decades of struggle to regain their traditional homelands, the Yurok Tribe was re-organized and was granted its own reservation in 1988. As a result of the 1988 Hoopa-Yurok Settlement Act (PL-100-580), the Yurok Indian Reservation was established.

The ancestral lands of the Yurok Tribe extend unbroken along the Pacific Ocean coast (including usual and customary off-shore fishing areas) from Damnation Creek, its northern boundary, to the southern boundary of the Little River drainage basin, and unbroken along the Klamath River, including both sides to the associated tributary watershed boundaries from the mouth upstream to the Bluff Creek drainage basin. The Yurok Tribe considers cultural resources sites along and associated with the Klamath River to be part of a larger ethnographic riverscape (King 2004, Yurok Tribe 2012). Sites include fishing areas; a fish dam (weir) site; many different types of resource gathering sites, complex trail systems that connect villages, camps, the river, ceremonial sites, gathering areas, and other Tribes; and 47 villages with graves/cemeteries.

The Yurok Tribe is the largest tribe in California, with over 4,500 enrolled tribal members and over 200 tribal government employees. The Yurok Tribe is actively pursuing economic development and management of fisheries, forestry, and cultural programs, both on the reservation and Yurok ancestral lands.

Resighini Rancheria: The Resighini Rancheria is located on the southern banks of the Klamath River Estuary, surrounded by the Yurok Reservation. The tribe is composed of Yurok ancestry and has a very similar cultural history to that of greater Yurok culture. Land known as the Resighini Rancheria was designated by Secretarial Order and was officially declared a reservation in 1939. In 1975, a group of Yurok Indians stood together and formally created a non-traditional form of government with a constitution and bylaws which was approved and ratified by the last Indian Commissioner Bruce Thompson from the Department of Interior of the United States. However, the disastrous flooding of 1964 (see also Figure 3.6-14) led to the temporary evacuation of Resighini Rancheria.

Today, the tribal government consists of a General Council with an elected Tribal Council to operate our governmental and private tribal affairs as well as represent the tribal needs of our small membership. The Tribal Council consists of five tribal members who are elected annually by staggered two-year terms of Chairman, Vice Chairman, Secretary, Treasurer and Councilperson. Their general membership serves on boards, committees, commission and corporations to assist the Tribal Council.

Hoopa Valley Tribe: Wallace (1978) summarizes ethnographic information regarding Hupa primarily collected by Goddard (1903). Hupa are members of the Athabascan language family and they call themselves Natinixwe. Hupa ancestral territory is centered in Hoopa Valley and the area surrounding the Trinity River near its confluence with the Klamath River. Hupa, Karuk, and Yurok share similar cultural traits and regularly interact with each other.

Hupa were organized in villages with a relatively loose political structure. Villages typically consisted of family groups (Wallace 1978). Villages varied in size and consisted of rectangular cedar plank houses. For substances, traditional Hupa people primarily used fish and aquatic resources, but also utilized terrestrial resources such as mammals, birds, reptiles insects, and other fauna (Wallace 1978). Hupa also harvest acorns and hunted in upland areas around the Trinity and Klamath River for deer, elk, birds, and fur-bearing mammals. The hides of mammals were used for a variety of clothing and bird feathers and pelts are used for ceremonial regalia.

Hupa tools reflect their emphasis on the acquisition of fish and other aquatic resources and include harpoons, nets, and hooks. Facilities constructed to harvest fish include weirs and dams. The Hupa used canoes for fishing and transportation along the Trinity and Klamath rivers but obtained their canoes from the Yurok. Transportation along the river and streams was essential to Hupa ceremonial activity.

Like the Karuk and the Yurok, the Hupa's religious and ceremonial practices highlight their relationship to a river, the Trinity River, and its associated resources. Of particular importance are world renewal ceremonies and ceremonies for bountiful harvests of fish and other resources (Wallace 1978). World renewal ceremonies include the White Deerskin and Jump ceremonies at which the earth and the creator are honored for providing food and facilitating the prosperity of the tribes. Ceremonies to ensure harvests of fish and acorns include the First Salmon ceremony and Acorn Feast (Wallace 1978). Hupa, Karuk, and Yurok regularly attend each other's ceremonies and the ceremonies are conducted for the benefit of all the groups.

Euro American settlement of the as a result of the Gold Rush, ultimately resulting in the establishment of the original Hoopa Valley Reservation in 1864. President Harrison expanded the Hoopa Valley Indian Reservation in 1891 to include the Klamath River Reserve that extended one mile on either side of the Klamath River from the Pacific Ocean for 22 miles upstream, as well as the lands one mile on either side of the river between the two reservations (Salter 2003). The 1988 Hoopa-Yurok Settlement Act (PL-100-580) divided the reservation again, separating it into the Hoopa Valley Reservation and the Yurok Indian Reservation (Salter 2003).

The culture of Karuk, Hupa, and Yurok is closely tied to the Klamath and Trinity Rivers. These tribes subsist wholly or in large part on the resources acquired from the river, most of their sacred sites are located along it, and their cultural traditions are related to it (Bright 1978, Pilling 1978, Wallace 1978). Contemporary Hupa practice their traditional activities and are actively engaged in programs related to improving the health of the Trinity River and its fishery.

3.12.2.2 Historic Period

Euro American exploration of the Klamath region began in the early 19th century. Jedediah Strong Smith and Peter Skene Ogden explored current Siskiyou and Klamath County in 1826 and 1827 for beaver as part of fur trade, and in 1829 a party of Hudson Bay Company trappers and explorers, led by Alexander Roderick McLeod, also passed through the area (Klamath Hydroelectric Project 2004). The fur trade ended in the mid-1840s. Largely, the area remained sparsely occupied by Euro Americans until the mid-1800s, when mining and logging attracted settlers to the area.

The discovery of gold at Sutter's Mill in Coloma in 1848 was the catalyst that caused a dramatic alteration of both Native American and Euro American cultural patterns in California. A flood of immigrants entered the California and the Klamath region once news of the discovery of gold spread. Initially, the Euro American population grew slowly, but soon exploded as the presence of large deposits of gold were confirmed. The non-Native American population of California quickly swelled from an estimated 4,000 Euro Americans in 1848 to 500,000 in 1850 (Bancroft 1888). The discovery of gold and the large influx of primarily Euro American immigrants had a positive effect on the growth and economic development of California as a state, but a negative effect on Native American cultures. The discovery of gold in California marked the beginning of a relatively rapid decline of both Native American populations and culture. The influx of primarily European Americans displaced Native Americans from their traditional territory, discouraged the use of traditional languages and the practice of religious ceremonies, and Euro American economic pursuits (e.g., gold mining, logging, ranching, and farming) limited the practice of traditional subsistence activities.

Gold was discovered by Abraham Thompson and his party just north of the present-day location of the City of Yreka in 1851 (Hoover et al. 2002). Known as "Thompson's Dry

Diggins", the population quickly exploded to 2,000 miners, and the town of Shasta Plains was established (Hoover et al. 2002). The town primarily included tents and brush shanties, but also included a saloon built out of shakes and canvas by Sam Lockhart. The first permanent house in the town was built by D.H. Lowry and his wife.

Euro American settlement in the Klamath River watershed continued to grow through the 1850s due to the completion of roads such as the Southern Emigrant Road, also known as the Applegate Trail, in 1846 (Klamath Hydroelectric Project 2004). These roads brought prospectors to the region and helped to establish communities such as Henley (Cottonwood), Gottville, Happy Camp, and Somes Bar. Fertile soil and plentiful water sources provided opportunities for homesteading and the private development of agriculture and ranching, particularly in the area around current Upper Klamath Lake, but also extending downriver, occupying the rich alluvial terraces along the river through the canyon. The expansion of Euro Americans in southeastern Oregon resulted in execution of treaties with the various Klamath River tribes and the relocation of these groups in the area (Klamath Hydroelectric Project 2004). Shasta women married into ranching families at this time and are recognized as being instrumental in the tribes' long-term survival today.

Logging began in the Klamath Basin in the 1860s and sustained logging enterprises appeared in the 1880s (Klamath Hydroelectric Project 2004). Early companies were generally small, family-run operations managed by ranching families trying to supplement their income. In 1867, President Ulysses S. Grant signed legislation to create a land-grant subsidy for the construction of the Oregon and California Railroad (Klamath Hydroelectric Project 2004). The grant allowed the Oregon and California Railroad Company to select off-numbered sections from the public domain for the construction of the railroad. In 1887, the Oregon and California Railroad Company claimed "lieu" lands on the Pokegama Plateau as compensation for other lands that had already been claimed by homesteaders or military and wagon road companies. Title to these lieu lands were immediately (and illegally) transferred to the Pokegama Sugar Pine Lumber Company. To move the logs from the Pokegama Plateau, the Pokegama Sugar Pine Lumber Company built a log chute on the rim of the Klamath River Canyon and the first railroad in Klamath County (Gavin 2003). During this period, larger scale logging companies such as Pokegama Sugar Pine Lumber Company and Klamath River Lumber and Improvement Company were established on the north rim of the Klamath River Canyon.

The end of the nineteenth and beginning of the twentieth centuries witnessed an ongoing and growing immigration into the area, which was facilitated by the construction of the railroad through the region. The railroad provided a reliable means of transportation in the area and stimulated regional cultural and economic development. In addition to improving transportation, a railroad grade constructed at the northern end of Lower Klamath Lake functioned as a dike that facilitated drainage of wetlands for agriculture and control of the flow of water from the Klamath River.

The Oregon and California Railroad constructed in 1877 was the first railway through the region (Klamath Hydroelectric Project 2004). It extended from Siskiyou County, California, to Jackson County, Oregon, and facilitated travel and the transport of goods between Sacramento and Portland. Subsequently, the Southern Pacific Railroad Company acquired the Oregon and California Railroad, and by 1909 agricultural and lumber products of the Klamath Basin could be distributed to a nationwide market.

The first hydroelectric development in the Klamath Basin was established in 1891 in the Shasta River Canyon below Yreka Creek to provide electricity to the City of Yreka (Klamath Hydroelectric Project 2004). Four years later, in 1895, the Klamath Falls Light & Water Company built a power plant along the banks of the Link River and soon thereafter began power generation for the town of Klamath Falls (Klamath Hydroelectric Project 2004). The first decade of the 20th century brought a number of mergers and reorganizations of power companies in the specific project reach of Klamath River canyon currently under study. The California-Oregon Power Company (COPCO) was one of the companies that emerged from this period of reorganization (Klamath Hydroelectric Project 2004). The USBR's Klamath Irrigation Project, authorized in 1905, was developed by the DOI to supply farmers with irrigation water and farmland in the Klamath Basin. Link River Dam is the principal source of water for Reclamation's Klamath Project and the irrigation system and serviced areas are situated upriver of the Proposed Project.

COPCO proposed to develop hydroelectric power facilities along the Klamath River. Residents in the Klamath Falls area were divided over COPCO's proposal to dam and generate power on the river. Farmers feared the depletion of precious irrigation water while other businesses saw COPCO operations as an addition to the local economy. Regardless, with the increasing power needs of both irrigation and lumber mills and a huge influx of military personnel stationed at Medford and Klamath Falls, it was only a matter of time before additional power generation facilities were needed in the area. Envisioned in 1911, the Klamath Hydroelectric Project (Klamath Hydroelectric Project) was built in phases through 1962 (Kramer 2003a,b). Klamath Hydroelectric Project facilities were constructed by COPCO beginning with Copco No. 1 Dam (1918), followed by Copco No. 2 Dam (1925), and reconstruction of the old East Side facility in 1924. After World War II, regional population growth prompted a new round of hydroelectric power expansion highlighted by COPCO's Big Bend project (J.C. Boyle Dam and powerhouse) in 1958 and the construction of the Iron Gate facilities in 1962. While the Iron Gate facilities were still under construction, COPCO merged with Pacific Power & Light, currently PacifiCorp. PacifiCorp currently owns and operates the Klamath Hydroelectric Project.

The development of the Klamath Hydroelectric Project played a significant role in the area's economic development, both as part of a regionally significant, locally owned and operated private utility and through the role that increased electrical capacity played in the expansion of the timber, agriculture, and recreation industries during the first six decades of the 20th century. The Klamath Hydroelectric Project dams and associated facilities are recommended as eligible for inclusion on the National Register of Historic Places (NRHP) as the Klamath Hydroelectric Historic District (KHHD) under Criterion A for its association with the industrial and economic development of southern Oregon and northern California from 1903–1962 (Kramer 2003a,b; Cardno Entrix 2012). Economic development continues in the region, but it is now driven by tourism and recreation rather than gold mining, agriculture, or logging.

3.12.2.3 Known Tribal and Historical Resources in the Vicinity of the Proposed Project

Summary of California Historical Resources Information System Record Searches

In 2017, the KRRC conducted an updated records search at the California Historical Resources Information System's Northeast center at Chico, State University, for a study area that includes the length of the Klamath River from the Oregon-California state line, 40 miles downstream to Humbug Creek. The section of river below Iron Gate Dam (the most downstream Lower Klamath Project dam) was included in the records search since this 18-mile long area lies within the altered FEMA 100-year floodplain following dam removal, where cultural resources have the potential to be affected. The records search area included a 0.5-mile wide buffer, extending on either side of the shorelines of Copco No. 1 Reservoir and Iron Gate Reservoir, and from the center point of the Klamath River in all other areas.

The KRRC's 2017 record search compliments the cultural resource record searches previously performed as part of the Klamath Hydroelectric Project Relicensing (FERC 2007) and 2012 KHSA EIS/EIR studies (PacifiCorp [2004] and Cardno Entrix [2012]).

The records search included gathering archaeological site forms, survey and excavation reports, maps, and other records. Survey and site locations were hand plotted onto USGS topographic maps at the Northeast Information Center. Research of historic registers included the California Historic Landmarks, National Register of Historic Places (NRHP), California Register of Historical Resources, California Points of Historical Interest, California Inventory of Historic Resources, and the California State Historic Resources Inventory. In April 2017, the KRRC visited the Klamath National Forest office and the Siskiyou County Museum, both in Yreka, California to collect additional historic information. Klamath National Forest Heritage Program Manager Jeanne Goetz conducted a search of records for Forest Service lands within or near the KRRC records search area and provided appropriate archaeological site record forms (Appendix B: *Definite Plan – Appendix L*).

The KRRC also conducted a background literature search to identify known cultural resources and also to determine the types of cultural resources likely to occur within the area of the Proposed Project. In addition, online newspaper archives were searched, including the National Digital Newspaper Program archives provided by the Library of Congress and National Endowment for the Humanities (www.chroniclingamerica.loc.gov); Genealogy Bank newspaper archives provided by NewsBank, Inc. (www.geneaologybank.com); the California Digital Newspaper Collection repository provided by University of California, Riverside (www.cdnc.ucr.edu); and newspaper archives provided by www.Ancestry.com.

In May 2017, the KRRC obtained cultural sources data from PacifiCorp, including GIS shapefiles with previous survey and resource locations, as well as, a copy of the final cultural resources technical report prepared for Klamath Hydroelectric Project relicensing (PacifiCorp 2004). In addition, the KRRC contacted Dr. Joanne Mack, Professor Emeritus at Notre Dame University, a primary researcher in the Upper Klamath Basin, to discuss the Proposed Project and to learn of her on-going research in the area that might not be reflected in published or unpublished literature. The KRRC also consulted with Dr. Brian Daniels, Director of Research and Programs for the Penn Cultural Heritage Center at the University of Pennsylvania Museum, regarding ethnographic information, archival documents, and oral histories pertaining to tribal cultural resources within the California records search area.

The KRRC contacted the Native American Heritage Commission in June 2017, to secure a review of the Sacred Lands file for a 0.5-mile wide area on either side of the Klamath River corridor, extending from the California-Oregon state line downstream to the Pacific Ocean. In a June 14, 2017 letter, the Native American Heritage Commission stated that there was a positive result, with the recommendation to contact the Karuk Tribe, Yurok Tribe, and Shasta Nation. The Native American Heritage Commission also provided a consultation list of 29 tribes with traditional lands or cultural places located within the boundaries of Del Norte, Humboldt, and Siskiyou counties.

The KRRC records search and literature review (Appendix B: *Definite Plan – Appendix L*) identified that 58 previous cultural resources investigations have been conducted within the records search study area, with five studies (Kramer 2003a,b; Cardno Entrix 2012; Durio 2003; PacifiCorp 2004) completed specifically for the Proposed Project (Appendix B: *Definite Plan – Appendix L*). Several of these studies are archaeological, ethnographic, or historical overviews, while others describe the findings of specific archaeological excavations.

The majority of the past surveys involve pedestrian field survey and cultural resources monitoring. Overall, an estimated 8,189 acres of federal, state, and/or private land have been previously surveyed within the records search area and except for some proposed disposal sites, encompasses the current boundaries of the Proposed Project.

The KRRC California record searches identified 206 previously recorded cultural resources, consisting of 120 archaeological sites,1 ethnographic property, 9 built environment resources, 68 isolated finds, and 8 resources of an undetermined resources type (Appendix B: *Definite Plan – Appendix L*). By type, these resources include 114 prehistoric, 59 historic-period, 23 multiple-component (prehistoric and historic period), 1 ethnographic property, and 9 resources whose temporal association is unknown.

Archaeological Sites

The known archaeological sites on file at the Northeast Information Center represent roughly 60 percent of the previously recorded resources along the Klamath River from the Oregon-California state line to Humbug Creek. The sites consist of 49 prehistoric, 48 historic-period, and 23 multiple-component (both historic and pre-historic at the same location) sites. Identified prehistoric period sites include villages; campsites; lithic scatters; lithic scatters with associated cultural features; toolstone quarries; a possible ceremonial site with multiple features; and a human burial site.

The historic-period archaeological sites consist of late-nineteenth or early-twentieth century properties associated with the development of agriculture, including settlements or features such as homesteads; logging; mining; commercial; public works (hydroelectric); and transportation. Agricultural-related sites include settlements (homesteads), irrigation ditches, rock features, and artifact scatters.

Logging-related sites focus on elements of the former Klamathon townsite, including the town and lumber mill and the associated Pokegama log chute and ditch flume. Mining related sites, located in the Klamath River area below Hornbrook, include two quartz mines and four placer mines with ditches and/or tailings. The Beswick Hotel, ranch, and

Klamath Hot Springs area represents the single commercial property. An extensive refuse scatter associated with the Copco No. 1 Village is the sole public works site. Finally, transportation-related sites consist of an abandoned segment of the Klamath Lake Railroad, a collapsed trestle and segment of railroad grade, a segment of Topsy Road, a road leading to Horseshoe Ranch, and a segment of the California-Oregon Stage Road.

The multiple component sites include both prehistoric and historic-period components. Prehistoric components associated with these sites include housepit villages, a housepit village with a documented historic-period cemetery, lithic scatters, a toolstone quarry, and a rockshelter. Historic-period components comprise mining camps and/or tailings features, agricultural related resources such as historic ranches and artifact scatters, and a possible commercial property associated with a former saloon.

Table 3.12-1. Non-confidential Historic-period Cultural Resources within the Area of Analysis.[1]

Primary No.	State Trinomial	Resource Type	Site Type	General Vicinity	NRHP Eligibility

[1] Table 3.12-1 was developed based on Table 3.5-3 3 Previously Recorded Archaeological Sites and Built Environment Resources in the KRRC's September 30 CEQA Technical Submittal. Table 3.5-3 is included as Appendix W of this EIR, and is available online at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/lower_klamath_ferc14803/table3.5_3.pdf

* National Register of Historic Places (NRHP) Eligibility from Cardno ENTRIX (2012) and/or NEIC site records:
- 3: Appears eligible for listing in the National Register of Historic Places;
- 3S: Appears eligible for separate listing;
- 4S2: May become eligible for separate listing in the National Register of Historic Places when more historical or architectural research is performed on the property;
- 7: Not evaluated.
- 8. Eligibility determinations were not made for all historic-period cultural resources listed in this table, but all historic-period cultural resources listed in this table are considered during impact analysis evaluation.

The site recorded solely as an ethnographic property consists of a natural rock landform in the Iron Gate area that features prominently in the cultural history of Shasta tribes. A group of eight sites, termed the Pollock Sites, represents undetermined site components.

Information provided in Table 6-8 in Appendix B: *Definite Plan – Appendix* L regarding the National Register of Historic Places eligibility of the archaeological sites is based on recommendations provided by Cardno Entrix (2012), or by eligibility information noted on site records that were not part of the Cardno Entrix study. Overall, one site is listed in the National Register of Historic Places as a contributor to a district, one site is individually eligible, three sites are contributors to a district, determined eligible, 29 sites appear eligible for listing, 2 sites might become eligible for listing when more historical research is performed; 4 sites have been found ineligible, and the remaining 80 sites have not been evaluated for National Register of Historic Places eligibility.

During State Water Board AB 52 consultation with the Shasta Indian Nation and Shasta Nation it was agreed that tribal cultural resources reflected in PacifiCorp (2004) and Daniels (2006), qualify as tribal cultural resources. Additionally, the Shasta Indian Nation provided updated tribal cultural resources information which is included in Confidential Appendix Q. A process to determine tribal cultural resource eligibility for previously unknown tribal cultural resources or refining understanding of existing tribal cultural resources following Proposed Project activities is discussed in Potential Impact 3.12-1.

Historical Built Environment Resources

The KRRC records search (Appendix B: *Definite Plan – Appendix L, Table 6-3*) identified nine historic-period built environment resources associated with the historic themes of commerce, settlement, transportation, and public works, as described below. The single commerce-themed resource includes a former service station converted to residence

(Klamath Kamp). Two settlement-related sites have been recorded, consisting of a post-1930s duplex residence with associated structures and the Frank Wood cabin, a late 1890s to 1950s era homesite. Transportation-related sites consist of a one-lane, wooden and steel beam truss bridge over the Klamath River (Ash Creek Bridge) west of Interstate 5, and the concrete State Route 263, T-beam bridge over the Klamath River at the confluence of Shasta River. Public works sites include four recorded elements of the Klamath Hydroelectric Project, including Copco No.1 Hydroelectric Powerhouse and Dam; Copco No. 2 Hydroelectric Powerhouse; Fall Creek Hydroelectric Powerhouse; and the Copco No. 2 Wooden Stave Penstock.

Besides these nine built environment resources, standing historic-period structures have been identified at several archaeological sites, including a ranch house and bunkhouse at the Beswick Hotel site (CA-SIS-513-H) and a shed at Copco II Ranch (CA-SIS-2239-H). The historic Spannaus Barn was noted at prehistoric/ethnographic site CA-SIS-2574, but was not recorded as an element of the site.

National Register of Historic Places eligibility information for these nine sites indicates that the two Klamath River bridges have been determined eligible for listing in the National Register of Historic Places. The four hydroelectric related sites were noted by Cardno Entrix (2012) as appearing eligible for separate listing, but these sites have also been documented as contributing elements to the Klamath Hydroelectric historic district (Kramer 2003b) which has yet to be concurred upon by the California and Oregon State Historic Preservation Officers. Also recommended as National Register of Historic Places eligible is the Frank Wood cabin. The final two resources, composed of a residence and a former service station, have been found ineligible for the National Register of Historic Places.

Isolated Finds

The KRRC records search (Appendix B: *Definite Plan – Appendix L, Table 6-3*) identified 68 individual resources not directly associated with sites (i.e., isolated finds or individual low-density concentrations of artifacts or features that do not appear to be associated with a larger site but could indicate Native American use of the area), including 65 prehistoric resources, 2 historic-period resources, and 1 isolated feature of unknown age. Prehistoric isolates include a rock cairn, bedrock milling feature, possible cupule boulders, an incised cobble, ground/battered stone and flaked stone artifacts. Forty-one isolate locations were found to contain flakestone manufacturing debris (debitage) ranging from 1 flake to as many as 13 flakes in a single location. Debitage includes obsidian, chert, and basalt. Eleven isolates contain both tools and debitage.

The historic-period isolates consist of one rusted horseshoe and the remains of a wagon. The isolate of unknown age is described as a rocky depression measuring 8.2 feet in diameter.

Potential Archaeological Districts

As part of the Klamath Hydroelectric Project relicensing study (FERC 2007), five areas containing multiple prehistoric sites were identified along the same section of the Klamath River which was considered as a potential National Register of Historic Places District (PacifiCorp 2004, FERC 2007). This potential district includes four groups of multiple sites in Oregon located at the head of Link River and the mouth of Upper Klamath Lake, Teeter's Landing, Spencer Creek/mouth of upper Klamath River Canyon, and near Frain Ranch. In California, a cluster of three villages near the headwaters to

Iron Gate Reservoir, comprised the fifth potential district group. The National Register of Historic Places eligibility of this district has not been finalized.

A historic-period archaeological district was also considered for the Frain Ranch, in Oregon (PacifiCorp 2004). Due to their association with early homesteading and the beginning of ranching and agriculture within the upper Klamath River, four Frain Ranch area sites were envisioned for this district. The National Register of Historic Places eligibility of this district has not been finalized at this time.

Potential Klamath River Hydroelectric Project District

The Klamath River Hydroelectric Project District comprises seven hydroelectric generation facilities and their related resources located along the Klamath River and its tributaries in Klamath County, Oregon and Siskiyou County, California. Beginning at the Link River Dam, in Klamath Falls, Oregon, the Project boundary continues southwest along the Klamath River to include the Keno Dam Complex and the J.C. Boyle Complex in Oregon. Within California, the Klamath Hydroelectric Project boundary includes the Fall Creek, Copco No. 1 and Copco No. 2 complexes, and terminating at Iron Gate Dam. The Klamath Hydroelectric Project facilities were constructed between 1903 and 1958 by the California Oregon Power Company (COPCO) and its predecessors and are now owned and operated by PacifiCorp under FERC License Nos. 2082 (Kramer 2003a,b) and 14803.

The proposed Klamath River Hydroelectric Project District includes the hydroelectric facilities and various diversion dams; support structures; linear elements such as flumes, canals, and tunnels; and other related buildings and structures. A historic context statement (Kramer 2003a) and Determination of Eligibility (Kramer 2003b) developed for the Klamath Hydroelectric Project notes its eligibility to the National Register of Historic Places as a District under Criterion A for its association with the industrial and economic development of southern Oregon and northern California (Kramer 2003b). The California and Oregon State Historic Preservation Officers have not concurred with this eligibility recommendation. Table 6-11 of Appendix B: *Definite Plan – Appendix L*, identifies key features of the three hydroelectric complexes located in California that are part of the Proposed Project in reference to the National Register of Historic Places eligibility recommendations.

Upper Klamath River Stateline Archaeological District

The newly designated Upper Klamath River Stateline Archaeological District (BLM 2016) is located along the Klamath River, in California, less than 0.5-miles from the Oregon-California state line. The district encompasses three pre-contact village sites that contribute to the district’s significance and one lithic scatter that does not contribute. Archaeological research indicates site use in the district extended from circa 1,000 years ago or earlier to possibly as late as the 1840s (BLM 2016). The district was determined eligible for the National Register of Historic Places at the local level of significance under Criterion D in the areas of Prehistoric Archaeology, Native American Ethnic Heritage, Commerce, Economics, Religion, and Politics/Government. The California State Historic Preservation Officer and the Keeper of the National Register of Historic Places have concurred with the district’s eligibility, and it would therefore qualify as an Historical Resource for the purposes of CEQA.

Ethnographic Information and Tribal Cultural Resources

The ethnographic information presented here for the California portion of the Lower Klamath Project identified tribal cultural resources, and other culturally sensitive areas along the Klamath River in the Proposed Project area are based on ethnographic inventory reports prepared by the Klamath Tribes (Deur 2004), Shasta Nation (Daniels 2003, 2006), Karuk Tribe (Salter 2003), and Yurok Tribe (Sloan 2003) for the FERC Relicensing study, the 2012 KHSA EIS/EIR, and during AB 52 consultation meetings between the State Water Board the Shasta Indian Nation and the Shasta Nation (Confidential Appendices P and Q).

The Klamath Tribes identified several culturally important locations in the Klamath Basin, and noted that tribal fisheries were impacted as a result of impediment of anadromous fish passage due to Klamath River dams (Deur 2004). The Klamath Tribes also identified places along the Klamath River between J.C. Boyle Dam (Oregon) and the Scott River (California) that have tribal cultural value (Theodoratus et al. 1990).

The Shasta Nation reports (Daniels 2003, 2006) present a list of village sites recorded in ethnographic literature, a list of locations that the Shasta consider traditional cultural properties, and another inventory of 11 locations, drawn from the first two listings, that are eligible for the National Register of Historic Places.

The Karuk (Salter 2003) and Yurok (Sloan 2003) ethnographic reports draw upon oral interviews, other writings, ethnographical literature, and a review of natural and cultural resources within the Klamath River to discuss each tribe's traditional and historical relationships with the river, and its resources, to subsistence, spiritual culture, and identity. These tribes recognized the entire Klamath River as part of an important cultural (ethnographic) riverscape.

Klamath Cultural Riverscape

The Klamath River Inter-Tribal Fish and Water Commission incorporated information from existing ethnographic studies, in addition to information provided by the Hoopa Valley Tribe, into a report that focused on the Klamath River (King 2004). The entire length of the river was then identified as a type of cultural or ethnographic landscape, termed the Klamath Riverscape, due to the relationship between The Klamath Tribes, Shasta, Karuk, Hoopa, and Yurok tribes and the river and its resources (Gates 2003, King 2004). The characteristics that contribute to the riverscape's cultural character include natural and cultural elements such as the river itself; its anadromous and resident fisheries; its biological diversity; and its cultural sites, sacred places, uses, and perceptions of value by the tribes (King 2004). Gates (2003) and King (2004) recommend the Klamath Riverscape as eligible for the National Register of Historic Places based on its association with broad patterns of tribal environmental stewardship, spiritual life, and relationships between humans and the non-human world. The ethnographic reports for the riverscape and its eligibility determination have not been submitted to the Oregon and California State Historic Preservation Officers for national or state register for concurrence (USBR and CDFG 2012). This EIR recognizes the Klamath Cultural Riverscape as a Tribal Cultural Resource under Public Resources Code, section 21074.

The Klamath Riverscape's contributing elements include the resources described in the 2012 KHSA EIS/EIR's discussion of tribal trust resources and resources traditionally used by tribes (see Appendix V – 2012 KHSA EIS/EIR *Section 3.12 Tribal Trust*). It is clear from formal consultation under AB 52 with the Yurok Tribe that the health of the Klamath River as a whole, as well as the fishery in particular, are of critical importance to the Tribe's well-being and identity, forming a core for cultural, spiritual, and economic life, and that the Klamath River as a whole constitutes a vital Tribal Cultural Resource. Formal and informal consultation, and comments from tribal representatives from the Karuk Tribe, Hoopa Valley Tribe, and the Klamath Tribe, also underscore the high degree to which the Klamath River's water quality and fisheries are important cultural resources.

Historical Landscape Analysis

As part of the Project Area records search, a historical landscape analysis was conducted to identify locations where post 1850s era settlement and resource developments occurred within the records search area (AECOM 2018). The sources for this study included the review of the General Land Office records, including California plat maps (1856, 1876, 1880, and 1881) and surveyor's notes; a variety of published and manuscript resources (Beckham 2006, Boyle 1976, Kramer 2003a, PacifiCorp 2004, USDI 1989); and USGS maps available at http://historicalmaps.arcgis.com/usgs. Other map searches included the David Rumsey collection, Northwestern California map collection at Humboldt State University, Library of Congress digital collections, and Online Archive of California. Historical landscape information was digitized into a GIS format and a table prepared with site-specific information annotated by Township/Range/Section (Appendix B: *Definite Plan – Appendix L,* Table 6-12). In summary, this research indicated roads, railroads, bridges, logging features, ditches, fence lines, buildings, homesteads, ranches, sites associated with military encampments, and several townsites.

KRRC is currently completing the review of the J.C. Boyle Collection (MI 165306) housed at the Southern Oregon Historical Society in Medford, Oregon. This archive contains photo albums, newspaper clippings, maps, manuscripts, financial records, and Copco annual reports belonging to Copco Engineer J.C. Boyle, and pertaining predominately to construction of Copco No. 1 Dam and Reservoir. This archive is a valuable source of information concerning the pre-inundation historical landscape of the Copco No. 1 area and provides important information regarding cultural and historical resources that may be encountered during reservoir drawdown. In addition, archival and historical landscape research is currently underway at local County repositories and historical societies to provide information regarding cultural and historical resources that may be anticipated during reservoir drawdown at J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoirs.

3.12.3 Significance Criteria

Criteria for determining significance of impacts on historical and tribal cultural resources are based upon consultation, referenced texts, the Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.), and professional judgment.

Impacts to historical and tribal cultural resources are significant if they include the following:

- Physical demolition, destruction, relocation, or other alteration of the historical or tribal cultural resource or its immediate surroundings such that the significance of the historical or tribal cultural resource would be materially impaired.
- Exposure or substantial movement of human remains or associated funerary items[143].
- Exposure of, substantial movement of or increased access to other historic tribal cultural resources leading to increased access and looting[144] of tribal cultural resources above levels occurring under existing conditions.
- Elimination or substantial restriction[145] of access of tribal members to their respective tribal cultural resources above levels occurring under existing conditions.

Tribal cultural resources are defined in Public Resources Code Section 21074 as either a site, feature, place or cultural landscape that is geographically defined in terms of the size and scope of the landscape, sacred place, or object with cultural value to the affected tribe, and that is:

1. Listed or eligible for listing in the national or California Register of Historical Resources, or in a local register of historical resources, or
2. A resource that the lead agency determines is a tribal cultural resource, as further described below.

A lead agency has discretion in identifying unlisted resources as tribal cultural resources, but such a determination requires substantial evidence under the criteria used to determine listings in the historical register and considering the significance of the resource to a California Native American tribe (Public Resource Code, Sections 5024.1, 21074). California Native American tribes traditionally and culturally affiliated with the geographic area of a project may have expertise concerning their tribal cultural resources (Public Resource Code, Section 21080.3.1).

3.12.4 Impact Analysis Approach

The historical and tribal cultural resources impact analysis is based on a review of existing information, such as the results of the California Historical Resources Information System confidential record searches, KRRCs identification efforts (Appendix B: *Definite Plan – Appendix L*) and the AB 52 process with Native American tribes and representatives. Additionally, information received during public scoping was also used to identify potentially important cultural resources (Appendix A).

Known tribal cultural resources within the Proposed Project Area of Analysis include archaeological sites and districts, ethnographic villages, historic period Shasta communities, cemeteries, and cultural landscapes associated with the historical uses of the environments surrounding Iron Gate and Copco No. 1 reservoirs.

---

[143] Substantial movement is defined as movement that would displace tribal cultural resources completely or predominantly outside of existing cultural context in a manner that would impair its cultural significance.
[144] Refers to the illicit collection of artifacts or other tribal cultural resources.
[145] Substantial restriction is defined as loss of access during ceremonial windows or periods of hunting and gathering or other traditional activities associated with a particular tribal cultural resource.

Parts of AB 52 (Gatto 2014) amended Public Resources Code to require consultation with California Native American tribes, when requested, and consideration of tribal cultural resources in the CEQA environmental review process. Following the public scoping meetings, the State Water Board conducted a series of confidential consultation meetings with the Shasta Indian Nation, Yurok Tribe, and Shasta Nation. During consultation, the State Water Board sought information regarding the identification of areas with religious or cultural importance to these tribes, potential impacts of the Proposed Project on such resources, and mitigation measures to avoid, minimize or mitigate adverse effects to identified resources. Information discussed as part of AB52 consultation is incorporated into the impact analyses for historical and tribal cultural resources, as appropriate. AB 52 consultation resulted in development of, and agreement on, mitigation measures with the Shasta Indian Nation and the Yurok Tribe. Consultation with the Shasta Nation informed development of mitigation measures, but the AB 52 process concluded without agreed-upon mitigation measures.

The impact analysis approach for historical and tribal cultural resources also considered existing studies related to reservoir inundation and drawdown with respect to resources located within the Iron Gate and Copco No. 1 reservoir footprints, as described below.

3.12.4.1 Studies on Effects of Reservoir Inundation on Cultural Resources

Lenihan et al. (1981), conducted an interagency, interdisciplinary study on the effects of freshwater reservoirs on cultural resources in order to address conservation management of inundated resources. A hierarchical scheme composed of three levels of cultural resources was assessed for inundation effects: artifacts and artifact assemblages; archaeological site or loci; and regional environmental data base, settlement and resource utilization patterns. The use of the hierarchical scheme was intended to include cultural values beyond discrete sites or artifacts that include spatial, temporal, and organizational relationships between the entities within an environmental and cultural context.

This approach is particularly applicable to landscape level resources such as traditional cultural properties and ethnographic landscapes, even though these property type names came into use after the Lenihan et al. (1981) study. When a river with a long history of cultural use is dammed and water is impounded, the cultural landscape is adversely affected through direct impacts to the archaeological or historical sites themselves and to the relationships of these properties to their environment and to each other on local and broader scales. Besides the changes to the environmental setting, processes of inundation that could affect cultural resources are sediment transport and deposition, erosion processes of wave action along shorelines, and saturation and slumping of submerged strata (Lenihan et al. 1981). Note that slumping, or short-term hillslope instabilities, as may occur during reservoir drawdown are discussed in Section 3.11 *Soils, Geology, and Mineral Resources*, Potential Impact 3.11-3, as well as below for tribal cultural resources (Potential Impact 3.12-2) and historical resources (Potential Impact 3.12-13). Erosion of sediment stored within the Lower Klamath Project reservoirs during reservoir drawdown and the potential for downstream sedimentation due to the released sediment is discussed in Section 3.11 *Soils, Geology, and Mineral Resources*, Potential Impact 3.11-5.

Four factors regarding the extent of impacts to archaeological sites by these processes include the characteristics of the reservoirs themselves (size and operation-fill rate and drawdown frequency); location of sites within the impoundment; geological foundation of a site; and characteristics of the site itself (Lenihan et al. 1981). Erosion processes are most damaging along the edges of the reservoirs in wave action zones that vary vertically with reservoir operations. In general, cultural resource sites located within the wave action zone are most heavily affected, while inundated sites beyond the shore are less affected by erosion and may be capped with sediment. A multitude of other factors, such as, slope, vegetation coverage, substrate, soil and water chemistry, also influences the extent of the impacts to a cultural resource site from inundation. Surface artifact displacement from water movement results in an overrepresentation of heavier weight artifacts (such as, groundstone) and an underrepresentation of lighter weight artifacts (such as, lithic flakes). Damage from vandalism, both intentional and unintentional, increases to sites exposed through erosion and reservoir fluctuations. All of these impacts limit the ability to reconstruct human behavior through artefactual, paleoenvironmental, and site analyses; through direct dating techniques and relative dating of vertical and horizontal placement; and through contextual relationships.

Surveys for previously inundated ancestral Puebloan archaeological sites being exposed due to lowering lake levels as a result of drought at Lake Mead, the reservoir behind Hoover Dam, in Southern Nevada resulted in situations where inundation preserved the sites (Haynes 2008). Sites in shoreline locations were eroded as water regressed, resulting in extensive damage to architectural remains and in the removal of the surface artifact assemblages. In lower energy situations, inundation resulted in capping of the sites with sediment that enhanced preservation. Both architectural and non-architectural features and surface artifacts remained. In other situations, effects of inundation and drawdown resulted in differential artifact removal and secondary re-deposition. Factors contributing to impacts from inundation and later exposure include: energy levels of the reservoir at the site location; terrains upon which the sites sit; weight of artifacts; and artifact collecting once sites were exposed. The results of these surveys on lands exposed from natural drawdown at Lake Mead, a man-made reservoir, are directly applicable to the proposed drawdown of the reservoirs along the Klamath River.

3.12.5 Potential Impacts and Mitigation

3.12.5.1 Potential Impacts to Tribal Cultural Resources

For the purposes of the mitigation measures TCR-1 through TCR-7, the following definitions apply:

Affected Tribes: Tribes on the Native American Heritage Commission list that (1) have expressed interest in participating in further development of the Tribal Cultural Resources (TCRs) measures for the Lower Klamath Project (Project) within 60 days of the Klamath River Renewal Corporation’s (KRRC) January 8, 2018, notice and (2) are traditionally and culturally affiliated with the Area of Potential Effect or otherwise affected by the Project. As of August 13, 2018, the following Native American tribes have expressed interest in participating in further development of such mitigation measures: Cher-Ae heights Indian Community of the Trinidad Rancheria, Karuk Tribe, Klamath Tribes, Modoc Tribe of Oklahoma, Quartz Valley Indian Reservation, Shasta Indian Nation, Shasta Nation, and the Yurok Tribe.

Consultation: Consultation with Affected Tribes in a manner consistent with applicable law. KRRC intends to implement these requirements consistent with California Environmental Protection Agency's "Policy on Consultation with California Native American Tribes," CIT-15-01 (August 20, 2015).

Project Implementation: Project implementation is defined as pre-construction activities, reservoir drawdown, dam removal, restoration activities, and other ground-disturbing activities that comprise the Project, as stated in the Definite Plan.

Potential Impact 3.12-1 Pre-dam-removal activities that involve disturbance of the landscape, including construction or improvement of associated roads, bridges, water supply lines, staging areas, disposal sites, hatchery modifications, recreation site removal and/or development, and culvert construction and improvements could result in potential exposure of or damage to known Tribal Cultural Resources through ground-disturbing construction and disposal activity and increased access to sensitive areas.

Pre-dam removal activities involving ground disturbance, construction or improvement of associated roads, bridges, water supply lines, staging areas, disposal sites, hatchery modifications, recreation site removal and/or development, and culvert construction and/or improvements would occur within the Area of Analysis *Subarea 1* (Figure 3.12-2).

Tribal cultural resources are known to be present within Area of Analysis *Subarea 1* (Figure 3.12-2). Cultural resource sites identified at the edges of Copco No. 1 Reservoir include prehistoric archaeological sites with habitation debris and several contributing elements of the ethnographic landscape (Cardno Entrix 2012, Daniels 2006, Heizer and Hester 1970, PacifiCorp 2004). In addition, ethnographic village sites have been identified within Copco No. 1 Reservoir (Heizer and Hester 1970, Daniels 2006). Native American burials and traditional use areas (for ceremonies) within the Copco No. 1 Reservoir footprint have also been identified through ethnographic research and consultations with the Shasta people. At least one ethnographic village site has been identified within Iron Gate Reservoir by PacifiCorp (2004) and Daniels (2006). Specific TCR locations known to the Shasta people, which include TCRs as reflected in PacifiCorp (2004) and Daniels (2006), and as updated by Confidential Appendix Q, Attachment 4, are cataloged in Confidential Appendices P and Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places (NRHP) in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis.

Due to the nature of ground-disturbing activities and a general increase in the level of activity (e.g., construction, surveys) within the Area of Analysis *Subarea 1*, pre-dam removal activities that would involve ground disturbance have the potential to result in the following significant impacts to known TCRs identified in Confidential Appendices P and Q, as well as unknown TCRs:

- Physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of the TCR would be materially impaired; and/or
- Exposure or substantial movement of TCRs leading to increased access and looting above levels occurring under existing conditions.

Note that TCR sites located within the reservoir fluctuation zones (Confidential Appendices P and Q) may be periodically at risk of looting during low water periods under existing conditions and may have suffered significant degradation in the existing condition.

Implementation of mitigation measures TCR-1 (TCRMP), TCR-2 (LVPP), TCR-3 (IDP), TCR-4 (Endowment)[146] would reduce these impacts considerably, and, for many resources is expected to avoid impacts completely, through the design and implementation of construction plans to completely avoid impacts, or on-the-ground modifications to Proposed Project implementation to avoid impacts. For impacts for which it is not feasible to completely avoid impacts, these impacts may be reduced to a less-than-significant level. The measures (listed fully, below) include among other requirements, field worker training, limits to worker and public access, tribal monitors, surveys, and identification of protocols and best practices upon discovery or disturbance of TCRs during implementation of the Proposed Project. With timely discovery and appropriate steps to address exposure or damage, many TCRs can maintain their current level of cultural significance. Additionally, providing a means for the long-term protection or enhancement of affected TCRs can mitigate for some impacts.

However, the impact of exposing, disturbing or otherwise damaging tribal human remains, or associated funerary items, is itself profound. While the mitigation measures are expected to considerably reduce impacts, they cannot reasonably be expected to eliminate such exposure or disturbance, particularly where, as here, the number of potentially affected burials is high. While treating remains and associated funerary objects with the appropriate respect and procedures can reduce and avoid compounding the harm from the initial damage, it cannot do so fully. Additionally, in light of the high density of TCRs within the Limits of Work, and the nature of the construction involved, significant risk remains that other TCRs may sustain damage that results in a material impairment of the resource's significance. In light of the particular harm of exposing human remains even where they are treated appropriately after exposure, and the likelihood of significantly impairing other types of TCRs in light of the type of construction actions and the density of resources, the impact would remain significant and unavoidable.

Mitigation Measure TCR-1 – Develop and Implement a Tribal Cultural Resources Management Plan.

The KRRC shall develop a Historic Properties Management Plan (HPMP). The HPMP shall include measures to avoid, minimize, or mitigate the Project's adverse impacts to TCRs. The HPMP shall include a Tribal Cultural Resources Management Program (TCRMP), which will state such measures.

KRRC shall develop the TCRMP in consultation with Affected Tribes. The KRRC shall finalize the HPMP during FERC's hearing on the license surrender application for the Project. The KRRC shall propose the HPMP for FERC's approval as a term of the license surrender order.

[146] Mitigation Measures TCR-6, TCR-7, and TCR-8 could also further reduce the potential impact. However, at this point it is not clear whether the measures are feasible (see Potential Impact 3.12-9.) Therefore, this EIR does not rely on implementation of these measures, in reaching its significance determinations.

In developing the TCRMP, KRRC shall engage in good faith consultation with the Affected Tribes that are traditionally and culturally affiliated with a specific portion of the APE or with potentially affected TCRs. Where a particular tribe has identified a specific TCR, the primary consultation about that TCR shall be with the affected tribe. All such consultation shall be subject to the schedule for HPMP development. If consensus cannot be reached during TCRMP development, KRRC shall record the disputed issues, positions on the disputed issues, and KRRC's proposed resolution, in the HPMP that is submitted to FERC.

The TCRMP shall include the following elements consistent with applicable law:

1. The TCRMP shall include an inventory of known and potential TCRs that could be affected by the Project. Appendix B: *Definite Plan – Appendix L* includes a preliminary inventory of such resources. KRRC will continue to develop the inventory through the consultation process for the license surrender application under authority of the National Historic Preservation Act (NHPA) Section 106.

   Based on AB 52 consultation, KRRC acknowledges that the Shasta Indian Nation and Shasta Nation are primarily concerned with TCRs associated with Iron Gate, Copco No. 1, and Copco No. 2 reservoirs, and tributary sub-watersheds such as Fall Creek, Bogus Creek, and Deer Creek. The TCRMP shall include TCRs known to the Shasta Indian Nation, which include TCRs as reflected in PacifiCorp (2004) and Daniels (2006) and as updated by Attachment 4 of the Confidential Appendix Q. The TCRMP shall include TCRs known to the Shasta Nation, which include the TCRs identified in the Confidential Appendix P. The TCRMP shall include TCRs known to other Affected Tribes.
2. The TCRMP shall include provisions to protect the confidentiality of known TCRs. The TCRMP shall also include provisions to share information collected by the KRRC with: Affected Tribes that are traditionally and culturally affiliated with the known TCR(s); regulatory agencies that have authority over protecting such resources, as necessary; or as necessary with the permission of such tribes in order to implement appropriate protective or enhancement measures. These provisions will be consistent with California Public Resources Code Section 21082.3(c).
3. The TCRMP shall assure that the Project will avoid, minimize, or mitigate adverse impacts to TCRs, consistent with California Public Resources Code section 21084.3(a). In developing the plan, the KRRC will consider measures listed in California Public Resources Code section 21084.3(b) that, if feasible, may be appropriate to avoid, minimize, or mitigate adverse impacts:

   (1) "Avoidance and preservation of the resources in place, including, but not limited to, planning and construction to avoid the resources and protect the cultural and natural context, or planning greenspace, parks, or other open space, to incorporate the resources with culturally appropriate protection and management criteria.

   (2) Treating the resource with culturally appropriate dignity taking into account the tribal cultural values and meaning of the resource, including, but not limited to, the following:

   (A) Protecting the cultural character and integrity of the resource.

   (B) Protecting the traditional use of the resource.

   (C) Protecting the confidentiality of the resource.

(3) Permanent conservation easements or other interests in real property, with culturally appropriate management criteria for the purposes of preserving or utilizing the resources or places in a manner consistent with the KHSA.

(4) Protecting the resource."

4. The TCRMP shall require a training program for KRRC's field personnel associated with the Project. The training program will be designed to train KRRC field personnel to work collaboratively with tribal monitors and will focus on field procedures (across the range of field personnel) as necessary for appropriate and respectful treatment of TCRs; and will be intensive and systematic, in light of the scale, complexity, and schedule of the Project undertakings.
5. The TCRMP shall identify TCR areas that will have limited or no public access during Project implementation. During that period, the KRRC shall: install adequate signage to clearly mark areas with limited or no public access areas; install fencing where necessary and feasible to reduce access; and provide appropriate training to field personnel. Upon the recommendation of a tribe that has identified the TCR area, the KRRC may consider, and the TCRMP may include, other equally effective measures to reduce public access in lieu of (or in addition to) those identified immediately above.
6. The TCRMP shall include site-specific mitigation measures for potentially affected TCRs. The TCRMP shall provide for ongoing consultation or site-specific mitigation refinement with the relevant Affected Tribe(s) with a traditional and cultural affiliation to an impacted TCRs, as appropriate and feasible consistent with the schedule for Project implementation.
7. The TCRMP shall identify any areas where the KRRC, before Project implementation, shall conduct any additional cultural resource surveys, consistent with California Public Resources Code section 21074.
8. The TCRMP shall provide that the KRRC, following reservoir drawdown and dam removal, shall undertake intensive surveys of TCRs, archaeological, and other historical resources within the area of analysis, using joint teams of archaeologists and tribal monitors. The TCRMP shall specify the methods for such surveys. It shall also specify the process by which Affected Tribes will nominate, and KRRC will select and compensate tribal monitors. During this process, an Affected Tribe that is traditionally and culturally affiliated with the area may nominate tribal monitor(s) for KRRC's consideration; and KRRC shall make the selection after consultation with Affected Tribes. KRRC shall select and pay tribal monitor(s) for the purpose of Project implementation. In the event that KRRC does not select a tribe's recommended monitor, an Affected Tribe that is traditionally and culturally affiliated with the area may request participation of its recommended tribal monitor in these surveys at its own cost. KRRC's field personnel, in consultation with tribal monitors, shall record these surveys in a manner consistent with applicable law. KRRC shall provide recorded survey data pertaining to a known TCR to the Affected Tribes that are traditionally and culturally affiliated with that TCR.
9. The TCRMP shall state a range of appropriate measures, and a protocol to select from such range, to address the disturbance or exposure of known TCRs during Project implementation. The KRRC shall implement measures necessary to ensure the protection of disturbed or exposed TCRs.
10. The TCRMP shall provide that the KRRC will identify and avoid TCRs during the siting and construction of new recreational sites, to the extent feasible. The

KRRC shall address potential conflicts consistent with California Public Resources Code section 21084.3(a) and (b).

11. The TCRMP shall provide for restoration actions associated with any ground disturbances such as grading and manual or machine excavation, so as to protect TCRs. The KRRC shall consider limiting or completely avoiding mechanical weed control activities (e.g., mowing, hand-weeding) or herbicide use to protect TCRs in areas identified by Affected Tribes, as necessary. In revegetation efforts, the KRRC shall incorporate specific plant species that are important to Affected Tribes with a traditional and cultural affiliation to the area at issue, to the extent that doing so is feasible and complies with the requirements of the federal and state approvals of the Project. The KRRC shall provide training regarding these actions to its field personnel.
12. The TCRMP shall incorporate the results of the KRRC's Bathymetric Survey, and specifically, the refined understanding of sediment thickness in Iron Gate and Copco No. 1 reservoirs, to inform monitoring efforts for potential exposure of TCRs during and following reservoir drawdown. Information from this review shall inform the Inadvertent Discovery Program (described below), which will be part of the TCRMP.
13. The KRRC shall consult with Affected Tribes in the planning process for the redesign and relocation of the water supply line for the City of Yreka to identify, avoid if feasible, or mitigate effects to TCRs during the siting and construction of the water supply line. The KRRC shall address potential conflicts consistent with California Public Resources Code section 21084.3 (a) and (b).
14. Consistent with KHSA Section 7.6.6, the TCRMP shall include recommended measures to identify, avoid, minimize, or mitigate effects to TCRs during modifications of Iron Gate Hatchery, consistent with California Public Resources Code section 21084.3 (a) and (b).
15. Consistent with KHSA Section 7.6.6, the TCRMP shall also include recommended measures to identify, avoid, minimize, or mitigate adverse impacts to TCRs during rehabilitation and expansion of Fall Creek Hatchery, consistent with California Public Resources Code section 21084.3 (a) and (b).
16. The TCRMP shall include a dispute resolution process in the event that, during Project implementation, Affected Tribes dispute which measures to apply to avoid, minimize, or mitigate the Project's adverse impacts to a specific TCR with which the Affected Tribes are traditionally and culturally affiliated. The process shall include neutral mediation to be undertaken consistent with the schedule for Project implementation. In consultation with Affected Tribes, the KRRC shall engage a standing mediator who is available to resolve disputes about which measures to apply.

Mitigation Measure TCR-2 – Develop and Implement a Looting and Vandalism Prevention Program.

In consultation with Affected Tribes and jurisdictional law enforcement, the KRRC shall develop and implement a Looting and Vandalism Prevention Program (LVPP), specifically to deter looting and vandalism to TCRs associated with the Project. The LVPP, which may be part of the TCRMP, shall include the following elements consistent with applicable law:

1. The LVPP shall include appropriate measures to deter looting and vandalism during Project Implementation. The KRRC shall implement these measures for a

minimum of 3 years following completion of dam removal, or until KRRC has transferred applicable Parcel B lands to the States or third parties under the terms of the KHSA Section 7.6.4.

2. The LVPP shall specify the frequency of monitoring efforts of known TCR areas and other areas subsequently identified by the KRRC or tribal monitors during Project implementation. Monitoring frequency shall not be less than quarterly, with allowances for additional targeted monitoring that is triggered by natural or opportunistic events, such as a large magnitude flood event. The LVPP shall provide that monitoring need and frequency will vary depending on the level of risk associated with various activities during Project implementation.
3. The LVPP shall include a training program on looting and vandalism prevention and site documentation, for the benefit of KRRC's field personnel as well as tribal monitors.
4. The LVPP shall include protocols for communications and reporting to law enforcement and other relevant state and federal agencies, consistent with applicable law.
5. The LVPP shall include appropriate measures to restrict public access to specific Project areas where known TCRs, or those identified through inadvertent discovery, are located. KRRC shall implement these measures until it has transferred the Parcel B lands to the states or third parties under KHSA Section 7.6.4. Specific measures to be considered shall include: fencing; posting of signs; strategic plantings; strategic routing of access roads, boating access points and trails; specific recommendations for land use or land transfer in the KHSA Section 7.6.4 process or other means determined necessary and feasible to protect TCRs from opportunistic looting and public access (authorized and unauthorized).
6. The LVPP shall include appropriate measures to prevent or restrict public access to reservoir areas during reservoir drawdown and dam removal.
7. The LVPP shall include appropriate measures to prevent or restrict public access to newly exposed reservoir areas following reservoir drawdown. Such measures shall limit use of off-road vehicle paths and informal roads and tracks, and unauthorized use of developed and dispersed recreation sites. KRRC shall implement these measures until it transfers Parcel B lands to the states or third parties pursuant to KHSA Section 7.6.4, subject to an assignment of continuing responsibilities by the transferee.

Mitigation Measure TCR-3 – Develop and Implement Inadvertent Discovery Plan (IDP).

In consultation with Affected Tribes, the KRRC shall develop and implement an Inadvertent Discovery Program (IDP), which shall be a part of the TCRMP. The IDP shall establish protocols for the discovery of unanticipated or previously unknown TCRs, including human burials or human remains discovered during Project implementation. The IDP shall provide for compliance with applicable law regarding cultural resources and human remains; state work site protocols to be followed in the event of an inadvertent discovery; and identify appropriate point of contacts associated with the protocols. The IDP shall include protocols for work in areas known to have a high chance of inadvertent discoveries, including the Iron Gate, Copco No. 1, Copco No. 2 reservoir areas, as well as the altered FEMA 100-year floodplain area between Iron Gate Dam and Humbug Creek following dam decommissioning.

The IDP shall include the following specific elements:

1. The IDP shall acknowledge that there may be unknown TCRs in association with TCRs known to the Shasta Indian Nation, which include TCRs as reflected in PacifiCorp (2004) and Daniels (2006) and as updated by Confidential Attachment 4 of the Confidential Appendix Q.
2. The IDP shall state protocols that KRRC shall implement for sites that are addressed under California Public Resources Code 5097.993 and/or for sites found to contain TCRs, human burials, or human remains during and after drawdown activities. These protocols shall identify appropriate agency and tribal contacts for such situations. In the case of human remains in California, the KRRC shall also notify the county coroner and follow the procedures stated in California Health and Safety Code section 7050.5(b) to the extent feasible. Upon discovery, the KRRC's environmental monitor shall notify the KRRC's qualified archaeologist of the discovery, and the KRRC's qualified archaeologist shall complete a letter report to assess and document the discovery. The KRRC shall circulate the letter report to Affected Tribes, the Native American Heritage Commission for inadvertent discoveries on private and state lands in California, and other appropriate land management agencies, within 72 hours of the discovery.
3. The IDP shall state protocols that KRRC will implement for reservoir drawdown or restoration activities following an inadvertent discovery. Such protocols shall be consistent with the Definite Plan and shall take into account potential downstream environmental impacts; cultural resource impacts in the Iron Gate, Copco No. 1, Copco No. 2 reservoir areas; mitigation and stabilization for tribal and cultural resources found in the APE outside of the reservoirs; and mitigation in the altered FEMA 100-year floodplain area between Iron Gate Dam and Humbug Creek following dam decommissioning. The IDP shall identify the measures that the KRRC will follow to protect TCRs following an inadvertent discovery.
4. The IDP shall provide for tribal monitors to participate in monitoring during Project implementation. The tribal monitors shall be present as feasible and appropriate pursuant to the schedule for different phases of Project implementation, to address unknown TCRs that are exposed. Pursuant to item (6), the monitoring schedule for tribal monitors shall consider that monitoring frequency and duration may differ by geographic area or Project phase or activity.
5. The IDP shall provide for the development and implementation of a training program regarding the inadvertent discovery of cultural resources and human remains during Project activities. All of KRRC's field personnel and tribal monitors shall be instructed on site discovery, avoidance, and protection measures, including information on the statutes protecting cultural resources.
6. The IDP shall establish the frequency of specific monitoring efforts during Project implementation in identified areas where the discovery of unidentified TCRs may be likely given currently available information and other known archaeologically or culturally sensitive areas that may be identified by the tribal monitors. Monitoring locations will be specified during the development of the Inadvertent Discovery Program in the HPMP. Monitoring frequency during Project activities that cause ground disturbance shall not be less than quarterly, with allowances for additional targeted monitoring that is triggered by natural or opportunistic events during the reservoir drawdown or a subsequent large magnitude flood event. Such monitoring efforts shall be led by KRRC's archaeologists in consultation with tribal

monitors and shall include the field reconnaissance of newly exposed sediments for surface features, to include, but not be limited to intensive, pedestrian survey for areas with relatively low slopes (<30 percent) and that are sufficiently dried to permit for safe access for pedestrian survey and to permit safe access for survey vehicles. In areas where intensive, pedestrian survey is not possible, KRRC in consultation with tribal monitors may use low-elevation aerial survey methods (e.g., unmanned aerial vehicles) or barge surveys to accomplish monitoring.

7. The IDP shall include a timeline, in consultation with Affected Tribes, for completing treatment measures and assessing California Register significance for discovered cultural resources and human burials or remains.
8. The IDP shall include dispute resolution procedures in the event that Affected Tribes disagree on which measures to apply to protect TCRs following inadvertent discovery. When the inadvertent discovery occurs on private or state lands in California, the procedures set forth in California Public Resources Code section 5097.98 will be followed where feasible, including mediation pursuant to California Public Resources Code section 5097.94. To the extent that inadvertent discoveries occur on federal or tribal lands, appropriate procedures under tribal or federal law will apply.

Mitigation Measure TCR-4 – Endowment for Post-Project Implementation.
The TCRMP shall include a provision for the KRRC to provide funding for an endowment or other appropriate organization (e.g., a non-profit mutual benefit organization) to protect and enhance TCRs that are exposed due to the Project implementation on state and private lands in California, on a long-term basis following license surrender. This endowment shall include funding for monitoring, including supplementing or enhancing law enforcement resources, and shall also be available to cover measures that will be implemented following license surrender, including measures related to looting and vandalism protections. The endowment shall be governed in a manner that is representative of Affected Tribes that are traditionally and culturally affiliated with the TCRs impacted by Project Implementation. The KRRC shall consult with Affected Tribes, with the assistance of the standing mediator during development of the TCRMP, to develop the specifications for funding and governance.

Significance

Significant and unavoidable with mitigation

Potential Impact 3.12-2 Drawdown of Iron Gate, Copco No. 1, and Copco No. 2 reservoirs could result in shifting, erosion, and exposure of known or unknown, previously submerged Tribal Cultural Resources.
The Proposed Project would draw down Iron Gate, Copco No.1, Copco No. 2 and J.C. Boyle reservoirs at a rate between 2 and 5 feet per day (i.e., 1 to 2.5 inches per hour). Drawdown of Copco No. 1 would begin November 1 of dam removal year 1 at a maximum rate of 2 feet per day, and drawdown of all reservoirs would occur at a maximum rate of 5 feet per day beginning January 1 of dam removal year 2 and continue until March 15 of the same year. The analysis for Potential Impact 3.12-2 focuses on the California Lower Klamath Project reservoirs, including Copco No.1, Copco No. 2, and Iron Gate, which are contained within Area of Analysis *Subarea 1* (Figure 3.12-2).

Since the Lower Klamath Project reservoirs were constructed, fine sediments composed primarily of organic material (including dead algae), but also including some silts and clays, have accumulated along the reservoir bottoms. The distribution of sediment deposits varies within each reservoir (Figure 2.7-8 and 2.7-9). Because the accumulated sediments are primarily fine material, they would be easily eroded and flushed out of the reservoirs into the Klamath River during reservoir drawdown. The degree of sediment erosion would vary, with the majority of the erosion focused in the historical river channel that is currently submerged in Copco No. 1 and Iron Gate reservoirs (see Figures 2.7-5 and 2.7-6).

Following drawdown, 40 to 60 percent of the existing sediment deposits would remain in place in each of the former reservoir beds, primarily on terraces located above the historical river channel. The sediments that remain in the reservoir footprints would consolidate (dry out and decrease in thickness) (USBR 2012a), making them less subject to erosion. Further, during the drawdown period, aerial seeding of pioneer mixes would occur as the reservoir water level drops before the exposed reservoir sediments dry and form a surface crust. Pioneer seed mixes would contain a variety of riparian and upland common native species, and possibly a small amount of sterile non-native species to enhance initial erosion protection. Aerial seeding during reservoir drawdown would not result in any further disturbance of soil on the exposed reservoir terraces and the establishment of vegetation on the terraces would potentially reduce erosion of fine sediments. Recent laboratory tests of reservoir sediments showed vegetated sediments produced less erodible fine particles and aggregates during cycles of wetting and drying than unvegetated sediments (Appendix B: *Definite Plan – Appendix H*).

Although not currently anticipated by KRRC, the Proposed Project may also include hydroseeding from a barge on exposed reservoir terraces as the water recedes during reservoir drawdown. Hydroseeding from a barge would be accomplished by placing a ground rig on one barge with another boat used to ferry materials from shore. A moveable pier or other engineered method of accessing the supply boat as the water level recedes would also be needed. If it occurs, barge hydroseeding would occur in the higher elevation portion of the reservoir shoreline, until the reservoir levels become too low to operate (i.e., March of dam removal year 2).

The Proposed Project also includes barge-mounted pressure spraying during reservoir drawdown that would target six locations in Copco No. 1 Reservoir and three locations in Iron Gate Reservoir within which to maximize erosion of sediment deposits and subsequently excavate to the historical floodplain elevation to create wetlands, floodplain areas and off-channel habitat features (see Appendix B: *Definite Plan – Appendix H Figures 5-4 and 5-7*).

Tribal cultural resources are known to be present within Area of Analysis *Subarea 1* (Figure 3.12-2). Cultural resource sites identified at the edges of Copco No. 1 Reservoir include prehistoric archaeological sites with habitation debris and several contributing elements of the ethnographic landscape (Cardno Entrix 2012, Daniels 2006, Heizer and Hester 1970, PacifiCorp 2004). In addition, ethnographic village sites have been identified within Copco No. 1 Reservoir (Heizer and Hester 1970, Daniels 2006). Native American burials and traditional use areas (for ceremonies) within the Copco No. 1 Reservoir footprint have also been identified through ethnographic research and consultations with the Shasta Nation and Shasta Indian Nation. At least one ethnographic village site has been identified within Iron Gate Reservoir by PacifiCorp

(2004) and Daniels (2006). Specific TCR locations known to the Shasta people, which include TCRs as reflected in PacifiCorp (2004) and Daniels (2006), and as updated by Confidential Appendix Q, Attachment 4, are cataloged in Confidential Appendices P and Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis.

It is unknown whether adverse effects have already occurred to known or unknown, previously submerged TCR sites due to saturation within reservoir sediments and overlying water currents. However, impacts to these sites would likely result from shifting and exposure of reservoir sediment deposits during and after drawdown. Some TCR sites within the reservoir footprints may remain covered in sediment, or capped, resulting in some degree of preservation and protection.

Tribal cultural resource sites located in areas of steep or perched slopes, such as those along the steeper edges in the reservoir fluctuation zones[147], may experience shifting and slumping as a result of the underlying strata not being able to support the weight of overlying saturated soils. This is of particular concern for diatomaceous deposits located along the rim and below the Copco No. 1 Reservoir water level (see also Section 3.11.2.2 *Geomorphology* and Potential Impact 3.11-3). While the Proposed Project maximum drawdown rates (i.e., between 2 and 5 feet per day) are intended to minimize the potential for shifting and slumping of sediment deposits during reservoir drawdown, some sediment movement could still occur and could displace tribal cultural resources located in areas of steep or perched slopes that have relatively less thick sediment deposits. Note that some of the tribal cultural sites located within the reservoir fluctuation zones may be experiencing macro-scale wave-induced erosion impacts as part of existing conditions. Existing damage to exposed tribal cultural resources at some of these sites may be evident as wave cut terraces (beachlines) and other areas of accelerated erosion or scouring, as well as pedestaled and redeposited artifacts within the reservoir fluctuation zones. Given the proposed drawdown rates (2 to 5 feet per day), the reservoir shoreline would move below the normal fluctuation zone for each reservoir within 1 to 3 days of beginning drawdown. As this is a relatively short time frame compared to the continuous wave action that happens in this zone under existing conditions, reservoir drawdown alone is not expected to result in additional erosion-induced destruction or material alteration of the known tribal cultural resource sites in a way that would undermine their current or historical tribal significance relative to existing conditions. If it occurs, barge hydroseeding within the reservoir fluctuation zone would not result in additional wave-induced shoreline erosion outside of the range of existing conditions because barges tend to generate low wave heights due to their wide, flat bottoms and low operating speeds. Further, any concentrated additional wave-induced erosion from barge hydroseeding would be limited to a shorter duration (i.e., over several hours within a single day) than that of wind-action on the slowly downward-moving reservoir surface. Therefore, barge hydroseeding would be unlikely to exacerbate erosion impacts beyond that of reservoir drawdown itself, which would be within the range of existing conditions.

[147] For Copco No. 1 Reservoir, the normal maximum and minimum reservoir operating levels are between 2,607.5 and 2,601.0 feet mean sea level (MSL), respectively, or a range of 6.5 feet for the reservoir fluctuation zone (PacifiCorp 2004b). For Iron Gate Reservoir, levels are between 2,330.0 and 2,324.0 feet MSL, respectively, or a range of 4 feet for the fluctuation zone (PacifiCorp 2004b).

Additional potential impacts to TCR sites within the reservoir footprints, including short-term erosion, surface/shallow subsurface disturbance (i.e., sediment slumping), artifact displacement, and precipitation-induced runoff disturbance are discussed in Potential Impact 3.12-7. Increased potential for looting of exposed TCRs at Iron Gate, Copco No. 1, and Copco No. 2 reservoirs during and following reservoir drawdown activities is discussed in Potential Impact 3.12-6.

Overall, the increased likelihood of impacts to known or as-yet unknown previously submerged TCRs due to drawdown of Iron Gate, Copco No. 1, and Copco No. 2 reservoirs would be a significant impact in light of the following:

- Increased potential for shifting, erosion, and/or exposure of TCRs that results in destruction or material alteration of the resources in a way that would undermine current or historical significance, in light of an existing condition in which the TCRs are under water.
- The large number of known TCRs, and the high potential for the presence of as-yet unknown TCRs, that are currently submerged by Copco No.1, Copco No. 2, and/or Iron Gate reservoirs.

Implementation of Mitigation Measures TCR-1 (TCRMP), TCR-2 (LVPP), TCR-3 (IDP), and TCR-4 (Endowment)[148] would reduce these impacts considerably, and, for many resources is expected to avoid impacts completely or to reduce the impact to less than significant. The measures (listed fully, below) include, among other requirements, timely surveys of exposed land, on-side tribal monitors, limits to public access, and identification of protocols and best practices upon discovery or disturbance of TCRs in project implementation. With timely discovery and appropriate steps to address exposure, shifting or erosion impacts, many TCRs can maintain their current level of cultural significance. Additionally, providing a means for the long-term protection or enhancement of affected TCRs can mitigate for certain impacts.

However, the impact of exposing or disturbing tribal human remains, or associated funerary items, is itself profound. While the mitigation measures are expected to considerably reduce impacts, they cannot reasonably be expected to eliminate such exposure or disturbance, particularly in light of evidence that the number of submerged burial sites is high. Thus, while drawdown is not generally anticipated to have large effects on material below the earth's surface at the time of reservoir inundation, where slumping is a risk and where so many sites are involved (including some sites that have been subject to wave action with an erosive effect) material risk remains that some burials may be affected. While treating remains and associated funerary objects with the appropriate respect and procedures can reduce and avoid compounding the harm from the initial exposure or movement, it cannot do so fully. In light of the particular harm of exposing human remains even where they are treated appropriately after exposure, the impacts would remain significant and unavoidable.

Significance

Significant and unavoidable with mitigation

[148] Mitigation Measures TCR-6, TCR-7 and TCR-8 could also further reduce the potential impact. However, at this point it is not clear whether the measures are feasible (see Potential Impact 3.12-8). Therefore, this EIR does not rely on implementation of these measures in reaching its significance determinations.

Potential Impact 3.12-3 Reservoir drawdown could result in short-term erosion or flood disturbance to tribal cultural resources located along the Klamath River.

Hydroelectric Reach

The Hydroelectric Reach from the California-Oregon state line to Copco No. 1 Reservoir includes prehistoric archaeological riverside sites with habitation debris, house pits and rock features and cemeteries; as well as ethnographic places and other features of the cultural landscape (PacifiCorp 2004, Daniels 2006). Historic period refuse scatters, an historical hotel ruin sites, historical ranching sites, and historic roads are also present (Cardno Entrix 2012). There are known TCR sites located within the Area of Analysis *Subarea 3* (Figure 3.12-4) along the Klamath River between J.C. Boyle Dam and Copco No.1 Reservoir (Confidential Appendices P and Q). Certain of these sites may be impacted by increased flows during drawdown of J.C. Boyle Reservoir in Oregon because they are situated along the river's edge. It is a profound concern of the Shasta Nation that particular TCR sites along this reach would be flooded, and possibly destroyed, during drawdown (see also Confidential Appendix P as well as Shasta Nation consultation letter [2/1/2017] and public scoping letter [2/1/2017]).

As the Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities are located below this section of the Klamath River, the TCRs in this area would only be affected by the drawdown of J.C. Boyle. J.C. Boyle Reservoir has a relatively small storage capacity (3,495 acre-feet) and is not operated by PacifiCorp as a flood control reservoir. PacifiCorp operates J.C. Boyle Reservoir to produce hydroelectric power. Under current operations, when the inflow to J.C. Boyle Reservoir is below approximately 2,800 cfs, water is typically stored at night and released for power generation during the day which coincides with peak energy demand. When the inflow to the reservoir is greater than approximately 2,800 cfs, water does not need to be stored to generate power since the maximum capacity of the two turbine units in the J.C. Boyle Powerhouse is 2,850 cfs and any additional inflow to the reservoir spills over the dam. Spillage over the dam and flow through the J.C. Boyle Bypass reach in excess of the typical 100 cfs bypass flows generally occurs during the months of January through May when the Klamath River inflow to J.C. Boyle Reservoir tends to be greater than 2,800 cfs (Appendix B: *Definite Plan*). All flows diverted for power generation are returned to the Klamath River downstream stream of the J.C. Boyle Powerhouse in the J.C. Boyle Peaking Reach. Flows in the Klamath River between J.C. Boyle Reservoir and the upstream end of Copco No. 1 Reservoir vary by season and year, ranging from a daily mean value of less than 1,000 cfs during summer low flow periods to as high as 10,800 cfs in the spring of 1972 (Figure 3.12-7).

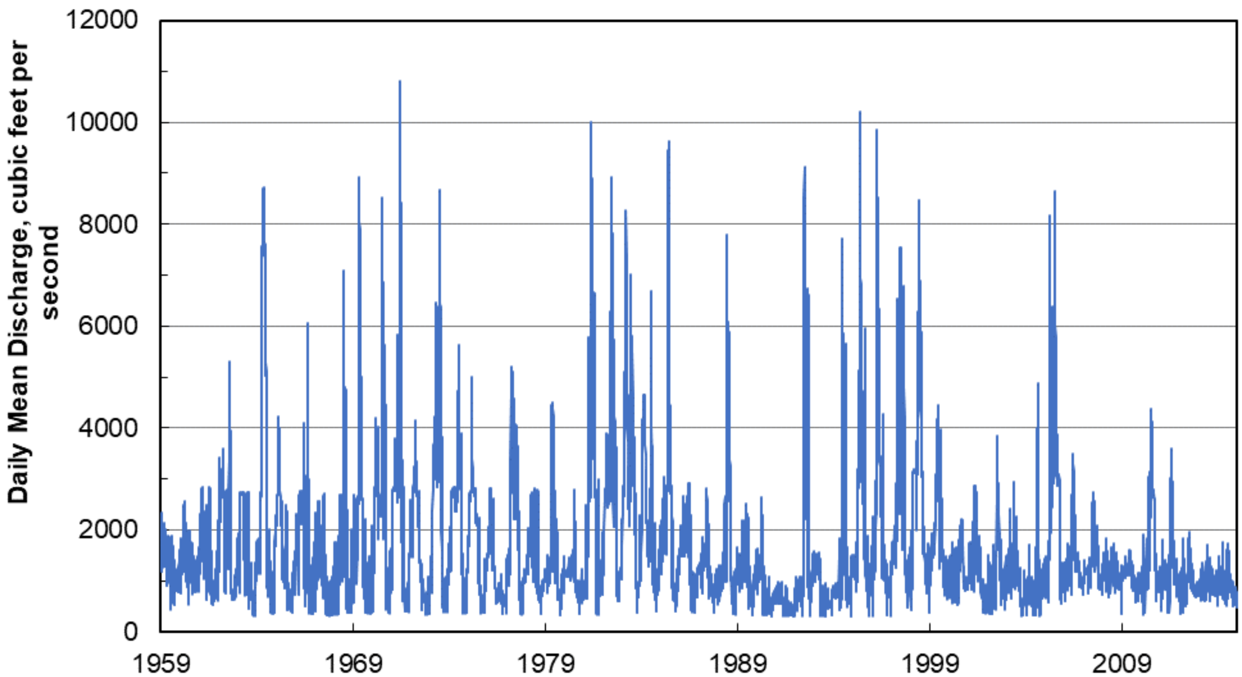

Figure 3.12-7. Discharge (flow) for Klamath River Downstream from J.C. Boyle Powerhouse, 1959–2015. Source: USGS 2016.

The proposed drawdown of the Lower Klamath Project reservoirs is designed to minimize potential flood risks, including carefully drawing down the reservoirs using controlled flow releases and the increased storage availability in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs once drawdown has begun to accommodate for potential winter flow events. Drawdown of J.C. Boyle Reservoir would occur from January 1 to March 15 of dam removal year 2. During drawdown, release flows at J.C. Boyle Dam would range from 1,000 to 3,000 cfs for short durations (1−2 days) (Appendix B: *Definite Plan*). As shown in Figure 3.12-7, flows of this magnitude are typical for the Klamath River upstream of Copco No. 1 Reservoir and downstream from J.C. Boyle Powerhouse and are well below maximum flows (close to 11,000 cfs). Accordingly, the average increase in Klamath River flow due to drawdown of J.C. Boyle Reservoir is expected to be small, from less than 1 percent up to 8 percent during the months of January and February of dam removal year 2 (Appendix B: *Definite Plan*). Thus, the Proposed Project would not result in drawdown flows that are out of the normal range of flows experienced under existing conditions. Since drawdown releases from J.C. Boyle Dam would not cause flooding of the river between the dam and Copco No. 1 Reservoir, the Shasta TCR sites located along this reach of the Klamath River would not be subject to short-term erosion and/or flood disturbance related to the removal of J.C. Boyle Dam.

Many of the Shasta TCR sites located along the river in this reach are located within the current FEMA 100-year floodplain. Because J.C. Boyle Reservoir is not a flood control reservoir, the FEMA 100-year floodplain extent in the Klamath River between J.C. Boyle Dam and Copco No. 1 Reservoir would not change with dam removal (see Appendix K). Thus, there would be no long-term change in the flooding potential for Shasta TCR sites due to removal of J.C. Boyle Dam. Overall, there would be no significant impact of the

Proposed Project on Shasta TCR sites located between J.C. Boyle Dam and Copco No. 1 Reservoir.

Middle Klamath River

Known TCRs within the Area of Analysis *Subarea 2* (Figure 3.12-3) include resources identified in PacifiCorp (2004) and Daniels (2006), as updated by Confidential Appendix Q, Attachment 4, and are cataloged in Confidential Appendices P and Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis.

Under the Proposed Project, drawdown of the four reservoirs would occur simultaneously beginning in January of dam removal year 2 (Copco No. 1 Reservoir would also experience early drawdown starting November of dam removal year 1 at a lower rate) (see also Section 2.7.2 *Reservoir Drawdown*). Drawdown of Copco No. 2 may occur later, at the start of May of dam removal year 2. The reservoir releases would be controlled and would vary by reservoir depending on the type of dam, discharge capacity, water year type, and the volume of water and sediment within the reservoir (Appendix B: *Definite Plan*). The proposed drawdown of the Lower Klamath Project reservoirs is designed to minimize potential flood risks, including drawing down the reservoirs using controlled flow releases and the increased storage availability in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs once drawdown has begun to accommodate for winter flow events. If a flood event occurred during drawdown, the flood flows would be retained using the newly available storage capacity in each reservoir and drawdown would continue after flood risks have ended. Current conditions do not allow the Lower Klamath Project reservoirs to assist in flood prevention in this manner as the reservoirs' current operations occur within a narrow reservoir storage rage and do not provide adequate space for storage of winter flows. The Proposed Project drawdown rates are consistent with the historical discharge rates from the reservoirs, where flow rates downstream of the dams would not increase substantially above median historical rates, if at all. Discharges from Copco No. 1 and Iron Gate reservoirs would be similar to, or less than, seasonal 10-year flood flows from the reservoirs (see also Potential Impact 3.6-1).

Thus, drawdown releases from the Lower Klamath Project dams would not cause flooding of the Middle and Lower Klamath River, riverside TCR sites located in Area of Analysis *Subarea 2* (Figure 3.12-3), downstream of Iron Gate Dam either along the reach from Iron Gate Dam (RM 193) to Humbug Creek (RM 174) or further downstream. Therefore, these resources would not be subject to increased short-term erosion or flood disturbance as a result of reservoir drawdown that could destroy or materially alter TCRs in a way that would undermine current or historical cultural significance.

However, hydrologic and hydraulic modeling of floodplain inundation shows that removal of the Lower Klamath Project dams could result in minor alterations to the FEMA 100-year floodplain inundation area downstream of Iron Gate Dam, along the 18-river mile stretch of the Middle Klamath River between RM 193 and 174 (i.e., from Iron Gate Dam to Humbug Creek) (USBR 2012c). Changes in the extent of the floodplain inundation area could increase the risk of flood damage to TCRs that are not currently located within the FEMA 100-year floodplain but would be following dam removal, where flood damage could involve physical destruction or relocation of TCRs such that the significance of the TCR would be materially impaired. This would be a significant impact in the short term and long term. Implementation of TCR-1, TCR-2, and TCR-3 would reduce impacts, although for the reasons described in Potential Impact 3.12-1, the impacts would remain significant and unavoidable.

Lower Klamath River and Klamath River Estuary
Because drawdown is not expected to increase flood risk and because dam removal is not expected to alter the floodplain downstream of Humbug Creek, no increased erosion or flooding-related risk of damage to cultural resources is expected over the current conditions in these areas in either the short term or the long term.

There is the potential for the morphology of the Klamath River Estuary to change in light of sediment releases from the drawdown of the reservoirs (see Potential Impact 3.2-3). These changes to the estuary have a low-risk potential to affect estuary-based Yurok Tribe TCRs; however, there is some risk of potential impacts that would not occur absent implementation of the Proposed Project. The Yurok Tribe has adopted ordinances and policies to address impacts to cultural resources on the Yurok Reservation, which includes the Klamath River Estuary. In the unlikely event that such Proposed Project-related impacts would occur to resources in the area of the Klamath River Estuary, implementation of Mitigation Measure TCR-5 would reduce the potential impacts to less than significant.

Mitigation Measure TCR-5 – Implementation on Yurok Reservation.
Mitigation Measures TCR-1, TCR-2, and TCR-3 do not apply on the Yurok Reservation. The Yurok Tribe's Cultural Resource Ordinance and Inadvertent Discovery Policy shall apply to such TCRs on the Yurok Reservation.

Significance
No significant impact in the short term or long term for the Hydroelectric Reach between J.C. Boyle Dam and Copco No. 1 Reservoir

Significant and unavoidable with mitigation in the short term and long term for the Middle Klamath River from Iron Gate Dam to Humbug Creek

No significant impact in the short term or long term for Middle Klamath River downstream of Humbug Creek and Lower Klamath River excluding the Yurok Reservation (approximately RM 0 to RM 45)

No significant impact with mitigation on the Yurok Reservation (approximately RM 0 to RM 45) along Lower Klamath River and Klamath River Estuary

Potential Impact 3.12-4 Project activities associated with removal of Iron Gate, Copco No. 1, and Copco No. 2 dams could result in physical disturbance to known or unknown tribal cultural resources from blasting or other removal techniques.
Blasting and other dam removal techniques could cause significant adverse impacts to known or unknown TCRs located in the immediate vicinity[149] of Iron Gate, Copco No.1 and Copco No. 2 dams. While minor ground vibration and sounds from blasting and other dam removal techniques may extend throughout the 0.25-mile distance from each

[149] For the purposes of this analysis, "immediate vicinity" is defined as within 0.25 miles of Copco No. 1, Copco No. 2, and Iron Gate dams.

of the dams, the vibration and sounds would not result in significant impacts to TCRs because they would not result in physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of the TCR would be materially impaired.

However, direct physical disturbance associated with blasting and other removal techniques could significantly impact those TCR sites that directly overlap with the blasting locations. The KRRC proposes complete removal of dam facilities, including, in some instances, excavation of concrete below the existing streambed level, in order to prevent future development of fish barriers as the river morphology changes. Removal of the concrete dam structures would require blasting and drilling which could destroy, relocate, or alter those TCRs sites that directly overlap with the blasting locations or their immediate surroundings such that the significance of these TCRs would be materially impaired.

There is at least one TCR that was present before dam construction that would be potentially impacted. It is unknown the extent to which the resource survives currently as it is no longer accessible. To the extent the site still exists, removal of the dam has a high likelihood of significantly degrading the site. There is also the potential for as-yet unknown sites to be impacted within the blasting zone, or by other techniques associated with the removal of these features, in light of the density of sites in the Hydroelectric Reach.

Implementation of mitigation measures TCR-1 (TCRMP), TCR-2 (LVPP), TCR-3 (IDP), and TCR-4 (Endowment)[150] would reduce impacts to TCRs associated with dam removal activities, but impacts would remain significant and unavoidable.

Significance

Significant and unavoidable with mitigation

Potential Impact 3.12-5 Ground disturbance associated with reservoir restoration, recreation site removal and/or development, and disposal site restoration could physically disturb known Tribal Cultural Resources. Additionally, ongoing road and recreation site maintenance has the potential to disturb known Tribal Cultural Resources.

The proposed Reservoir Area Management Plan includes restoration activities that would occur both within the reservoir footprint and in upland areas (i.e., disposal, staging, and hydropower infrastructure demolition areas, access roads, former recreational areas) within the Area of Analysis *Subarea 1* (Figure 3.12-2). Known TCR locations include those reflected in PacifiCorp (2004) and Daniels (2006), and as updated by Confidential Appendix Q, Attachment 4, which are cataloged in Confidential Appendices P and Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis.

[150] Mitigation Measures TCR-6, TCR-7 and TCR-8 could also further reduce the potential impact. However, at this point it is not clear whether the measures are feasible (see Potential Impact 3.12-9). Therefore, this EIR does not rely on implementation of these measures, in reaching its significance determinations.

After reservoir drawdown, the following ground-disturbing activities would be implemented in the former reservoir areas to stabilize remaining sediments over time and to restore riparian, floodplain, and wetland habitats:

- Active seeding[151] via ground equipment to revegetate reservoir areas with native grasses, sedges, rushes and forbes immediately after reservoir drawdown and planting of acorns, shrub seedlings, and pole cuttings as early as feasible;
- Manual removal/treatment of invasive exotic vegetation, which may include manual weed extraction, solarization (covering round areas with black visqueen), tilling, and use of herbicides;
- Planting of woody riparian trees and shrubs along the river banks in the former reservoir areas; and
- Installation of floodplain and off-channel habitat features such as large wood, roughening of the floodplain to enhance establishment of vegetation, and rectifying any non-natural fish passage barriers in mainstems and tributaries.

Within the reservoir footprint portions of the Area of Analysis *Subarea 1*, numerous TCR sites have been identified, including prehistoric archaeological sites with habitation debris, village sites, house pits and rock features and burial sites; as well as ethnographic places and other features of the cultural landscape (Confidential Appendices P and Q). Additionally, there may be many as-yet unknown TCRs located within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs. Artifacts within the reservoir footprint may be materially impaired through physical demolition, destruction, relocation, or alteration by construction equipment (e.g., tilling) or hand tools (e.g., shovels for planting trees) during the aforementioned reservoir restoration activities. The proposed Reservoir Area Management Plan also includes long-term monitoring of vegetation growth, invasive exotic vegetation, and fish passage to ensure objectives are accomplished; however, these activities are not expected to be ground-disturbing.

Within the upland portions of the Area of Analysis *Subarea 1* (i.e., outside of the Copco No. 1 and Iron Gate reservoir footprints, including the fluctuation zone), known TCRs include those reflected in PacifiCorp (2004) and Daniels (2006), and as updated by Confidential Appendix Q, Attachment 4, and are cataloged in Confidential Appendices P and Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis. Proposed upland restoration activities include active management of invasive exotic vegetation species, which may include ground-disturbing activities such as manual weed extraction, solarization (covering of ground areas with black visqueen), tilling, and planting (Appendix B: *Definite Plan − Appendix H*) (see also Section 2.7.5 *Restoration of Upland Areas Outside of the Reservoir Footprint*). These activities may result in material impairment of TCRs located

[151] The Reservoir Area Management Plan includes aerial pioneer seeding using helicopters during the winter/early spring during and following reservoir drawdown (Appendix B: *Definite Plan – Appendix H*). Aerial seeding is not a ground-disturbing activity. Fall overseeding, which is potentially ground-disturbing, would be completed with a ground-based broadcast seeder over the mowed or rolled vegetation remaining from the pioneer seeding (Appendix B: *Definite Plan – Appendix H*). Hydroseeding via barge during reservoir drawdown is potentially a ground-disturbing activity, although this activity is not currently anticipated by KRRC. Potential impacts due to barge hydroseeding are discussed in Impact 2.

within upland portions of the Area of Analysis *Subarea 1* from physical demolition, destruction, relocation, or alteration by construction equipment (e.g., tilling) or hand tools (e.g., shovels for planting trees). Non-ground-disturbing, proposed upland restoration activities include the possible use of herbicides for controlling invasive exotic vegetation; collecting seeds for local nurseries to grow trees and shrubs; and implementing a short-term Storm Water Pollution Prevention Plan (SWPPP)/Erosion Control Plan.

Ground-disturbing activities associated with ongoing road and recreation site maintenance within the Area of Analysis *Subarea 1* (Figure 3.12-2) include grading and excavating, which may also result in material impairment due to physical demolition, destruction, relocation, or alteration of TCRs located in both upland and reservoir footprint locations.

In summary, several known and potentially many as-yet unknown TCRs could be significantly adversely impacted due to the aforementioned ground-disturbing activities associated with revegetation and restoration of riparian, floodplain, and wetland habitat within former reservoir areas and upland areas, as well as ongoing road maintenance and potential recreation site construction and maintenance, if any.

Implementation of Mitigation Measures TCR-1 (TCRMP), TCR-2 (LVPP), TCR-3 (IDP), and TCR-4 (Endowment)[152] would reduce these impacts considerably, and, for most resources is expected to avoid impacts completely, through designing restoration plans to completely avoid impacts, or by on-the-ground changes to implementation to avoid impacts. Using hand tools to restores sensitive areas will reduce the risk and severity of potential damage as compared to use of heavy equipment. For impacts that it is not feasible to completely avoid, the impacts may be reduced to a less than significant level. The measures include, among other requirements, field worker training, limits to worker and public access, tribal monitors, surveys, and identification of protocols and best practices upon discovery or disturbance of TCRs in project implementation. With timely discovery and appropriate steps to address exposure or damage, many TCRs can maintain their current level of cultural significance. Additionally, providing a means for the long-term protection or enhancement of affected TCRs can mitigate for some impacts.

However, the impact of exposing or disturbing tribal human remains, or associated funerary items, is itself profound. The mitigation measures are expected to considerably reduce - but cannot be reasonably be expected to completely avoid - such exposure or disturbance, particularly in light of the density of villages in the reservoir bed areas. While treating remains and associated funerary objects with the appropriate respect and procedures can reduce and avoid compounding the harm from the initial damage, it cannot do so fully.

Additionally, in light of the high density of TCRs in the restoration areas, and because some of the contemplated restoration involves significant earth-moving with heavy equipment, such as potentially regrading areas and enhancing wetlands, significant risk remains that other TCRs may sustain damage that results in a martial impairment of the

[152] Mitigation Measures TCR-6, TCR-7 and TCR-8 could also further reduce the potential impact. However, at this point it is not clear whether the measures are feasible (see Potential Impact 3.12-9). Therefore, this EIR does not rely on implementation of these measures, in reaching its significance determinations.

resource's significance. In light of the particular harm of exposing human remains even where they are treated appropriately after exposure, and the likelihood of significantly impairing other resources in light of the type of construction actions and the density of resources, the impact would remain significant and unavoidable.

Significance
Significant and unavoidable with mitigation

Potential Impact 3.12-6 During and following reservoir drawdown activities at Iron Gate, Copco No. 1, and Copco No. 2 reservoirs there is an increased potential for looting of Tribal Cultural Resources (short-term and long-term).
During and immediately following reservoir drawdown[153], TCRs located within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs would no longer be partially or completely covered by reservoir waters and thus would be more accessible and at greater risk for looting. For these known TCR sites, plus as-yet unknown sites, some tribal representatives assert that the reservoirs offer the best protection against looting because the reservoir waters currently prevent looter access.

Known TCRs within the Area of Analysis *Subarea 1* (Figure 3.12.2) include resources identified in PacifiCorp (2004a) and Daniels (2006), as updated by Confidential Appendix Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis. Within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs, which is the focus of this Potential Impact 3.12-5 analysis, numerous TCR sites have been identified. Additionally, there may be many as-yet unknown TCRs located within the footprints of the California reservoirs. Note that many of the known TCR sites are located within the reservoir fluctuation zones and several of these are associated with relatively shallow sediment deposits (approximately 0.2 to 2 feet deep). Tribal cultural resource sites located within the reservoir fluctuation zones may be periodically at risk of looting during low water periods under existing conditions.

Within the reservoir footprints, Proposed Project restoration activities would occur during and immediately following reservoir drawdown (i.e., dam removal years 1 and 2) as well as post-dam removal year 1, including active seeding to revegetate reservoir areas with native grasses, sedges, rushes and forbes, and planting of acorns, shrub seedlings, and pole cuttings, all of which would stabilize sediments remaining in the reservoir footprints (see also Potential Impact 3.12-4). Revegetation activities would reduce erosion of fine sediments (Appendix B: *Definite Plan – Appendix H*) and would physically cover the remaining sediment deposits with a variety of vegetation, thus decreasing the potential for exposure and looting of TCRs located within the reservoir footprints. However, in general, sensitive areas located within the reservoir footprints would be subject to exposure and increased access since they would no longer be partially or completely covered by reservoir waters. This could increase the potential for looting of TCRs above levels occurring under existing conditions. The potential severity of this impact is underscored by significant anecdotal evidence of an extensive looting problem in the

[153] Consideration of exposure or substantial movement of tribal cultural resources during pre-dam removal ground-disturbing activities that could lead to increased access and looting above levels occurring under existing conditions is discussed in Potential Impact P-1.

area, and by statements made by tribal members regarding the deep impact of past and ongoing looting, particularly in light of a history of repeated dispossession in the area.

Implementation of Mitigation Measure TCR-2 (LVPP) and TCR-4 would significantly reduce the impacts of looting in the short term and long term. However, illegal looting remains a pervasive problem in the vicinity, as related through extensive anecdotal evidence by tribal members and archaeologists with experience in the area. Therefore, although it is likely that the LVPP would be effective in protecting most resources through the intensive monitoring and broad range of tools to address the concern, it would be unlikely to be completely effective. The impact of looting of certain resources is profound, and could result in material impairment of a resources' significant or result in the exposure or disturbance of human remains. Therefore, the increased risk of looting remains significant and unavoidable.

Significance

Significant and unavoidable with mitigation in the short term and long term

Potential Impact 3.12-7 Short-term erosion caused by high-intensity and/or duration precipitation events could cause exposure of or disturbance to known or unknown tribal cultural resources within the reservoir footprints immediately following reservoir drawdown and prior to vegetation establishment/full stabilization of sediment deposits.

Immediately following reservoir drawdown[154], high-intensity and/or long-duration precipitation events could occur that would result in surface erosion of remaining reservoir sediment deposits and cause exposure of or disturbance to TCRs located within the reservoir footprints. Known TCRs to be within the Area of Analysis *Subarea 1* include resources identified in PacifiCorp (2004a) and Daniels (2006), as updated by Confidential Appendix Q. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis. Within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs, which is the focus of this analysis for Potential Impact 3.12-7, numerous TCR sites have been identified (Confidential Appendices P and Q). Additionally, there may be many as-yet unknown TCRs located within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs.

Since the Lower Klamath Project reservoirs were constructed, fine sediments composed primarily of organic material (including dead algae), but also including some silts and clays, have accumulated along the reservoir bottoms (see Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). The distribution of sediment deposits varies within each reservoir (Figure 2.7-8 and 2.7-9). Because the accumulated sediments are primarily fine material, a percentage of them would be easily eroded and flushed out of the reservoirs into the downstream Klamath River during reservoir drawdown, with the majority of the erosion focused in the original river channel (Figures 2.7-5 and 2.7-6). However, following drawdown, 40−60 percent of the sediment deposits accumulated behind the dams would remain in place in each of the former reservoir beds, primarily on terraces located above the original river channel. The sediments that remain in the reservoir footprints would consolidate (dry out and

[154] Consideration of potential shifting-, erosion-, and exposure-related impacts to tribal cultural resources during reservoir drawdown is discussed in Potential Impact 3.12-2.

decrease in thickness) (USBR 2012a), making them less subject to erosion. Further, during the drawdown period, seeding (by helicopter and potentially barge) of pioneer mixes would occur as the reservoir water level drops and before the exposed reservoir sediments dry and form a surface crust. The seeded native grasses are expected to become well established within weeks after application (January to March of dam removal year 2), which would reduce erosion of the remaining reservoir sediment deposits during cycles of wetting (i.e., from precipitation events) and drying (Appendix B: *Definite Plan – Appendix H*). During the first summer and fall following reservoir drawdown (dam removal year 2), additional seeding application would occur including grasses and ground cover, with monitoring and targeted revegetation for areas that do not meet vegetation cover goals (Appendix B: *Definite Plan – Appendix H*).

During the period of weeks when seeded native grasses have not yet become well established within the reservoir footprints, high intensity and/or long-duration precipitation events could increase erosion of remaining reservoir deposits through sediment cracking and gully erosion, and destroy or materially impair TCRs in a way that would undermine current or historical cultural significance, including through substantial movement of human remains. This could increase disturbance impacts to TCRs that were already affected during drawdown (see Potential Impact 3.12-4), or impact additional TCRs that were not affected by erosion during drawdown. The risk of this occurring would be higher for TCRs located in areas where post-reservoir sediment deposition was relatively thin (i.e., areas where sediment deposits are less than 2 feet deep) and would be limited to TCRs that were located above ground prior to reservoir inundation[155].

However, since 40−60 percent of the reservoir sediment deposits are predicted to remain in place following drawdown, many TCRs that were located above ground at the time of reservoir inundation are expected to remain substantially covered, even those located within reservoir sediment deposits that are less than 2 feet deep (see Confidential Appendices P and Q). For those sites located within deeper reservoir sediment deposits, the overlying sediment layer would offer protection from surface cracking and gully erosion that may result from high intensity and/or duration precipitation events and these deeper sites would not be likely to be destroyed or materially impaired in a way that would undermine current or historical cultural significance.

The risk of continued erosion and subsequent exposure of or disturbance to TCRs located in the reservoir footprints, particularly for those associated with relatively shallow (e.g., less than 2 feet deep) sediment deposits (see Confidential Appendices P and Q), would decrease within weeks to months following reservoir drawdown as revegetation stabilizes the remaining sediments. Monitoring and targeted revegetation activities included in the proposed Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) would reduce the risk of impacts to TCRs located in areas of large crack or gully formation. As the system returns to riverine conditions within the reservoir

[155] For tribal cultural resources that were located below ground prior to inundation, the Proposed Project is not expected to result in exposure or disturbance impacts because sediment erosion would be limited to the fine materials accumulated since the reservoirs were constructed (see Potential Impact 3.12-2). These tribal cultural resources would remain buried, their significance to the Shasta Nation would not be materially impaired, and there is no anticipated impact.

footprints, with revegetated terraces along the river and sides of the former reservoirs, long-term erosion and sediment transport rates would return to natural rates for this portion of the watershed (USBR 2012c).

Implementation of Mitigation Measures TCR-1 (TCRMP), TCR-2 (LVPP), and TCR-3 (IDP)[156] would reduce these impacts, overall they would remain significant and unavoidable for the reasons described for the erosion related to reservoir drawdown (Potential Impact 3.12-2).

Significance

Significant and unavoidable with mitigation in the short term

Potential Impact 3.12-8 Long-term (post-removal) impacts to Tribal Cultural Resources as a result of dam removal from increased looting opportunities and from surface and subsurface erosion of Tribal Cultural Resources.

Following drawdown of Iron Gate, Copco No.1, and Copco No. 2 reservoirs, 40−60 percent of the reservoir sediment deposits would remain in place, primarily on areas at higher elevation than the active river channel within the reservoir footprints (see also Potential Impacts 3.12-4 and 3.12-8). During tribal consultations, some tribal representatives expressed strong concerns that long-term erosion of remaining sediment deposits within the Lower Klamath Project reservoirs would disturb or destroy TCRs that are located there (see also Confidential Appendix P). In addition, the Proposed Project includes transfer of PacifiCorp lands immediately surrounding the Lower Klamath Project ("Parcel B lands") from PacifiCorp to the KRRC prior to dam removal, where Parcel B lands contain all of the Copco No. 1 Reservoir footprint and the majority of the Iron Gate Reservoir footprint (Figure 3.12-5). The Proposed Project then provides that the KRRC would transfer Parcel B lands to the respective states (i.e., California, Oregon), as applicable, or to a designated third-party transferee, following dam removal. The lands would thereafter be managed for public interest purposes (KHSA Section 7.6.4.A).

The potential for increased looting opportunities and surface erosion to result in long-term impacts to known or unknown TCRs due to the Proposed Project is discussed below for resources located within the reservoir footprints and within Parcel B lands.

Tribal Cultural Resource Sites Within the Reservoir Footprints Prior to Land Transfer

Tribal cultural resources known to the Shasta Nation to be within the Area of Analysis *Subarea 1* include resources identified in PacifiCorp (2004a) and Daniels (2006), as updated by Confidential Appendix Q, Attachment 4. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis. Within the footprints of Copco No. 1, Copco No. 2, and Iron Gate reservoirs, numerous TCR sites have been identified including village and cairn sites (Confidential Appendices P and Q). Additionally, there may be many as-yet unknown TCRs located within the footprints of Copco No. 1, Copco No. 2 and Iron Gate reservoirs.

[156] Mitigation Measures TCR-6, TCR-7 and TCR-8 could also further reduce the potential impact. However, at this point it is not clear whether the measures are feasible (see Potential Impact 3.12-8). Therefore, this EIR does not rely on implementation of these measures, in reaching its significance determinations.

As described in Potential Impacts 3.12-2 and 3.12-6, following reservoir drawdown, the remaining sediment deposits would consolidate through air drying and would decrease in thickness (USBR 2012a). Revegetation efforts under the Proposed Project would support re-establishment of native species on newly exposed reservoir sediments, including grasses and woody riparian species, where the latter would be planted at densities of several hundred plants per acre. It is expected that former wetland areas within the reservoir footprints would revert to wetland vegetation without long-term active revegetation inputs (Appendix B: *Definite Plan – Appendix H*).

While a portion of the fine sediments that have deposited since the dams were constructed would erode rapidly during reservoir drawdown (see Potential Impacts 3.12-4 and 3.12-8), erosion rates would decrease over weeks to months, as the remaining sediment deposits are stabilized by drying and by active and passive revegetation. As the system returns to riverine conditions within the reservoir footprints, long-term erosion and sediment transport rates would also return to natural rates for this portion of the watershed (USBR 2012c). Previous wave action within the reservoir fluctuation zone would cease as the reservoir shoreline would no longer exist, with a long-term benefit over current conditions to the known and as-yet unknown TCR sites located within the reservoir fluctuation zone (Confidential Appendices P and Q).

Thus, in the long term, drying, consolidation, and stabilization (due to re-vegetation) of the remaining sediment deposits would substantially limit the potential for erosion to result in exposure or substantial movement of TCRs buried within the deposits, or those that were located below the ground surface prior to construction and inundation of Copco No.1, Copco No. 2, and/or Iron Gate dams, such that increased access and looting above levels occurring under existing conditions would be unlikely. Instead, long-term drying, consolidation, and stabilization of the sediment deposits remaining in the reservoir footprints have the potential to preserve and protect known or as-yet unknown TCRs within or beneath the deposits. The potential for long-term erosion-related impacts on TCRs within the reservoir footprints is therefore different from and significantly less than the potential for erosion-related impacts to these resources in the periods during and immediately following reservoir drawdown (Potential Impact 3.12-4). However, despite the protection offered from the remaining sediment deposits, the vulnerability of existing TCRs to long-term exposure due to natural rates of erosion and sediment transport for the watershed would still increase as compared to existing conditions where the reservoir waters offer almost complete protection from access and looting (with the exception of resources located within the reservoir fluctuation zone). The potential impact of this increased potential is underscored by significant anecdotal evidence of an extensive looting problem in the area, and by tribal members' testimony regarding the deep impact of past and ongoing looting, particularly in light of a history of repeated dispossession in the area.

Implementation of Mitigation Measure TCR-1 (TRMP), TCR-2 (LVPP), and TCR-3 (IDP), would reduce long-term impacts to TCRs from increased looting opportunities and surface and subsurface erosion, however, these impacts would remain significant.

Tribal Cultural Resource Sites Within Parcel B Lands After Transfer

Known TCRs within the Area of Analysis *Subarea 4* (Figure 3.12-5) include resources identified in PacifiCorp (2004a) and Daniels (2006), as updated by Confidential Appendix Q, Attachment 4. Resources identified as villages, cairns or burial sites, or sites eligible for the National Register of Historic Places in a subsequent compilation by Cardno ENTRIX (2012) were also considered as part of this analysis. Numerous TCR sites have been identified completely inside or partially inside Parcel B lands (Confidential Appendices P and Q).

It is unknown what public use the lands in Parcel B would ultimately serve. The California Natural Resources Agency (CNRA) and California Department of Fish and Wildlife (CDFW) have begun speaking with interested stakeholders on various recreation, water quality, tribal, resource protection, conservation, and economic uses of the land, including with tribal governments and Siskiyou County representatives. While the lands would be managed for public interest, this could include a range of uses, including open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially other uses. Certain future land uses (e.g., open space) would presumably result in less potential for impacts to TCRs.

However, certain land uses, if undertaken in areas with TCRs, would have the potential to increase public access to TCRs beyond the level of simply removing the reservoirs, and it could therefore result in additional impacts due to construction, looting, illegal excavation, vandalism, and other destruction or damage within the Area of *Subarea 4* (Figure 3.12-5). Existing and potentially new recreation facilities along the river corridor may also direct the public to favorable landforms (e.g., flat topography, close to tributary confluences and other water sources) that coincide with locations chosen by tribal ancestors for habitation and other cultural uses. Increased access to TCRs due to land transfer has the potential to lead to looting above levels occurring under existing conditions or to land uses that result in material alteration of TCRs in a way that would undermine their current or historical tribal significance.

Further, future Parcel B land transfer could result in uses of lands currently not submerged that eliminate or substantially restrict access of tribal members to TCRs during ceremonial windows or periods of hunting and gathering or other traditional activities associated with a TCR. It is unclear what public use of Parcel B lands could result in such an increased barrier over the existing private ownership by PacifiCorp. For currently submerged lands, there is currently no access such that future land use decisions for the reservoir footprint portions of Parcel B would likely result in access-related benefits as compared with existing conditions.

In 2017, the Kikaceki Land Conservancy was formed, which includes representation of Shasta people with ancestry in the area affected by the Proposed Project. In the ongoing consultation process under NHPA section 106, KRRC will address whether this existing land conservancy, or other entities which represent Affected Tribes, could continue to implement measures for TCR protection and enhancement after the KRRC has completed Project implementation. The express mention of the Kikaceki Land Conservancy in this EIR in no way excludes the claims of any other traditionally and culturally affiliated tribes, or harms any other tribes' rights.

The process for determining future land use under the KHSA Section 7.6.4 has the potential to offer TCRs appropriate protection through a variety of land use strategies: that process remains unaltered by this EIR. Implementation of TCR-6 (Land Transfer), TCR-7 (Land Easement and Transfer Stipulations), and TCR-8 (Off-site Land Transfer) have the potential to reduce the impact of future land use decisions to less than significant. These measures are in alignment with the general proposed measures for consideration to mitigate impacts to TCRs described in Public Resources Code section 21084.3, subdivision (b)(3).

However, the ultimate feasibility of these measures is uncertain. The process for determining future land uses under KHSA Section 7.6.4 has not advanced to the point at which competing uses, financial limitations, parcel access requirements, or other constraints have become clear. Additionally, because the KRRC has a set amount of funding with which to implement the Proposed Project, its ability to undertake purchase of lands outside Parcel B as a mitigation measure is also uncertain, and thus the feasibility of Mitigation Measure TCR-8 (Off-site Land Transfer) is also uncertain. Because the ultimate feasibility of these measures is uncertain, and the State Water Board lacks the authority to impose them through its Clean Water Act section 401 certification, this EIR does not rely on implementation of these measures, although it is disclosing them because it is likely that the protections would be viable for at least some portion of the identified lands, and because they represent a potentially feasible path to protect TCRs.

Mitigation Measure TCR-6 – Land Transfer.
The State Water Board has determined, and KRRC has acknowledged, that transfer of some Parcel B lands to an entity representative of Affected Tribes which are traditionally and culturally affiliated with TCRs on such lands, could foster tribal cultural and conservation practices and promote tribal identity; and further, that such transfer could be an appropriate measure to address past disturbance of TCRs caused during construction of Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam, and to mitigate the impacts to TCRs caused by Project implementation.

Pursuant to KHSA Section 7.6.4, the California Natural Resources Agency (CNRA) and CDFW have begun the process to determine the disposition of Project-related (or “Parcel B”) lands, totaling approximately 8,000 acres, for public interest purposes. In California, that process is anticipated to involve the following steps: (1) inspections and preliminary due diligence regarding the condition of the Parcel B lands; (2) consultation with KHSA parties and other stakeholders regarding disposition; (3) for each parcel, a proposal by CNRA and CDFW regarding proposed transferee and other terms; (4) actual transfer of Parcel B lands from PacifiCorp to KRRC, upon KRRC’s notice that it has secured all necessary permits for dam removal; and (5) subsequent transfer from KRRC to California or the third-party transferee, by parcel.

Based on AB 52 consultation, the State Water Board has identified the following potential mitigation measure, which is dependent on the outcome of the process required by KHSA Section 7.6.4. The Shasta Indian Nation has proposed the transfer of selected Parcel B lands (as identified in Confidential Appendix Q they have identified as possessing the most significant tribal cultural value to the Shasta Indian Nation and also having central importance to other Shasta peoples. The Shasta Indian Nation has proposed transfer to an entity, such as the Kikaceki Land Conservancy, that includes representation of the several bands of Shasta peoples. While it is too early in the process to determine the feasibility of such transfer, this measure is included for analysis in the Environmental Impact Report. In the process required by KHSA Section 7.6.4, the KRRC shall support consideration of transfers of selected lands to an entity representative of Affected Tribes that are traditionally and culturally affiliated with the TCRs on such lands, in circumstances where the lands have resources of critical tribal importance and such transfer would be a cost-effective approach to protect such resources.

Mitigation Measure TCR-7 – Proposal for Land Easement and Transfer Stipulations. The CNRA and CDFW have begun initial discussions in a stakeholder process for determining land disposition as described in KHSA Section 7.6.4, including discussions with Shasta people.

1. For TCRs and such sites that are protected under Public Resources Code 5097.993, land easement and transfer stipulations could ensure that protection measures described in the TCRMP encumber the title for all subsequent owners for other lands not returned to the Shasta people. Any such land easement or transfer stipulations shall be consistent with KHSA Section 7.6.4 and other applicable terms.
2. There is also the potential to coincide public wildlife conservation management areas with lands that contain tribal cultural values to restrict public access where feasible and promote protection of cultural sites.
3. These mechanisms can also provide the opportunity for Shasta people to access TCRs through creation of tribal conservation easements.

Mitigation Measure TCR-8 – Off-site Land Transfer.
At any time prior to completing the TCRMP, the KRRC may identify parcels of land not subject to the process under KHSA Section 7.6.4, that may be appropriate for transfer to an entity representative of Affected Tribes (such as the Kikaceki Land Conservancy), as off-site mitigation for Project-related impacts to TCRs. Any such transfer involving the KRRC is subject to funding availability consistent with the terms (including funding authorities) of the KHSA.

Significance
Significant and unavoidable prior to land transfer

No significant impact with mitigation after land transfer

Potential Impact 3.12-9 Klamath Cultural Riverscape Contributing Aspect – Combined effects on the Klamath River fishery of dam removal, changes in hatchery production, and increased habitat for salmonids.
Many California Native American tribes located in the Klamath River Basin historically relied on fish (such as salmon, steelhead, and Pacific lamprey) for food, currently use fish in their diet, including some members at a subsistence level of reliance, and have and continue to consider fish to be an important part of their culture (Section 3.12.2 *[Historical Resources and Tribal Cultural Resources] Environmental Setting* and Appendix V – 2012 KHSA EIS/EIR *Section 3.12 Tribal Trust*). Under existing conditions, these fish may include adult Chinook and coho salmon returns to Iron Gate Hatchery. CDFW operates Iron Gate Hatchery with an annual production goal (CDFW 2014) (see also Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries*) of 75,000 coho salmon smolts, and six million fall-run Chinook salmon yearlings and smolts.

The ability to meet the above production goals varies annually based on adult returns and hatchery performance. Coho salmon production has averaged 75,000 yearlings (achieving production goals) and 866 adult returns on an annual basis (CDFW 2014). Coho returns to Iron Gate Hatchery have significantly and steadily declined from a high of 2,466 adults in the 2001/2002 return year to a low of 38 adults in the 2015/2016 return year (CDFW 2016). From 2005 through 2018 actual fall-run Chinook salmon yearling production has averaged 955,931 (exceeding production goals), and actual smolt production has averaged 4,276,728 (around a million fewer smolts than the goal on average) (K. Pomeroy, CDFW, pers. comm., 2018). The fall-run Chinook salmon hatchery spawner return goal is 8,000 fish. Total Chinook salmon returns to Iron Gate Hatchery between 1978 and 2016 ranged from 2,558 to 72,474 and averaged 16,206 fish (CDFW 2017). From 2000 to 2016, adult winter steelhead returns to Iron Gate Hatchery averaged 242 and peaked at 631 in 2001 (CDFW 2016). Returns have been declining, and in 2016 no adult steelhead returned to the hatchery (CDFW 2016). The low adult returns of steelhead have resulted in no production of steelhead yearlings from Iron Gate Hatchery since 2012.

It appears that progeny from Iron Gate Hatchery releases have contributed appreciably to in-river tribal harvest since the late 1960s (PacifiCorp 2004a). PacifiCorp (2004a) estimates that based on smolt-to-adult survival studies conducted on Iron Gate fall Chinook salmon, the Iron Gate Hatchery production contributes about 50,000 fish annually to the Chinook and coho salmon fisheries (including commercial, tribal and recreational fisheries), in addition to escapement back to the hatchery.

The Proposed Project includes the continued operation of Iron Gate Hatchery and the reopening of Fall Creek Hatchery. The Iron Gate and Fall Creek hatcheries would be operated for eight years following dam removal (Section 2.7.6 *Hatchery Operations* and Section 3.3.5.6 *Fish Hatcheries*). The total production goals for both hatcheries would be reduced from the current production at Iron Gate Hatchery, whereby fall-run Chinook salmon smolts (both age 0 and age 1 yearling smolts) would be reduced by about 43 percent relative to current (2005 through 2018) releases, coho yearling production would remain the same, and steelhead production would continue to be zero.

Operation of the hatcheries at a combined reduced capacity following dam removal would be likely to reduce average annual hatchery Chinook salmon returns (by around 7,120 fewer fish) compared with existing conditions (Potential Impact 3.3-7) between post-dam removal years 3 and 10 (Table 3.3-11). There would be no change to the coho salmon population through dam removal year 9 relative to existing conditions as a result of shifting all coho production to Fall Creek Hatchery (Potential Impact 3.3-9) and there would be no change to steelhead production relative to existing conditions since steelhead have not been released since 2012.

No reduction in hatchery adult returns would be evident until post-dam removal year 3 (Section 3.3.5.6 *Fish Hatcheries*), by which time the first adult returns from the progeny of naturally spawning Chinook salmon in newly accessible habitat upstream of the prior location of Iron Gate Dam would occur (Potential Impact 3.3-7). Between post-dam removal years 3 and 10, both hatchery returns and returns from newly accessible habitat would occur, offsetting reductions due to lower hatchery capacity in the early years of the Proposed Project, as total adult returns of Chinook salmon, and the associated tribal fishery resource, increase towards overall higher levels.

The elimination of hatchery production after eight years following dam removal under the Proposed Project would eliminate the congregation of returning hatchery adults to the reach downstream of the prior location of Iron Gate Dam. Combined with the removal of the dams, which would increase the likelihood that adults would disperse further upstream, these factors would be likely to reduce the incidence of fish disease and parasites in the Klamath River (see Section 3.3.5.5 *Fish Disease and Parasites*). Further, since hatchery juveniles would no longer be released after post-dam removal year 7, fish disease would be less likely to affect outmigrating smolts. Higher smolt survival would result in an increase in adult returns available for in-river tribal harvest (PacifiCorp 2004a). Overall, it is anticipated that the Proposed Project would help to reduce the incidence of fish disease and parasites in the Klamath River and thus would be beneficial.

As described in Section 3.3.5.9, Potential Impact 3.3-7, quantitative modeling of fall-run Chinook salmon populations predict that the Proposed Project would increase Chinook salmon abundance. Median escapements to the Klamath Basin are predicted to be higher (median increase greater than 30,000) with the Proposed Project than under existing conditions. The potential for tribal harvest is therefore also predicted to be greater with the Proposed Project due to increased numbers of Chinook salmon adults (affecting the number of fish available annually), and the decrease in the probability of low escapement leading to fishery closures (affecting the number of years in which fishing will be available for more than ceremonial purposes).

While a reduction (around 7,120 fish on average) in total fall-run Chinook salmon returns for up to four years under the Proposed Project would constitute a potential short-term alteration in Chinook salmon as a tribal fishery resource, it is within the existing degree of annual variability in hatchery-origin Chinook salmon returns (2,558 to 72,474 for the period 1980 to 2001 [CDFW 2016b]) and natural Chinook salmon returns (6,957 to 91,757 for the period 1980 to 2001 [CDFW 2016a]). The Proposed Project would be unlikely to represent a material impairment of the Klamath Riverscape as a resource or a substantial restriction of tribal access to the fishery relative to existing conditions, even in the short term. This assessment is bolstered by the lack of reduction in hatchery-origin coho adult returns that would occur under the Proposed Project and the lack of change in hatchery operations from the existing condition for steelhead and spring-run Chinook (neither of which the hatchery produces) under the Proposed Project.

In addition, survival of natural and hatchery smolts is predicted to increase by post-dam removal year 1 from reduced incidence of disease (see Section 3.3.5.5 *Fish Disease and Parasites*) and increased natural production from newly accessible habitat is predicted to increase salmon abundance by post-dam removal year 3 (see Section 3.3.5.6 *Fish Hatcheries*). Thus, reduced hatchery production goals for eight years following dam removal would be a less than significant impact in the short term. In the long term, the loss of hatchery production would be more than replaced by increased natural production (Potential Impact 3.3-7), and the cessation of hatchery operations would be beneficial to the Klamath River fishery TCR by helping to reduce the incidence of fish disease and parasites.

As described in Section 3.3.5.9, the Proposed Project would not have a significant short-term impact and would have a long-term beneficial effect on spring-run Chinook salmon (Potential Impact 3.3-8), coho salmon (Potential Impact 3.3-9), steelhead (Potential Impact 3.3-10), Pacific lamprey (Potential Impact 3.3-11), and redband trout (Potential Impact 3.3-14). The tribal fishery resource is anticipated to benefit from the Proposed

Project in the long term as a result of population improvements for these tribal trust species.

As described in Section 3.3.5.9, the Proposed Project would not have a significant short- or long-term impact on green sturgeon (Potential Impact 3.3-12), Lost River and shortnose suckers (Potential Impact 3.3-13), eulachon (Potential Impact 3.3-15), longfin smelt (Potential Impact 3.3-16), and freshwater mussel species *M. falcata* and *G. angulate* (Potential Impact 3.3-16). Freshwater mussel *Anodonta spp*. would experience a significant and unavoidable impact under the Proposed Project (Potential Impact 3.3-16).

As discussed under Section 3.12.2.3 *Known Tribal and Historical Resources in the Vicinity of the Proposed Project [Klamath Cultural Riverscape]*, the influence of the Proposed Project on the riverscape as a whole, and overall ecosystem health, are more important than the individual potential impacts on specific species. Based on the assessment that there would be a short-term, less-than-significant effect on most tribally significant species (with the exception of *Anodonta ssp.*) under the Proposed Project; the relatively short duration of a predicted measurable decline in fall-run Chinook adult returns from reduced hatchery operations that falls within the existing variation of hatchery returns; the lack of predicted impact from the closure of the hatchery after eight years as compared to the existing conditions (i.e., baseline); the predicted increases in fish production and health from dam removal; and the long-term benefits on much of the key tribal trust species (e.g., Chinook salmon, coho salmon, steelhead, and Pacific lamprey) resulting from improved river ecosystem function and increased habitat access, the riverscape is anticipated to benefit under the Proposed Project.

<u>Significance</u>

No significant impact in the short term

Beneficial in the long term

Potential Impact 3.12-10 Klamath Cultural Riverscape Contributing Aspect: Ability of tribes to use the Middle and Lower Klamath River for ceremonial and other purposes due to alterations in riverine water quality and the extent of nuisance and/or noxious blue-green algae blooms.

California Native American tribes, such as Karuk, Yurok, Resighini Rancheria, Hoopa Valley, and Klamath, currently consume considerable amounts of fish and may ingest or contact water during fishing, bathing, collection and washing of basket and plant materials, and during tribal ceremonies such as the Boat Dance (DOI 2011) (see also Section 3.12.2.1 *Tribal Cultural Chronology and Ethnography (including Historic and Pre-Historic Periods – Northwest California Culture Area*). Under current conditions, seasonal blooms of nuisance blue-green algae regularly occur in Lower Klamath Project reservoirs and are released from Iron Gate and Copco No. 1 reservoirs into the Middle and Lower Klamath River. This can result in elevated concentrations of algal toxins in the water commonly exceeds public health advisory postings for water contact and inhibit the use of the Middle and Lower Klamath River for tribal purposes. Released blue-green algae can also clog fishing nets as well as result in elevated concentrations of algal toxins in the water, further interfering with tribal use of the river (see Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*).

Based on available data, measured concentrations of the algal toxin microcystin in fish tissue have varied in the Middle and Lower Klamath River, but instances of microcystin bioaccumulation have been reported at levels that exceed public health guidelines (in addition to the water column exceedances mentioned above) (see Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project – Algal Toxins*). Because of health risks associated with direct ingestion of fish tissue and water, as well secondary health risks due to dermal exposure to water containing elevated levels of algal toxins, tribes have had to adopt precautionary steps to avoid ingestion and water contact (DOI 2011).

Despite the slightly increased total nutrient concentrations anticipated under the Proposed Project in the Hydroelectric Reach (see Potential Impact 3.2-8), elimination of the reservoir environment that currently supports growth conditions for toxin-producing nuisance blue-green algal species such as *Microcystis aeruginosa* would result in decreases in high seasonal concentrations of chlorophyll-*a* (greater than 10 ug/L) and periodically high levels of algal toxins (greater than 8 ug/L microcystin) generated by suspended blue-green algae in the Hydroelectric Reach, the Middle and Lower Klamath River as well as the Klamath River Estuary (see Potential Impact 3.2-12). The anticipated reductions in blue-green algae concentrations under the Proposed Project would support Cultural Use of Klamath River waters without risk of adverse health effects, which would improve tribal members' access to the river above levels occurring under existing conditions. This would be a beneficial effect. Since drawdown of the reservoirs would begin in winter and would be largely complete by March/April (i.e., the beginning of the algal growth season) of dam removal year 2, reductions in chlorophyll-*a* and algal toxins would be a short-term benefit as well as a long-term benefit since the reduction would begin during dam removal year 2 and it would continue beyond post-dam removal year 1 (Potential Impact 3.2-12).

Significance

Beneficial in the short term and long term

3.12.5.2 Potential Impacts to Built Environment and Historic-period archaeological Resources

Potential Impact 3.12-11 Facilities removal would result in significant impacts to Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and the Klamath River Hydroelectric Project District as a whole.

The Proposed Project would include removal of large-scale contributing elements of the Klamath River Hydroelectric Project District, an historical resource recommended eligible for listing to the California Register of Historical Resources for the role in early development of electricity and economy of the southern Oregon and northern California regions (Cardno Entrix 2012; Kramer 2003a,b).

Under the Proposed Project, J.C. Boyle Dam, Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, and many of the associated hydroelectric facilities would be removed. (see Section 2 *Proposed Project*) Proposed Project activities would directly impact the historical significance of the dam structures and hydroelectric facilities and other associated properties. Removal of the three California dams (the major contributors of significance), would preclude the ability for the district to remain eligible for listing with the California Register of Historical Resources. Thus, facilities removal would be a significant impact on the resource.

As the core of the Proposed Project is removal of the Lower Klamath Project dams and associated facilities, historical restoration and "adaptive re-use" is simply not feasible as mitigation for these facilities. Dams and other hydroelectric facilities are not able to be relocated, making this form of mitigation not feasible. Maintaining some structures in place is considered in Section 4.3 *Partial Removal Alternative*.

Documentation measures that meet the National Park Services Secretary of the Interior standards for documentation of historical architectural and engineering properties are the only feasible form of mitigation because avoidance and minimization measures would not be possible.

The Proposed Project includes a Cultural Resources Plan (Appendix B: *Definite Plan – Appendix L*) that considers potential impacts to historic built environment resources, including the Klamath River Hydroelectric Project District. The Cultural Resources Plan proposes updating the Request for Determination of Eligibility for listing on the NRHP to include Iron Gate Dam (which has reached 50 years of age since the Request was first filed. Additionally, the Cultural Resources Plan sets forth a process for addressing potential impacts through avoidance and preservation in place as a first priority, then minimization, then resource-specific approaches where avoidance and minimization are not feasible. Where documentation is used, the Cultural Resources Plan recommends adopting protocols consistent with the Secretary of the Interior's Standards for Archaeological Documentation, Historical Documentation, and Architectural and Engineering Documentation; the ACHP Section 106 Archaeology Guidance; and other guidance from the appropriate SHPOs and/or THPOs, as applicable.

However, elements of the Cultural Resources Plan are not final. The Cultural Resources Plan would be further developed by KRRC working through the FERC process to comply with Section 106 of the National Historic Preservation Act of 1966, as codified in 36 CFR Part 800. As stated in the Cultural Resources Plan, mitigation measures and other protective measures would be developed and implemented to protect historic built environment resources.

Overseeing development and implementation of the Cultural Resources Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process through the Cultural Resources Working Group and FERC to develop a Historic Properties Management Plan and a Programmatic Agreement that will be finalized and implemented, at this time the Historic Properties Management Plan and the Programmatic Agreement are not finalized and the State Water Board cannot require their implementation. While the State Water Board anticipates that implementation of the Historic Properties Management Plan and the Programmatic Agreement would reduce impacts to the historical built environment, the core of the Proposed Project is removal the hydroelectric facilities and much of the context for these historic resources, such that historical restoration, "adaptive re-use," or relocation of the structures and buildings is not feasible. Even with documentation, the impact to the resource and its context would be significant and the historic resource would be materially impaired. Thus, while the inclusion of documentation measures in conformance with the Secretary of the Interior's guidance would lessen the impact to the resource, the impact to the Klamath Hydroelectric Historical District under the Proposed

Project would be significant and unavoidable even with inclusion of the KRRC's proposed mitigation measure.

Significance

Significant and unavoidable

Potential Impact 3.12-12 Pre-dam-removal activities that involve disturbance of the landscape, including construction or improvement of associated roads, bridges, water supply lines, staging areas, disposal sites, hatchery modifications, recreation site removal and/or development, and culvert construction and improvements could result in potential exposure of or damage to historic-period archaeological resources (identified in Table 3.12-1) through ground-disturbing construction and disposal activity and increased access to sensitive areas.

Historic-period cultural resources are known to be present within Area of Analysis *Subarea 1* (Figure 3.12-2) and are identified in Table 3.12-1. Pre-dam removal activities involving ground disturbance, construction or improvement of associated roads, bridges, water supply lines, staging areas, disposal sites, hatchery modifications, recreation site removal and/or development, and culvert construction and/or improvements would occur within the Area of Analysis *Subarea 1* (Figure 3.12-2).

Due to the nature of ground-disturbing activities and a general increase in the level of activity (e.g., construction, surveys) within the Area of Analysis *Subarea 1*, pre-dam removal activities that would involve ground disturbance have the potential to result in the following impacts to historic-period cultural resources through physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings; and/or exposure or substantial movement of the resources leading to increased illicit looting resulting in a significant impact.

To reduce impacts to historic-period cultural resources associated with pre-dam removal activities, the KRRC is developing a Historic Properties Management Plan to identify historic properties and include measures to implement before and during drawdown and dam removal activities to protect significant historic, cultural, and tribal resources during Proposed Project implementation. The Historic Properties Management Plan will be submitted to FERC for approval before the commencement of any ground disturbing activities (including reservoir drawdown).

Additionally, the KRRC has committed to implement a Looting and Vandalism Prevention Program (LVPP) to reduce looting and vandalism to TCRs and historic-period cultural resources (Mitigation Measure TCR-2), and an Inadvertent Discovery Plan (IDP) that would include actions to implement in the event an inadvertent discovery (e.g., human remains) (Mitigation Measure TCR-3), both of which would provide for compliance with applicable laws regarding cultural resources and human burials.

Implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP) would reduce these impacts considerably, and, for many resources is expected to avoid impacts completely through the design and implementation of construction plans or on-the-ground modifications to Proposed Project implementation. For impacts for which it is not feasible to completely avoid, these impacts may be reduced to a less than significant level with implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP).

Overseeing development and implementation of the Historic Properties Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process through the Cultural Resources Working Group and FERC to develop the Historic Properties Management Plan and a Programmatic Agreement that will be finalized and implemented, at this time the Historic Properties Management Plan and the Programmatic Agreement are not finalized and the State Water Board cannot require their implementation. While the State Water Board anticipates that implementation of the Historic Properties Management Plan and the Programmatic Agreement, including any modifications developed through the FERC process that provide the same or better level of protection for historic-period cultural resources, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Historic Properties Management Plan and the Programmatic Agreement, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance
Significant and unavoidable impact with mitigation

Potential Impact 3.12-13 Drawdown of Iron Gate, Copco No. 1, and Copco No. 2 reservoirs could shift, erode, or exposure historic-period archaeological resources resulting in increased potential for damage and looting.
The Proposed Project would draw down Iron Gate, Copco No.1, Copco No. 2 and J.C. Boyle reservoirs at a rate between 2 and 5 feet per day (i.e., 1 to 2.5 inches per hour). Drawdown of Copco No. 1 would begin November 1 of dam removal year 1 at a maximum rate of 2 feet per day, and drawdown of all reservoirs would occur at a maximum rate of 5 feet per day beginning January 1 of dam removal year 2 and continue until March 15 of the same year. The analysis for this potential impact focuses on the California Lower Klamath Project reservoirs, including Copco No. 1, Copco No. 2, and Iron Gate, which are contained within Area of Analysis *Subarea 1* (Figure 3.12-2).

Since construction of Lower Klamath Project reservoirs, fine sediments composed primarily of organic material (including dead algae), but also including some silts and clays, have accumulated on the reservoir bottoms covering the original topography and potentially historic-period cultural resources that were present prior to reservoir construction. The distribution of sediment deposits associated with sediment deposition following reservoir construction varies within each reservoir (Figures 2.7-8 and 2.7-9). Because the accumulated sediments are primarily fine material, they will be easily eroded and flushed out of the reservoirs into the Klamath River during reservoir drawdown. The degree of sediment erosion will vary, with the majority of the erosion focused in the former river channel that is currently submerged in Copco No. 1, Copco No. 2, and Iron Gate reservoirs (see Figures 2.7-5 and 2.7-6). The Proposed Project also includes barge-mounted pressure spraying during reservoir drawdown that would target six locations in Copco No. 1 Reservoir and three locations in Iron Gate Reservoir within which to maximize erosion of sediment deposits and subsequently excavate to the historical floodplain elevation to create wetlands, floodplain areas and off-channel habitat features (see Appendix B: *Definite Plan – Appendix H Figures 5-4 and 5-7*).

Following drawdown, approximately 40 to 60 percent of the sediment deposited since construction of Lower Klamath Project reservoirs would remain in the former reservoir footprints, primarily on terraces located above the historical river channel. The sediments that remain in the reservoir footprints would consolidate (dry out and decrease in thickness) (USBR 2012a), likely making them less subject to erosion. Further, during reservoir drawdown, aerial seeding of pioneer seed mixes would occur following the receding reservoir waters. Aerial seeding during reservoir drawdown would not result in any further disturbance of soil on the exposed reservoir terraces and the establishment of vegetation on the terraces would potentially reduce erosion of fine sediments. Recent laboratory tests of reservoir sediments showed vegetated sediments produced less erodible fine particles and aggregates during cycles of wetting and drying than unvegetated sediments (Appendix B: *Definite Plan – Appendix H*).

Although not currently anticipated by KRRC, the Proposed Project may also include hydroseeding from a barge on exposed reservoir terraces as the water recedes during reservoir drawdown. Hydroseeding from a barge would be accomplished by placing a ground rig on one barge with another boat used to ferry materials from shore. A moveable pier or other engineered method of accessing the supply boat as the water level recedes would also be needed. If it occurs, barge hydroseeding would occur in the higher elevation portion of the reservoir shoreline, until the reservoir levels become too low to operate (i.e., March of dam removal year 2). If barge hydroseeding occurred, additional disturbances of reservoir sediments would occur as wave action from the barge would increase disturbance of sediment adjacent to the receding reservoir's shoreline, potential increasing the chance for slope instability and exposure of historic-period archaeological resources.

Historic-period cultural resources associated with late-nineteenth and early-twentieth century settlement, agriculture, logging, mining, hydroelectric, and transportation facilities are known to be present within the proposed Limits of Work (Area of Analysis *Subarea 1)* (Figure 3.12-2). Known historic-period archaeological sites along the margin of Copco Reservoir include ruins of buildings (P-47-002824) and refuse dumps (P-47-003917 and P-47-003922). Other known but unrecorded historic period sites at Copco Reservoir included early homesteads[157], such as the lands of Ward, Keeton, Reimundo, and Pecard (Daniels 2017), and Spannaus, Lennox and Kempler. Additionally, there are references to railroads, irrigation ditches, buildings, camps, roads, trails, bridges, and agricultural fields in the historic record that are not attributed to a specific location but could be encountered during Copco Reservoir drawdown (see Appendix B: *Definite Plan – Appendix L, Table 6-12*)

Known historic-period cultural resources along the shoreline of Iron Gate Reservoir include a homestead site (P-47-003940), several stacked rock wall segments (P-47-003943, P-47-003942, and P-47-003937), and a location with dozens of historical rock cairns believed to be the result of field clearing (P-47-003945) (Cardno ENTRIX 2012, PacifiCorp 2004). Additionally, there are references to homesteads of Griever, Madero, and Spearing, rock walls, irrigation ditches, bridges, road trails, railroads, former gauge stations that could be encountered during Iron Reservoir drawdown.

Specific historic-period cultural resources located at the sites identified above include features, such as buildings, foundations, cellars, wood posts, rock stacks, refuse deposits, wells, privies, and orchards. Associated artifacts may include whole of fragmented glass or ceramic containers, table ware, lighting, or electrical artifacts. Metal

[157] Some historic-period resources may also be considered Tribal Cultural Resources and are included in Potential Impacts 3.12-1 through 3.12-10.

artifacts may include fencing, wire, containers, fasteners, tools, and roofing. Other structural and personal artifacts may include brick or mortar, wood, rubber, some plastics, and textiles. These archaeological materials can be discovered in concentrations, such as in a refuse dump, or as isolated artifacts.

The condition of historic-period cultural resources inundated under the reservoirs is unknown, however it is anticipated that deposits of artifacts, features and sites are present and could be impacted from shifting and erosion of reservoir sediment deposits during and after drawdown. Some historic-period cultural resources within the reservoir footprints may remain covered in sediment, or capped, resulting in some degree of preservation and disturbance minimization.

Due to the nature of ground-disturbing activities during drawdown within the Area of Analysis *Subarea 1* that have the potential to result in physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings; and/or exposure or substantial movement of the resources leading to increased illicit looting, the impact of drawdown to historic-period cultural resources would result in a significant impact. However, as discussed in Potential Impact 3.12-2, the KRRC is developing a Historic Properties Management Plan, LVPP, and IDP to identify historic properties and include measures to implement before and during drawdown and dam removal activities to protect historic, cultural, and tribal resources. Implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP) would reduce significant drawdown impacts considerably, and, for many resources is expected to avoid impacts completely through the design and implementation of construction plans or on-the-ground modifications to Proposed Project implementation. For impacts that it is not feasible to completely avoid, the impacts may be reduced to a less than significant level with implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP).

Overseeing development and implementation of the Historic Properties Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process through the Cultural Resources Working Group and FERC to develop the Historic Properties Management Plan and a Programmatic Agreement that will be finalized and implemented, at this time the Historic Properties Management Plan and the Programmatic Agreement are not finalized and the State Water Board cannot require their implementation. While the State Water Board anticipates that implementation of the Historic Properties Management Plan and the Programmatic Agreement, including any modifications developed through the FERC process that provide the same or better level of protection for historic-period cultural resources, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Historic Properties Management Plan and the Programmatic Agreement, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance

Significant and unavoidable with mitigation

Potential Impact 3.12-14 Reservoir drawdown could result in short-term erosion or flood disturbance to historic-period cultural resources located along the Klamath River.

As discussed in Potential Impact 3.12-3, the proposed drawdown of the Lower Klamath Project reservoirs is designed to minimize potential flood risks, including carefully drawing down the reservoirs using controlled flow releases and the increased storage availability in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs once drawdown has begun to accommodate for potential winter flow events and drawdown would not result in flows that are out of the normal range of flows experienced under existing conditions.

Hydrologic and hydraulic modeling of floodplain inundation shows that removal of the Lower Klamath Project dams could result in minor alterations to the FEMA 100-year floodplain inundation area downstream of Iron Gate Dam, along the 18-river mile stretch of the Middle Klamath River between RM 193 and 174 (i.e., from Iron Gate Dam to Humbug Creek) (USBR 2012c). Changes in the extent of the floodplain inundation area could affect potential historic-period cultural resources currently located within the FEMA 100-year floodplain (P-47-00522 [Empire Quartz Mine], P-47-00536 [Klamathon Townsite and Limber Mill], P-47-003937 [Rock Wall], P-47-004212 [Bridge], and P-47-004427 [artifact scatters]) which could result in a significant impact to historic-period cultural resources.

As discussed in Potential Impact 3.12-11, the KRRC is developing a Historic Properties Management Plan and an IDP to identify historic properties and include measures to implement before and during drawdown and dam removal activities to protect historic, cultural, and tribal resources. Implementation of the Historic Properties Management Plan and Mitigation Measure TCR-3 (IDP) may reduce impacts to resources identified in the 18-river mile stretch below Iron Gate Dam but given their proximity to Iron Gate Dam and their future inclusion in the altered 100-year floodplain following completion of the Proposed Project, impacts would remain significant and unavoidable.

As implementation of the Proposed Project is not anticipated to result in any other changes to the FEMA 100-year floodplain, or result in drawdown flows above historically recorded flows, potential impacts to historic-period cultural resources along other portions of the Klamath River would result in no significant impact.

Significance

Significant and unavoidable with mitigation for Middle Klamath River from Iron Gate Dam (RM 193) to Humbug Creek (RM 174)

No significant impact for Hydroelectric Reach excluding Iron Gate Dam, Middle Klamath River downstream of Humbug Creek, Lower Klamath River, Klamath River Estuary

Potential Impact 3.12-15 Project activities associated with removal of Iron Gate, Copco No. 1, and Copco No. 2 dams could result in physical disturbance to historic-period cultural resources from blasting or other removal techniques.

As described in Potential Impact 3.12-4, blasting and other dam removal techniques could cause significant adverse impacts to historic-period cultural resources located in the immediate vicinity[158] of Iron Gate, Copco No.1 and Copco No. 2 dams. The direct

[158] For the purposes of this analysis, "immediate vicinity" is defined as within 0.25 miles of Copco No. 1, Copco No. 2, and Iron Gate dams.

physical disturbance associated with blasting and other removal techniques could significantly impact historic-period archaeological resources that directly overlap with the blasting locations.

Though no data has identified historic-period cultural resources in the immediate vicinity of Iron Gate, Copco No. 1, and Copco No. 2 dams, but given the use of lands surrounding Proposed Project dams prior to construction of the Lower Klamath Project, this potential impact analysis assumes that historic-period archeological resources may be present in the immediate vicinity. For historic-period cultural resources that may be present in the immediate vicinity, impacts to these resources associated with dam removal would be significant and unavoidable.

As discussed in Potential Impact 3.12-11, the KRRC is developing a Historic Properties Management Plan and an IDP to identify historic properties and include measures to implement before and during drawdown and dam removal activities to protect historic, cultural, and tribal resources. Implementation of the Historic Properties Management Plan and Mitigation Measure TCR-3 (IDP) may reduce impacts to resources in the immediate vicinity of Iron Gate, Copco No. 1, and Copco No. 2 dams, but given construction activities and their potential for impacts to potential historic-period cultural resources, impacts would remain significant and unavoidable.

Significance

Significant and unavoidable with mitigation

Potential Impact 3.12-16 Ground disturbance associated with reservoir restoration, recreation site removal and/or development, and disposal site restoration could physically disturb historic-period cultural resources. Additionally, ongoing road and recreation site maintenance may have the potential to disturb known historic-period cultural resources.

As discussed in Potential Impact 3.12-5, the Proposed Project includes a Reservoir Area Management Plan that includes restoration activities that would occur both within the reservoir footprint and in upland areas (i.e., disposal, staging, and hydropower infrastructure demolition areas, access roads, former recreational areas) within the Area of Analysis *Subarea 1* (Figure 3.12-2). Historic-period archaeological resources are located within the footprints of Lower Klamath Project reservoirs.

Ground-disturbing activities associated with ongoing road, restoration, and recreation site maintenance within the Area of Analysis *Subarea 1* (Figure 3.12-2) include grading and excavating, which may result in material impairment due to physical demolition, destruction, relocation, or alteration of historic-period cultural resources located in both upland and reservoir footprint locations resulting in a significant impact.

However, as discussed in Potential Impact 3.12-11, the KRRC is developing a Historic Properties Management Plan, LVPP, and IDP to identify historic properties and include measures to implement before and during drawdown and dam removal activities to protect historic, cultural, and tribal resources. Implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP) would reduce significant post-dam removal restoration impacts considerably, and, for many resources is expected to avoid impacts completely, through the design and implementation of construction plans or on-the-ground modifications to Proposed Project implementation. For impacts that it is not feasible to completely avoid, the impacts may be reduced to a less than significant level with implementation of the Historic Properties Management Plan, Mitigation Measure TCR-2 (LVPP), and Mitigation Measure TCR-3 (IDP).

Overseeing development and implementation of the Historic Properties Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has initiated a process through the Cultural Resources Working Group and FERC to develop the Historic Properties Management Plan and a Programmatic Agreement that will be finalized and implemented, at this time the Historic Properties Management Plan and the Programmatic Agreement are not finalized and the State Water Board cannot require their implementation. While the State Water Board anticipates that implementation of the Historic Properties Management Plan and the Programmatic Agreement, including any modifications developed through the FERC process that provide the same or better level of protection for historic-period cultural resources, would reduce impacts to less than significant, because the State Water Board cannot ensure implementation of the Historic Properties Management Plan and the Programmatic Agreement, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance

Significant and unavoidable impact with mitigation

3.13 Paleontologic Resources

This section of the EIR analyzes the potential impacts of the Proposed Project on paleontologic resources.

3.13.1 Area of Analysis

The Area of Analysis for paleontologic resources includes the region within and adjacent to the Klamath River 100-year floodplain, in Siskiyou, Humboldt, and Del Norte counties, from the Oregon-California state line to the Klamath River's mouth near Requa, CA (Figure 3.13-1).

The Area of Analysis is defined to be within 1,000 feet of the FEMA Flood Zones A and AE. For areas of the Klamath River that do not have FEMA Flood Zone designation, the Area of Analysis is defined to within 3,000 feet of the National Hydrography Dataset Klamath River centerline. For the area upstream of Iron Gate Dam, the Area of Analysis is defined to be within a five-mile buffer of the National Hydrography Dataset Klamath River centerline.

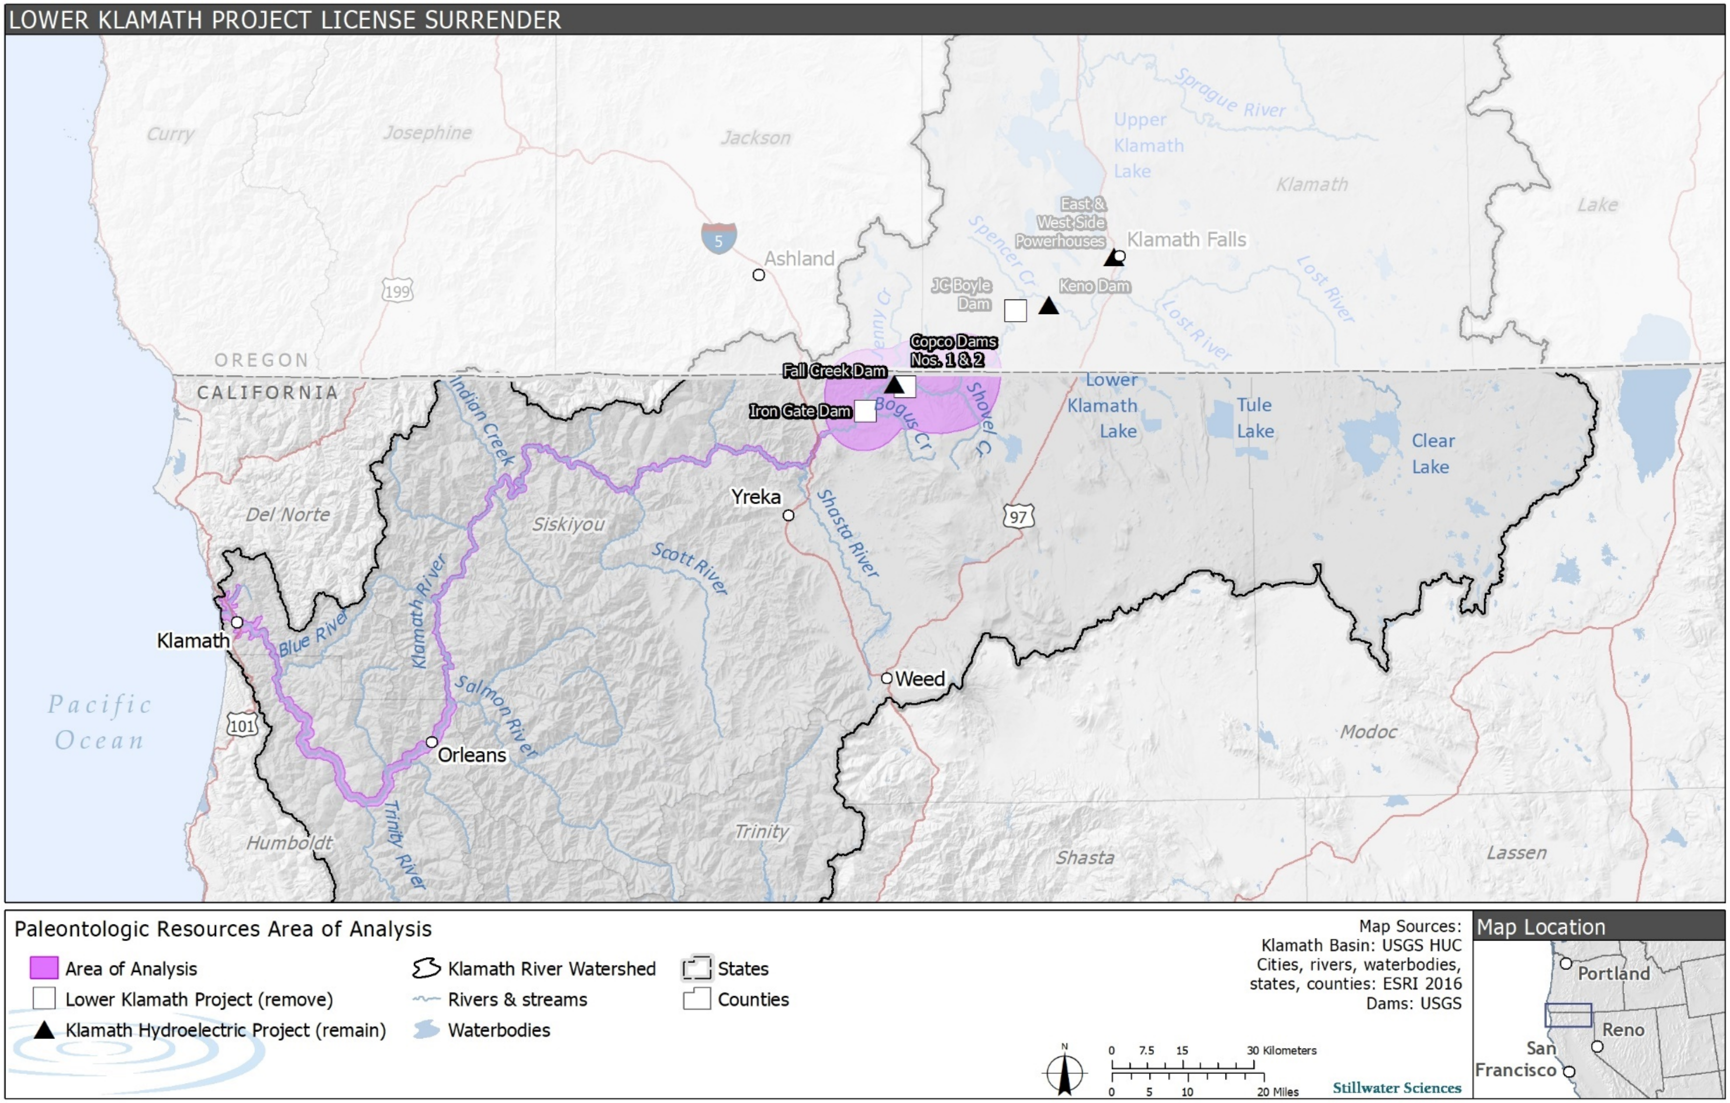

Figure 3.13-1. Area of Analysis for Paleontologic Resources.

3.13.2 Environmental Setting

The Klamath River passes through four main regional rock types that dominate the geology and which span the Mesozoic and Cenozoic eras. The four main rock types include metamorphic, igneous (volcanic), fluvial sedimentary, and marine sedimentary (Figure 3.11-2). Metamorphic rocks are rocks that have changed into different rock types due to changes in temperature and pressure. Sometimes rocks that have fossils in them become sufficiently metamorphosed that the fossils no longer exist. Igneous volcanic rocks are rocks that are formed as a process related to volcanic eruptions, so generally these types of rocks do not contain fossils. Though, sometimes volcanic deposits can entomb organisms during deposition, thus preserving these organisms which can later turn into fossils. Fluvial sedimentary rocks are rocks formed from river sediments. Marine sedimentary rocks are rocks formed from sediments in the ocean.

While the majority of bedrock deposits within the Area of Analysis for paleontologic resources are not fossil-bearing units, exceptions include an unnamed diatomite deposit along the shores of Copco No. 1 Reservoir and the Hornbrook Formation (USGS 1983, Elliot 1971). Additional details about the regional geologic framework are presented in Section 3.11.2.1 *Regional Geology*.

3.13.2.1 Bedrock Geology

The eastern portion of the Klamath Basin (the Cascade Range Geomorphic Province, approximately east of U.S. Interstate 5; Figure 3.11-1) is underlain by Tertiary and Quaternary volcanic rocks (Wagner and Saucedo 1987). These rocks generally do not contain fossils. To the west, in the Klamath Mountains and Coast Ranges Geomorphic Provinces, the Klamath Basin is underlain by Paleozoic and Mesozoic metasedimentary (metamorphic) and igneous rocks (Wagner and Saucedo 1987, Irwin 1994, Delattre and Rosinski 2012, Ernst 2015). The igneous rocks lack fossils and the metasedimentary rocks have been deformed sufficiently to destroy fossils; accordingly, no fossils have been documented in these rocks. There are also mapped Quaternary fluvial[159] deposits, discontinuously, along the entire Klamath River (Hotz 1967, 1977; Wagner and Saucedo 1987; Delattre and Rosinski 2012), as well as diatomite deposits along the banks of Copco No. 1 Reservoir (USGS 1983). While these fluvial deposits may contain fossils, no fossils have been documented to exist in the Area of Analysis for paleontologic resources.

The Late Cretaceous Hornbrook Formation (Hornbrook Formation) is mapped at the boundary between the Cascade Range and Klamath Mountains geomorphic provinces, 2 of California's 11 geomorphic provinces (Peck et al. 1956, Elliot 1971, Nilsen et al. 1983, Nilsen 1984, Sliter et al. 1984, Nilsen 1993, Irwin 1994, Nilsen 1994, Elliot 2007, Surpless 2015). The Cascade Range Geomorphic Province is the region from northern California into southwestern Canada where topographic forms are dominated by the volcanism associated with the Cascades volcanoes. The Klamath Mountains Geomorphic Province is a region in northwestern California and southwestern Oregon where the landforms and topography are controlled by uplifted ancient subduction zone and igneous (plutonic) rocks. Plutonic rocks are igneous rocks that formed beneath the surface of the Earth. Hornbrook Formation rocks are composed of marine and non-

[159] Quaternary refers to the Quaternary Period, a time range between 2.56 million years ago and extends to today. Fluvial refers to sediments deposited as a result of processes associated with rivers.

marine sedimentary rocks formed between 100 and 66 million years ago, but possibly as early as 113 million years ago (Surpless 2015). Nilsen et al. (1983), along with previous mappers, documented that many of the subunits within the Hornbrook Formation have fossils including mollusks, ammonites, foraminifers, plant fossils, and paleosols.

3.13.2.2 Paleontologic Resources

Two mapped geologic units that contain paleontologic resources are present within the Area of Analysis: (1) the unnamed diatomite deposit at Copco No. 1 Reservoir; and (2) the Hornbrook Formation. The diatomite deposit is determined to be of Low Paleontologic Potential because these fossil diatoms (algae): 1) do not occur in association with significant vertebrate fossils; 2) are not rare; and 3) it is not thought that the distribution of fossils and fossil species has a significant spatial variation. The fossils in the Hornbrook Formation are documented to include megafossils (e.g., Gastropoda) and microfossils (e.g., Foraminifera), but it is not known if the fossil abundance varies spatially within this geologic unit.

The Klamath River cuts across the Hornbrook Formation in the region of Hornbrook, California, along approximately three river miles (Figure 3.13-2). The different sub-units within the Hornbrook Formation are listed relative to Geologic Symbol (symbology on the map), Unit Description (rock type), and Fossil Description (absence/presence; fossil types) in Table 3.13-1. All Hornbrook Formation units are within the Area of Analysis for paleontologic resources, but some of these mapped units are separated from the active channel by Quaternary Alluvium. Many of the fossil sampling locations are along Blue Gulch and Klamathon Road, south of Hornbrook, California (Nilsen 1993). Fossil biostratigraphy[160] was used to provide age control for the stratigraphic correlation of geologic units in the region of Hornbrook, California, along with geologic units elsewhere in northern California (Sliter et al. 1984). Type sections (unique and identifiable sedimentary stratigraphic sections) for each sub-unit in the Hornbrook Formation are located outside of the Area of Analysis (Nilsen 1993).

[160] Fossil biostratigraphy is the ability to date the age of rock formations based on the presence of fossils.

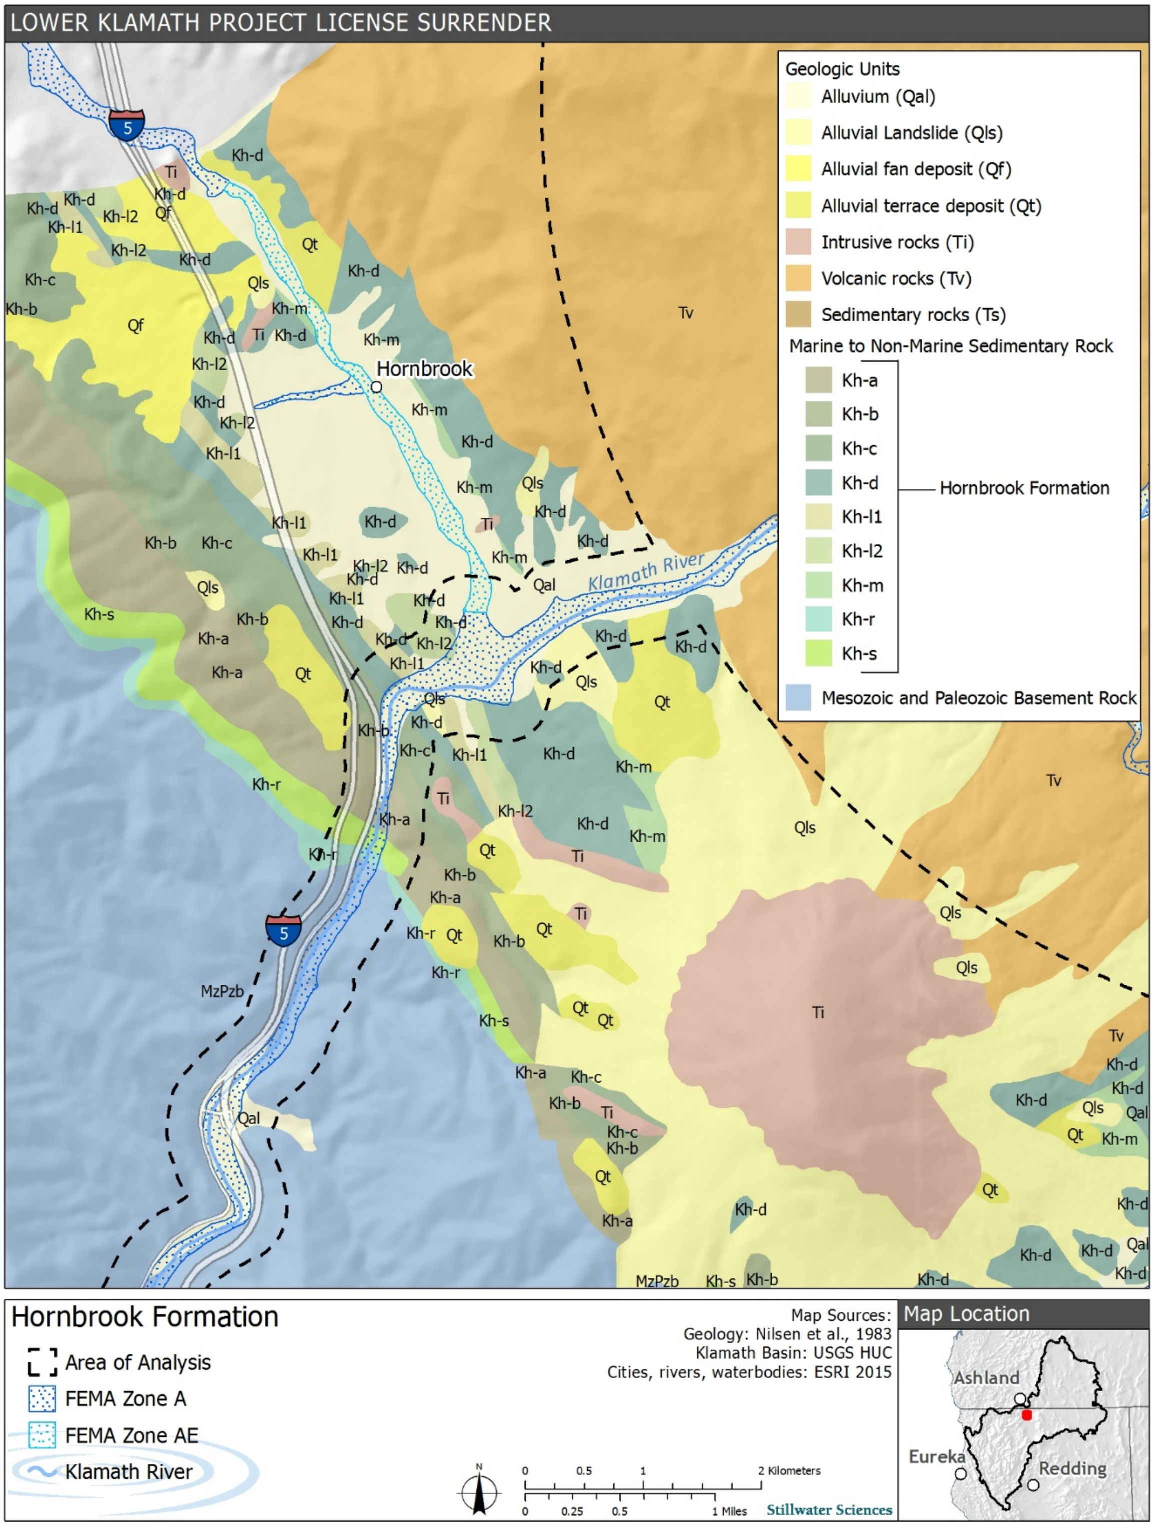

Figure 3.13-2. Late Cretaceous Hornbrook Formation mapped along the Klamath River (Nilsen et al. 1983). Hornbrook Formation unit descriptions are presented in Table 3.13-1.

The Hornbrook Formation is exposed in road cuts along Klamathon Road and the Old Hornbrook Highway in the region of Hornbrook, California. These outcrops include subunits IKh-d, Kh-l1, and Kh-l2.

Table 3.13-1. Hornbrook Formation Geologic Unit and Fossil Descriptions.

Geologic Symbol	Unit Description	Fossil Description
Kh-a	Marine Sandstone with local conglomerate; hummocky cross strata in upper part	Molluscan fossils
Kh-b	Marine siltstone with some mudstone and very fine-grained sandstone; local coal beds	Molluscan fossils
Kh-c	Marine sandstone and conglomerate with thin interbeds of shale	Unfossiliferous
Kh-d	Marine shale, mudstone, and thin-bedded, fine-grained sandstone	Ammonites and foraminifers
Kh-l1	Very fine- to fine-grained lens of hummocky cross stratified marine sandstone; lower unit	Molluscan fossils
Kh-l2	Very fine- to fine-grained lens of hummocky cross stratified marine sandstone; upper unit	Molluscan fossils
Kh-m	Thick bed of marine turbidite sandstone	—
Kh-r	Nonmarine conglomerate, sandstone, pebbly mudstone, and siltstone; locally a basal breccia	Plant fossils, paleosols
Kh-s	Marine conglomeratic sandstone characterized by large-scale trough cross strata	Molluscan fossils

3.13.3 Significance Criteria

Criteria for determining significant impacts on paleontologic resources are based upon Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgment. Effects on paleontologic resources are considered significant if the Proposed Project would:

- Result in the destruction of any High Potential Paleontologic Resources, as defined in Table 3.13-2 and discussed further below.
- Result in substantial adverse effects on any High Potential Paleontologic Resources, as defined further below.

In general, destruction of High Potential Paleontologic Resources includes the physical demolition, relocation, or alteration of the paleontologic resource that would alter or remove the factors that are the basis for determining the significance of the paleontologic resource. These factors include taxonomic, phylogenetic, paleoecologic, taphonomic, biochronologic, or stratigraphic data uniquely related to the paleontologic resource. See definitions for, and an explanation of, these terms below.

In general, a substantial adverse effect on High Potential Paleontologic Resources is defined as a loss of fossils or their surrounding material contributing to the potential loss of taxonomic, phylogenetic, paleoecologic, taphonomic, biochronologic, or stratigraphic information. An explanation of each of these types of paleontologic information and the definition of substantial adverse effect specific to that type of information is provided below. While the below definitions are provided for examples of fossils from organisms' bodies, they also apply to trace fossils (fossils of a burrow, boring, feces, footprint, track, or some other physical evidence of life preserved in the rock record), as well as the material surrounding fossils and trace fossils.

- Taxonomic information includes the hierarchical classification of biological organisms (e.g., genus, species). A substantial adverse effect on taxonomic information would occur if rocks with fossils or their surrounding material that included significant taxonomic information were destroyed, such as fossils that had body parts with geometry that helped identify those species in a specific taxonomic way.
- Phylogenetic information describes how an extant species (one that no longer exists) may relate to other species in an evolutionary way (i.e., the "family tree" of the different species). A substantial adverse effect on phylogenetic information would occur if rocks with fossils or their surrounding material that included significant phylogenetic information were destroyed, such as fossils that have physical features that tie that species to other species in the "family tree" with the physical development of that species' physical form.
- Paleoecologic information inferred from the fossil related to the climate at time of deposition A substantial adverse effect on paleoecologic information would occur if rocks with fossils or their surrounding material that included significant paleoecologic information were destroyed, such as pollen, isotope, or other information that can be used as a proxy for the prehistoric climate.
- Taphonomic information describes how the organism(s) had been modified prior to fossilization (e.g., the erosion or modification of the shapes or forms of the pre-fossilized materials as they were transported in a landslide, tsunami, river flow or some other process). A substantial adverse effect on taphonomic information would occur if rocks with fossils or their surrounding material that included significant taphonomic information were destroyed, such as a fossil that had been modified by some physical process prior to fossilization, especially if that process is linked to some physical behavior of the organism or some physical process related to where the organism existed.
- Biochronologic information describes where fossils fit into the geologic time scale. A substantial adverse effect on biochronologic information would occur if rocks with fossils or their surrounding material that included significant biochronologic information were destroyed, such as if there is some chronologic information that linked the species with rocks of a particular age or age range.
- Stratigraphic information describes the layering of geologic materials with time, including information about superposition[161]). A substantial adverse impact on stratigraphic information would occur if rocks with fossils or their surrounding material that included significant stratigraphic information were destroyed, such as information about overlying or underlying geologic, biologic, or chemical data or trends in data.

[161] Superposition refers to a sedimentary deposit that is on top of another sedimentary deposit, the deposit on top is "superposed" over the lower sedimentary deposit. The superposed deposit is therefore younger than the underlying deposit.

3.13.4 Impacts Analysis Approach

Paleontologic resources are defined as any fossilized remains, traces, or imprints of organisms, preserved in or on the Earth's crust, that are of paleontologic interest and that provide information about the history of life on Earth. The Society of Vertebrate Paleontology published the “Standard Guidelines for the Assessment and Mitigation of Adverse Impacts to Nonrenewable Paleontological Resources” and this guide, updated in 2010, was developed to help evaluate the potential of destroying paleontologic resources during construction projects. These guidelines include an: “(a) assessment of the potential for land to contain significant paleontologic resources which could be directly or indirectly impacted, damaged, or destroyed by proposed development and (b) formulation and implementation of measures to mitigate these adverse impacts, including permanent preservation of the site and/or permanent preservation of salvaged fossils along with all contextual data in established institutions” (SVP 2010). These guidelines provide criteria for designating the potential paleontologic sensitivity of a site, along with the corresponding recommended mitigation measures required for high, moderate, or low potential for containing significant paleontologic resources (Table 3.13-2, SVP 2010).

Paleontologic potential consists of both: (a) the potential for yielding abundant or significant vertebrate fossils or for yielding a few significant fossils, large or small, vertebrate, invertebrate, plant, or trace fossils and (b) the importance of recovered evidence for new and significant taxonomic, phylogenetic, paleoecologic, taphonomic, biochronologic, or stratigraphic data. Rock units that contain potentially datable organic remains older than late Holocene, including deposits associated with animal nests or middens, and rock units that may contain new vertebrate deposits, traces, or trackways are also classified as having high potential.

Significant nonrenewable paleontologic resources are fossils and fossiliferous deposits (rocks with fossils or fossil traces) here defined as consisting of identifiable vertebrate fossils, large or small, uncommon invertebrate, plant, and trace fossils, and other data that provide taphonomic, taxonomic, phylogenetic, paleoecologic, stratigraphic, and/or biochronologic information. Paleontologic resources are considered to be older than recorded human history and/or older than middle Holocene (i.e., older than about 5,000 radiocarbon years), as outlined in the Standard Procedures for the Assessment and Mitigation of Adverse Impacts to Paleontological Resources (SVP 2010). In other words, significant nonrenewable paleontologic resources include vertebrate fossils and their taphonomic and environmental indicators, along with invertebrate or botanical fossils in association with a vertebrate assemblage, or plant or invertebrate fossils that are defined as significant by a qualified vertebrate paleontologist[162]. In addition, if invertebrate, plant, or trace fossils are known to have an association with a significant vertebrate fossil

[162] Based on the SVP (2010), a qualified vertebrate paleontologist is a practicing scientist who is recognized in the paleontological community as a professional and can demonstrate familiarity and proficiency with paleontology in a stratigraphic context. A paleontological Principal Investigator shall have the equivalent of the following qualifications: (1) a graduate degree in paleontology or geology, and/or a publication record in peer reviewed journals; and demonstrated competence in field techniques, preparation, identification, curation, and reporting in the state or geologic province in which the project occurs. An advanced degree is less important than demonstrated competence and regional experience; (2) at least two full years professional experience as assistant to a Project Paleontologist with administration and project management experience; supported by a list of projects and referral contacts;(3) proficiency in recognizing fossils in the field and determining their significance; (4) expertise in local geology, stratigraphy, and biostratigraphy; and (5) experience collecting vertebrate fossils in the field.

and those invertebrate, plant, or trace fossils are present in a given rock, then there are potentially more of the significant fossil found in those rocks.

Of the various ways that nonrenewable paleontologic resources could be harmed, which includes excavation using heavy equipment, the fossil bearing geologic units in the Area of Analysis are exposed in regions that have exposure to river flows and could be harmed by erosion and undercutting. It is possible that river flows would be sufficiently large to erode the fossil bearing bedrock, undercutting this bedrock, leading to slope failure. If this were to happen, nonrenewable paleontologic resources could be harmed by the destruction of these outcrops through erosion and slope failure (landslides). Because the Hornbrook Formation is classified with a Low Paleontologic Potential, it was not evaluate further.

Table 3.13-2. Paleontologic Potential (SVP 2010).

Paleontologic Potential	Definition
High	Rock units from which vertebrate or significant invertebrate, plant, or trace fossils have been recovered are considered to have a high potential for containing additional significant paleontologic resources. Rocks units classified as having high potential for producing paleontologic resources include, but are not limited to, sedimentary formations and some volcaniclastic formations (e.g., ashes or tephras), and some low-grade metamorphic rocks which contain significant paleontologic resources anywhere within their geographical extent, and sedimentary rock units temporally or lithologically suitable for the preservation of fossils (e.g., middle Holocene and older, fine-grained fluvial sandstones, argillaceous and carbonate-rich paleosols, cross-bedded point bar sandstones, fine-grained marine sandstones, etc.). Paleontologic potential consists of both (a) the potential for yielding abundant or significant vertebrate fossils or for yielding a few significant fossils, large or small, vertebrate, invertebrate, plant, or trace fossils and (b) the importance of recovered evidence for new and significant taxonomic, phylogenetic, paleoecologic, taphonomic, biochronologic, or stratigraphic data. Rock units which contain potentially datable organic remains older than late Holocene, including deposits associated with animal nests or middens, and rock units which may contain new vertebrate deposits, traces, or trackways are also classified as having high potential.
Undetermined	Rock units for which little information is available concerning their paleontologic content, geologic age, and depositional environment are considered to have undetermined potential. Further study is necessary to determine if these rock units have high or low potential to contain significant paleontologic resources. A field survey by a qualified professional paleontologist (see “definitions” section in this document) to specifically determine the paleontologic resource potential of these rock units is required before a paleontologic resource impact mitigation program can be developed. In cases where no subsurface data are available, paleontologic potential can sometimes be determined by strategically located excavations into subsurface stratigraphy.
Low	Reports in the paleontologic literature or field surveys by a qualified professional paleontologist may allow determination that some rock units have low potential for yielding significant fossils. Such rock units will be poorly represented by fossil specimens in institutional collections, or based on general scientific consensus only preserve fossils in rare circumstances and the presence of fossils is the exception not the rule, e.g., basalt flows or recent colluvium. Rock units with low potential typically will not require impact mitigation measures to protect fossils.
No	Some rock units have no potential to contain significant paleontologic resources, for instance high-grade metamorphic rocks (such as gneisses and schists) and plutonic igneous rocks (such as granites and diorites). Rock units with no potential require no protection nor impact mitigation measures relative to paleontologic resources.

The Paleontologic Potential was determined for each geologic unit within the paleontologic resources Area of Analysis using existing geologic and paleontologic peer review literature and data from the USGS, University of California Museum of Paleontology database (UCMP 2017), and geologic and paleontologic professional societies. Relevant geologic maps (Nilsen et al. 1983, Wagner and Saucedo 1987) were georeferenced and digitized, and a reconnaissance field survey was conducted on August 22, 2017 to evaluate the likelihood that mapped geologic units are exposed or otherwise could be impacted by the Proposed Project.

The following sources were assessed to determine the scope of existing local policies relevant to the Proposed Project:

- Siskiyou County General Plan (Siskiyou County 1980):
  - Land Use Policy 41.12 (Siskiyou County 1997)
  - The Conservation Element (Siskiyou County 1973), Archaeology, Objective F

The aforementioned policy (and objective) are stated in generalized terms, consistent with their overall intent to protect paleontologic resources. By focusing on the potential for impacts to paleontologic resources within the paleontologic resources Area of Analysis, consideration of the more general local policy listed above is inherently addressed by the specific, individual analyses presented in Section 3.13.5 *[Paleontologic Resources] Potential Impacts and Mitigation*.

3.13.5 Potential Impacts and Mitigation

Potential Impact 3.13-1 The Proposed Project could result in substantial adverse effects on, or destruction of, High Potential Paleontologic Resources through exposure or slope failure.

An on-site evaluation was conducted August 22, 2017, to evaluate the potential for exposure of paleontologic resources in the Area of Analysis. In the region of Hornbrook, CA, the Hornbrook Formation is exposed in road cuts along Klamathon Road and the Old Hornbrook Highway, in the form of partially lithified and fully lithified rock[163]. Based on observations of the Klamath River cutbank from the Old Hornbrook Highway and along Klamathon Road, the Hornbrook Formation bedrock is not presently exposed along the north bank of the Klamath River in this region. The banks of the river in this area are well vegetated and, downstream of the end of the Old Hornbrook Highway, they are armored by materials that form the road base for U.S. Interstate 5.

Under the Proposed Project, there are two scenarios that could result in erosion of the Hornbrook Formation along the Klamath River, which could impact paleontologic resources contained within the river banks. First, if as a result of dam removal, the river were to downcut (incise) upstream of the contact between the Mesozoic to Paleozoic bedrock and the Hornbrook Formation, this could lead to undercutting of the northern bank of the Klamath River and an over-steepened cutbank, possibly leading to erosion and slope failure within the Hornbrook Formation. Second, if as a result of dam removal, the Klamath River were to migrate laterally northwards on the outer bend of the river just south of Hornbrook (the same region discussed in the first scenario), the lateral migration could also possibly result in erosion and slope failure of the Hornbrook

[163] Lithified means the material has transformed from sediment to sedimentary rock.

Formation. However, the base level (e.g., the lowest level to that erosion can happen due to running water) of the river in the region of Hornbrook is controlled downstream by Mesozoic to Paleozoic basement rock and this base level control pre-dated the installation of any dams, including the Lower Klamath Project, on the Klamath River.

The evaluation of river flow rates, and the potential for bank erosion during drawdown downstream of the Lower Klamath Project dams, is documented in the geology (Potential Impact 3.11-6) and flood hydrology sections (Section 3.6.5 *[Flood Hydrology] Potential Impacts and Mitigation*). The KBRA expired on December 31, 2015 due to a lack of Congressional authorization, and the 2016 Amended KHSA, under which dam removal is currently proposed, does not involve a connected action. Consequently, this CEQA analysis considers the potential effects of dam removal using Klamath River flows as defined by the NMFS and USFWS 2013 Joint Biological Opinion (2013 BiOp) (NMFS and USFWS 2013a), which is currently the standard to which the USBR Klamath Irrigation Project operates. The 2013 BiOp operations requirements and court-ordered flushing flows would determine how instream flows through the Lower Klamath Project and releases from Iron Gate Dam are managed (NMFS and USFWS 2013, U.S. District Court 2017c). A summary of the hydrology information used in this EIR is provided in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and potential impacts of reservoir drawdown on flood hydrology is addressed in Section 3.6.5 *[Flood Hydrology] Potential Impacts and Mitigation*. The proposed drawdown rates for each of the four dams are similar in magnitude to historical flow rates and discharge statistics for these reservoirs. Flow rates downstream of the dams are not anticipated to exceed substantially median historical rates. In other words, discharges during drawdown would be similar to, or less than, the seasonal 10-year flood rates of discharge.

Based on the analysis of Potential Impact 3.11-6, there could be bank erosion and slope failures in the lower river, but the magnitude of this bank erosion will not be substantial given that the flow rates will be similar or lower than flow rates during the operation of the Lower Klamath Project dams. Thus, there is a low likelihood that changes to river discharge under the Proposed Project would lead to downcutting or erosion of the Hornbrook Formation to a greater degree than existed prior to the construction of facilities associated with the creation of the Lower Klamath Project.

The different sub-units of the Hornbrook Formation are mapped in continuous to discontinuous regions surrounding and beyond the Area of Analysis for paleontologic resources. The fossils mapped by previous researchers were found in regions within and outside the Area of Analysis (Peck et al. 1956, Nilsen et al. 1983, Sliter et al. 1984), but fossils used at type sections[164] to correlate geologic units in the Hornbrook Formation are mapped outside of the Area of Analysis. The fossils contained within the Hornbrook Formation are not vertebrates nor do they contain significant taxonomic, phylogenetic, paleoecologic, taphonomic, biochronologic, or stratigraphic data. While there have been identified plant fossils in some Hornbrook Formation subunits, they are not considered to be associated stratigraphically within a given vertebrate assemblage. Considering these factors, the Hornbrook Formation is interpreted to be of Low Paleontologic Potential.

[164] Type sections as defined in Section 3.13.2.2 *Paleontologic Resources*

Overall, given that there is a low likelihood that changes to river discharge under the Proposed Project would lead to additional downcutting or erosion of the Hornbrook Formation and the formation's Low Paleontologic Potential, there would be no impact to paleontologic resources due to implementation of the Proposed Project.

Significance

No significant impact

3.14 Land Use and Planning

This section discusses the environmental setting for land use and planning, as well as potential environmental impacts and associated mitigation measures for the Proposed Project. This section does not address the potential effects of removal of the three California Lower Klamath Project dams on property values or changes in property tax revenues. The State Water Board received several comments expressing concerns about economic and property value changes; these issues are further addressed in Section 5.4 *Social and Economic Factors Under CEQA*. CEQA Guidelines Section 15064 (e) states that *"Economic and social changes resulting from a project shall not be treated as significant effects on the environment. Economic or social changes may be used, however, to determine that a physical change shall be regarded as a significant effect on the environment. Where a physical change is caused by economic or social effects of a project, the physical change may be regarded as a significant effect in the same manner as any other physical change resulting from the project"*. Further summary of comments related to land use issues received during the NOP public scoping process, as well as the individual comments themselves, is included in Appendix A.

Section 3.15 *Agriculture and Forestry Resources* focuses on the potential direct changes to agricultural and forestry that would occur as a result of the removal of Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam. Section 3.15 describes Siskiyou County's agricultural and forestry land uses, identifies the acreages of agricultural and forestry land in Siskiyou County, and describes the factors contributing to changes in irrigated agricultural land and to forestry resources in the County. Section 3.21 *Hazards and Hazardous Materials* describes the potential impacts to wildfire suppression associated with removal of the Lower Klamath Project facilities. Forest vegetation communities and the potential effects of the Proposed Project on wildlife associated with these communities are discussed in Section 3.5 *Terrestrial Resources*. Additionally, the removal of the dams may alter the flood regime for a portion of the river downstream from Iron Gate Dam. Potential changes in flood risk under the Proposed Project are described in Section 3.6 *Flood Hydrology*.

3.14.1 Area of Analysis

The Area of Analysis for land use and planning includes California lands within the Project Boundary (Figure 3.14-1). This area includes Parcel B lands within California, as well as California lands that are within the proposed Limits of Work but not within Parcel B lands (i.e., Fall Creek Hatchery area, small portions of the Iron Gate Reservoir footprint, Jenny Creek Bridge).

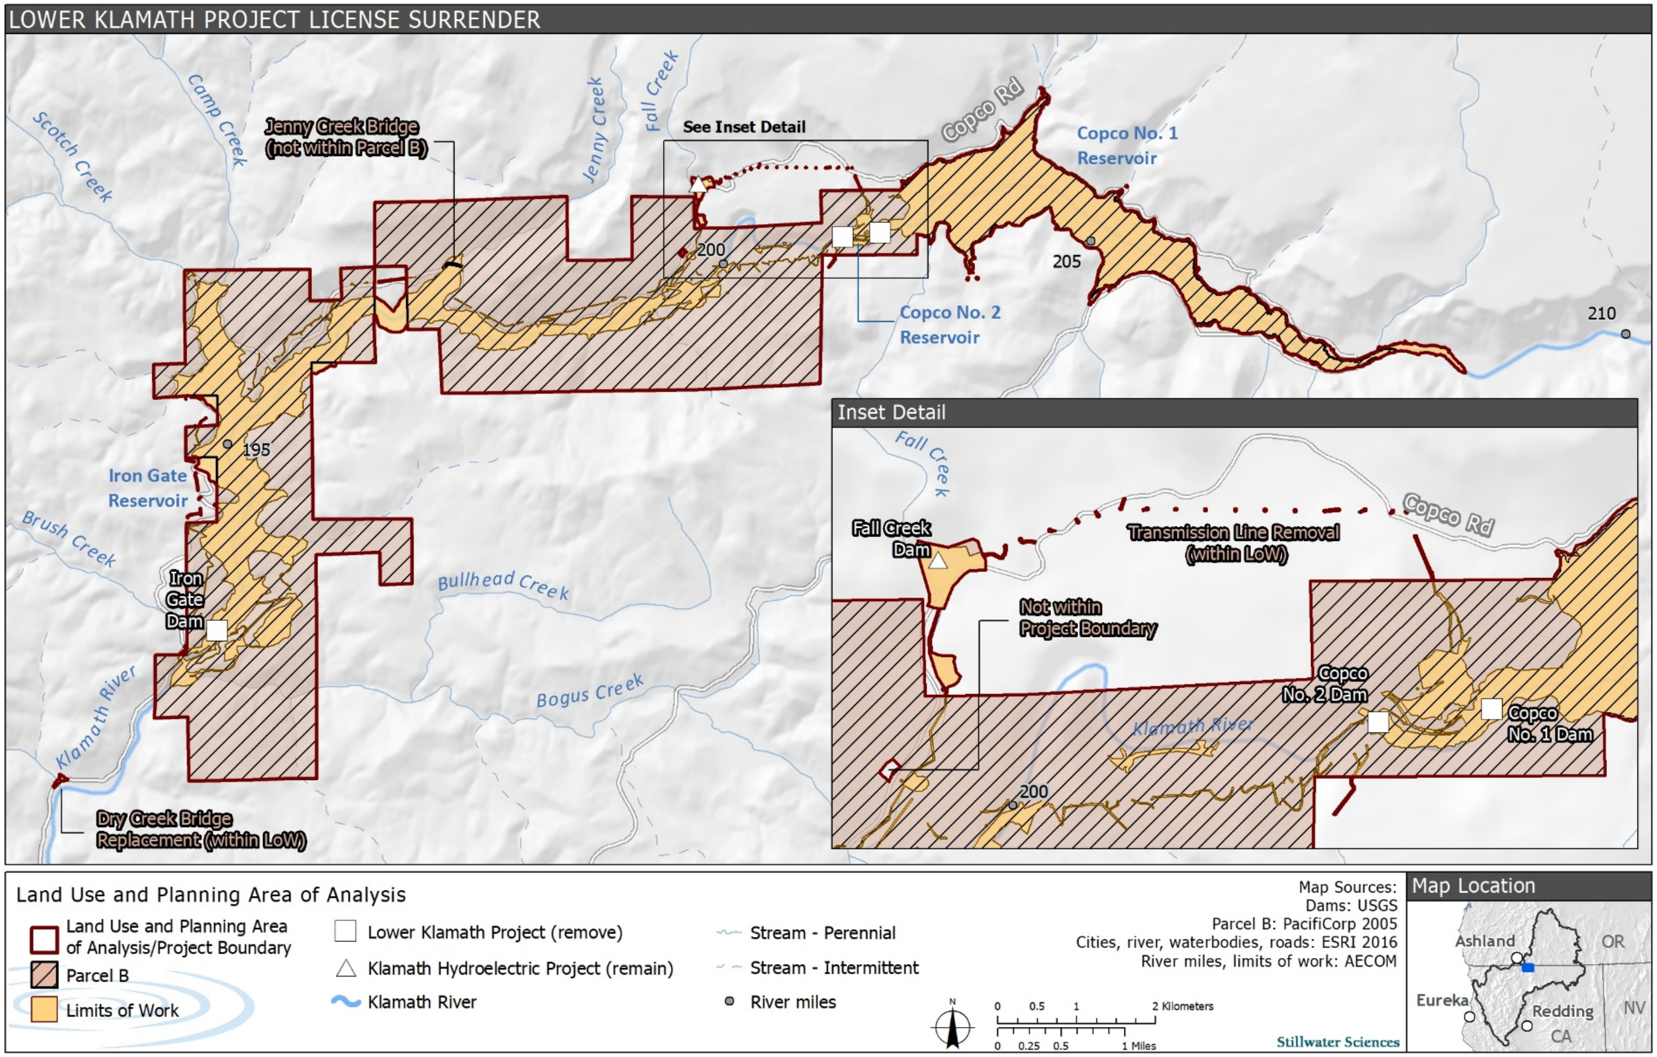

Figure 3.14-1. Land Use and Planning Area of Analysis.

3.14.2 Environmental Setting

3.14.2.1 Land Ownership

The Area of Analysis for land use and planning contains approximately 7,176.5 acres of submerged and non-submerged lands, which includes Parcel B lands owned by PacifiCorp that encompass most of the Copco No. 1, Copco No. 2, and Iron Gate reservoir footprints and adjacent areas of the dams, powerhouses, ancillary facilities, fish hatcheries, recreation areas, and certain transmission lines and access roads. Approximately 2,299 acres of the Area of Analysis (also the Project Boundary) are within the proposed Limits of Work (Figure 3.14-2), which include the areas identified as construction/demolition and staging areas in the immediate vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams and reservoirs, and as well as other identified construction areas for the Iron Gate and Fall Creek hatchery modifications (see also Section 2.7.6 *Hatchery Operations*) and the City of Yreka water supply pipeline (see also Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*).

Table 3.14-1. Land Ownership in Acres within the Area of Analysis for Land Use and Planning.

Project Feature	BLM[1]	PacifiCorp Parcel A[1]	PacifiCorp Parcel B[1]	Other Private	Total (ac)
California portion of the Project Boundary (equivalent to the Area of Analysis)	59.3	21.8	7,013.1	82.3	7,176.5
California portion of the proposed Limits of Work	59.3	21.8	2,135.6	82.3	2,299.0

[1] Small adjustments were made to the boundaries of the BLM dataset to alleviate overlap with the PacifiCorp Parcel B dataset.

PacifiCorp Lands

PacifiCorp owns the majority of the land (7,034.9 acres) within the Area of Analysis for land use and planning (Table 3.14-1). Of this total, 2,157.4 acres are within the California portion of the proposed Limits of Work. Upon transfer of FERC License No. 14803 from PacifiCorp to the KRRC, the KRRC would take ownership of Parcel B lands. Per the KHSA Section 7.6.4, the KRRC will transfer ownership of Parcel B lands to the respective States or to a designated third-party entity following completion of the Proposed Project (Section 2.7.10 *Land Disposition and Transfer*).

U.S. Bureau of Land Management

The U.S. Bureau of Land Management (BLM) manages Mallard Cove Recreation Area at Copco No. 1 Reservoir, and several BLM parcels are crossed by transmission lines and Copco Road at Iron Gate Reservoir. In total, BLM manages 59.3 acres within the Area of Analysis for land use and planning.

Private Lands

Most of the land surrounding Copco No. 1 Reservoir is privately owned. Other smaller areas of privately-owned land are located adjacent to Iron Gate Dam and Fall Creek Dam. In total 82.3 acres of private lands are located within the Area of Analysis for land use and planning.

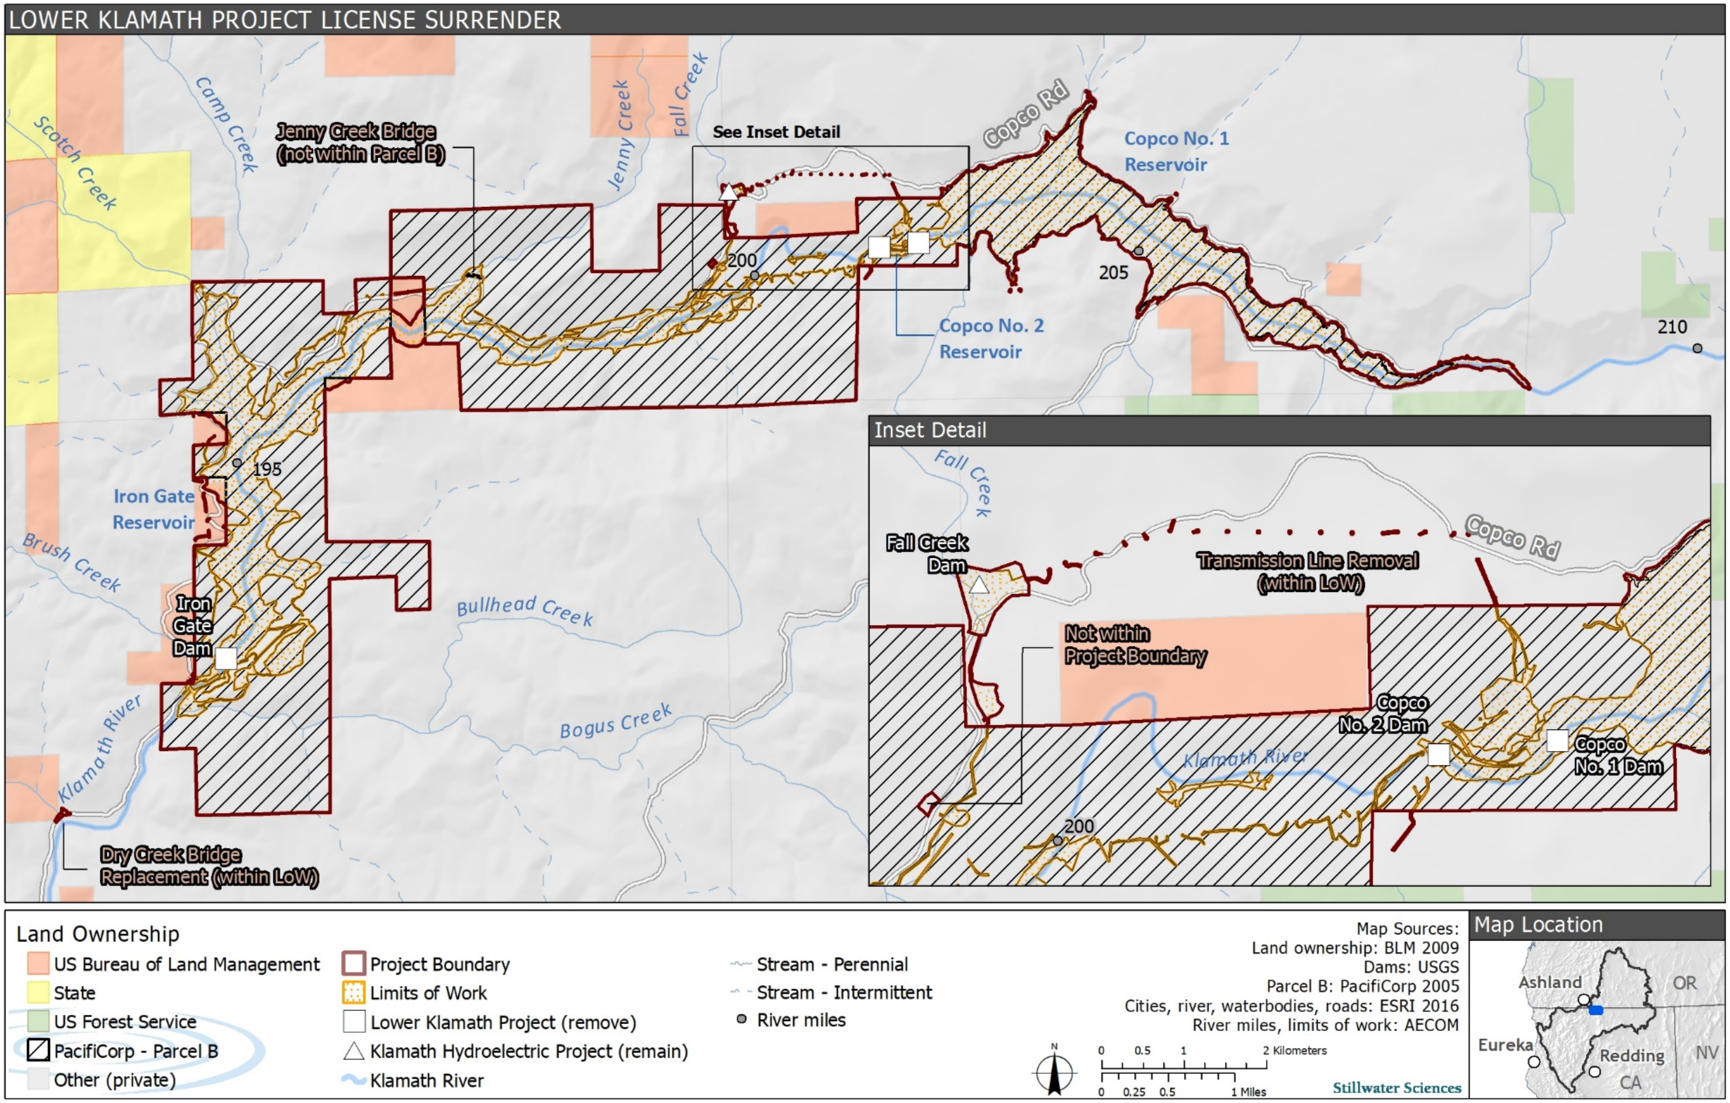

Figure 3.14-2. Surrounding Land Ownership.

3.14.2.2 Land Uses

The Area of Analysis for land use and planning is located within Siskiyou County. Figure 3.14-3 portrays the existing land uses by zoning classification within the Area of Analysis for land use and planning. Land uses within the Area of Analysis are designated by the county using the following generalized categories: Agriculture – Grazing, Forestry Resources, Open Space – Natural Resources, Rural Residential, and Commercial – Services, with many parcels currently vacant. The closest urban area is the City of Yreka, 20 miles to the southwest. Most of the land in the Area of Analysis is devoted either to agriculture/grazing or to open space and conservation of natural resources. A small portion is devoted to hydroelectric operations and recreation sites. There are residential developments on private parcels adjacent to Copco No. 1 Reservoir and the Klamath River throughout the Area of Analysis for land use and planning.

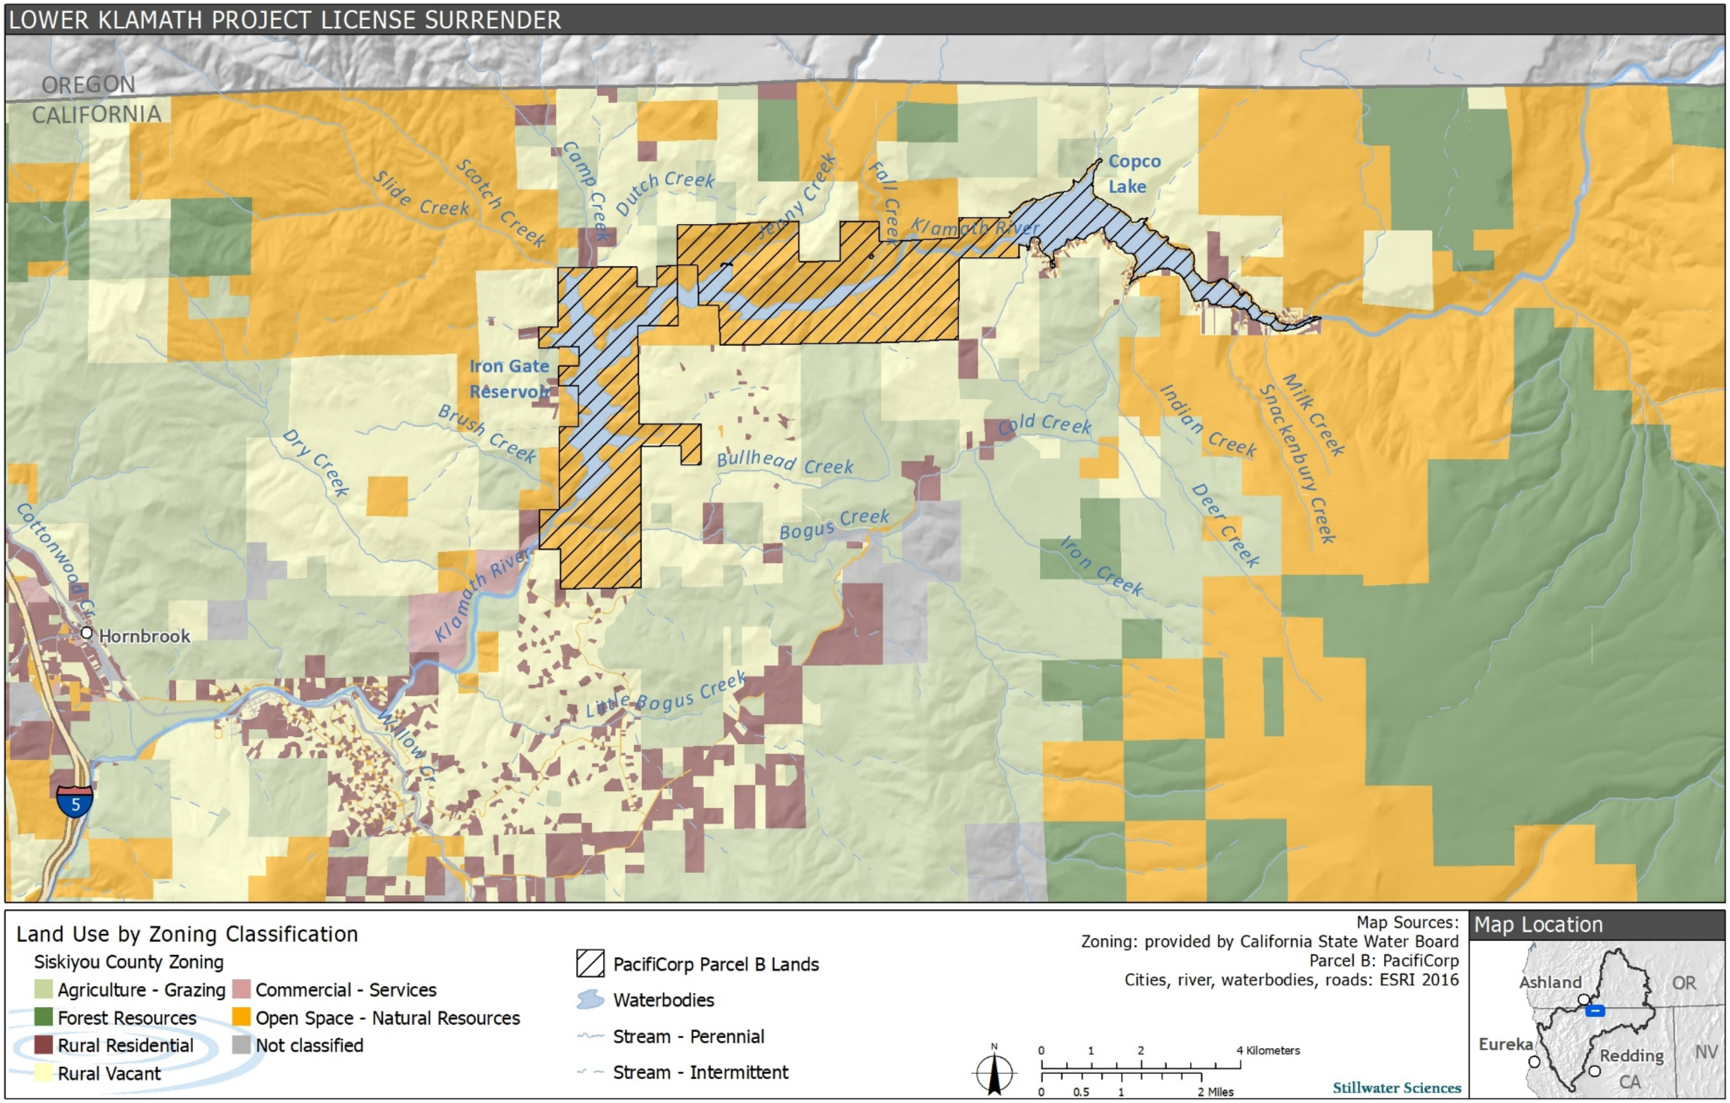

Figure 3.14-3. Siskiyou County Land Use by Zoning Classification.

Open Space/Recreation/Public Lands

Federal and state agencies own and/or manage public lands in the Area of Analysis for land use and planning. These include public lands primarily managed by BLM and USDA Forest Service. These areas are used for public recreation and open space, as well as forest and mineral resources. Other privately-owned recreation facilities (e.g., recreational vehicle parks) operate along the Klamath River downstream from Iron Gate Dam (see also Section 3.20 *Recreation*).

The majority of the Area of Analysis for land use and planning is categorized as Open Space – Natural Resources under the Siskiyou County Zoning Ordinance, which includes recreation and public lands. In general, these are undeveloped lands not in active use and include timber production, grazing land, and developed and dispersed recreational uses (see also Section 3.15 *Agriculture and Forestry Resources* and Section 3.20 *Recreation*).

Residential/Developed

In the Area of Analysis for land use and planning, there are residential developments along portions of the Copco No. 1 Reservoir. These developments are mostly low-density rural residential (R-R). Zoning is one unit per acre per County Zoning Ordinance Table 10-6.5501. The residential properties within the Area of Analysis are located primarily along the southern and northeastern Klamath River shorelines, along Ager-Beswick Road and Copco Road, respectively. Many parcels are vacant and undeveloped. There are residential subdivided areas (mostly vacant) south and east of Iron Gate Dam and additional residential lands along the Klamath River downstream of Iron Gate Dam. Residents typically have the ability to access the Lower Klamath Project reservoirs for boat travel and recreational uses.

Inundated Lands

Lands currently inundated by the reservoirs in Siskiyou County have land use designations and zoning that correspond with the adjacent lands (generally Open Space – Natural Resources, Agriculture-Grazing, and Rural Vacant). The reservoirs are utilized for open space/recreational uses.

Commercial/Industrial

The three California Lower Klamath Project dam facilities, which are considered commercial-industrial from a land-use perspective, are summarized in Section 2.3.2 *Copco No. 1 Dam and Associated Facilities,* Section 2.3.3 *Copco No. 2 Dam and Associated Facilities*, and Section 2.3.4 *Iron Gate and Associated Facilities*. Additional details are included in Appendix B: *Definite Plan*.

Existing Infrastructure

Existing infrastructure potentially affected by the Proposed Project within the Area of Analysis includes the City of Yreka water supply pipeline, existing domestic wells, recreation sites and facilities, and roads. Details regarding the City of Yreka water supply are presented in Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation* and Section 3.8 *Water Supply/Water Rights*. Additional information on private wells can be found in Section 3.7 *Groundwater*. Utilities are described in both Section 3.17 *Public Services* and Section 3.18 *Utilities and Service Systems*. Recreation facilities are described in Section 3.20 *Recreation*. The existing roads in the land use and planning Area of Analysis are owned by PacifiCorp, the Federal Government, Siskiyou County or private entities, details of which can be found in Section 3.22 *Traffic and Transportation*.

PacifiCorp is responsible for maintaining approximately 14.5 miles of roads within the Area of Analysis.

3.14.3 Significance Criteria

Criteria for determining significance on land use and planning are based on Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgment. Effects on land use and planning are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

- Physically divide an established community.
- Conflict with any land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect in a manner that would prevent the avoidance or mitigation result sought to be achieved by the plan, policy, or regulation.

3.14.4 Impact Analysis Approach

The approach to the impact analysis for land use considers the baseline of existing uses of land and evaluates both the short-term Proposed Project construction-related activities as well as the potential long-term land-use conditions after the Proposed Project is completed. The analysis considers whether Proposed Project actions would create physical barriers that substantially change the connectivity between areas of a community or cause a significant environmental impact due to a conflict with a land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect. In addition to the analysis provided in Potential Impact 3.14-2, each resource topic analyzes applicable land use plans, policies or regulations that pertain to that topic. Consideration of habitat conservation plans and natural community conservation plans, which typically falls under the "Land Use and Planning" section of Appendix G of the CEQA Guidelines, is discussed in Section 3.5.4 *Impact Analysis Approach* of this EIR.

3.14.5 Potential Impacts and Mitigation

Potential Impact 3.14-1 Removal of the reservoirs, construction-related traffic, and/or land transfer would not change connectivity between areas of a community.
The Proposed Project includes the removal of the Lower Klamath Project reservoirs as well as restoration of the reservoir areas (Section 2 *Proposed Project*). The Proposed Project also includes the transfer of PacifiCorp lands immediately surrounding the Lower Klamath Project (i.e., Parcel B lands, see Figure 3.14-1) from PacifiCorp to the KRRC prior to dam removal, and then to California and Oregon, as applicable, or to a designated third-party transferee, following dam removal. The lands would thereafter be managed for public interest purposes (Section 2.7.10 *Land Disposition and Transfer*).

KRRC proposes to fence certain areas within the Area of Analysis for land use and planning. The Proposed Project would install cattle exclusion fencing around the reservoir restoration areas where they abut grazing land and where the existing topography does not already provide a barrier to cattle access (e.g., steep rocky terrain, residential areas, managed forests). The cattle exclusion fencing would be installed to protect revegetation efforts and to replace the function of the reservoirs as natural barriers to cattle movement*.* The exclusion fencing would be placed in accordance with applicable Federal, State, and county regulations and guidance *(*Appendix B: *Definite Plan – Section 6.1.1*). The proposed fencing would not physically divide an existing ranching community since it would be placed in locations where the reservoirs currently serve as a physical barrier to keep livestock on their designated lands and thus there would be no impact on connectivity relative to existing conditions.

PacifiCorp currently owns most of the land inundated by the reservoirs (Figure 3.14-2). Removing the reservoirs would remove lake water access for those in the community who use boats to travel between one reservoir recreational area to another (recreational impacts are discussed in Section 3.20 *Recreation*), or between residences. However, no roadways are proposed to be removed as part of the Proposed Project and although boating transport between reservoir shorelines would no longer be possible once the reservoirs are removed, there would be no change to road access as a result of reservoir removal. Since boating between reservoir shorelines as a means of travel is not the only available option for the community, reservoir removal would not create a physical barrier to travel for the community and there would not be a significant impact to connectivity due to the Proposed Project.

During construction activities, short-term, construction-related traffic could result in physical barriers to residents and local ranchers if road access were to be discontinued or substantially interrupted within the Area of Analysis. This would be a significant impact. Section 3.22 *Transportation and Traffic* analyzes the proposed Traffic Management Plan (Traffic Management Plan) included in Appendix B: *Definite Plan – Appendix O2*. Implementation of the proposed Traffic Management Plan would avoid the creation of a physical barrier to the community through construction strategies, such as scheduling, detour plans, signage and traffic control such that the potential impact would be less than significant.

The roads within the Area of Analysis, if not owned by Siskiyou County, are generally owned or managed by PacifiCorp (Figure 3.14-4). In the short term, between the time of license transfer and decommissioning of the dams, PacifiCorp would continue to maintain these roads (approximately 14.5 miles) as part of normal Lower Klamath Project operations and maintenance (KRRC and PacifiCorp 2017). After completion of the Proposed Project, these roads, which are primarily located on the south side of the California Lower Klamath Project reservoirs and were constructed for dam facility maintenance, may no longer be needed. While portions of these roads may currently be utilized by local residents, there are alternative access routes that connect to county roads, and so even if these roads are not maintained in the future, there would be no long-term physical barrier to road access under the Proposed Project and the impact would not be significant.

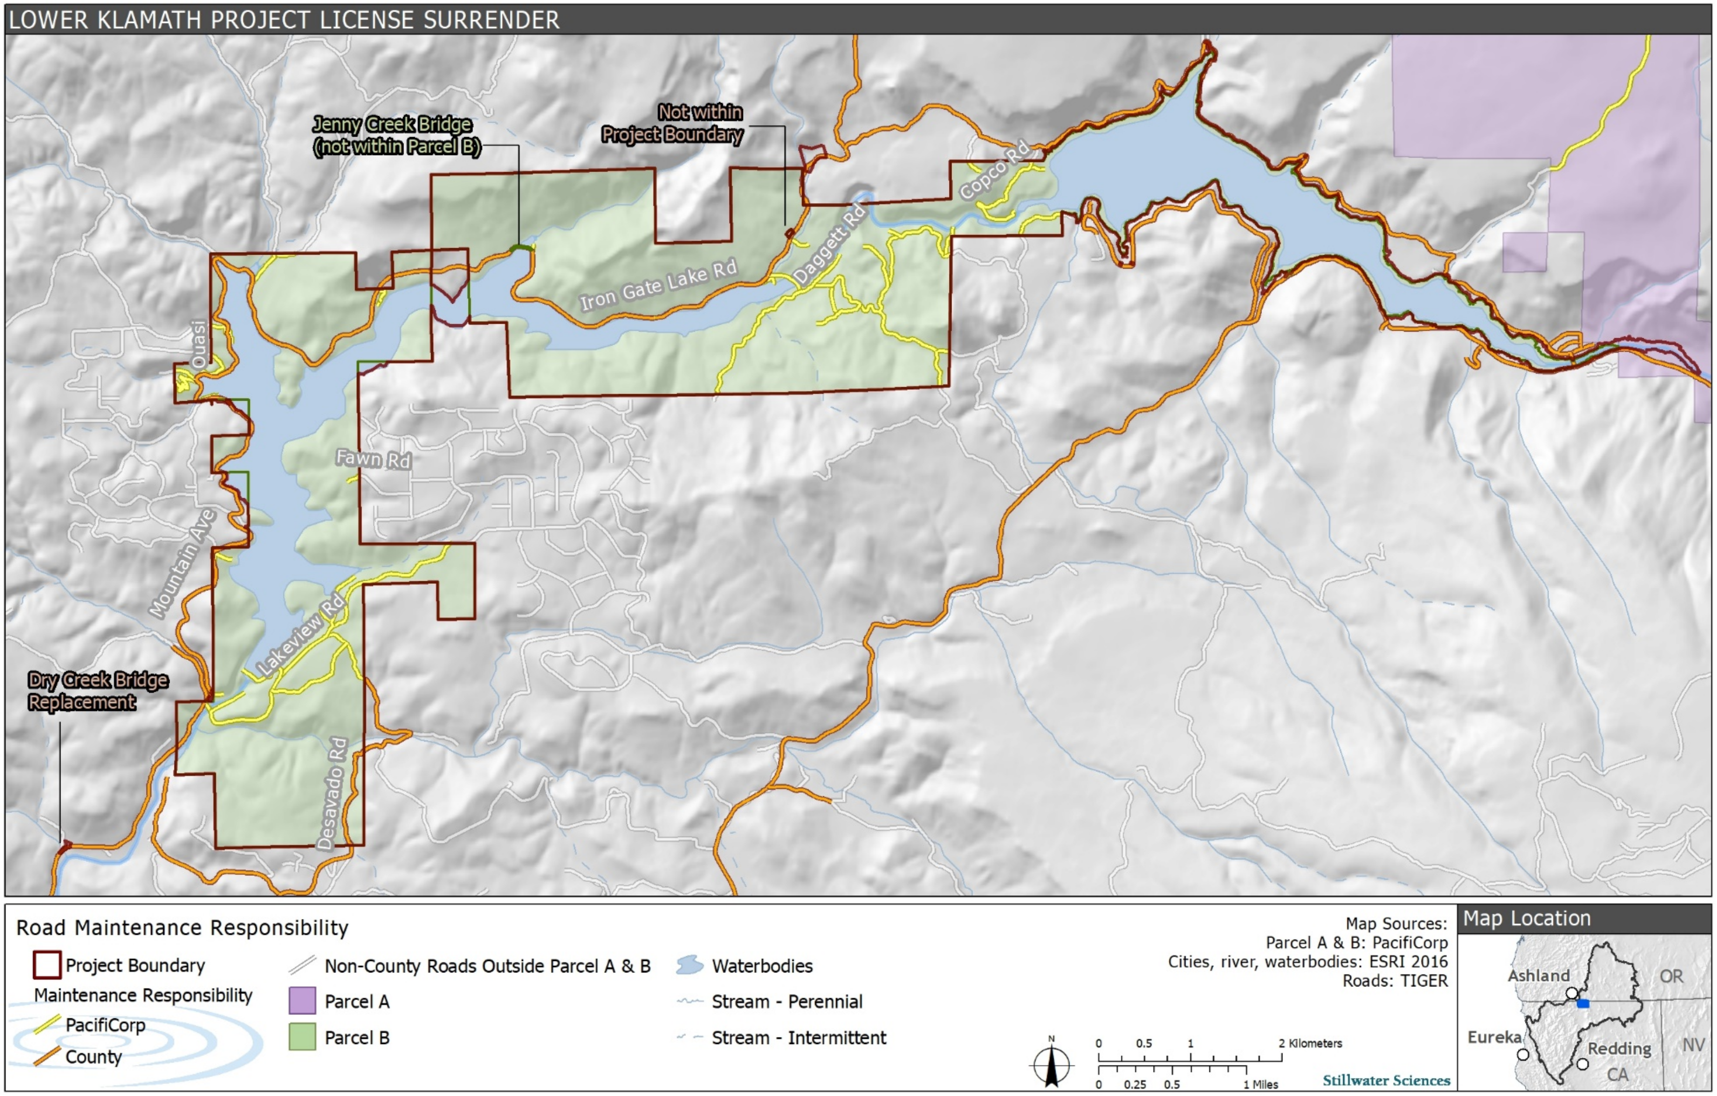

Figure 3.14-4. Road Maintenance Responsibility within the Land Use and Planning Area of Analysis.

Significance
No significant impact in the short term or long term

Potential Impact 3.14-2 The Proposed Project would not conflict with an applicable land use plan, policy, or regulation adopted for the purpose of avoiding or mitigating an environmental effect in a manner that would prevent the avoidance or mitigation result sought to be achieved by the plan, policy, or regulation.
The Proposed Project includes the removal of the Lower Klamath Project dams and reservoirs and includes other items such as restoration of the reservoir footprints (see also Section 2.7.4 *Restoration Within the Reservoir Footprint*). Given the number of public agencies owning or regulating land use within the Area of Analysis for land use and planning, there are several relevant land use or land management plans to consider in association with the Proposed Project.

Siskiyou County
For the most part, the Area of Analysis is classified as Open Space – Natural Resources. All areas within the Area of Analysis for land use and planning are currently designated and zoned by the county's General Plan and Zoning maps (see Figure 3.14-3) and would continue to be classified as such after the Proposed Project is completed, resulting in no change from existing conditions. In addition, implementation of the Proposed Project itself would not change the county's General Plan designations or Zoning map.

General Plan of Siskiyou County
Non-federal lands within the land use and planning Area of Analysis are under the jurisdiction of the Siskiyou County General Plan (General Plan) (Siskiyou County 2017a). The General Plan applies to the unincorporated area of Siskiyou County, California, and includes separate elements that were adopted over the course of several years, primarily in the 1970–80s. Elements of the General Plan include land use, noise, conservation, energy, seismic safety, geothermal energy, and housing. The General Plan guides land use policy within the Area of Analysis, including Copco No. 1, Copco No. 2, and Iron Gate reservoirs and the surrounding recreational lands (FERC 2007).

Land use within the Area of Analysis would remain consistent with the Siskiyou County General Plan elements. For instance, removal of Lower Klamath Project facilities would be aligned with the objectives of the existing Siskiyou County Open Space element (which is to preserve 15 percent of the gross land area of a proposed development as open space, under either private or public ownership) and the Conservation element (which is to "conserve and protect the land resources" of the county, to "protect and conserve the lakes, streams and reservoirs of the county….for recreation areas but more important as wildlife habitat," and to "conserve and maintain habitat for wildlife species [including fish] and plant life."). The Proposed Project would replace certain lakes in Siskiyou County (i.e., the reservoirs) with a more natural river system (potentially including developed river recreational use areas) and habitat restoration, and other lakes in Siskiyou County would be preserved. Because the overall effect of the Proposed Project will be to preserve the water resources of Siskiyou County, the Proposed Project will not prevent the results that the Open Space and Conservation elements of the County's general plan are intended to achieve. Additionally, non-federal lands previously inundated by the Lower Klamath Project reservoirs, and surrounding Parcel B lands would be managed in the public interest and consistent with the Siskiyou County General Plan. Accordingly, the Proposed Project would be consistent, and not conflict, with county land use plans in a manner that would prevent the results sought to be achieved by those plans.

Siskiyou County Zoning Ordinance

Non-federal lands within the land use and planning Area of Analysis are under the jurisdiction of the Siskiyou County Zoning Ordinance (Siskiyou County 2017b). The Siskiyou County Zoning Ordinance guides land development in unincorporated portions of Siskiyou County by regulating allowable uses and structures in various zones. Uses within the Area of Analysis are generally residential, commercial, industrial, agricultural, timberland, and open space. Hydroelectric facilities, including changes to them, are subject to local review in part through the zoning code. The Area of Analysis for land use and planning is located on land zoned Open Space surrounded by: AG-1, prime agricultural; AG-2, non-prime agricultural; and R-R, rural residential agriculture. Most rural residential agriculture lands remain vacant. Since the uses on these lands would not change (i.e., agricultural lands would remain as agricultural, rural residential lands would remain as rural residential, and open space would remain as open space), the Proposed Project would not result in a conflict with the County's Zoning Ordinance that would prevent achievement of the objectives of the Zoning Ordinance.

The Wild and Scenic Rivers Act

The Wild and Scenic Rivers Act (P.L. 90-542) is discussed and analyzed in detail in Section 3.20 *Recreation*. Two portions of the Klamath River are currently designated under the Wild and Scenic Rivers Act. The first one is the 11-mile "scenic" segment from the California/Oregon state line to the J.C. Boyle powerhouse. The second "recreational" section for the Middle and Lower Klamath River begins 3,600 feet downstream of Iron Gate Dam and extends to the Pacific Ocean. Both of these segments are located outside of the Land Use Area of Analysis and, as described in Potential Impact 3.20-7, the Proposed Project would be beneficial to the long-term scenic quality, recreational quality, fisheries, and wildlife of the California Klamath River wild and scenic river segment, and it would be beneficial to the long-term resource values of the eligible and suitable wild and scenic river segment. Thus, the Proposed Project would not result in a conflict with the Wild and Scenic Rivers Act.

BLM Redding Resource Management Plan (RMP) (BLM 1993)

The Redding RMP is a 15-year strategy addressing where and how the BLM will administer public lands under its jurisdiction within the Redding Resource Area, which includes Butte and Tehama counties and the majority of Shasta, Siskiyou, and Trinity counties. As such, it governs management of BLM's Mallard Cove Recreation Area at Copco No. 1 Reservoir and several BLM parcels are crossed by transmission lines and Copco Road at Iron Gate Reservoir (FERC 2007). Recreational sites managed by BLM are discussed in Section 3.20 *Recreation*. The RMP objectives for the Klamath River include: maintaining water-oriented recreation opportunities along the river, improving the condition of the riparian zone to Class II on anadromous fish streams, and maintaining the scenic quality in the river condition upstream of Copco No. 1 Reservoir. Although the Proposed Project would result in the loss of one of BLM's reservoir accesses (i.e., the Mallard Cove Recreation Area), the Proposed Project would nevertheless be consistent with the objectives of the Redding RMP and would not prevent the result the RMP seeks to achieve. As discussed in more detail in Potential Impact 3.20-2, removal of this site would not result in a significant adverse impact on reservoir-based recreation because there are a number of similar opportunities in the vicinity of the Lower Klamath Project and, as described in Section 3.20 *Recreation*, the

Proposed Project will include a Recreation Plan which is expected to be finalized in June 2019. The Draft Recreation Plan includes potential recreation opportunities identified in the Detailed Plan (USBR 2012) as well as those identified through recent stakeholder outreach efforts. Thus, removal of the Mallard Cove Recreation site would not result in a substantial adverse land use impact.

USDA Forest Service Klamath National Forest Land and Resource Management Plan (USDA 2010)

The purpose of this plan is to coordinate and disclose programmatic management direction for the Klamath National Forest. The plan establishes the management direction and associated long-range goals and objectives for the forest; specifies the standards, timing, and vicinity of the practices necessary to achieve that direction; and establishes the monitoring and evaluation requirements needed to ensure that the direction is carried out. There are no lands of the Klamath National Forest within the Project Boundary, although there are some parcels near the east end of Copco No. 1 Reservoir. The plan designates those lands as late-successional reserve, and are managed to enhance habitat for late-successional and old growth-related species (FERC 2007). Additional analysis of Forest Lands is found in Section 3.15 *Agriculture and Forestry Resources*. That analysis concludes that the Proposed Project will not result in a conflict with the Klamath National Forest Land and Resource Management Plan in a manner that will cause a substantial adverse impact to the physical environment. See Section 3.15 *Agriculture and Forestry Resources* for more information on forest resources.

Significance

No significant impact

3.15 Agriculture and Forestry Resources

This section discusses potential impacts on agricultural and forestry resources under the Proposed Project. This section describes existing agricultural land uses in Siskiyou County, in which the Proposed Project is located, identifies the acreage of agricultural lands in the county, including Important Farmland and Grazing Land, and describes the factors contributing to potential changes in irrigated agricultural land as a result of the Proposed Project. The forestry resources analysis focuses on the direct changes that would occur as a result of dam removal under the Proposed Project. In support of the forestry impact analysis, this section describes existing tree species, forested acreages, riparian vegetation, and large woody debris in the Area of Analysis (see below).

Relatively few comments were received during the NOP public scoping process relating to agriculture. Some of the comment topics are not analyzed in the Lower Klamath Project EIR because they are do not concern environmental impacts of the Proposed Project. One comment expressed concern that landowners in the Scott and Shasta valleys will be required to stop farming in light of water supply impacts from the Proposed Project; while this comment was not accompanied by supporting evidence, this section does address the concern in light of the public's interest. Potential impacts of the Proposed Project on water supply, which by definition includes water supply for agriculture, are discussed in detail Section 3.8 *Water Supply/Water Rights*). Potential impacts related to flood control are discussed in Section 3.6 *Flood Hydrology*.

No public comments were received during the NOP public scoping process regarding forestry resources. See Appendix A for additional information regarding scoping comments.

3.15.1 Area of Analysis

For agricultural and forestry resources the Area of Analysis includes all lands within the Project Boundary plus a half-mile buffer around Copco No. 1 (Figure 3.15-1). This analysis area was chosen to correspond with the area where changes in hydrology and water supply are anticipated due to the Proposed Project and could indirectly affect irrigated agriculture. Additional information pertaining to the potential hydrologic and water supply impacts of the Proposed Project are presented in Sections 3.6 *Water Supply/Water Rights* and 3.8 *Flood Hydrology*.

3.15.2 Environmental Setting

3.15.2.1 Important Farmland

The California Department of Conservation (DOC) developed land use classifications for farmland in Siskiyou County. These classifications are based on the land's suitability for agricultural production by considering physical and chemical characteristics of the soil (soil temperature range, depth of the groundwater table, flooding potential, rock fragment content, and rooting depth), location, growing season, and moisture available to sustain high-yield crops. Analyses of these characteristics were used to develop "Important Farmland" classifications that include Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance. Along with Grazing Land, these Important Farmland classifications were collectively defined by the DOC as "Agricultural Land."

DOC (2016a) estimated that Siskiyou County had 1,146,245 acres of agricultural land in 2012, of which 756,486 acres were identified as Important Farmland and 389,759 acres as Grazing Land (DOC 2016a). In 2014, Siskiyou County had 1,146,010 acres of agricultural land. Of this total, 754,297 acres were identified as Important Farmland and 391,713 acres were identified as Grazing Land (DOC 2016a). Table 3.15-1 summarizes the most recent DOC farmland conversion data, identifies the 2012 and 2014 acreages of agricultural land in Siskiyou County, and shows the net change in acreage over the two-year period.

Table 3.15-1. Summary of Agricultural Land Conversion in Siskiyou County, 2012–2014.

Important Farmland Category	Acres		Net Change (2012–2014)	
	2012	2014	Acres	Percent
Prime Farmland	74,973	70,724	-4,069	-5.6
Farmland of Statewide Importance	27,305	25,963	-1,342	-4.9
Unique Farmland	34,838	35,365	527	1.5
Farmland of Local Importance	619,550	622,245	2,695	0.4
Important Farmland Subtotal	**756,486**	**754,297**	**-2,189**	**-0.3**
Grazing Land	389,759	391,713	1,954	0.5
Agricultural Land Total	**1,146,245**	**1,146,010**	**-235**	**-0.02**

Source: DOC 2016a

DOC's 2014 Field Report for Siskiyou County identifies the factors contributing to changes in agricultural land uses from 2012–2014. According to the 2014 Field Report, some Important Farmland (i.e., Prime Farmland, Farmland of Statewide Importance, or Unique Farmland) was converted to Farmland of Local Importance and Grazing Land by leaving formerly irrigated land idle for three or more reporting update cycles, going out of production, or conversion of irrigated uses to cultivation of non-irrigated grain crops (DOC 2016b). A total of 24 acres were converted from farmland to urban and built-up land between 2012 and 2014 (DOC 2016a).Conversely, irrigated cropland was added near the town of Dorris. Additions of new cropland were primarily alfalfa or other irrigated hay crops, often in the form of center-pivot fields (DOC 2016b).

Most of the land in the Area of Analysis is classified by the DOC as Grazing Land, with a small area of Unique Farmland located approximately two miles south of Copco No. 1 Reservoir (Figure 3.15-1).

Parcels zoned by Siskiyou County for Agriculture-Grazing are located within the Area of Analysis to the north and south of Copco No. 1 Reservoir (Figure 3.14-1). There are a number of parcels located immediately upstream of Copco No. 1 Reservoir that are used primarily for grazing and hay production. The DOC (2016c) identified these lands as Prime Farmland or Farmland of Statewide Importance (Figure 3.15-1). The pastures/fields on these properties are flood-irrigated via direct diversions from the free-flowing Klamath River upstream of Copco No. 1 Reservoir. There are a few agriculture parcels with grazing land located between 1.2 and 3 miles north of Copco No. 1 Reservoir (Figure 3.15-1). Another agricultural operation is located on land designated as Farmland of Local Importance and is approximately 0.5-miles southwest of Keaton Cove along the Ager-Beswick Road in the Deer Creek drainage. The pastures on all these properties are flood-irrigated from direct diversions on tributary streams that flow into the reservoir. None of the properties mentioned above rely on Copco No. 1 Reservoir for irrigation water.

The land surrounding Iron Gate Reservoir is entirely BLM or Parcel B property and does not contain any parcels zoned for agriculture under the Siskiyou County General Plan (Figure 3.14-1). DOC (2016) describes most of the terrain around Iron Gate Reservoir as grazing lands. However, there is some open, relatively flat land south of the reservoir in the Long Gulch watershed that is broken into individual parcels that seem based on a review of Google Earth (2016a) aerial imagery, to be used primarily for what appears to be cannabis production. The DOC (2016c) identified these Long Gulch lands as Farmland of Local Importance or suitable for grazing (Figure 3.15-2). Based on a review of Google Earth (2013 and 2016a) aerial photographs, the water source for these parcels appear to be wells. The elevation of these parcels ranges from 110 to 140 feet above the reservoir water surface elevation with the closest parcel being 0.34 miles south of Iron Gate Reservoir.

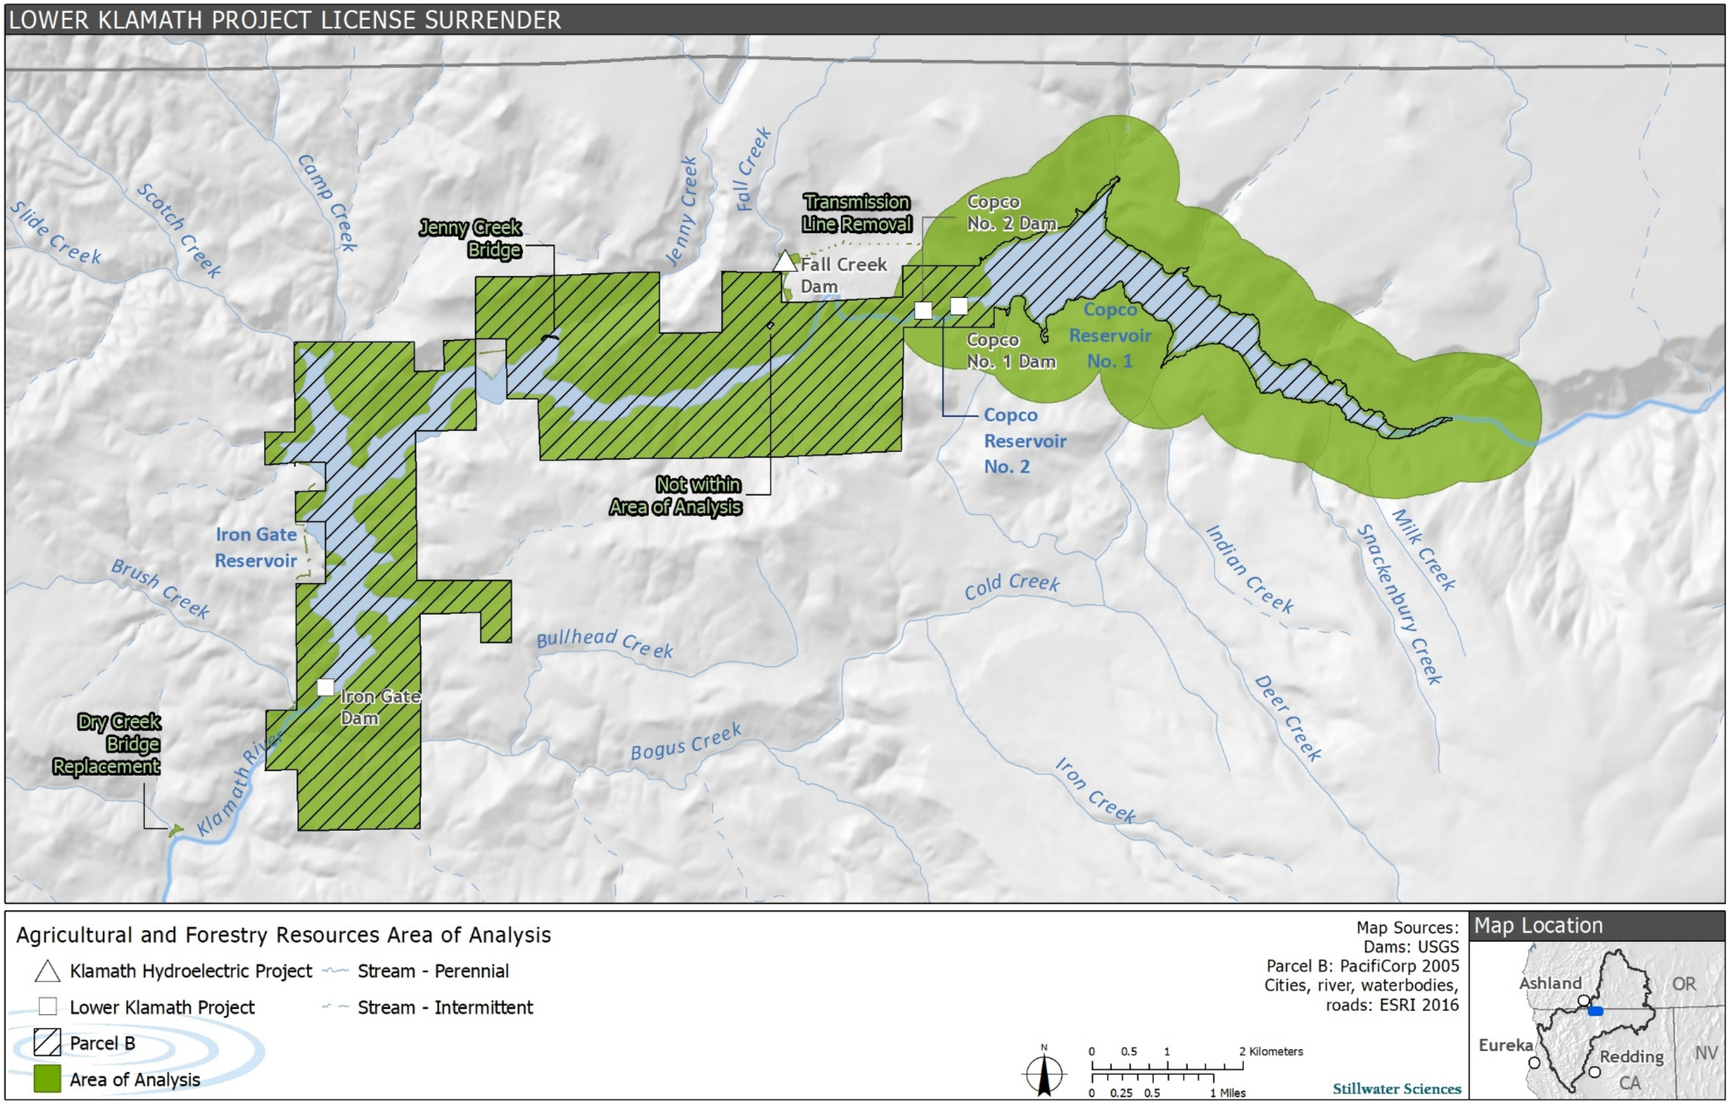

Figure 3.15-1. Agricultural and Forestry Resources Area of Analysis.

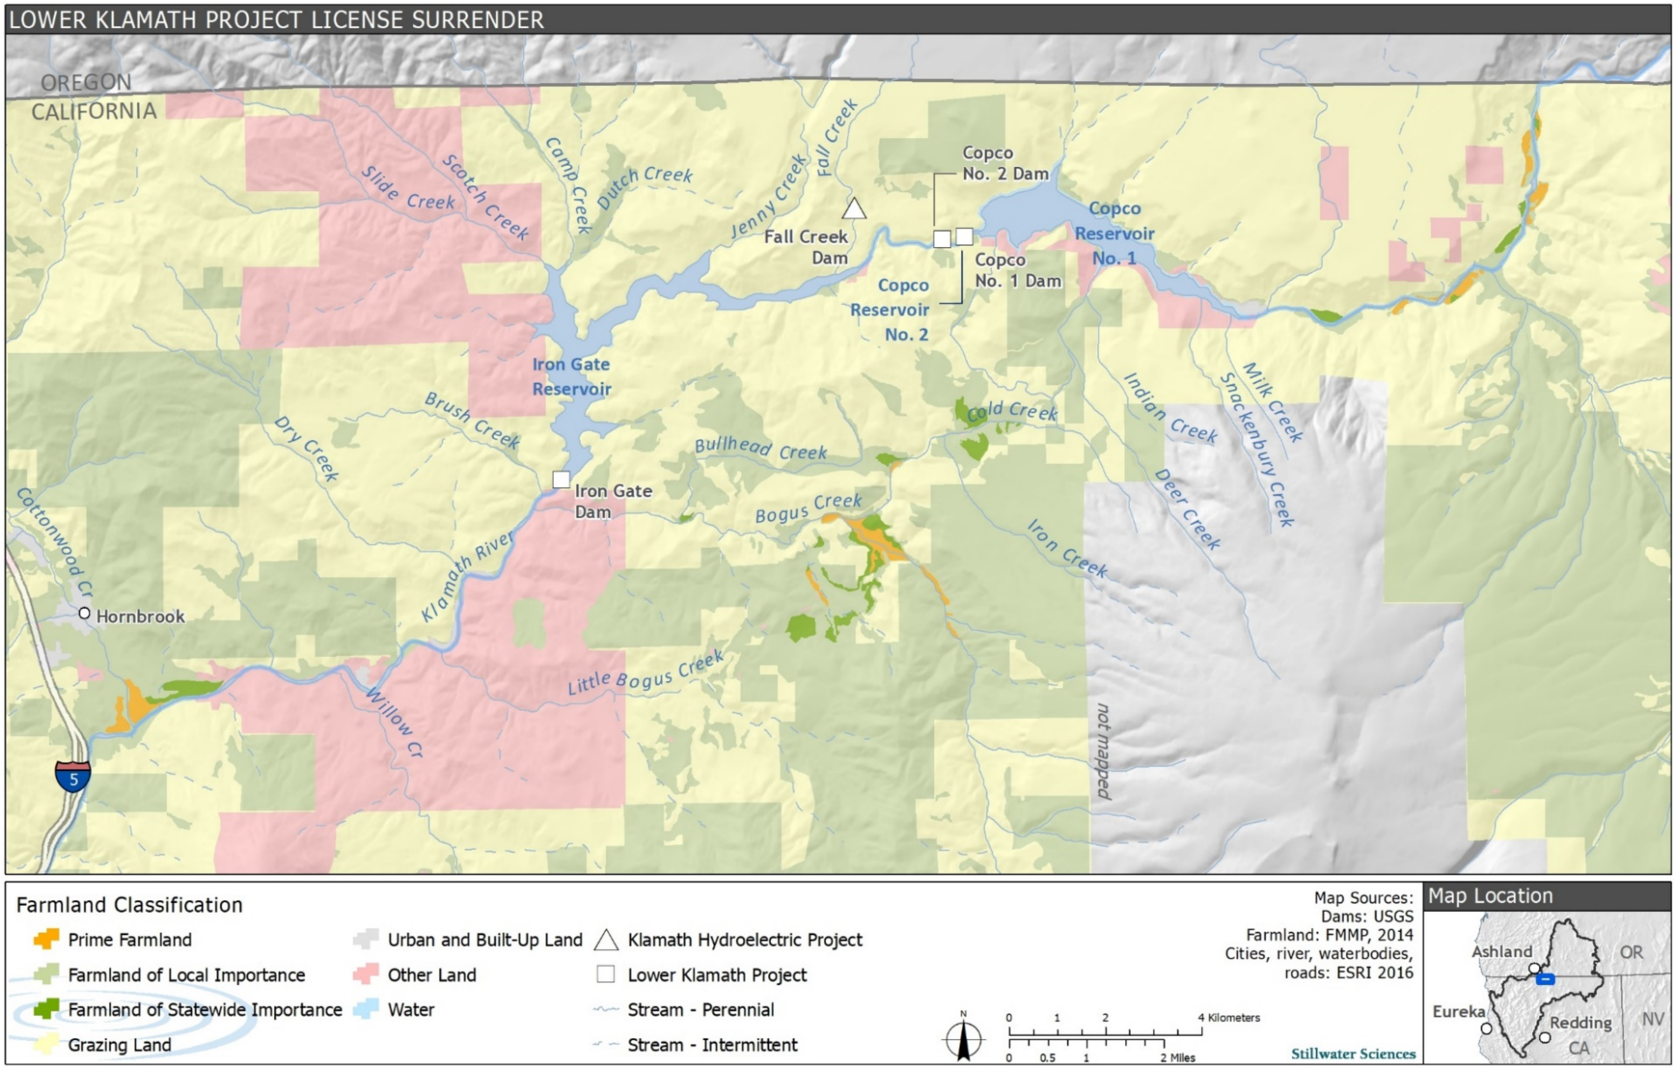

Figure 3.15-2. Farmland classification along the Klamath River from Interstate 5 to the Oregon-California state line (Adapted from DOC 2016c).

3.15.2.2 Existing County Zoning

Lands currently inundated by the reservoirs in Siskiyou County have land use zoning classifications that correspond with the adjacent lands (generally Rural Vacant, Agriculture-Grazing, or Open Space-Natural Resources). There are no lands zoned for forestry resources within the Area of Analysis from the eastern end of Copco No. 1 Reservoir downstream to Iron Gate Dam (Figure 3.14-1). If dam removal occurs, the submerged lands would not require new land use designations or zoning because they do not change with an ownership transition until there is some action that triggers rezoning and a land use amendment (Plucker 2011).

3.15.2.3 Williamson Act

Under the California Land Conservation Act of 1965, also known as the Williamson Act, local governments can enter into contracts with private property owners to protect land (within agricultural preserves) for agricultural and open space purposes. Siskiyou County had 421,125 acres under Williamson Act contracts in 2013, the most recent year for which data are available (DOC 2015). The nonrenewal of a contract is the most common mechanism for termination of Williamson Act contract lands. In Siskiyou County in 2013, approximately 2,428 acres were in some stage of the nonrenewal process, approximately seven acres of contract land terminated through nonrenewal expirations, and no property owners initiated new nonrenewal processes (DOC 2015).

No Williamson Act parcels are within the agriculture and forestry Area of Analysis. Twelve parcels located within five miles of project facilities are under Williamson Act contracts and the nearest of which are located approximately two miles south of Copco No. 1 Reservoir.

3.15.2.4 Forestry Resources

The Lower Klamath Project is located in a transition zone between the Great Basin and California Floristic provinces. In Oregon, the Lower Klamath Project (i.e., J.C. Boyle facilities) generally is located within the interior valley, ponderosa pine, and mixed conifer vegetation zones. In California, similar upland tree habitats are present, but the representation of ponderosa pine, mixed conifer, and lodgepole pine is lacking or much reduced. Further, there are no lands that are zoned Forest Resources under the Siskiyou County General Plan within the agriculture and forestry Area of Analysis (Figure 3.14-1). However, some of the lands (primarily near the upstream end of Copco No. 1 Reservoir) in the Lower Klamath Project may be managed for forest resources as a compatible use with existing Open Space zoning.

PacifiCorp (2004) identified and mapped a variety of land cover types from the Link River Dam to the Shasta River. In addition, vegetation datasets are available through CALVEG (Classification and Assessment with Landsat of Visible Ecological Groupings) datasets available through the California Land Cover Mapping & Monitoring Program (USDA Forest Service 2017a) and data from USFWS (2017). These datasets were utilized to create the vegetation maps presented in Appendix G: *Vegetation Communities and Habitat Types* and provide summary acreages described in Table 3.5-1. The upland tree acreage between the Oregon-California state line and Iron Gate Dam and extending 0.25 miles on either side of the Klamath River is presented below in Table 3.15-2. See Section 3.5.2.1 *Vegetation Communities* for a description of the vegetation types within 0.25 miles of the Klamath River between the Oregon-California state line and the Klamath River Estuary.

Table 3.15-2. Upland tree habitats and mapped between the Oregon-California state line and Iron Gate Dam.

Upland Tree Habitats	Acres	Description, Dominant Species, and Location
Montane hardwood oak	1,813	Moderately open tree canopy, moderately dense shrub layer, moderately dense herbaceous layer. Yellow starthistle and medusahead occur in about 25 percent of stands in the project vicinity. Most abundant around Copco No. 1 Reservoir.
Montane hardwood oak-conifer	2,656	Dense tree cover, sparse shrub layer, moderately open herbaceous layer. Most abundant along the J.C. Boyle Peaking and Bypass reaches, at Copco No. 1 Reservoir, at Fall Creek, and along the Copco No. 2 bypassed reach.
Ponderosa pine	68	Moderate canopy cover, relatively sparse shrub cover, moderately open herbaceous layer.
Juniper	457	Open canopy, shrub layer varies from sparse to dense, herbaceous layer ranges from sparse to dense.
Mixed conifer	9	Dense tree cover often is two-layered, open shrub layer, moderately sparse herbaceous layer.
Total of all upland tree habitats	5,003	

Late-successional Conifer Forest

According to the Northwest Forest Plan (USDA Forest Service and BLM 1994), late-successional forests are those in which the biggest, oldest, and most dominant trees create a mature canopy, with shade-tolerant trees occupying and flourishing on the forest floor. Typically, late-successional forests include trees at least 80 years old. Late-successional forests provide important habitat for a large number of wildlife species.

PacifiCorp (2004) determined that only 13 acres of forest near the J.C. Boyle peaking reach include late-successional conifer forest with large-diameter trees[165]. However, 8,435 acres of younger forests, having trees with small to moderately large diameters (11 to 24 inches) also occur (PacifiCorp 2004 as referenced in FERC 2007) between J.C. Boyle and Shasta River. No late-successional conifer forest exists within the Lower Klamath Project.

3.15.3 Significance Criteria

For the purposes of this EIR, impacts on Agriculture and Forestry Resources would be significant if they resulted in the following:

- Substantial conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the

[165] Large-diameter trees are greater than 24 inches in diameter, as measured 4.5 feet above the forest floor.

Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use.

- Conflict with existing zoning for agricultural use or a Williamson Act contract where the conflict would result in a substantial adverse environmental impact.
- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Public Resources Code Section 12220(g)), timberland (as defined by Public Resources Code Section 4526), or timberland zoned Timberland Production (as defined by Government Code Section 51104(g)).
- Substantial loss of forest land or conversion of forest land acreage to non-forest use.
- Other changes in the existing environment that could result in significant conversion of Farmland acreage to non-agricultural use, or significant conversion of forest land acreage to non-forest use.

3.15.4 Impact Analysis Approach

Existing land uses were identified from a variety of sources including Federal and State agencies and the respective counties. The effects analysis identifies direct and indirect effects on agricultural and forest resources under the No Project Alternative, the Proposed Project, and the other alternatives. The types of potential effects that were analyzed included temporary effects associated with dam removal, demolition, and staging and permanent effects such as changes in land use and required changes to local land use plans and zoning ordinances. The State Water Board also considered possible conflicts or inconsistencies between the proposed alternatives and Federal, State, regional, local, or tribal land use plans, policies, or controls relevant in the area of analysis. Temporary and permanent direct and indirect conversions of agricultural and forest lands were also analyzed.

This section includes an evaluation of potential conflicts between the existing and proposed agriculture and forestry land uses associated with the Proposed Project. Physical changes resulting from the Proposed Project and the various alternatives (Section 4 *Alternatives*) are addressed throughout this EIR. Where significant adverse environmental impacts would occur, this EIR offers mitigation measures for reducing the physical impacts on the environment that would be caused by the Proposed Project.

3.15.5 Potential Impacts and Mitigation

Agriculture and forest use resources within the area of analysis are regulated by several Federal, State, and local plans, laws, and policies, which are listed below and considered in this assessment.

- Farmland Protection Policy Act of 1981
- USDA Forest Service Klamath National Forest Land and Resource Management Plan
- California Land Conservation Act of 1965 (Williamson Act)
- California Forest Practice Rules
- Siskiyou County Zoning Ordinance

The Farmland Protection Policy Act (FPPA) of 1981 is intended to minimize the impact Federal programs have on the unnecessary and irreversible conversion of farmland to nonagricultural uses. It assures that to the extent possible federal programs are administered to be compatible with state, local units of government, and private programs and policies to protect farmland. Federal agencies are required to develop and review their policies and procedures to implement the FPPA every two years. The FPPA does not authorize the Federal Government to regulate the use of private or nonfederal land or, in any way, affect the property rights of owners. For the purpose of FPPA, farmland includes prime farmland, unique farmland, and land of statewide or local importance. Farmland subject to FPPA requirements does not have to be currently used for cropland. It can be forest land, pastureland, cropland, or other land, but not water or urban built-up land. Projects are subject to FPPA requirements if they may irreversibly convert farmland (directly or indirectly) to nonagricultural use and are completed by a Federal agency or with assistance from a Federal agency.

The Klamath National Forest Land and Resource Management Plan is used to coordinate and disclose programmatic management direction for the Klamath National Forest. The plan establishes the management direction and associated long-range goals and objectives for the forest; specifies the standards, timing, and vicinity of the practices necessary to achieve that direction; and establishes the monitoring and evaluation requirements needed to ensure that the direction is carried out. There are no lands of the Klamath National Forest within the Project Boundary, although there are some parcels near the east end of Copco No. 1 Reservoir. The plan designates those lands as late-successional reserve, and are managed to enhance habitat for late-successional and old growth-related species (FERC 2007).

The Williamson Act enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open space use. In return, landowners receive property tax assessments which are much lower than normal because they are based upon farming and open space uses as opposed to full market value.

The California Forest Practice Rules were developed to implement the provisions of the Z'berg-Nejedly Forest Practice Act of 1973 in a manner consistent with other laws, including but not limited to, CEQA. The intent of the rules is that no timber harvesting plan shall be approved which fails to adopt feasible mitigation measures or alternatives from the range of measures set out or provided for in these rules, which would substantially lessen or avoid significant adverse impacts which the activity may have on the environment. The Lower Klamath Project does not propose to harvest timber as part of the Proposed Project.

The Siskiyou County zoning ordinance guides land development in unincorporated portions of Siskiyou County by regulating allowable uses in various zones. Non-federal lands within the land use and planning Area of Analysis are under the jurisdiction of this ordinance. Zones are grouped by six main uses—residential, commercial, industrial, agricultural, timberland, and open space (see Section 3.14 *Land Use and Planning* for more information). Hydroelectric facilities are subject to local review in part through the zoning code. The Area of Analysis for land use and planning is located on land zoned Open Space surrounded by: AG-1, prime agricultural; AG-2, non-prime agricultural; and R-R, rural residential agriculture. Most rural residential agriculture lands remain vacant.

Potential Impact 3.15-1 Conversion of Farmland to non-agricultural use or conflict with Williamson Act land or agricultural zoning.

The Proposed Project would use existing road systems to facilitate dam decommissioning and removal. However, upgrades to existing roads would be necessary to allow for the heavy traffic expected during deconstruction. The disposal site for Iron Gate Dam spoils is located on flat land approximately 3,000 feet northeast of the dam. The permanent disposal site for deconstruction spoils from Copco No. 1 and No. 2 would occur at the current location of the maintenance buildings and residence. Disposal sites at J.C. Boyle Dam will include the original borrow sites, spillway, scour hole below the emergency spillway, and abutment locations. As these roads and disposal sites are existing and/or on lands not designated for agriculture, their use for disposal would not directly convert Farmland to non-agricultural use. The analysis of the capacity and use of existing roads is presented in Section 3.22 *Transportation and Traffic*. The Proposed Project would not result in the conversion of farmland within the Area of Analysis for agriculture and forestry resources to non-agricultural uses, and it would not conflict with existing zoning or Williamson Act contracts. There can be no conflict with Williamson Act land because there are no contract parcels within the agriculture and forestry Area of Analysis. Agricultural zoning would not change since existing classifications would remain the same following drawdown. Reservoir drawdown may increase agricultural opportunities on currently inundated lands; however, due to uncertainties in the ultimate land use of the inundated reservoir lands, this is speculative (see also Section 2.7.11 *Land Disposition and Transfer*). The Parcel B lands could ultimately be managed for wide potential range of public interest uses, including but not limited to open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially other uses.

Significance

No significant impact

Potential Impact 3.15-2 Conversion of forest lands to non-forest use or conflict with forest zoning.

Implementation of the Proposed Project would not affect the forest lands or forest uses surrounding Copco No. 1, Copco No. 2, or Iron Gate reservoirs or in the larger agriculture and forestry Area of Analysis. There are no lands zoned for forest resources within the Area of Analysis, from the eastern end of Copco No. 1 Reservoir downstream to Iron Gate Dam (Figure 3.14-1). The Proposed Project would use existing road systems to facilitate dam decommissioning and removal. However, upgrades to existing roads would be necessary to allow for the heavy traffic expected during deconstruction. The disposal site for Iron Gate Dam spoils is located on flat land approximately 3,000 feet northeast of the dam. The permanent disposal site for deconstruction spoils from Copco No. 1 and No. 2 would occur at the current location of the maintenance buildings and residence. Disposal sites at J.C. Boyle Dam will include the original borrow sites, spillway, scour hole below the emergency spillway, and abutment locations. The vegetation would be removed in preparation for debris disposal. Topsoil would be used to cap the site and be seeded once disposal is completed. Trees would be planted on the finished disposal sites. As these roads and disposal sites are existing and/or on lands not designated for forestry, their use for disposal would not directly convert forest lands to non-forest use. Thus, there would be no changes in land use under the Proposed Project that would conflict with current forest use or zoning. There is the potential for an increase in forest land due to revegetation of previously inundated lands with woody species, however the full extent to which lands would reseed with forest species is unknown.

Significance

No significant impact

Potential Impact 3.15-3 Indirect conversion of Farmland to non-agricultural use or forest land to non-forest use.

The Proposed Project would use existing road systems to facilitate dam decommissioning and removal. However, upgrades to existing roads would be necessary to allow for the heavy traffic expected during deconstruction. Disposal sites are located as described above. The use of these roads or disposal areas would not indirectly convert farmland to non-agricultural use or forest land to non-forest use.

Significance

No significant impact

Potential Impact 3.15-4 Other changes in the existing environment that could result in conversion of Farmland to non-agricultural use or conversion of forest land to non-forest use.

The Proposed Project would not involve other changes in the existing environment that could result in the conversion of Farmland to non-agricultural use or conversion of forest land to non-forest use. For example, the irrigated farmlands classified as Prime or of Statewide Importance are located primarily at the farthest eastern extent of Copco No. 1 Reservoir and farther upstream along the Klamath River (Figure 3.15-2). These farmlands are flood-irrigated from direct diversions that are either located on the free-flowing reach of the Klamath River upstream of the Project or along tributaries. The headworks of these diversions would still be operational following the removal of the dams since they are situated on the natural channels of the river and tributaries and do not divert from the Lower Klamath Project reservoirs. Impacts on agricultural crops (primarily hay production) are not expected since the irrigation season occurs after the scheduled drawdown period (November to March; see also Table 2.7-1) and these fields are not reliant on the reservoirs for their water supply. There is a possibility that agricultural diversion headworks downstream of each dam would experience siltation or otherwise be affected during reservoir drawdown. However, the Proposed Project includes measures to address these temporary supply issues (see Potential Impact 3.8-3).

Farmlands of Local Importance are located primarily in the Deer Creek drainage that flows into Copco No. 1 Reservoir along the south shoreline and in the Camp and Dutch creek watersheds on the north side of Iron Gate Reservoir (Figure 3.15-1). Based upon analysis of Google Earth (2013 and 2016b) aerial imagery and well data in Section 3.7 *Groundwater*, these lands are irrigated by diversions from their respective tributaries or use wells for stock watering and do not rely on water within the reservoirs for irrigation. See Section 3.7 *Groundwater* for an analysis of groundwater issues.

In the Lower Klamath Basin, some agricultural diversion of water occurs for farming and ranching from tributaries such as the Shasta, Scott, Salmon, and Trinity rivers. However, the Lower Klamath Project is located on the mainstem Klamath River. Therefore, these diversions of water from tributaries would not be affected by removal of the Lower Klamath Project dams. In addition, removal of the Lower Klamath Project dams would not place flow obligations on small agricultural diverters in tributaries to the Klamath River or the mainstem itself. (see Potential Impact 3.8-1 for more information.) Ongoing efforts to establish minimum flow requirements in the Mid and Lower Klamath basins and prior flow standards recommended by the North Coast Regional Water Quality Control Board focus only on the flow needs of Klamath River tributaries and do not consider any flow contributions to the mainstem river.

Disposal of Iron Gate Dam demolition debris would be placed on a 36-acre plot of Parcel B land approximately one mile south of the dam. This area is currently zoned as Open Space – Natural Resources under the Siskiyou County General Plan, but is open, non-irrigated grassland that is used for grazing. The site would be cleared of vegetation and topsoil in preparation for debris disposal, which would temporarily halt any grazing activity. Once disposal is completed, the site would be regraded, capped with topsoil, and seeded. This would restore the area and allow for continued grazing. This temporary disturbance would be a less than significant impact in light of the availability of other lands for grazing and the small area involved.

Areas around the Lower Klamath Project reservoirs currently support open range grazing by cattle, which are able to move freely around the reservoir areas, with the exception of areas that present topographic barriers. To protect revegetation efforts and to replace the function of the reservoirs as natural barriers, the KRRC is proposing to use cattle exclusion fencing around the reservoir areas after drawdown. The proposed fencing would be a wildlife friendly design that excludes open-range cattle while allowing the natural movement of deer, turtles, and other wildlife. The fence may be required to fully isolate the reservoir restoration areas. No grazing land would be lost as a result of the fence installation since the fencing would only surround the currently inundated lands. Therefore, the proposed fencing would result in no significant impact.

Scoping comments expressed the concern that reservoir removal could affect local groundwater wells. However, based on available information, Farmland within the Area of Analysis does not rely upon groundwater wells for cultivated area irrigation, instead using flood irrigation by diverting surface water from tributaries to the Klamath River. Within the Area of Analysis, there are two wells located on Farmland of Local Importance in the Deer Creek subwatershed (tributary to Copco No. 1 Reservoir) and another in the Camp Creek subwatershed (tributary to Iron Gate Reservoir) that may be used for stock watering. The Deer Creek subwatershed wells are located approximately 2,000 ft south of Copco No. 1 Reservoir and adjacent to Deer Creek. As such, they are likely highly influenced and recharged by Deer Creek. The bottom of the Camp Creek well extends below the Iron Gate Reservoir bed elevation. Therefore, the Proposed Project's effect on agriculture-related wells within the Area of Analysis would not be likely to result in the conversion of Farmland to non-agricultural uses and there would be a less than significant impact. In any event, implementation of the Groundwater Well Management Plan (as described in Section 2.6.8.6 *Groundwater Wells Management* and in Appendix B: *Detailed Plan*), including well deepening, would return the production rate of any affected groundwater supply well to conditions experienced prior to dam decommissioning. Therefore, the potential for conversion of Farmland to non-agricultural uses resulting from lowering groundwater levels as a result of the Proposed Project would be less than significant.

The land within the agriculture and forestry Area of Analysis is not zoned forest land, does not contain commercial forest land, and is not used for forestry purposes.

However, the Lower Klamath Project would allow previously inundated lands to revegetate and potentially increase the amount of forest cover within the Area of Analysis, which would be beneficial for forest land. Therefore, the Lower Klamath Project would not result in conversion of forest land to non-forest use in the short term or long term.

Significance

No significant impact for conversion of farmland to non-agriculture uses

No significant impact for conversion of forest land to non-forest use

3.16 Population and Housing

This section discusses existing population and housing data and potential impacts associated with the Proposed Project. The following subsections describe the environmental setting with respect to demographics and housing data in the Area of Analysis defined below. This analysis uses data from the U.S. Census, county and city plans, and other sources for projected housing availability.

The State Water Board did not receive any comments related to population and housing issues during the NOP public scoping process (see Appendix A).

3.16.1 Area of Analysis

The Area of Analysis for population and housing extends beyond the Project Boundary to encompass the following urban and rural communities in California: the community of Hornbrook, the City of Yreka, and the residential rural areas near Copco No.1, Copco No. 2, and Iron Gate reservoirs. The Area of Analysis includes communities with the potential to house workers migrating into the area for Proposed Project construction activities (see also Section 3.16.4 *Significance Criteria*). The Area of Analysis also includes the area where two residences downstream of Iron Gate Dam are noted to be affected by change in flood elevations (FEMA 100-year floodplain) as well as 34 habitable structures that are already affected by these flood elevations. Effects of flood elevations upon these residences are analyzed in more detail in Section 2.7.8.4 *Downstream Flood Control* and in Section 3.6 *Flood Hydrology*, where it was determined that “loss of structures that are not feasible to move or elevate would be a significant impact.”

3.16.2 Environmental Setting

Regulations at the federal, state, and local levels regarding housing are generally concerned with the proper construction, provision of, and the siting of housing for a variety of incomes. Since no new residential structures are proposed as part of the proposed project, this is not analyzed further.

The Proposed Project does not call for the construction of new homes. There are approximately 12 residences proposed for demolition currently owned by PacifiCorp for use by workers maintaining the dams or other PacifiCorp properties. There will be no need to replace these residences.

As noted above, 36 residences downstream of Iron Gate Dam are affected by change in the FEMA 100-year floodplain elevations. The impacts to these residences are analyzed in Section 3.6 *Flood Hydrology*. Since these residences represent only 0.15 percent of the total County housing stock, they are not considered a substantial loss and are not further addressed in the Population and Housing section.

Siskiyou County census data is presented, along with data for Yreka and Hornbrook. Yreka and Hornbrook could both temporarily house workers needed for the Proposed Project. According to the U.S. 2010 Census, Yreka had a population of approximately 7,800 and Hornbrook had a population of approximately 250. However, approximately

82 structures were destroyed in 2018 by the Klamathon Fire[166] in the general Hornbrook area, thereby potentially affecting available housing noted in the 2010 Census.

3.16.2.1 Demographic Data

According to Siskiyou County Housing Element (Siskiyou County 2014), the population in Siskiyou County was expected to grow from a population of 44,893 persons in 2010 to 46,369 persons in 2020, representing a three percent increase in population. U.S. Census Bureau 2017 noted that the population of Siskiyou County has been in slow decline since 2010 with July 1, 2017 population estimate at 43,853.

According to the California Employment Development Department (California Employment Development Department 2018), there were a total of 17,210 workers employed in August 2018, and 1,000 unemployed (5.5 percent unemployment). This is up from the 16,770 jobs in Siskiyou County August 2013, which reflected employment in the midst of an economic downturn, with 11 percent of the county's workforce unemployed. Conversely, there were 18,140 jobs in Siskiyou County as of September 2000, when unemployment was at a 20-year low (5.8 percent unemployment). Construction trades amounted to 7.6 percent of the workforce with 1,282 jobs. (Siskiyou County 2014).

3.16.2.2 Housing Data

Table 3.16-1 shows housing and occupancy estimates for Siskiyou County based on 2010 U.S. Census data. Siskiyou County's overall vacancy rate was 18.4 percent representing 4,405 units. Hornbrook had a high vacancy rate, at 30.8 percent, out of 156 total units in 2010. Yreka and its surrounding area had a lower housing availability vacancy rate of 7.6 percent, which is still more than twice California's 2016 vacancy rate of 3.3 percent). There were 281 vacant units available for rent in the City of Yreka (U.S. Census Bureau 2010b).

[166] More details about the Klamathon Fire can be found online at: http://www.fire.ca.gov/current_incidents/incidentdetails/Index/2108 (Accessed December 19, 2018).

Table 3.16-1. Siskiyou County Housing Units (2010 Census information).

	Hornbrook		City of Yreka		Siskiyou County	
	Number	**Percent**	**Number**	**Percent**	**Number**	**Percent**
Occupied Housing Units	108	69.2	3,394	92.4	19,505	81.6
Owner-Occupied	72	66.7	1,751	51.6	12,629	64.7
Renter-Occupied	36	33.3	1,643	48.4	6,876	35.3
Vacant Housing	48	30.8	281	7.6	4,405	18.4
Total Housing Units	**156**		**3,675**		**23,910**	

Source: U.S. Census Bureau 2010b

Updated information for 2016 (U.S. Census Bureau 2016) indicates that there were 317 vacant units in Yreka and 4,989 vacant units in the County. As noted earlier, the Klamathon Fire destroyed 82 structures in the Hornbrook area and it is unknown how this translates to loss of available rental units.

The Yreka Housing Element reports 2013 rental costs ranging from $475 to $1,100 per month (City of Yreka 2014). According to the 2012-2016 American Community Survey five-year estimate, the median monthly rent in the City of Yreka was $758 and for Siskiyou County $828 (U.S. Census Bureau 2016).

3.16.3 Significance Criteria

Criteria for determining significance on population and housing are based Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.). Effects on population and housing are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

1. Induce substantial unplanned population growth in an area, either directly (e.g., by proposing new homes and businesses) or indirectly (e.g., through extension of roads or other infrastructure).
2. Displace substantial numbers of existing people or housing, necessitating the construction of replacement housing elsewhere.

3.16.4 Impact Analysis Approach

The Proposed Project will not directly cause the elimination of existing housing (except for removing existing PacifiCorp housing, which is no longer needed). The Proposed Project will also not create a long-term increase in housing needs or induce long-term population growth. The analysis of potential effects of the Proposed Project is therefore focused on the temporary worker population required for construction activities and their potential need for housing within the Area of Analysis. The peak need for worker housing would occur over an approximate two-year construction period with lesser need for housing during preparation and follow-up restoration/monitoring activities. Hatchery personnel would remain the same as currently occurring.

The impact analysis is therefore determined by comparing projected housing needs with projected housing availability. Communities were analyzed for their potential to temporarily house workers using California Department of Finance housing and population data, where available, in addition to city level and Census Block Group level 2010 U.S. Census data (U.S. Census Bureau, 2010a–c) and 2012-2016 American

Community Survey data (U.S. Census Bureau 2016), and county and city plans, where available.

3.16.5 Potential Impacts and Mitigation

Potential Impact 3.16-1 Inducing substantial unplanned population growth in an area, either directly or indirectly.
The Proposed Project would not directly induce substantial population growth, as it does not require the construction of new homes or the demolition of existing homes (except for a small number of residences owned by PacifiCorp and used by workers maintaining the dams (see also Potential Impact 3.16-2). The potential effects of the Proposed Project would be limited to the influx of the temporary worker population required for construction activities (see Table 2.7-13). Proposed construction activities would require an average of 105 workers and a peak of 175 workers during the anticipated four-month peak period when work on three dams would occur at the same time. During the majority of the two-year construction activity period there would be fewer workers (35-105) required. Table 3.16-1 indicates that the City of Yreka has 317 vacant units and the County, as a whole, has 4,989 vacant units, some of which may be close enough to the Proposed Project to provide an ample supply for the short-term influx of workers. It is also likely that many from the local construction workforce (7.6 percent of the workforce with 1,282 jobs. (Siskiyou County 2014) will already live in the county and will not need short-term housing. As such, the Proposed Project would not result in a substantial influx of population and there would be a less than significant impact on population growth in the Area of Analysis.

<u>Significance</u>
No significant impact

Potential Impact 3.16-2 Displacement of substantial numbers of existing people or housing, necessitating the construction of replacement housing elsewhere.
The residential communities of Ager and Beswick surround Copco No.1 Reservoir (34 miles from Yreka) and Iron Gate Reservoir (25 miles from Yreka). The Proposed Project does not propose, nor will result in, a displacement of substantial numbers of people or housing. Therefore there is no need to provide replacement housing elsewhere.

Based on the number of available rental housing units in Siskiyou County and the existing conditions vacancy rate (see Table 3.16-1), there are sufficient opportunities to house the projected workforce for the Proposed Project. The Siskiyou County Housing Element (Siskiyou County 2014) noted that almost 1,300 people in the county are currently in the construction trades, suggesting that should a local workforce be needed for Proposed Project implementation, there is an ample number of construction workers that currently reside within the county. As noted in Table 2.7-13, average workforce and peak workforce for the four-month duration of construction activities that would occur simultaneously on all three dams would be 105 and 175 workers, respectively. This represents a short-term, 0.4 percent increase of the County population and would be comparable in size to the reduction of use during construction activities at the recreational facilities surrounding the reservoirs (see comparison in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation*).

Existing housing currently owned and maintained by PacifiCorp would be removed as part of the Proposed Project, but this would no longer be needed to maintain the dam facilities (Appendix B: Definite Plan).

Aside from the PacifiCorp housing associated with the dam facilities, implementation of the Proposed Project would not displace existing housing within the Area of Analysis. The potential effects of the Proposed Project on housing are limited to the need for an additional temporary worker population during construction activities and their potential need for housing. As existing vacancy rates (see Table 3.16-1) are relatively high, and there are an ample number of construction workers that currently reside within the county, there would not be a need to displace existing residents due to construction activities. The loss of the residences PacifiCorp currently owns would not create a need to build replacement housing elsewhere. As a result, there would be no significant impact.

Significance

No significant impact

3.17 Public Services

This section describes the environmental setting for public services as well as potential environmental impacts to public services and associated mitigation measures under the Proposed Project.

For a discussion of other resource topics associated with public services, see Section 3.8 *Water Supply/Water Rights*, Section 3.10 *Greenhouse Gas Emissions*, Section 3.20 *Recreation*, Section 3.21 *Hazards and Hazardous Materials*, and Section 3.22 *Transportation and Traffic*.

The State Water Board received a comment expressing concern about there being a single access route to the Copco Dam area and the potential impacts of construction activities or traffic on the safety of other road users such as school busses, residents, pedestrians, livestock, and dogs. The comment also noted that the road could be damaged during construction activities. The State Water Board also received comments expressing concern related to how fire suppression efforts will be impacted and whether there would be a replacement plan for loss of the reservoirs. The State Water Board did not receive any other comments related to public services during the NOP public scoping process (see Appendix A).

3.17.1 Area of Analysis

The Area of Analysis for public services includes lands within the Project Boundary (Figure 2.2-4). This area includes the area in the immediate vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams and reservoirs, and areas identified as construction/demolition and staging areas. The construction/demolition and staging areas are described in specific detail in this EIR in Section 2 *Proposed Project* and in Sections 5.3, 5.4, and 5.5 of Appendix B: *Definite Plan*. Consideration of public services also includes considering routes that would be used by public service providers, which are analyzed under Section 3.22 *Traffic and Transportation*.

3.17.2 Environmental Setting

The following section describes the environmental setting for public services, including fire protection, police protection, schools, and parks, among others.

3.17.2.1 Fire Protection

The Governor's Office of Emergency Services (CalOES) coordinates preparedness for and response to natural disasters, including fires, by activating the California Standardized Emergency Management System (SEMS) used by all California public safety agencies. Siskiyou County has a cooperative fire protection agreement with the California Department of Forestry and Fire Protection (CALFIRE). The cooperative agreement also includes: 29 Communities, 14 Fire Safe Councils, 30 Local Fire Departments, Siskiyou County Wildfire Protection Panel (including a county natural resources specialist, representatives from CALFIRE, USDA Forest Service, and other public members), Siskiyou County Board of Supervisors, CALFIRES's Siskiyou Unit Fire Prevention Bureau (including a Battalion Chief, two fire captains, and a Fire Prevention Specialist II), Volunteers in Prevention, Siskiyou County Arson Team, The California Conservation Corps, and the College of the Siskiyou Fire Program (CALFIRE 2015).

There are nine incorporated cities in the county that are responsible for fire protection within their respective cities: Yreka, Fort Jones, Etna, Weed, Mt. Shasta, Dorris, Dunsmuir, Montague, and Tulelake. Each fire protection service, mostly staffed by volunteers, is able to respond to a variety of emergency situations, including wildland fires, structure fires, earthquakes, search and rescue, civil disturbance, and hazardous materials incidents (CALFIRE 2015).

A discussion of emergency response to natural and man-made disasters can be found in Section 3.21 Hazards and Hazardous Materials and Section 3.22 Transportation and Traffic. An analysis of the loss of the reservoirs for firefighting purposes is included in Potential Impact 3.17-2 as well as Section 3.21 Hazards and Hazardous Materials. Water supply, in general, is included in Section 3.8 Water Supply/Water Rights.

The CALFIRE Siskiyou Unit serves Siskiyou County and covers more than 6,347 square miles (4,062,080 acres), with primary wildland fire responsibility for 1,269,672 acres. The CALFIRE Siskiyou Unit is comprised of 30 local fire departments and is active in local community outreach programs and public safety messages. The CALFIRE Siskiyou Unit suppression resources, at the peak of firefighting preparedness, included approximately 70 career personnel and 120 seasonal personnel (CALFIRE 2015).

The CALFIRE Siskiyou Unit has an Emergency Command Center known as the Yreka Interagency Command Center. The Yreka Interagency Command Center is located at the CALFIRE Siskiyou Unit Headquarters in Yreka and is a collaboration of CALFIRE and USDA Forest Service staff. The Yreka Interagency Command Center provides dispatching services for CALFIRE, USDA Forest Service, 30 local government departments, and five ambulance companies, most service the greater area of Siskiyou County. The Yreka Interagency Command Center is responsible for emergency call taking, dispatching, and tracking resources (CALFIRE 2015).

The CALFIRE Siskiyou Unit is divided geographically into four fire battalions: Battalion 1 – Scott Valley Battalion; Battalion 2 – Shasta Valley Battalion; Battalion 3 – Butte Valley Battalion; and Battalion 4 – McCloud Battalion. The Area of Analysis is located within the Shasta Valley Battalion region and is approximately 484,018 acres, with 376,598 acres designed as State Responsibility Area and 53,420 acres designated as Local Responsibility Area. The remaining area (54,000 acres) is designated Federal Responsible Area, generally within the Klamath National Forest and BLM lands. The Shasta Valley Battalion partners with 11 agencies, 10 Fire Safe Councils, 12 Siskiyou County Fire Departments within or bordering the Shasta Valley Battalion, and 11 cities and communities to: 1) reduce the total number of fires in the Battalion; 2) reduce the impact of large, damaging fires in the Battalion; and 3) reduce the number of campfire escapes (CALFIRE 2015).

The Shasta Valley Battalion consists of two CALFIRE stations: one in the City of Yreka and one in the community of Hornbrook. Both stations are open year round for fire permit issuance and other public services. The CALFIRE Siskiyou Unit headquarters, located at the Yreka Station, houses two Type III fire engines and one Type II dozer, the Hornbrook Forest Fire Station houses two Type III fire engines. The Hornbrook Station is located along the Interstate 5 near the California and Oregon border in Hornbrook and is committed to year round fire protection due to a contract with Siskiyou County. Paradise Craggy Lookout serves as the fire lookout for the Shasta Valley Battalion and is only staffed with emergency workers during high fire danger days and during and after lightning storms (CALFIRE 2015).

The closest fire department to the public services Area of Analysis is Copco Lake Fire Department, which is located at the easternmost end of Copco Lake. There are 12 volunteer firefighters staffed at the Copco Lake Fire Department (Copco Lake Fire Department 2017).

Fire hazards, including wildfires, are discussed in Section 3.21 Hazards and Hazardous Materials.

3.17.2.2 Police

The Siskiyou County Sheriff's Department provides law enforcement services to the unincorporated portions of Siskiyou County and is headquartered in Yreka, with substations in Dunsmuir, Mount Shasta, Etna, Happy Camp, Dorris, Hornbrook, McCloud, and Montague (Police Department 2017). The Sheriff's Department also contracts with cities, to help with operations (Siskiyou County 2017a).

The Enforcement Division of the Sheriff's Department is the division that contains patrol functions, detective functions, civil functions, search and rescue functions, and administrative functions (Siskiyou County 2017b). The Siskiyou County Sheriff's Department's Civil Office is located in Yreka. The closest Sheriff's station to the public services Area of Analysis is the Hornbrook Station, located at 22012 G Street in Hornbrook (Siskiyou County 2017c).

The California Highway Patrol is responsible for law enforcement on State and Federal highways in the Area of Analysis. There are two major thoroughfares that transverse the area, Interstate-5 and US 97. In addition, area patrols include State Route (SR)-3, SR-96, SR-139, SR-161, SR-263, SR-265, and hundreds of miles of unincorporated county roads. The main office for this region, which includes a communications center, is located in Yreka (CHP 2017a). The Yreka Communications Center dispatch area encompasses all of Siskiyou County, and parts of Modoc and Shasta counties. The Yreka Communications Center dispatches for: the Yreka and Mt. Shasta area offices; and the Dunsmuir Grade Commercial Vehicle Enforcement Facility (CHP 2017b). The Yreka Communications Center and the Yreka Area Office are located at 1739 South Main Street, Yreka, CA 96097 (CHP 2017b).

3.17.2.3 Medical Services

No Medical Services are provided directly within the Area of Analysis for public services. The closest Medical Services are provided at Fairchild Medical Center, which is located in Yreka, 20.2 miles from the Copco community (FMC 2017). The second closest medical facility is the Butte Valley Health Center, located in Dorris (BVHC 2017). The Butte Valley Health Center is 33.2 miles from the Copco community. The closest two hospitals nearby, include: Asante Rogue Regional Medical Center, located in Ashland, OR (ARRMC 2017), 47.7 miles from Copco, CA; and Sky Lakes Medical Center, located in Klamath Falls, OR (SLMC 2017), 51.8 miles from Copco, CA.

3.17.2.4 Schools

The Siskiyou County Office of Education oversees the school districts and educational programs to, “provide quality assistance and resources to schools as they deliver equitable learning opportunities for all students and provides a menu of powerful services to schools and communities supporting the learning goals of each child and family” (SCOE 2017a).

Siskiyou County has several charter schools, elementary schools, high schools, alternative education schools, and community day schools (SCOE 2017b). Yreka is served by the Yreka Union Elementary School District and the Yreka Union High School District. Bogus Elementary, Hornbrook Elementary, Willow Creek Elementary, Meadows Union Elementary, Little Shasta Elementary, and Montague Elementary are close to the Area of Analysis (Great Schools 2017).

Bogus Elementary School is the closest school to the public services Area of Analysis. It is 5.4 miles east of the Iron Gate Dam (Google Maps 2017a), and 5.3 miles southeast of Copco Dam No.1 and No.2 (Google Maps 2017b).

Bogus Elementary School is a K-8 grade, two-room school with a current enrollment of 14 students. There is one full-time teacher/principal/superintendent, one full-time instructional aide who additionally serves as part-time bus driver and part-time cafeteria coordinator/cook (Bogus Elementary School 2017). Bogus Elementary School is located at 13735 Ager-Beswick Rd., Montague, CA 96064-9434.

3.17.2.5 Parks, Park Facilities, and Other Public Facilities, including the Existing Reservoirs

The Area of Analysis for public services contains a number of recreational facilities that currently are well used primarily during the summer months. The reservoirs associated with the Lower Klamath Project, three of which are in California, could be considered public facilities. These park and other facilities are described in Section 3.20 Recreation.

3.17.3 Significance Criteria

Criteria for determining significance for public services are based on Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgment. Effects on public services are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

- Substantially increase public service response times for emergency fire, police, and medical services due to construction and demolition activities.
- Eliminate a long-term water source for wildfire services, and the associated increase in response times.
- Create a substantial adverse effect on schools services and facilities.

3.17.4 Impact Analysis Approach

The approach to the impact analysis for public services focuses on whether the Proposed Project will result in impairing existing public services or create a need for increased services related to fire, police, or medical facilities. The long-term effects of the Proposed Project would result in elimination of a long-term water source for wildfire services (e.g., the reservoirs) and the associated increase in response times. Otherwise, the long-term effects of the Proposed Project would be a reduction in hydropower operation activity and existing recreation, which could reduce the risk and need for emergency services, as a result of reduced traffic from those uses. Whether future land uses will create traffic that would meet or exceed the existing condition is, at this point, speculative. The Proposed Project, the removal of the four dams and associated facilities, will also not create a long-term need for additional school services or facilities.

This analysis includes a focus on short-term construction-related activities. Analysis of peak construction-related activity recognizes that other Project-related activities, including those that will occur prior to and following peak periods, would result in less of a potential impact because the risk of the need for emergency services is reduced with less use occurring in the area. The following analysis and referenced mitigation measures included for the peak construction-related activities would also be relevant to non-peak activities. These potential impacts would be considered short-term impacts. The analysis for the adequacy of public services for the Proposed Project is further addressed in several other sections including Section 3.21 Hazards and Hazardous Materials and Section 3.22 Transportation and Traffic.

Potential impacts related to maintaining acceptable service ratios, response times, or other performance objectives for any of the public services during the construction-related activities would be dependent on the Proposed Project's forethought in providing an Emergency Response Plan, Fire Management Plan, Traffic Management Plan (Traffic Management Plan), and Hazardous Materials Management Plan (Hazardous Materials Management Plan). These have been included in Appendix B: Definite Plan – Appendices O1 – O4. Mitigation measures have been added in Section 3.21 Hazards and Hazardous Materials and Section 3.22 Transportation and Traffic to address these concerns.

Finally, the analysis addresses whether the Proposed Project will impact school services or facilities during the period of activity for the Proposed Project. The effect on parks, park facilities, and other public facilities, including the existing reservoirs is analyzed in Section 3.20 Recreation.

3.17.5 Potential Impacts and Mitigation

Potential Impact 3.17-1 Increased public services response times for emergency fire, police, and medical services due to construction and demolition activities.
The Proposed Project could result in a significant impact if it results in substantial increases in emergency response times within the Area of Analysis. In general, development of an adequate Traffic Management Plan (Traffic Management Plan) would mitigate the potential short-term impacts of construction-related traffic and therefore minimize changes to public service response time. Under the Proposed Project, demolition and construction areas would be closed off to the public to reduce hazards. Due to the rural nature and low concentration of roads in the area, most existing roads are currently used, and would continue to be used, by emergency responders and for evacuation routes in the event of fire or other emergencies. The use of these roads for construction activities could interfere with emergency response and evacuation. The potential for substantial interruptions to road access for property owners within the public

services Area of Analysis during construction activities would not be a significant impact since alternative routes are or would be made available as part of the proposed Traffic Management Plan (Traffic Management Plan) (Section 3.22 *Transportation and Traffic*). The KRRC's Traffic Management Plan is a specialized program tailored to minimize impacts by applying a variety of techniques such as *Public Information, Motorist Information, Incident Management and Construction Strategies.* The major objectives of the Traffic Management Plan are to maintain efficient and safe movement of vehicles through the construction zone covered by activities in the Definite Plan and to provide public awareness of potential impacts to traffic on both haul routes and access roads to the four dams and associated facilities. The Traffic Management Plan outlines the structure and key requirements that would be incorporated by the KRRC's contractor into a final Traffic Management Plan. The final Traffic Management Plan would be informed by KRRC's contractor's specific means and methods for construction, which could refine the approach to access and traffic management. KRRC proposes that the final Traffic Management Plan would meet applicable regulatory permit requirements, as well as applicable state and local ordinances, as appropriate (Appendix B: *Definite Plan – Appendix O2)*.

Construction activities would involve staging and stockpiling areas and equipment that would be kept on-site for the duration of construction. The Limits of Work (Figures 2.7-2 and 2.7-4) would include activities that may result in accidental spills of flammable liquids or use of equipment that generates heat, such as welding, grinding, torch-cutting, gas and diesel generators. Other construction activities could result in open sparks or flame in vegetated open space that could further aggravate the risk of fire. Emergency and Security services would be provided by the construction contractor, therefore the Proposed Project would not increase the need for emergency services or the number of emergency responders. What is important for the reduction of impacts is that all construction workers have the knowledge and resources to respond to emergencies and all emergency preparation and work are overseen by a designated health and safety manager, which is proposed as part of the Proposed Project. In addition, the Proposed Project (Appendix B: *Definite Plan*) proposes that responding agencies and departments are made aware of the activities during the construction period so that they can implement their existing regulatory framework, establish an emergency contact process, and include inspections as needed throughout the process.

Mitigation Measure HZ-1 and Recommended Measure TR-1 would reduce the potential impacts related to construction activities since these measures require that the KRRC and its contractor(s) for the Proposed Project submit the additional documentation/details included in the final Emergency Response Plan, Fire Management Plan, Traffic Management Plan, and a Hazardous Materials Management Plan, and they work with applicable agencies prior to the start of construction. Implementation of these two measures would reduce the potential for a short-term increase in personal and public health and safety risks due to the Proposed Project as related to emergency response services. There would be no long-term impacts due to the Proposed Project construction-related activities since the construction would be completed in the short term.

Most of the roads within the Area of Analysis are currently owned or managed by PacifiCorp (Section 3.22.2.3 *Road Conditions*). PacifiCorp would continue to own and manage the roads contained within Parcel A and KRRC would own and manage the roads contained in Parcel B (see Figure 3.14-4). Section 3.21 *Hazards and Hazardous*

Materials discusses the transport of hazardous materials, emergency, and wildfire potential and includes Mitigation Measure HZ-1 to address potential impacts to emergency response under the Proposed Project. As discussed in Section 3.22 *Traffic and Transportation*, the Proposed Project also includes an Emergency Response Plan. Recommended Measure TR-1 includes coordination between the Traffic Management Plan and Emergency Response Plan and additional detail necessary to reduce impacts.

Overseeing development and implementation of the final Traffic Management Plan and final Emergency Response Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable good citizen agreements that will be finalized and implemented, at this time the Traffic Management Plan and Emergency Response Plan are not finalized and the State Water Board cannot require their implementation. Accordingly, the State Water Board anticipates that implementation of the final Traffic Management Plan and Emergency Response Plan, including the additional details in Recommended Measure TR-1 and any modifications developed through the FERC process that provide the same or better level of protection for transportation and traffic would reduce impacts to less than significant. However, because the State Water Board cannot ensure implementation of the final Traffic Management Plan and final Emergency Response Plan, it has determined the impact in this Draft EIR to be significant and unavoidable**.**

Significance
Significant and unavoidable with mitigation

Potential Impact 3.17-2 The Proposed Project's elimination of a long-term water source for wildfire services could substantially increase the response time for suppressing wildfires.

The Proposed Project would result in the removal of one readily available water source for wildfire services or increased emergency response times if other sources of water are not as readily available. Under the Proposed Project, removal of the Copco No.1, Copco No. 2, and Iron Gate reservoirs would remove a long-term water source for fire suppression crews after the reservoirs are removed. The removal of the reservoirs could increase turn-around time for helicopters or ground crews refilling with water for fire abatement purposes. However, the initial response times for existing aircraft with fire retardant would not be changed by the loss of the reservoirs. Following dam removal, helicopters and ground crews would still be able to extract water from the Klamath River (both the current channel and the channel reaches to be exposed in the current reservoirs following drawdown), Lake Ewauna, and Upper Klamath Lake. Retrieving water directly from the Klamath River is consistent with how wildfires are suppressed along the Klamath River downstream of Iron Gate Dam under current conditions.

With respect to Klamath River access, most helicopter water tanks require three feet of water depth to fill properly, so only deeper pools in the Klamath River would be able to be used by helicopters. CALFIRE uses the closest available water source that is suitable for fire-fighting, where suitability is determined by local conditions including water flow, depth of pool (2- to 3-foot minimum), amount of debris in pool, shoreline vegetation, and surrounding terrain. Rotor blade length and the length of bucket lines are also determinants, since there must be a safe amount of space to enter and exit the pool site. Individual pilots use their discretion to determine the closest and safest locations from which to withdraw water.

Analysis of aerial photos (Google Maps 2018) suggests the presence of pools with suitable conditions for helicopter filling in the currently free-flowing reaches of the Middle and Upper Klamath River, particularly in the reaches between Copco No. 1 and J.C. Boyle reservoirs and downstream of Iron Gate Dam. While source water would be available in the Klamath River in pools located in the river reaches exposed following reservoir drawdown, the travel time involved in accessing the newly formed pools would be greater than that for the existing Lower Klamath Project reservoirs because retrieval of water from relatively smaller, more narrow, river pools is more difficult than dipping directly from the broad water surface of a lake or reservoir, and only one helicopter at a time would have access to a given river pool versus multiple helicopters that can draw at one time from a large reservoir. Thus, response and travel times between water fills for helicopter crews would be expected to increase with the loss of the reservoirs. Wildfires can spread at a rapid speed, and involve high risks. Any amount of additional response time compared with existing conditions could result in a substantial increased risk of loss, injury, or death involving wildland fires and this would be a significant impact.

To compensate for the loss of reservoir water supply, the Proposed Project includes providing alternate water supply through dry hydrants that would be accessible to ground crews following removal of the dams. Flows in the Klamath River and tributaries are not expected to substantially change post-dam removal, as compared to current flows, and firefighting ground crews could still use the river as a water supply as long as physical access to water is provided. Dry hydrants are passive, unpressurized systems, with a screened intake placed in the channel above the channel bed. An above-ground fire hose is used to connect the intake to truck-mounted pumps (Figure 3.17-1). Placement of the dry hydrant must be in a location of satisfactory depth (during dry conditions), flow rate, and channel stability. The Definite Plan states that dry hydrants are commonly used as water supply for fighting fires in rural areas, and typical dry hydrants and fire truck pumps can supply over 1,500 gallons per minute, which is sufficient for rapid filling of typical water tankers and firefighting apparatus (Appendix B: *Definite Plan – Appendix O1*).

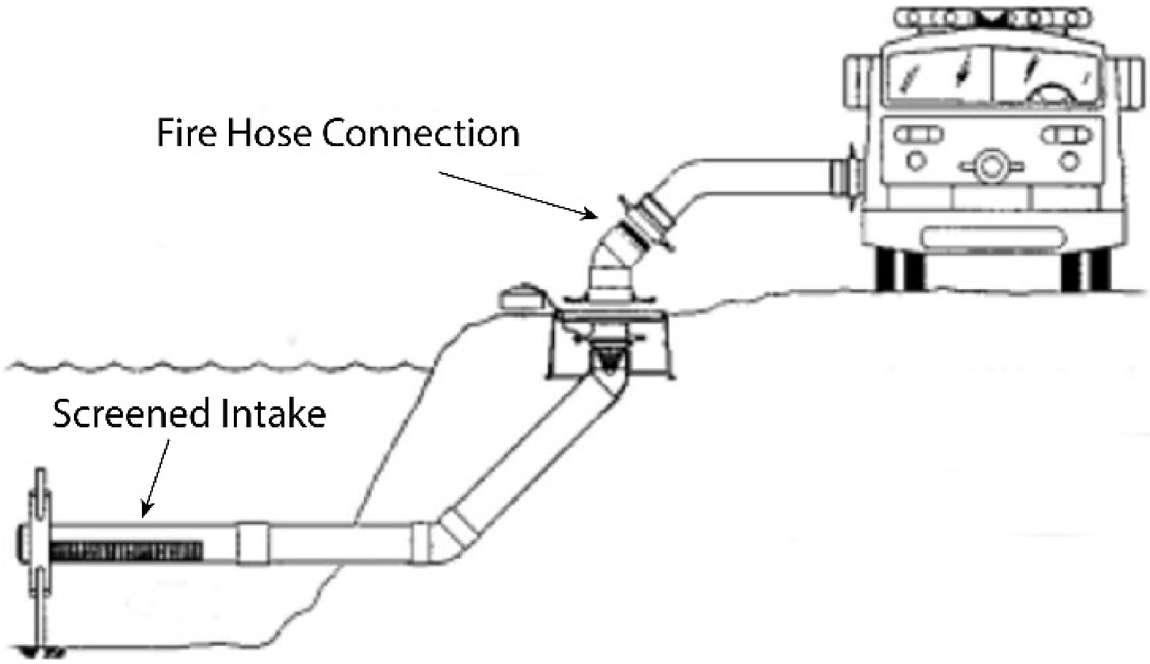

Figure 3.17-1. Diagram of Typical Dry Hydrant System.

Potential dry hydrant sites located within PacifiCorp or state-owned property boundaries that leverage existing, permanent infrastructure (e.g., fire stations, bridges, roads, and boat launches), would offer proximity and ease of access to current or anticipated post-removal Klamath River or tributary channels. Bridges and crossings would be desirable given the increased certainty of access to water post-removal and the ability to use the structure for mounting the dry hydrant rather than excavating earthen material for pump installation.

At Copco No. 1 Reservoir and the reach of the Klamath River upstream of the reservoir, eight potential dry hydrant sites were identified (Figure 3.17-2). Access to the mainstem Klamath River upstream of Copco No. 1 Dam after removal would be limited if the channel reoccupies its historical alignment as predicted. The historical Klamath River had a meandering shape in the Copco No. 1 Reservoir, and the mainstem would likely be either far from existing roads or difficult to access due to the presence of steep, high relief bluffs particularly near the Copco No. 1 Dam site.

Potential dry hydrants at Copco No. 1 Reservoir are labeled CP1 through CP8. CP1 would be located along Copco Road adjacent to where Beaver Creek would be expected to run post-removal, but, with sufficient flow, could be moved to where Copco Road crosses Beaver Creek upstream of the confluence with East Beaver Creek. CP2 would be located along the historical Klamath River and Copco Road downstream of Raymond Gulch at a location where the valley topography is less steep. CP3 would be located near the historical confluence of the Klamath River and Deer Creek off Patricia Avenue, close to Copco No. 1 Reservoir Fire Station. CP4 would be sited where Ager Beswick Road crosses Deer Creek. CP5 would be located at the Copco Road bridge over the Klamath River at the eastern margin of the reservoir adjacent to the Copco Lake Fire Department Station A. CP6 would be located on a bridge over the Klamath River upstream of the current influence of Copco 1 Dam, accessible off Ager Beswick Road.

CP7 would be located on a small bridge over the Klamath River off Ager Breswick Road and immediately upstream of the Shovel Creek confluence. CP8 would be located at a fishing access area off Ager Breswick Road where a rapid holds grade to maintain a deeper pool for water extraction.

At Iron Gate Reservoir, four potential dry hydrant locations were identified and labeled IG1 through IG4 (Figure 3.17-3). IG1 would be sited at the Lakeview Road bridge crossing over the Klamath River, downstream of Iron Gate Dam and adjacent to the Iron Gate Hatchery. IG2 would be located in the vicinity of the Camp Creek campground where Copco/Iron Gate Lake Road crosses Camp Creek. IG3 would be located at the bridge where Copco/Iron Gate Lake Road crosses Jenny Creek. IG4 would be sited where the Daggett Road bridge crosses the Klamath River, adjacent to the Fall Creek confluence and Copco/Iron Gate Lake Road.

The proposed dry hydrants are likely to be of limited use for firefighting compared with existing conditions because only ground crews can access them (i.e., they are of no use to aerial crews that can access the reservoirs under existing conditions). Hook-ups to the dry hydrants would require standardized equipment for all vehicles and existing CALFIRE pumper trucks would require special equipment such as hard suction lines (a flexible hose would collapse) to successfully draft from the dry hydrants. The ground crews would need to be able to get close to the river to draft from the dry hydrants because fire trucks typically can only lift water over short vertical distances (i.e., 10 to 14 feet, with a maximum 15-foot height from the intake) and drafting from bridges may require too much lift. Decreased response time associated with dry hydrants as compared with aerial crew access of reservoir water via helicopters would be a significant impact since it could increase the risk of loss, injury, or death involving wildland fires. Direct withdrawal from the river using a boat ramp, pumping stations equipped with pumps connected to wells or deep pools in the river, above-ground storage tanks with ready access for transferring water to pumper trucks, are likely to be better options than the dry hydrants proposed by KRRC because these alternatives would be easier to use and thus would reduce ground crew response time.

In the long term, the loss of the reservoirs, which are currently part of the existing conditions, would result in a substantial decrease in fire protection involving wildland fires due to longer response times and limitations on access to Klamath River water for fighting fires within the Area of Analysis for public services. While the proposed dry hydrants would provide a source of water to ground crews for firefighting, they do not offer the same degree of access as helicopter use of the reservoirs for wildfires occurring in the vicinity of the Lower Klamath Project, for which the reservoirs are the closest and safest source of water for aerial crews. One option that would assist in mitigating this impact would be to include appropriately placed dip ponds within the Proposed Project's restoration areas.

Recommended Measure PS-1 requires the KRRC and/or its Contractor(s) to develop, in consultation with the CALFIRE Siskiyou Unit, an updated Fire Management Plan that identifies long-term water sources for helicopter and ground crews (including construction and use of proposed dry hydrants, dip ponds, or other alternatives). Updating the CALFIRE Siskiyou Unit's Fire Management Plan with available sources of water for helicopters and ground crews following dam removal provides new information to support fire services in the absence of the reservoirs. The State Water Board anticipates that in the absence of the reservoirs, the identification and use of alternative water sources (e.g., dip ponds, river pools suitable for helicopter drafting, dry hydrants) for both ground and helicopter crews that are developed through the FERC process would significantly ameliorate response times and provide a level of protection to substantially reduce the public's risk of loss from wildfires, thereby reducing impacts to less than significant in many instances. However, where suitable replacement water sources cannot be identified in close proximity to a fire in a location for which the reservoirs would otherwise have been the nearest water source, long-term impacts to the public's risk of loss from wildfires remain significant and unavoidable.

Additionally, the terms of an updated Fire Management Plan and its incorporation of Recommended Measure PS-1 are not within the State Water Board authority, and the State Water Board therefore cannot ensure implementation of this measure. Thus, the State Water Board has determined the long-term impact in this EIR to be significant and unavoidable.

Recommended Measure PS-1 – Fire Management Plan.
The KRRC and/or its Contractor(s) shall develop a post-dam removal Fire Management Plan in consultation with the CALFIRE Siskiyou Unit. The Fire Management Plan shall identify long-term water sources for helicopter and ground crews (including construction and use of proposed dry hydrants, dip ponds, or other alternatives). After reaching agreement on the Fire Management Plan with CALFIRE Siskiyou Unit, the KRRC and/or its Contractor(s) shall submit the Final Fire Management Plan to the CALFIRE Siskiyou Unit and implement any portions of the plan for which the KRRC has identified responsibilities.

Significance
Significant and unavoidable

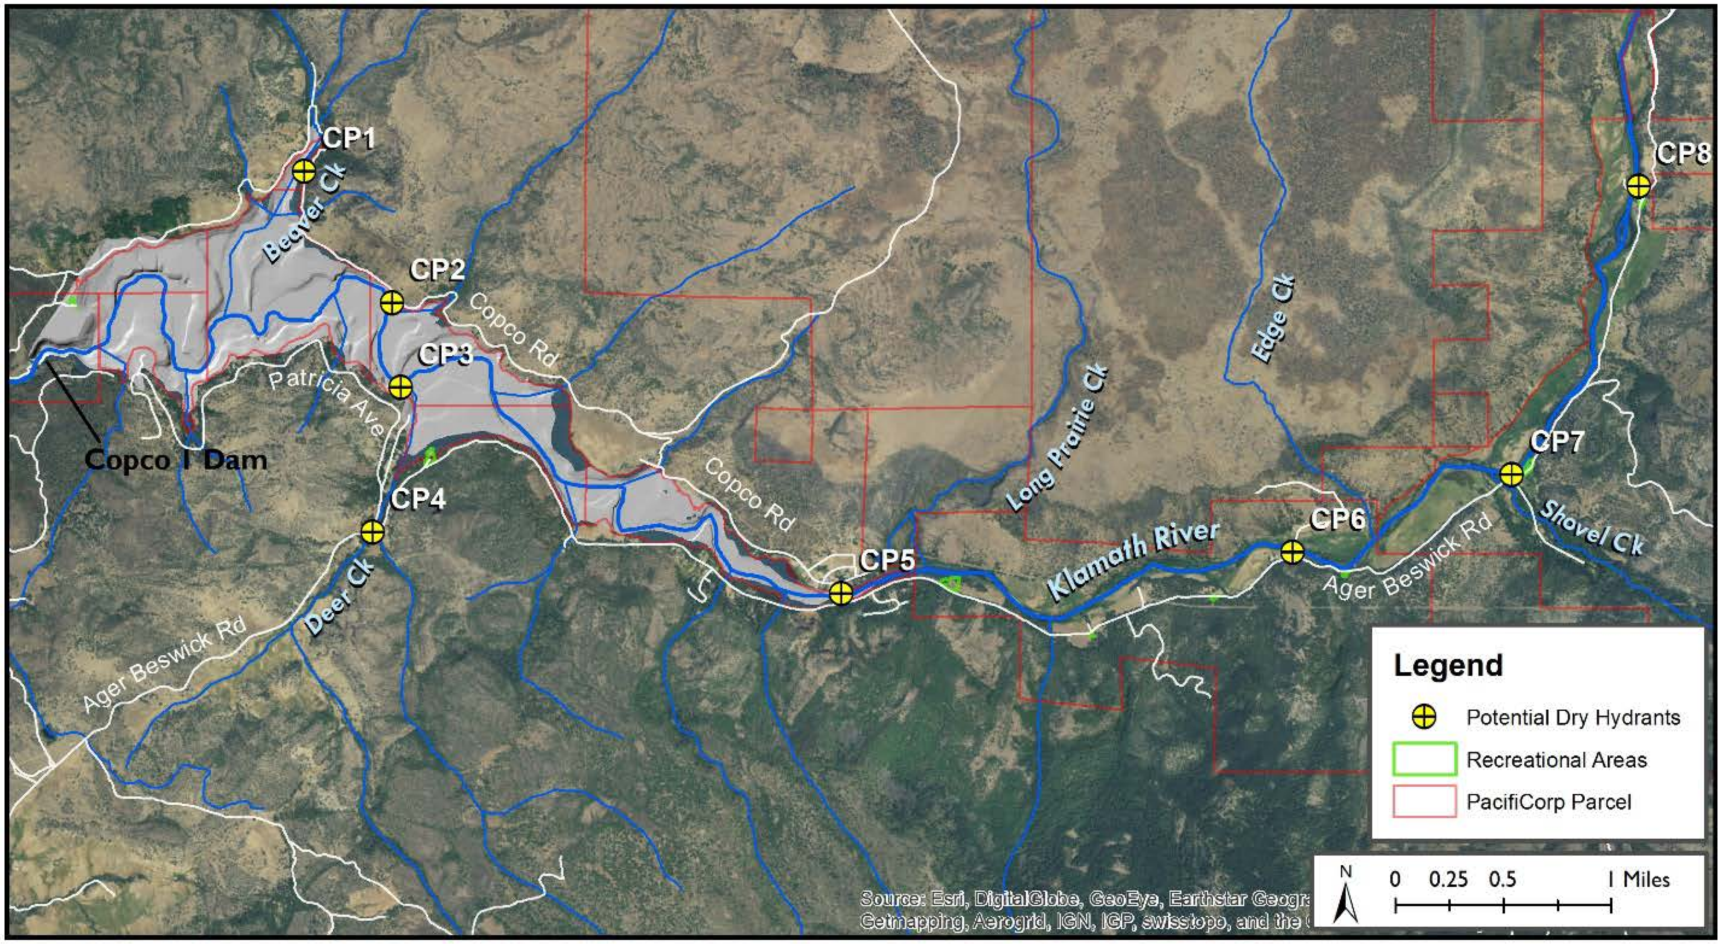

Figure 3.17-2. Locations of Potential Dry Hydrants for Copco No. 1 Reservoir.

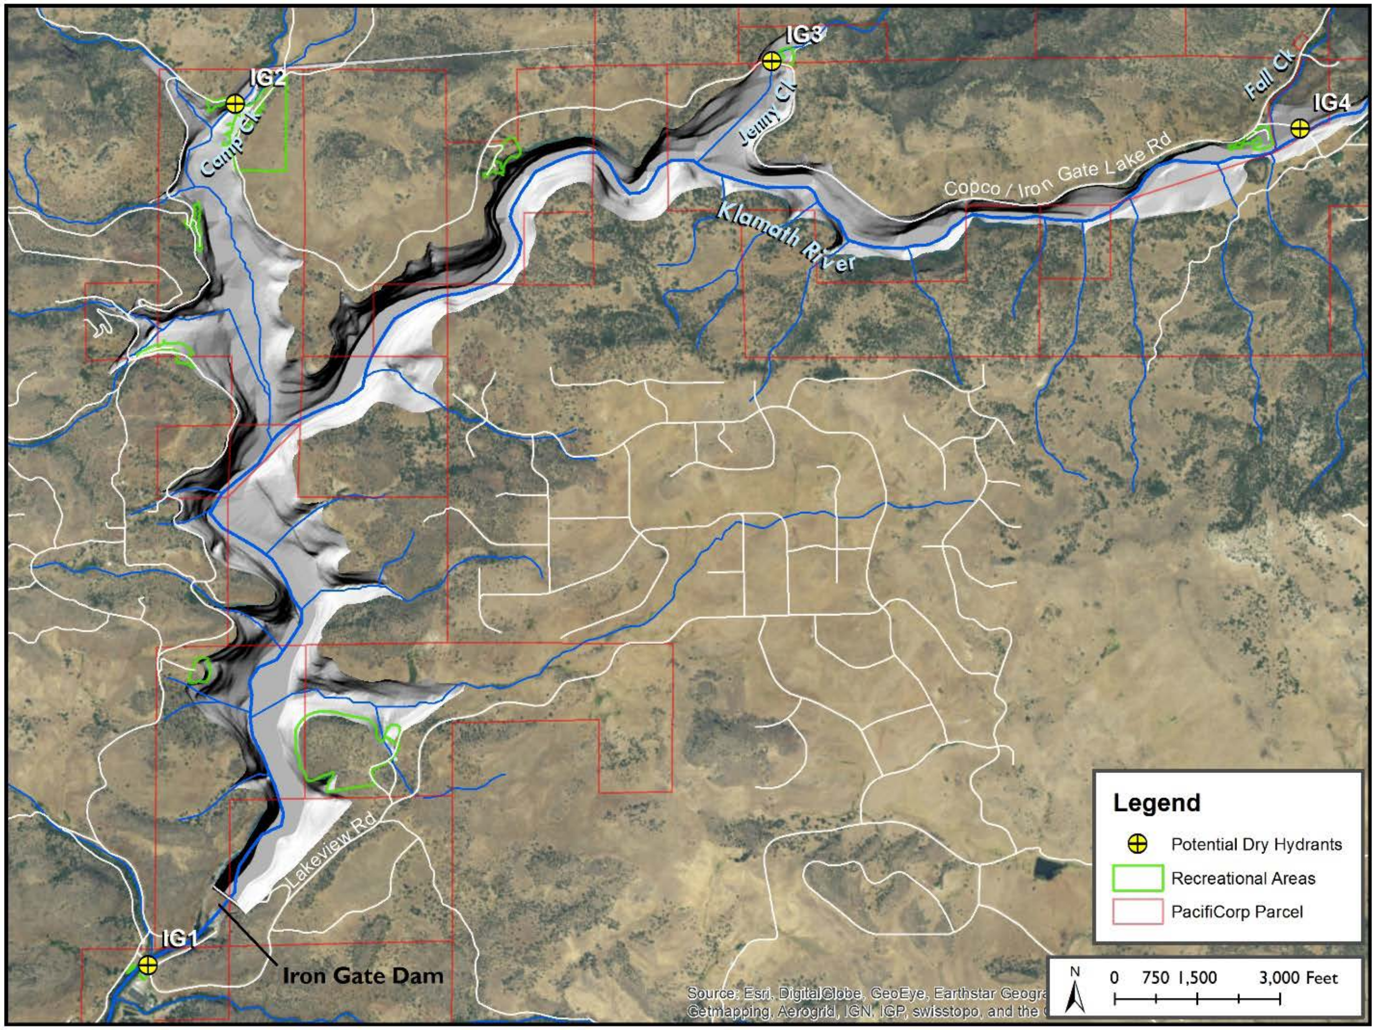

Figure 3.17-3. Locations of Potential Dry Hydrants for Iron Gate Reservoir.

Potential Impact 3.17-3 Potential effects on school services and facilities.
In the short term, Proposed Project construction activities could result in adverse effects on school services or facilities if it results in increased student enrollment that exceeds the capacity of the nearby schools. While the Proposed Project could have short-term impacts to school facilities and services during the construction period if a number of construction workers move into the area during the construction period, related impacts would be speculative as the contracting firms have not been selected. According to the Proposed Project schedule (Table 2.8-1), peak construction-related activity would primarily occur when school would not be in session. Therefore, the Proposed Project would not result in short-term impacts to school services and facilities.

In the long term, the Proposed Project does not have the potential to affect schools in terms of additional students or longer bus routes, nor would it generate the need for additional classrooms or school services. The removal of PacifiCorp housing related to the Lower Klamath Project dams and associated facilities may reduce the need for school facilities, depending on the occupancy of its residences. However, since the number of residences is small (i.e., one occupied residence at Copco No. 1 and No. 2 dams and two occupied residences at Iron Gate Dam), there would be no impact on school services and facilities due to the Proposed Project in the long term.

Significance
No significant impact

3.18 Utilities and Service Systems

including wastewater, stormwater, and solid waste, as well as potential environmental impacts to utilities and service systems due to implementation of the Proposed Project. Additional information related to utilities and service systems is discussed in Section 3.8 *Water Supply and Water Right*s, 3.21 *Hazards and Hazardous Materials*, and 3.22 *Transportation and Traffic*.

The State Water Board received several comments during the NOP public scoping process regarding potential impacts to Yreka's municipal water supply and the need to realign the water supply pipeline as part of dam removal. These issues are addressed in Section 3.8 *Water Supply/Water Rights*. The State Board also received comments regarding Clean Energy Sources and resulting lower utility rates. These issues are addressed in Section 3.10 *Greenhouse Gas Emissions*. The State Water Board did not receive any other comments related to utilities and service systems. The summary of comments received during the NOP public scoping process, as well as the individual comments themselves, are presented in Appendix A.

3.18.1 Area of Analysis

The Area of Analysis for utilities and service systems includes lands within the Project Boundary (Figure 2.2-4). The Area of Analysis for solid waste also includes consideration of disposal capacities for accommodating solid wastes at the Yreka Transfer facility near Hornbrook, CA, the Class 1 Landfill near Anderson, CA, and the Dry Creek landfill site in White City, OR., even though these areas are not shown as part of the Project Boundary.

3.18.2 Environmental Setting

The following section describes the environmental setting for utilities and service systems that could be affected by implementing the Proposed Project.

3.18.2.1 Wastewater

Siskiyou County does not provide wastewater treatment within the Area of Analysis for utilities and service systems. Generally, sewer and septic facilities are offered by local municipalities (SCEDC 2018). Yreka has one wastewater treatment plant that treats and disposes of both domestic and industrial sewage generated within the city's boundaries (City of Yreka 2018). The facility is designed to accommodate up to 1.3 million gallons per day (mgd) of average dry weather flow. Yreka's General Plan reported that average dry weather flow in 2003 was between 0.7 and 0.9 mgd (City of Yreka 2003).

All the communities in unincorporated areas of Siskiyou County, including the rural communities of Hornbrook and Copco Village, have a community wastewater treatment system, onsite septic systems (USBR 2012), or have arranged to use an adjacent city's wastewater treatment facilities. There are five community service districts that meet the demands for sewer and wastewater treatment in Siskiyou County (SCCDD 2014); these are all located outside of the Area of Analysis. The Area of Analysis is served by individual sewage disposal systems (i.e., septic tanks). These are allowed within unincorporated Siskiyou County through permits with the Siskiyou County Public Health

Department (PacifiCorp 2015). The Siskiyou County Public Health Department applies the Sewage Disposal Code to any new construction, alterations, repairs, reconstruction and removal of individual sewage disposal systems within the unincorporated areas of Siskiyou County (Siskiyou County 2018a).

Recreational facilities located along the shoreline of Copco No.1 and Iron Gate reservoirs have installed vault toilets (i.e., enclosed toilets that require periodic removal of waste generated) that are serviced routinely during usage periods with pumper trucks. The trucks discharge the collected wastewater into Yreka’s sewer system or other permitted facility.

The Proposed Project will require the use and maintenance of portable chemical toilets on site during construction activities. The quantity is determined by the number of workers.

3.18.2.2 Stormwater

Stormwater is managed by the individual municipalities within Siskiyou County. However, no municipal stormwater systems are located within the Area of Analysis for utilities and service systems. Stormwater captured by impervious surfaces at existing Lower Klamath Project facilities and the local communities of Hornbrook and Copco Village is conveyed by natural drainages. The Lower Klamath Project facilities do not have any stormwater disposal systems (FERC 2004).

3.18.2.3 Water Supply

The Proposed Project Area of Analysis is in an unincorporated area of Siskiyou County and is not served by any water district. Water supplies are provided to rural residences near the Lower Klamath Project facilities by private groundwater wells (USBR 2012). Additional information about surface and groundwater is described and analyzed in Section 3.7 *Groundwater* and 3.8 *Water Supply/Water Rights*.

3.18.2.4 Solid Waste

Solid waste in Siskiyou County is handled by the County’s General Services Sanitation Division which provides a fee-based solid waste disposal system for the entire county. The county operates five recycling and transfer sites: Black Butte Transfer Station, Happy Camp Transfer Station, Salmon River Area Collection Facility, Tulelake Transfer Station, and Yreka Transfer Facility (Siskiyou County 2018b). The Proposed Project site is within the jurisdictional boundaries of the Siskiyou County Integrated Solid Waste Management Regional Agency (CalRecycle 2018).

The Siskiyou County Source Reduction and Recycling Element (SRRE) establishes goals and methodologies for compliance with California AB 939, which establishes 50 percent diversion of solid waste from landfills. In 2017 CalRecycle found the County to be in substantial compliance with AB 939. The County regulates garbage and refuse disposal through the Siskiyou County Solid Waste Ordinance. (Siskiyou County 1963).

The Proposed Project proposes to dispose of solid waste at the County transfer station at the former landfill site on Oberlin Road, located two miles southeast of Yreka, California, which is the nearest transfer station that could be used for recycling and waste disposal/transfer during dam demolition. The transfer station is permitted to accept general residential, commercial, and industrial refuse for disposal, including municipal solid waste, construction and demolition debris, green materials, and agricultural debris. The Yreka Transfer Facility has a capacity of 100 tons per day. Currently, solid waste is transferred approximately 45 miles from the Yreka Transfer Facility to the Dry Creek Landfill facility near White City Oregon. In 2018 this facility had a total capacity of 76,800,000 tons with a life projected at over 100 years (Dry Creek Landfill 2018).

Hazardous materials, including batteries, paints, treated wood waste, and other hazardous materials, must be disposed at certified Class I landfill facilities, which are lined to prevent the contamination of underlying soils and groundwater. The Anderson Landfill in Anderson, California, is located 122 miles south of Hornbrook, California, and is permitted to accept hazardous waste. The Anderson Landfill had an estimated remaining capacity of 11,914,025 cubic yards (72 percent of capacity remaining) in 2008, with an anticipated closure date of 2055 (CalRecycle 2018). Some special wastes are also accepted at the Dry Creek Landfill facility located 45 miles north of Hornbrook, California, but they would require pre-approval prior to disposal.

Estimated quantities of solid waste are described in Section 2.7.1 *Dam and Powerhouse Deconstruction*, as well as the Definite Plan for the Lower Klamath Project (Appendix B: *Definite Plan – Tables 5.3-3, 5.4-3 and 5.5-3*), and are much less in volume than the limitations noted above, as discussed in Potential Impact 3.18-4.

3.18.3 Significance Criteria

Criteria for determining significance of potential impacts to utilities and service systems is informed by Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and based on professional judgment. Effects to utilities and service systems are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

- Require or result in the construction of new wastewater treatment and/or disposal facilities or expansion of existing facilities, due to inadequate capacity to serve the Proposed Project's anticipated demand or where the construction of such facilities could cause significant environmental impacts.
- Require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental impacts.
- Be served by a landfill with insufficient permitted capacity to accommodate the project's solid waste disposal needs.
- Violate applicable statutes and regulations related to solid waste.

3.18.4 Impact Analysis Approach

The approach to analyzing potential impacts related to utilities and service systems considers existing conditions as the baseline for utilities. Unlike many other projects, the Proposed Project would result in reduced long-term utility and services use due to the reduction of use from the operation of the dam facilities. Therefore, the majority of the impact analysis focuses on potential short-term, construction-related impacts associated with construction activities.

Of primary concern for short-term impacts is the export of solid waste from construction during construction activities before, during, and after reservoir drawdown. Short-term waste export is described in the Project Description. Hazardous material removal is analyzed in Section 3.21 *Hazards and Hazardous Materials*. Transport of hazardous materials and Section 3.22 *Transportation and Traffic*.

Water Supply is analyzed in Section 3.8 *Water Supply/Water Rights*.

Local regulations pertaining to impacts analyzed in this section include Siskiyou County General Plan policies, County stormwater regulations, onsite wastewater treatment system regulations for removal of septic systems and requirement for chemical toilets (Siskiyou County Code of Ordinance Title 5, Chapter 2 Sewage Disposal), and solid waste regulations such as the countywide Source Reduction and Recycling Element and Siskiyou County Code of Ordinance Title 5, Chapter 1 Garbage and Refuse Disposal.

3.18.5 Potential Impacts and Mitigation

Potential Impact 3.18-1 The Proposed Project could result in the construction of new wastewater treatment facilities or expansion of existing facilities, due to inadequate capacity to serve the Proposed Project's anticipated demand or where the construction of such facilities could cause significant environmental impacts. There are no municipal wastewater treatment facilities within the Area of Analysis for utilities and service systems. Siskiyou County regulates individual onsite wastewater treatment facilities (septic systems) through its Sewage Disposal Code (Siskiyou County Code of Ordinance, Title 5, Chapter 2 Sewage Disposal), implemented by the Siskiyou County Environmental Health Division.

Within the Area of Analysis for utilities and service systems, the area in which wastewater is generated includes wastewater collection facilities at recreation sites, where wastewater is pumped from vaults, then hauled to and disposed of at permitted sites (i.e., Yreka Wastewater Treatment Plant). The Proposed Project includes elimination of some of the recreational sites, resulting in removal of their wastewater facilities. As part of the removal of existing systems or for any new recreational facility proposed each facility would need to meet applicable wastewater system design requirements (i.e., Siskiyou County Code of ordinance, Title 5, Chapter 2 Sewage Disposal). Other wastewater treatment systems within the Area of Analysis consist of individual onsite wastewater treatment systems (i.e., septic systems). The septic tanks associated with PacifiCorp housing would be removed under the Proposed Project[167]. Those systems associated with surrounding residential or commercial uses would not be affected by the Proposed Project.

[167] Potential Impact 3.21-1 analyzes potential impacts due to the routine transport, use, or disposal of hazardous materials associated with the Proposed Project, including the removal and disposal of septic tanks. Additionally, note that the State Water Board has authority to review and approve any final plan developed to address removal and disposal of septic tanks through its water quality certification under Clean Water Act Section 401. The State Water Board has issued a draft water quality certification which sets forth requirements for hazardous materials management, including proper removal and disposal of septic tanks, as Condition 11.

The Proposed Project would make use of portable chemical toilet facilities during construction activities, which require providing adequate toilet facilities for work crews that are regularly cleaned, pumped, and have wastes disposed of by the toilet providers. Both County and State regulations dictate requirements for proper numbers of facilities and sanitary conditions. Based on Table 2.7-8 (workforce projections), the need for toilet facilities would be limited to the short-term (i.e., dam removal years 1 and 2) when construction activities and the number of workers (average 30 to 40) at each of the three California sites would co-occur. As closure of the existing Lower Klamath Project recreational facilities would occur prior to dam removal construction activities, there would be no overlap in recreational user wastewater generation and construction worker wastewater generation, and thus no substantial increase in the need for proper wastewater disposal at existing municipal treatment facilities due to the Proposed Project. Estimated traffic flow to recreational facilities under existing conditions is 166 visits/trips per day, compared to projected dam removal construction worker traffic flow of 105 average and 175 peak trips per day (see Potential Impacts 3.22-1 and 3.22-2). Based on these traffic flow estimates, overall construction worker requirements for toilet facilities during dam removal activities would be similar to that of recreational users under existing conditions and thus the Proposed Project would not result in the need for new treatment and/or disposal facilities or expansion of existing facilities, where the construction of such facilities could cause significant environmental impacts, and there would be no impact.

Since the total area of construction-related activities for the Proposed Project amounts to greater than one acre, the Proposed Project would be required to obtain coverage under the State Water Board Construction General Permit (2009-0009-DWQ as amended by 2010-0014-DWQ and 2012-0006-DWQ) (CGP). Each of the proposed construction areas, including staging, stockpiling, onsite disposal, and access-related areas, must be covered by the CGP. The CGP requires the applicant to address such items as employee wastewater generated during construction and spill containment and clean-up. Thus, meeting CGP requirements for onsite toilet facilities for short-term use by construction crews would not result in a significant impact as there will not be an increased need for permanent wastewater treatment facilities or an anticipated demand for additional wastewater treatment facilities.

Significance

No significant impact

Potential Impact 3.18-2 The Proposed Project could require or result in the construction of new stormwater drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental impacts.
There is no existing formal stormwater collection system in the Area of Analysis for utilities and service systems. Each of the proposed construction areas, including staging, stockpiling, on-site disposal, and access-related areas, must be covered by the CGP. This would require the applicant to address items such as erosion and sediment control, stormwater, spill prevention and containment, and site cleanup during the short-term construction period (two to three years), but would not require construction of new stormwater drainage facilities or expansion of existing facilities.

Significance

No significant impact

Potential Impact 3.18-3 The Proposed Project could exceed permitted landfill capacity to accommodate the project's solid waste disposal needs.

Potential Impact 3.18-4 The Proposed Project could violate applicable statutes and regulations related to solid waste.

The below analysis applies for both Potential Impacts 3.18-3 and 3.18-4.

Overall, the total volume of waste generated by the Proposed Project would be approximately 1.4 million cubic yards (see Table 2.7-3 for estimated quantities of waste disposal for Copco No. 1 Dam, Table 2.7-5 for Copco No. 2 Dam, and Table 2.7-7 for Iron Gate Dam). For the Proposed Project, the vast majority of waste (i.e., soil and concrete) generated by demolition of the Lower Klamath Project dam complexes would be disposed of onsite and would not require transport to a landfill, thereby providing a substantial diversion of wastes meeting the County's AB 939 requirements. The Proposed Project would make use of onsite disposal options for appropriate construction debris in keeping with applicable regulations related to solid waste disposal.

Waste material exported from the Proposed Project sites to the Yreka Transfer Station would amount to less than 15,000 cubic yards. The Yreka Transfer Station is permitted to accept up to 100 tons per day of general residential, commercial, and industrial refuse for disposal, including municipal solid waste, construction and demolition debris, green materials, and agricultural debris. Siskiyou County requires waste diversion, therefore solid wastes sent to the Transfer Facility will need to be sorted at the construction site. Volumes exceeding the daily limit of 100 tons per day will need to be hauled by the contractor, most likely to the Dry Creek Landfill, approximately 45 miles north of Hornbrook, California. The Proposed Project also would require disposal of approximately 700 tons of treated wood waste from the wooden staves at Copco No. 2 Dam, where the treated wood is considered a hazardous material. This and other hazardous materials must be disposed at facilities certified to receive them. The Anderson Landfill in Anderson, California, is located 122 miles south of Hornbrook, California, and is a Class I facility, lined to prevent contamination of underlying soils and groundwater, and permitted to accept hazardous waste, including treated wood waste. Section 3.21 *Hazards and Hazardous Materials* also addresses the volume and type of construction-related debris, particular hazardous wastes and the location of disposal.

Based on the anticipated volume of waste generation for the Proposed Project and the above identified capacities for local landfill facilities (described in Section 3.18.2.4 *Solid Waste*), there is sufficient permitted capacity to accommodate the solid waste disposal needs of the Proposed Project, in keeping with applicable statutes and regulations related to solid waste.

Significance

No significant impact

3.19 Aesthetics

This section identifies and describes potential impacts to scenic resources of the Klamath River and adjacent landscape due to implementation of the Proposed Project.

Several comments were received during the NOP public scoping process relating to potential dam removal impacts on aesthetics, including the likelihood of adverse impacts due to the loss of scenic reservoir views. Several commenters felt that the reservoir footprints would be left as bare slopes with only mud and debris for an extended period of time prior to restoration, and that the loss of reservoir views after implementing the Proposed Project would adversely affect the viability of residential communities that currently surround Copco No. 1 and Iron Gate reservoirs. Individual public scoping comments are presented in Appendix A of this EIR.

3.19.1 Area of Analysis

Removal of the Lower Klamath Project could affect aspects of scenic quality throughout the Klamath River in California, including aspects like water clarity, fish viewing opportunities, and riparian and channel characteristics of the river downstream of the dams. However, potential aesthetic effects on these aspects would decrease with distance downstream from the Lower Klamath Project as the river is affected more by tributary inputs and less by the dams and associated facilities. Therefore, the primary Area of Analysis for aesthetics is within the viewshed of the Lower Klamath Project reservoirs, which includes the proposed Limits of Work in California (i.e., Copco No. 1, Copco No. 2, and Iron Gate dams, reservoirs, and associated facilities, and the areas identified as construction/demolition areas and staging areas) plus a buffer to the ridgeline surrounding the reservoirs. The secondary Area of Analysis for aesthetics includes those areas within view of the Klamath River downstream from Iron Gate Dam to the confluence with the Shasta River (RM 179.5), as well as the portion of the Klamath River extending upstream from Copco No. 1 Reservoir to the Oregon-California border, because these river reaches may be affected by removal of the upstream dams.

The Primary and Secondary Areas of Analysis were generated in Geographic Information Systems (GIS) to approximate the viewshed visible from the Limits of Work and reaches of the Klamath River from the Oregon-California state line to the confluence with the Shasta River, respectively. Where the Primary and Secondary Areas of Analysis overlapped (e.g., at the upstream end of Copco No. 1 Reservoir, see Figure 3.19-1), precedence was given to the Primary Area of Analysis. The viewshed was digitized to follow ridgelines of steep slopes visible using a 10-meter digital elevation model (DEM) hillshade and USGS topographic maps. The area visible from the ground was confirmed using the terrain and ground-level view tools in Google Earth©. The viewshed only includes land that is anticipated to be continuously visible from the Limits of Work or the Klamath River. For example, when ridgelines or peaks appeared to be visible in the distance, but the land between the Limits of Work or Klamath River did not appear to be visible, those areas were not included. The viewshed is meant to be all encompassing of views from anywhere within the Limits of Work, and viewshed limits are approximate and generalized. The Primary Area of Analysis was expanded into Oregon where the viewshed from the Limits of Work in California extended beyond the state line, but it was truncated at the state line along the Klamath River based on the assumption that an on-the-ground viewer would only be looking downstream toward California for the assessment of potential aesthetics impacts in California.

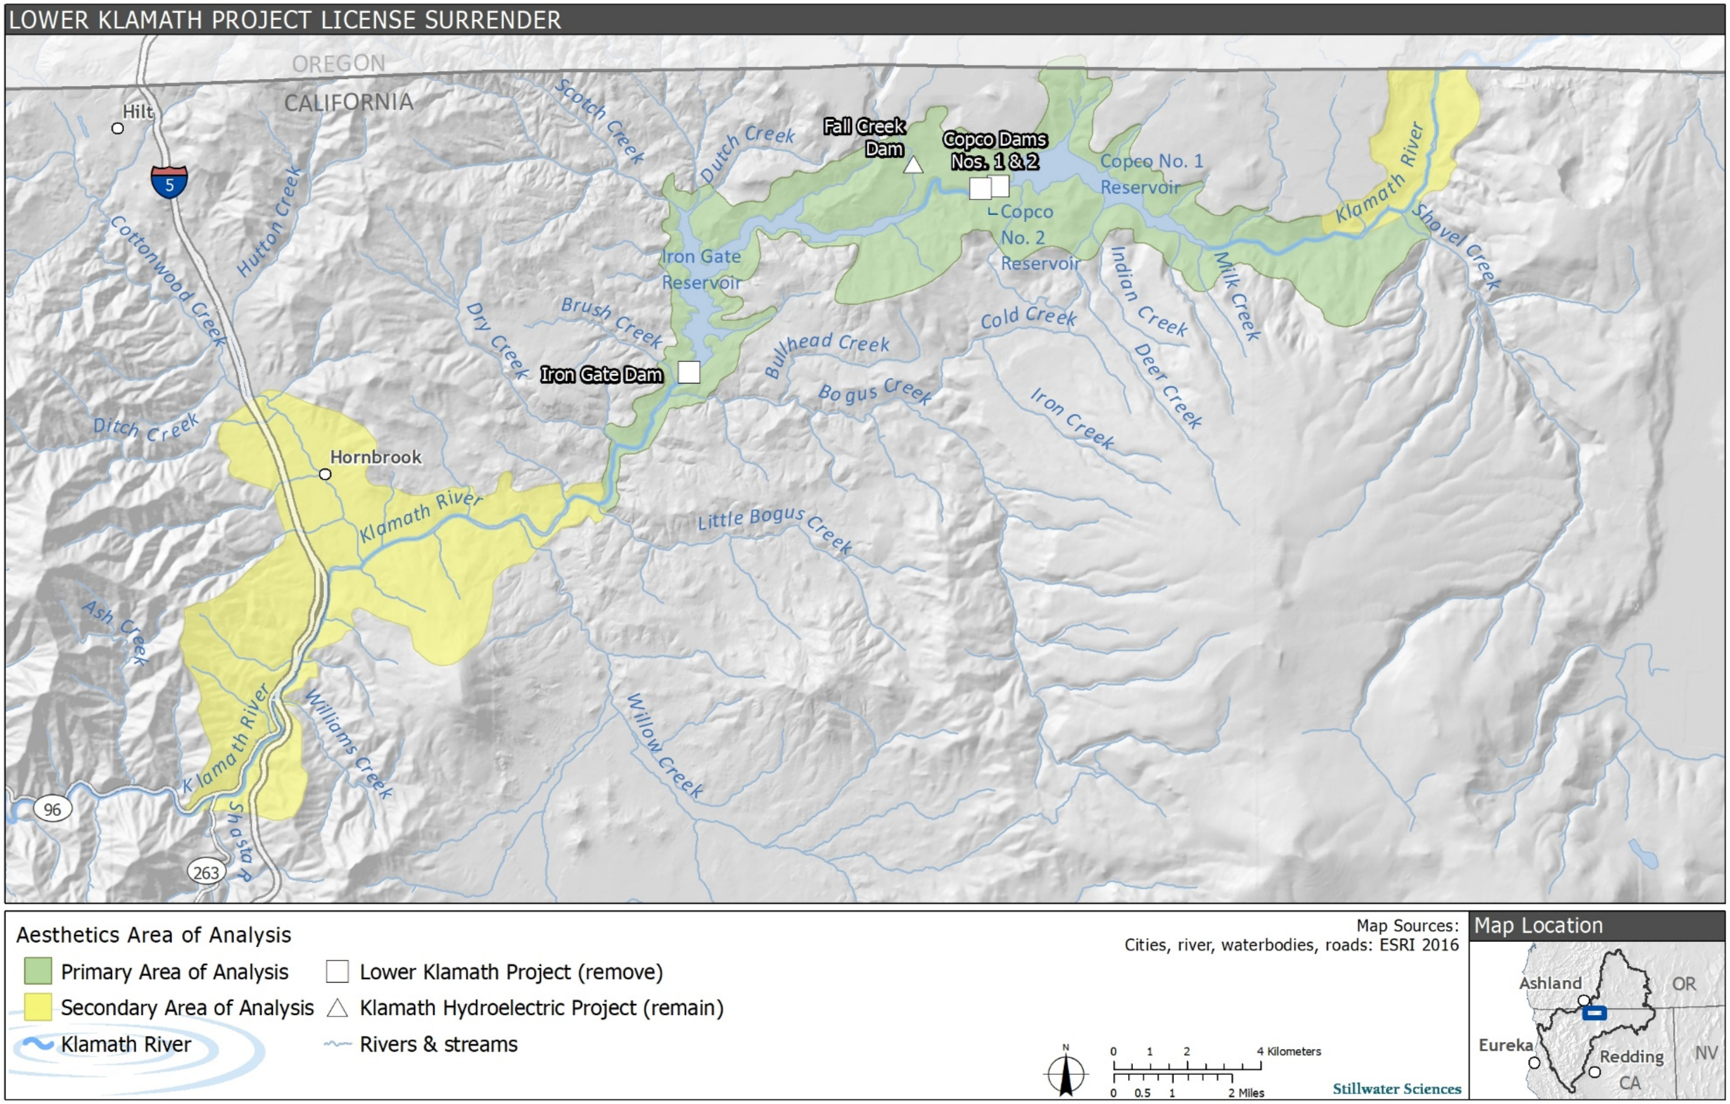

Figure 3.19-1. Aesthetics Area of Analysis.

3.19.2 Environmental Setting

The Klamath Basin as a whole contains widely varied scenic resources, including wetlands, uplands, rangelands, National Wildlife Refuges, farmlands, timberlands, and small urbanized areas in Yreka and along the Interstate 5 corridor. The Klamath Basin also supports vegetation communities including, but not limited to, montane hardwood and annual grasslands, as described in Section 3.5.2 *Environmental Setting*. Sightseeing opportunities to enjoy the scenic resources are widely available in the Klamath Basin generally, and more specifically within the Area of Analysis for aesthetics. Section 3.20 *Recreation* lists recreation resources, including Wild and Scenic River (WSR) segments, and locations in the surrounding region that offer wildlife viewing as well as opportunities for sightseeing, leisure drives, photography, and other forms of recreation.

This section provides further description of the environmental setting for scenic resources in the Area of Analysis pertinent to this and other resource impact analyses in this document.

3.19.2.1 PacifiCorp Analysis and Bureau of Land Management Methodology

PacifiCorp conducted a detailed visual evaluation of the project vicinity (FERC 2007) in 2002 and 2003 and documented it in the Land Use, Visual, and Aesthetic Resources Final Technical Report (PacifiCorp 2004a). This evaluation involved identifying and photographing key observation points during different seasons and documenting views of the reservoirs at different water levels. Photographs taken from these viewpoints portray typical scenic/landscape character along the Klamath River, including such features as canyon walls, channel configuration, water clarity, and bank and riparian appearance. Additional photographs were taken from selected locations in October 2010 (CDM 2010) and were compared to the 2003 photographs to verify the continued existence of earlier-documented conditions (Appendix R).

The following discussion describes the scenic resources found in the Area of Analysis for aesthetic resources. PacifiCorp (2004a) identified eight key observation points in the Hell's Corner Reach (Klamath River between J.C. Boyle Powerhouse and Copco No. 1 Reservoir), seven in the Copco No. 1 Reservoir area, twelve in the area of Iron Gate Reservoir, and three downstream of Iron Gate Dam.

These key observation points are not intended to be comprehensive but were selected to represent typical views (including scenic overlooks) for members of the public from riverside and/or reservoir communities and residences, recreational access sites, campgrounds, as well as scenic byways, and state highways 96, 169, and 101.

For their visual analysis, PacifiCorp used the Bureau of Land Management's (BLM) Visual Resource Management (VRM) process. Within their visual resource study area, PacifiCorp evaluated the way in which project features and operations fit into the overall visual landscape using the following three-step process: (1) identify the VRM classifications applicable within the study area; (2) define viewpoints from which Lower Klamath Project dams and associated facilities and operations could be seen; and (3) evaluate whether project facilities and operations, when seen from the viewpoints, conform to the objectives of the management classification in which they are found (PacifiCorp 2004a).

In response to the Federal Land Policy and Management Act (43 U.S.C. 35, §§ 1701 et seq.) and subsequent agency-specific regulations, federal land management agencies have developed systems specifically designed to inventory, evaluate and manage for scenic (visual) resources on public lands. As a result, the BLM developed the VRM system. The objective of BLM's VRM system is to manage public lands in a manner which will project the quality of the scenic (visual) values of those lands (BLM, 1984).

All BLM lands are assigned to one of four VRM classes, ranging from Class I, which includes the highest value scenery and associated protections, to Class IV, which reflects the lowest value scenery and associated protections. The VRM classes provide a valuation of existing visual resources and protection standards for determining Resource Management Plan conformance during project planning.

The Lower Klamath Project dams and associated facilities fall under the BLM Redding District Resource Management Plan. All of the facilities except three [all associated with J.C. Boyle] are located in areas that have been designated as a Class III area by an RMP or have been classified as a Class III area because the area has not been given a specific VRM class by BLM (PacifiCorp 2004). When evaluating project impacts, the objective for Class III visual resources is to "partially retain the existing character of the landscape. The level of change to the characteristic landscape should be moderate. Management activities may attract attention but should not dominate the view of the casual observer. Changes should repeat the basic elements found in the predominant natural features of the characteristic landscape" (BLM 1984).

For the purposes of this document, the site-specific, project level inventory is limited to the Area of Analysis and based upon a combination of original data from the 2004a PacifiCorp Technical Report and additional analysis from several key observation points. In addition to the aesthetic resources in the Area of Analysis being considered Class III, USBR and CDFW conducted a baseline Visual Resource Inventory within the Area of Analysis as part of the 2012 KHSA EIS/EIR, according to three components: scenic quality, visual sensitivity, and distance zones, as described below.

In terms of scenic quality, BLM's VRM methodology assigns public land a rating of A, B, or C (inherent scenic attractiveness), with A being the most distinctive and C being the most common, in terms of seven key factors including: color, water, vegetation, landform, influence of adjacent scenery, scarcity, and cultural modifications (BLM 1984). Based on review of the visual analysis completed for the 2012 EIS/EIR, all of the Proposed Project area would be contained within rating A landscapes due to the following key factors:

- **Color –** Some intensity or variety in colors and contrast of the soil, rock and vegetation, but not a dominant scenic element
- **Water –** Water flowing or still, dominant in the landscape when viewed from most KOPs, but not always clear and clean appearing
- **Vegetation –** A variety of vegetative types as expressed in interesting forms, textures, and patterns
- **Landform –** Steep canyons, some interesting erosional patterns or variety in size and shape of landforms; or detail features which are interesting though not dominant or exceptional

- **Influence of adjacent scenery –** Adjacent scenery moderately enhances overall visual quality
- **Scarcity –** Distinctive, though somewhat similar to others within the region
- **Cultural modifications –** Some modifications add favorably to visual variety while other add little or no visual variety or may be discordant

In terms of visual sensitivity, BLM's VRM methodology rates landscapes as either High, Moderate, or Low by analyzing the various indicators of public concern, including: type of users, amount of use, public interest, adjacent land uses, specially designated areas, and other factors. Based on review of the visual quality analysis completed for the 2012 EIS/EIR, all of the Area of Analysis would be considered High visual sensitivity because: (1) recreational sightseers are highly sensitive to changes in visual quality; (2) public interest and controversy in the area has increased in response to Proposed Project activities; (3) portions of the Area of Analysis are within the viewshed of residential areas; and (4) much of the Klamath River has been designated under the National Wild and Scenic Rivers Act (WSRA).

In terms of distance zones, BLM's VRM methodology classifies public lands as either foreground-middleground, background, or seldom seen. Based on review of the visual quality analysis, all of the Area of Analysis would be located with the foreground-middleground distance zone due to the proximity of views from recreational access sites along the river, campgrounds, key observation points along scenic highways, riverside and/or reservoir communities and residences, rivers, or other viewing locations, which are less than three to five miles away.

While all of the facilities have been classified as Class III as identified above, if BLM's Visual Resource Inventory Matrix (Table 3.19-1) is used the aesthetics Area of Analysis could be classified as VRM Class II, based on Class A distinctive scenic quality of high visual sensitivity as viewed from a foreground/middleground distance zone, from an inventory context. The objective of Class II is "to retain the existing character of the landscape. The level of change to the characteristic landscape should be low. Management activities may be seen, but should not attract the attention of the casual observer. Any changes must repeat the basic elements of form, line, color, and texture found in the predominant natural features of the characteristic landscape" (BLM 1984). If Class II objectives are applied, the changes due to the Proposed Project would be even more beneficial because they will return the areas to a more natural character, and would not change the significance of potential aesthetic impacts discussed in this section.

Table 3.19-1. Visual Resource Inventory Matrix.

Special Areas		Visual Sensitivity						
		High			**Medium**			**Low**
		I	**I**	**I**	**I**	**I**	**I**	**I**
Scenic Quality	**A**	II	II	II	II	II	II	II
	B	II	III	III* / IV*	III	IV	IV	IV
	C	III	IV	IV	IV	IV	IV	IV
		f/m	**b**	**s/s**	**f/m**	**B**	**s/s**	**s/s**
		Distance Zones

Notes:

Highlighted cells indicate visual resource inventory determinations for the affected environment

* If adjacent area is Class III or lower assign Class III, if higher assign Class IV

Key:

b: background

f/m: foreground/middleground

s/s: seldom seen

3.19.2.2 Wild and Scenic Rivers and Scenic Highways/Byways

Klamath River components are part of the National (and state) Wild and Scenic Rivers System because of their free-flowing condition and "outstandingly remarkable" values. According to the WSRA (16 U.S.C. 1271 et. seq.) these outstandingly remarkable values include scenic, recreational, geologic, fish, wildlife historic, cultural or other similar characteristics. These values along designated wild and scenic reaches are protected by both the federal and state WSRA to various degrees, but all designated river segments must maintain at least a generally natural appearance along their waterways. The natural-appearing scenic quality within the more immediate and prominent portions of these rivers is also protected along these WSR segments by the WSRA.

The WSR segment of the Klamath River that could be affected by the Proposed Project include the mainstem of the Klamath River beginning 3,600 feet downstream from Iron Gate Dam and continuing 189 miles downstream to the Pacific Ocean. This WSR segment is recognized for its outstandingly remarkable fisheries. It is classified under the California WSRA as recreational (river segments that are readily accessible by road or railroad, and that may have some development along their shorelines, and may have been impounded or diverted in the past (PRC § 5093.53), with portions of the tributaries classified as scenic and wild.

Scenery within the California Klamath WSR is dominated by natural settings. Its water appearance, anadromous fish and riparian vegetation within a forested river canyon are the primary scenic aspects. Since its designation in 1981, flow regimes have varied moderately in response to water resource competition, government mandated flow requirements and weather within the Klamath Basin. During summer months, fluctuations in the flow regime have typically been caused by water diversions (Van de Water et al. 2006). As described in Section 3.20 *Recreation*, reduced water clarity and discoloration resulting from seasonal algae blooms has impaired the scenic character and recreational opportunities of the Middle and Lower Klamath River (see also Section 3.2 *Water Quality* and Section 3.4 *Phytoplankton and Periphyton*).

In addition, in 1990, BLM found the 5.3-mile section of the Klamath River from the Oregon-California state line to Copco No. 1 Reservoir eligible and suitable for WSR designation. The river segment is free-flowing and possesses outstandingly remarkable scenic, recreational, fish, and wildlife values. This river segment is not a designated WSR and is not protected under the National WSRA and its Section 7(a) requirements. However, agencies are still required within their authorities, to protect this suitable river segment's free-flowing character, water quality, and outstandingly remarkable river values. This segment of the Klamath River is also listed on the Nationwide Rivers Inventory to ensure protection of its river values (NPS 2009).

In addition, there are three Scenic Byways located along the Klamath River and within the Klamath and Six Rivers National Forests. The "State of Jefferson" National Forest Scenic Byway is located primarily on California State Highway 96 (Highway 96) between Shasta River to Happy Camp, and the "Bigfoot" National Forest Scenic Byway is located on Highway 96 from Happy Camp to California State Highway 299 (Highway 299). There is also an "All American Road" as classified by the U.S. Department of Transportation's Federal Highway Administration - the Volcanic Legacy Scenic Byway—which goes from Lassen National Park in California and through the Proposed Project area via Highways 97, 140, and 62 on its way to Crater Lake National Park in Oregon. These byways provide excellent views for sightseers within the Klamath and Six Rivers National Forests and access to numerous other recreational activities (America's National Scenic Byways 2010).

3.19.2.3 Klamath Watershed

Along the northernmost, eastern edge, upstream of the Area of Analysis, the Klamath River borders remnants of central Oregon's Modoc Plateau province. The river flows through a broad, flat valley that gradually transitions to a narrow channel as it crosses the low, rolling ridges of the Cascade Mountains.

The Upper Klamath Basin begins at the headwaters of the Klamath River in south-central Oregon and extends downstream into north-central California. This area includes agricultural lands and the Upper Klamath Basin National Wildlife Refuge Complex, which is comprised of six wildlife refuges and contains the USBR Klamath Irrigation Project. Regionally, a variety of public lands contain notable scenic resources. Table 3.20-1 in Section 3.20.2.1 *Regional Recreation* lists locations within the aesthetics Area of Analysis and surrounding region that offer opportunities for wildlife viewing, sightseeing, leisure driving, photography, and other forms of recreation that benefit from scenic quality.

In the central section of the Upper Klamath Basin, starting upstream of J.C. Boyle Dam, the topography changes dramatically, dropping rapidly into the 1,000-foot-deep upper Klamath River Canyon. The ruggedness of the terrain exemplifies the surrounding landscape, where nearby mountain peaks often reach 5,000 feet in elevation. As the Klamath River passes through the Cascade Mountains, the upper Klamath River Canyon represents a transition from the desert landscape in the east to a mountainous landscape in the west. The steep-walled canyon is the predominant visual element in the region. As it flows through the deep gorge, the river changes from slack, slow-flowing water in the broad, flat valley to a torrent of cascading whitewater. Less than five miles downstream of J.C. Boyle Dam, the canyon and neighboring ridges gradually become flatter and wider as the river flows southwesterly across the state line and into

Copco No. 1 Reservoir. Here, along the Proposed Project's western edge, the topography surrounding Copco No. 1 and Iron Gate reservoirs is open and rolling.

3.19.2.4 Klamath River Key Observation Points

Within the Area of Analysis, PacifiCorp identified eight key observation points in the Hell's Corner Reach (between J.C. Boyle Powerhouse and Copco No. 1 Reservoir), and four downstream from Iron Gate Dam (PacifiCorp 2004a). Many of the reaches have similar characteristics with the aesthetic differences between high flows and low flows varying depending on the individual physical features of each reach (e.g., during low flows, more rocks and vegetation were visible at the river edges than at high flows; in shallower areas, lower flows affected channel depth more greatly.

Figures 3.19-2 and 3.19-3 depict views of the Klamath River from two of the selected key observation points downstream of Iron Gate Dam. Under the range of flows observed, river water continues to inundate the entire channel width. Higher flows exhibit deeper water depth and higher flow velocity. Views of the Klamath River, downstream of the Lower Klamath Project dams and associated facilities, show a free-flowing river with broad channel dimensions. As a result, exposed shoreline margins and riverbed deposits are exposed under a wider range of flow conditions than the upstream sections.

Views of the Klamath River, upstream of the Lower Klamath Project dams and associated facilities (Figures 3.19-4 and 3.19-5), show a free-flowing river with similar surface area dimensions over a range of flows due to the narrower channel. Only the shoreline margins are exposed at lower flows of approximately 350 cfs. During higher flow conditions ranging up toward 2,800 cfs, water extends into adjacent upland vegetation.

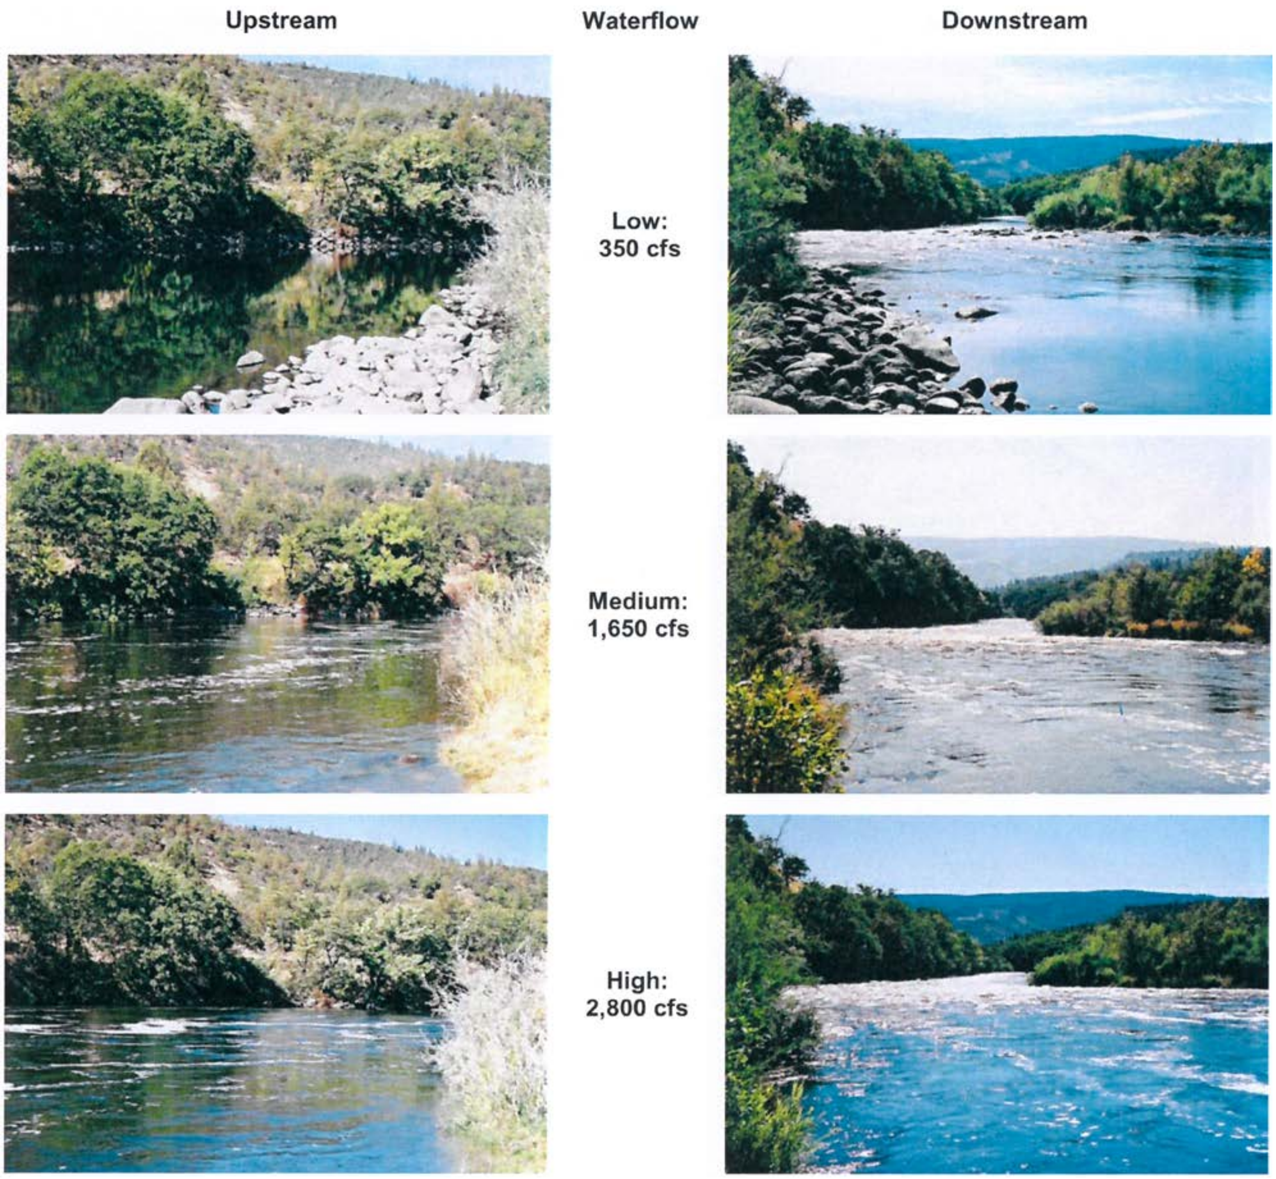

Figure 3.19-4. Views of Klamath River from Stateline Takeout. Source: PacifiCorp 2004a.

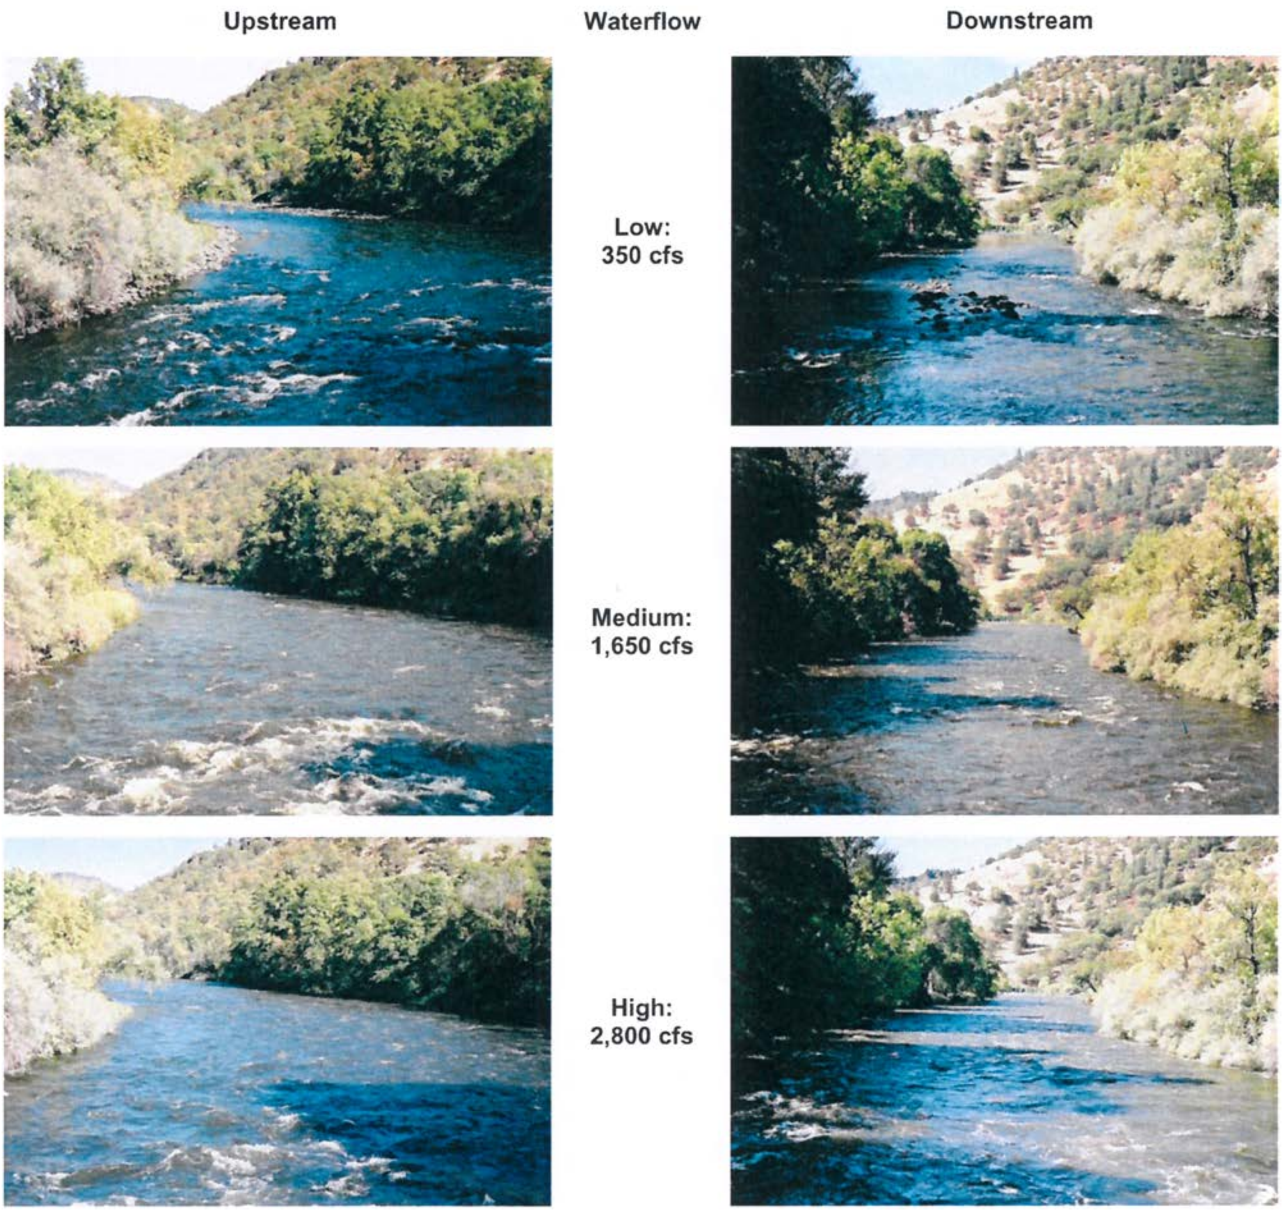

Figure 3.19-5. Views of Klamath River from Fishing Access #5 (Topsy Grade Road). Source: PacifiCorp 2004a.

3.19.2.5 PacifiCorp's Hydroelectric Project Facilities

Reservoirs

PacifiCorp (2004a) described the area landscape from nine key observation points in the vicinity of the reservoirs. All reservoirs were viewed under high pool and low pool conditions. In general, the reported visual observations of the reservoirs indicated that under normal operating conditions, the three reservoirs share the visual characteristics of open expanses of relatively flat water. Also, as described in sections 3.2 *Water Quality* and 3.4 *Phytoplankton and Periphyton*, seasonal algae blooms occur in the reservoirs, typically peaking in late summer to early fall. During particularly intense algal blooms, floating algae mats and scums often appear and concentrate in protected areas or along the shoreline where they are not exposed to wind.

Because the water surface elevations of these reservoirs do not fluctuate substantially, the visual appearance of the landscape does not change considerably over the course of the year. When the water surface is drawn down, limited shoreline material is exposed. However, this limited exposure does not detract from the view shown.

Residences along the Copco No. 1 Reservoir shoreline, of which there are approximately 140, have unobstructed views of the reservoir water surface. The waterbody dominates their views and likely enhances the aesthetic quality of this landscape. Views on Iron Gate Reservoir are similar, however, there are no permanent residences located along this reservoir's shoreline. Viewers are limited to recreationists utilizing the local roads and recreational facilities.

Lower Klamath Project Hydroelectric Facilities in California

PacifiCorp documented the scenic characteristics of the Lower Klamath Project facilities within the aesthetics Area of Analysis at the following seven key observation points (alphanumeric designations refer to key observation point designations and accompanying photographs in the PacifiCorp [2004a] report):

- C3: Copco No. 1 Dam and Powerhouse
- C4: Copco No. 2 Dam
- C6: Copco No. 2 Powerhouse
- C7: Copco Transmission Line
- IG8: Iron Gate Transmission Line
- IG9: Iron Gate Dam and Powerhouse from Iron Gate Fish Hatchery
- IG10: Iron Gate Fish Hatchery and Fish Ladder

In the PacifiCorp (2004a) report, the views of the three facilities from these key observation points were characterized using the BLM VRM system. The report describes each of the three facilities in the context of the BLM VRM classification for the surrounding area. It should be noted that these assessments were done using one single photo from quite close to each facility, which magnifies its influence on the visual landscape. These observations may be summarized by facility as follows:

- **Copco No. 1 Facilities**—Copco No. 1 Dam and Powerhouse were not considered to be consistent with the VRM Class III objectives of the surrounding area. The size and prominence of these facilities were considered to dominate the view from the key observation point. However, the Copco No. 1 transmission line was typically at a distance from the viewing points and would blend into the sky and not obstruct views of other parts of the landscape. Thus, the transmission line was considered to be consistent with VRM Class III objectives.
- **Copco No. 2 Facilities**—Copco No. 2 Powerhouse was not considered to be consistent with the VRM Class III objectives of the surrounding area because of its size and prominence the powerhouse dominates the view from the key observation point. However, although the Copco No. 2 Dam is large, it has been designed with colors and lines that blend with the landscape, and when viewed in isolation, or from a longer distance, could therefore be considered consistent with VRM Class III objectives.

- **Iron Gate Facilities**—The Iron Gate Dam, Powerhouse, and transmission lines were considered to be consistent with the VRM Class III objectives of the surrounding area in a detailed visual evaluation of the project vicinity as summarized in the Final EIS (2007) and documented in the *Land Use, Visual, and Aesthetic Resources Final Technical Report* (PacifiCorp 2004a). Although the dam and powerhouse are large, their colors and lines blend with the landscape. Similarly, the transmission line was typically at a distance from the viewing points and would blend into the sky and not obstruct views of other parts of the landscape. In instances where the support poles of the transmission lines were prominent, it was only for a short time while a viewer walks or drives by.

Figures 3.19-6 through 3.19-8 depict views of several project features located at Copco No. 1 and Iron Gate dams and associated facilities. The reservoir waterbodies are the dominant visual feature from both distant views and from shoreline locations.

Views of Copco No. 1 and Iron Gate dams are limited by topographic features that obstruct more distant views of these facilities. Views of Copco No. 1 Dam are limited to approximately 0.25 river miles downstream. Views are often blocked by local topography and the meandering course of the river. Views of Copco No. 2 Dam can also be limited because of local topography, the meandering course of the river, and vegetation. Copco No. 2 Dam can only be seen from a distance of approximately 500 feet due to these obstructions. Iron Gate Dam can be seen from a distance of approximately one mile at several residences located downstream of this facility. Views of the dam are partially obstructed by local topographic features.

3.19.3 Significance Criteria

Criteria for determining significant impacts on aesthetics are based upon Appendix G of the CEQA Guidelines (California Code of Regulations, title 14, section 15000 et seq.) and best professional judgement. Impacts are considered significant if the Proposed Project would:

- Cause a landscape to be inconsistent with the following Class III VRM objectives (BLM 1984): (1) the existing character of the landscape is partially retained; (2) the level of change to the characteristic landscape is moderate; (3) management activities may attract attention but would not dominate the view of the casual observer; and (4) changes would repeat the basic elements found in the predominant natural features of the characteristic landscape.
- Result in a loss of or substantial adverse change to scenic elements of a landscape (including, but not limited to, landforms, trees, and rock outcroppings) as viewed from a vista point, community, recreation site area, trail, scenic highway, or designated wild and scenic river reach.
- Substantially degrade the existing visual character or quality of the site and its surroundings.
- Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area.

3.19.4 Impact Analysis Approach

Aesthetic resources are generally not as amenable to simple quantification as other environmental resources considered under CEQA. Accordingly, the analysis of aesthetic resources in this EIR is primarily qualitative and acknowledges a degree of subjectivity, where one person's idea of what is aesthetically pleasing may not match another person's idea. However, certain guideposts or aesthetic goals can be used to guide an inquiry into what aesthetic changes many, or even most, viewers would find appealing or not. For these cases, the BLM's Visual Resource Management (VRM) methodology was used as guidance, since PacifiCorp previously had used this approach for a visual analysis of Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities (see also Section 3.19.2.1 *PacifiCorp Analysis and Bureau of Land Management Methodology*).

The Area of Analysis for aesthetics experiences four distinct seasons, within which Klamath River flows, reservoir water levels, and the appearance of vegetation vary. The detailed visual evaluation of the Project vicinity as summarized in the 2007 FERC EIS (FERC 2007) and documented in the *Land Use, Visual, and Aesthetic Resources Final Technical Report* (PacifiCorp 2004a) was used to characterize the Area of Analysis for aesthetics because the PacifiCorp (2004a) report included viewing the key observation points during different seasons and at different water levels over an extended time period. The PacifiCorp (2004a) report provides an assessment of a baseline measure of the scenic appeal of the aesthetics Area of Analysis through a Scenic Quality Evaluation consistent with the BLM inventory process. Scenic quality and sensitivity information were delineated and/or inventoried and documented spatially, in a manner that follows physical features in the landscape (PacifiCorp 2004a).

To evaluate the significance of potential impacts to scenic resources, the key observation points were reviewed to determine which scenic resources would be changed by the Proposed Project, with potential changes identified in terms of degree of contrast, relative size or scale, distance, visibility, and magnitude. Although the contrast rating forms provided in the BLM VRM process were not filled out for this EIR, the same basic steps were used to consider potential impacts of the Proposed Project. These steps include describing the characteristics of the existing landscape, as well as those of the Proposed Project, and assessing the contrast between the two. The scenic quality impact analysis for this EIR is built on the general premise that removal of human-made improvements and restoration of the area to more natural conditions (see Section 2.7.4 *Restoration Within the Reservoir Footprint*) would have overall beneficial effects on aesthetics for Class III visual resources, in light of the aesthetic resources significance criteria (see Section 3.19.3 *Significance Criteria*).

Changes in scenic quality were identified and evaluated by establishing a level of contrast (i.e., no effect [visual contrast is imperceptible], weak, moderate, and strong [contrast caused by the action would be substantial]) considering effects on form, line, color, texture, and comparing to approved VRM objectives for Class III areas. Light pollution effects that could be generated during construction were also considered.

Note that significance in visual contrast as defined under the BLM VRM system is not the same as a significance determination for the purposes of this EIR. The BLM VRM process and objectives are used as guidance for assessing the impacts of the Proposed Project, whereas the criteria used for significance determination for this EIR's impact analyses are guided by CEQA and professional judgement based on the significance criteria listed in Section 3.19.3 *Significance Criteria*.

This EIR analysis categorizes potential visual impacts associated with the project into five groups: (1) loss of open water vistas; (2) changes to the river channel, flows and water quality; (3) reservoir drawdown and restoration; (4) removal of the dams and associated facilities; and (5) construction impacts. Short-term construction-related impacts would occur during the deconstruction period, including reservoir drawdown and short-term restoration activities (zero to five years), while long-term impacts would include restoration activities beyond approximately five years following dam removal.

Because the Area of Analysis does not extend downstream of the confluence with the Shasta River (RM 179.5), the review of local plans and policies for aesthetics focuses on Siskiyou County. The following policies and objectives from the Siskiyou General Plan were reviewed and considered relevant to the Proposed Project: Conservation Element (1973) Objective F, and Scenic Highways Element (1975) Objectives 3 and 4. These objectives generally promote aesthetic characteristics of the land to benefit residents of the county and state, as well as tourists. The issues addressed by the aforementioned Siskiyou General Plan objectives, including revegetation of cut-and-fill slopes, are inherently addressed in the impact analyses presented in Section 3.19.5 *[Aesthetics] Potential Impacts and Mitigation*.

3.19.5 Potential Impacts and Mitigation

The Proposed Project involves removal of three dams in California (Copco No. 1, Copco No. 2, Iron Gate) and essentially all appurtenant features associated with the dams and related facilities, with the exception of buried features (Section 2.7 *Proposed Project*).

The Proposed Project includes reservoir drawdown prior to removal of the dams (Section 2.7 *Proposed Project*), which would expose the formerly inundated areas to view. The proposed reservoir restoration activities include revegetating the newly exposed reservoir areas with native species through hydroseeding and manual planting. Monitoring and adaptive management will be used to ensure affected areas are appropriately revegetated. Management of invasive exotic vegetation could include manual weed extraction, soil solarization (covering of ground areas with black visqueen), tilling, and use of herbicides (Section 2.7.4 *Restoration Within the Reservoir Footprint* and Appendix B: *Definite Plan*).

Under the Proposed Project, the hard lines of the dams and large expanses of water in the reservoirs would be changed to a more natural setting with river canyon landforms and vegetation framing a continuous river. Due to the surrounding mountainous topography, the dams themselves are not visible from more than one mile away. However, the long-term scenic change of removing the large expanses of water in the reservoirs would be visible for a very long distance around the prior reservoir locations and at most reservoir key observation points. Figures 2.7-5 and 2.7-6 show aerial photos of the existing reservoirs with an overlay of existing reservoir bathymetry, including the historical river channels. The historical river channels represent the projected long-term extent of the Klamath River following implementation of the Proposed Project. Immediately following reservoir drawdown, and until revegetation efforts are complete, areas within the reservoir footprints would appear barren and/or sparsely vegetated.

The existing water supply pipeline for the City of Yreka passes under the upstream end of Iron Gate Reservoir (Figure 2.7-17) and would be relocated prior to reservoir drawdown to prevent damage from increased water velocities and scour once the reservoir has been drawn down. Three options for modifying the pipeline are being explored. These include: (1) micro-tunneled crossing, (2) aerial crossing on a new utility bridge, and (3) aerial crossing on Daggett Road bridge (see also Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*). Also, several bridges within the aesthetics Area of Analysis would be replaced to address structural deficiencies and/or to raise them above the new 100-year flood elevation. The Proposed Project includes the complete removal of eight recreation sites (Table 2.7-14), including removal of structures, concrete, pavement, and most other existing recreation facilities, such as campgrounds and boat ramps that are currently located on the reservoir banks, and regrading and revegetating associated parking areas and trails (see also Section 2.7.8.3 *Recreation Facilities Management*). The removed recreation sites would be planted with a native seed mix as described in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*). Recreational facilities at Fall Creek and Jenny Creek Day-Use Areas at Iron Gate Reservoir, and the Iron Gate Fish Hatchery Day-Use Area, would remain and may be upgraded or enhanced (Table 2.7-15). Future enhancements at these locations would depend on the future ownership of Parcel B lands, where these three recreational facilities are located.

Aesthetic changes resulting from the aforementioned actions under the Proposed Project would occur in the short term (up to five years) and/or the long-term (more than five years). These aesthetic changes include the following:

- Long-term loss of open water vistas/views;
- Short-term and long-term changes in flows and channel morphology;

- Short-term and long-term changes in visual water quality, including increased turbidity and reduced algal blooms;
- Short-term bare/unvegetated area under former reservoirs after reservoir drawdown;
- Long-term visual changes due to removal of Lower Klamath Project dams and associated facilities, and improvements to or construction of new infrastructure (e.g., bridges, recreation facilities);
- Short-term visual impacts from stockpiles, lighting, and equipment.

Each of these potential aesthetic changes are analyzed below.

Potential Impact 3.19-1 Loss of Open Water Vistas.
The primary aesthetics Area of Analysis is rural. There are no major highways or towns within the viewshed of the reservoirs. However, there is a substantial amount of public land and public access to the area. While there is only one officially designated scenic overlook or vista point, recreational sites within the aesthetics Area of Analysis include the following:

- Nine developed recreation sites along the river corridor between the Oregon-California state line and Copco No. 1 Reservoir (all fishing access sites except for the “Stateline Take-out”);
- Two developed and two dispersed recreation sites at Copco No. 1 Reservoir;
- Eight developed and five dispersed recreation sites at Iron Gate Reservoir;
- Two developed recreation sites just downstream of Iron Gate Dam.

In 2001 and 2002, the California Lower Klamath Project reservoir recreation sites accounted for an average of 61,240 recreation days (defined as one visitor to a recreation area for any reason in a 24-hour period), and the river recreation sites accounted for an average of 12,500 recreation days, (PacifiCorp 2004), not including estimated angler days. In addition to the public land and recreational sites, there are also approximately 140 residences located around Copco No. 1 Reservoir, the majority of which are vacation homes. Also, several rural and local roads, mostly unpaved, provide access within and around the primary aesthetics Area of Analysis. Most of the nearby residents and the users of the recreational facilities associated with Iron Gate and Copco No. 1 reservoirs are there to enjoy activities on those reservoirs. Part of that experience includes the scenic, open water vistas of the area. (Potential impacts to recreational opportunities are discussed in further detail in Section 3.20 *Recreation*)

Sightseeing is a popular activity within the aesthetics primary Area of Analysis, with 39 percent of all respondents to a recreational survey of the area participating in that activity (PacifiCorp 2004b). However, sightseeing was less popular around the Lower Klamath Project dams and associated facilities, with only 30 percent and 32 percent of visitors participating in that activity at Copco No. 1 Reservoir and Iron Gate Reservoir, respectively (PacifiCorp 2004b). Conversely, 46 percent of respondents participated in sightseeing within the Hell's Corner River reach, between Copco No. 1 and J.C. Boyle reservoirs (which is in the secondary Area of Analysis and partly in Oregon), indicating that the river itself provides a more important visual resource for visitors than the reservoirs. Boat fishing, camping and resting/relaxing were the three most popular activities at both Copco No. 1 and Iron Gate reservoirs (PacifiCorp 2004b).

Long-term scenic vistas within the primary Area of Analysis would not necessarily be lost as a result of the Proposed Project, but they would be altered. Open water and lake vistas would be lost in favor of more natural river, canyon, and valley vistas. While not all people prefer a more natural, riverine setting, the results of prior surveys (PacifiCorp 2004b) suggest that in general the free-flowing river is preferred to the flatwater reservoir views. For those recreationalists that prefer lake and open water scenes, there are numerous other lakes and reservoirs in the region. In Siskiyou County there is vehicular access to more than 30 boatable lakes. There are another 56 boatable lakes in Jackson and Klamath counties to the north in Oregon (PacifiCorp 2004b). The recreation facilities within the aesthetics Area of Analysis were the primary destination of 54 percent of the recreation survey respondents (PacifiCorp 2004b), indicating that many users are just passing through and/or are visiting other destinations as well, reducing the severity of the impact of the loss of the Lower Klamath Project reservoirs.

Some of the owners of the residences located around Copco No. 1 Reservoir have expressed concerns about the loss of lake views from their property. Presumably those homeowners, whether permanent residents or sporadic users, chose to purchase or build those residences based on proximity to the reservoir. Because of the public access and recreational facilities, the Proposed Project would affect the environment of persons in general, not just individual property owners.

While the change from nearby flatwater reservoir views to further-away riverine views would presumably be considered a negative change for the owners and users of residences located around Copco No. 1 Reservoir, based on available survey results the change would not substantially degrade the existing visual quality of the primary Area of Analysis for the viewing public as a whole. Furthermore, although the reservoirs could be considered scenic resources in their own right, they are in general not consistent with the Class III VRM designation, because their creation changed the character of the natural landscape and they dominate the view from many public view locations. In addition, the Copco No. 1 and Iron Gate reservoirs often appear in a visually degraded condition due to summer algal blooms, which negatively impact a majority of recreational survey respondents (see Potential Impact 3.19-3). Once the river is restored, open water vistas would be replaced by a different, more natural setting and associated vistas, consistent with the VRM classification. Therefore, the long-term change from open water lake vistas to river, canyon, and valley vistas within the primary Area of Analysis would be less than significant.

Significance
No significant impact

Potential Impact 3.19-2 Changes in Flows and Channel Morphology.
The aesthetics primary Area of Analysis (i.e., within the viewshed of the Lower Klamath Project reservoirs, which includes the proposed Limits of Work in California, see Figure 3.19-1), is not visible from any of the nearby designated scenic byways, highways, or the WSR sections of the river. However, the Proposed Project could affect flows and channel morphology within the WSR sections that are associated with the aesthetics secondary Area of Analysis, which could affect scenic elements of the landscape as viewed from a vista point, community, recreation site area, trail, scenic highway, or river vantage point within the designated WSR sections.

Within the aesthetics secondary Area of Analysis, the stretch of the Klamath River from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir has been determined to be eligible for listing under the WSRA. In addition, the mainstem Klamath River from 3,600 feet below Iron Gate Dam downstream to the Klamath River Estuary has been designated as "Recreational" under the WSRA. There are a number of fishing access sites along the Klamath River from the California-Oregon state line to the upstream end of Copco No. 1 Reservoir, as well as downstream of Iron Gate Dam. The river is also visible from several roadways that run along the channel within the Area of Analysis.

Although the portion of the Hydroelectric Reach between Copco No. 1 Reservoir and the Oregon-California state line would not be impacted by any of the decommissioning or restoration activities occurring in California, flow characteristics within this reach (which is within the aesthetics secondary Area of Analysis) would be impacted by the removal of the J.C. Boyle Dam approximately 15 river miles upstream. Similarly, flow characteristics and channel morphology would change in the WSR segment downstream of Iron Gate Dam to the confluence with the Shasta River (RM 179.5).

Potential changes to flow characteristics include the timing, duration and magnitude of flows. These changes can impact the physical structure (morphology) of the river channel and the riparian vegetation. Much of the channel morphology within the secondary aesthetics Area of Analysis closest to the hydroelectric facilities is bedrock-controlled, which means flows do not have a significant influence on the channel configuration (Philip Williams & Associates, Ltd. [PWA] 2009), though there may be some minor changes to small alluvial floodplains. Comparing the annual hydrographs[168] from USGS stream gages on the Klamath River upstream and downstream of the Lower Klamath Project, similar patterns can be seen across years (USBR 2011). The primary flow-related effects of the Lower Klamath Project dams are: (1) dams create unnatural “steps” in the hydrograph due to controlled releases during the dry season, (2) dams generate somewhat higher flows in the late summer and lower flows in the late fall than what would occur naturally, and (3) dams allow attenuation of large storm events during the wet season. Though storm flows are somewhat attenuated by the dams, the impacts of that attenuation is lessened by non-attenuated tributary inputs; the hydrograph effects can still be discerned at the Seiad Gage (approximately RM 132.7) but are barely discernable at the Orleans Gage (approximately RM 58.9) (USBR 2011). Note that these hydrograph patterns would not be readily noticeable to the casual observer along the Klamath River and since they are outside of the aesthetics secondary Area of Analysis, they are not discussed further.

Overall, hydrologic modeling (see Section 3.6 *Flood Hydrology*) indicates that the flows in the Klamath River would not be expected to be substantially different from current conditions downstream of the confluence with the Shasta River (RM 179.5) due to tributary inputs. Water flow is expected to remain visually similar to current flow levels, and the existing river channel configuration patterns would likely be continued. Some aggradation of the channel immediately downstream of the dams is expected with the return of a natural sediment load. However, this would represent a return to natural

[168] A hydrograph is a graph depicting the rate of flow (discharge) versus time past a specific point in a river, channel, or conduit carrying flow. An annual hydrograph depicts rate of flow (discharge) over a 365-day period and often uses a water year designation (i.e., October 1 to September 30).

conditions and is considered desirable. The changes to flow characteristics within the secondary aesthetics Area of Analysis resulting from the Proposed Project would not result in a loss of or substantial adverse change to scenic elements of the landscape (including, but not limited to, landforms, trees, and rock outcroppings) as viewed from a vista point, community, recreation site area, trail, scenic highway, or designated WSR as compared with current conditions, and therefore, there would be no impact. See Section 3.6 *Flood Hydrology* for a discussion of potential impacts due to flood hydrology.

Significance
No significant impact

Potential Impact 3.19-3 Changes in Visual Water Quality.
There would be visible changes in downstream water quality resulting from the Proposed Project, including short-term increases in turbidity in the Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary during reservoir drawdown, as well as long-term decreases in summer algal blooms after dam removal.

Short-term Changes in Visual Water Quality
Due to their general lack of cohesion, the majority of the accumulated sediment deposits currently in the reservoirs would be eroded during reservoir drawdown (Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). The erosion of reservoir sediment deposits would result in short-term increases in turbidity and reduced clarity within and downstream of the Lower Klamath Project for several weeks to months during the reservoir drawdown period. Sediment jetting would be used at selected locations within Copco No. 1 and Iron Gate reservoirs to maximize erosion of accumulated sediments during drawdown. Revegetation efforts would occur immediately following drawdown, minimizing the potential for prolonged increases in turbidity due to erosion of sediment deposits remaining in the reservoir footprints (Section 2.7.4 *Restoration Within the Reservoir Footprint*).

Suspended sediment concentrations (and turbidity) are expected to return to background concentrations by the end of summer during dam removal year 1, with most of the erosion occurring by March 15, regardless of the water year type. The amount of the remaining sediment deposits in the active channel after drawdown would vary based on the hydrologic conditions, with a wet year eroding more than a dry year and the KRRC's proposal for sediment jetting increasing the potential that sediments on the two-year floodplain would be eroded to the extent possible (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). The short-term pulse of sediment could also cause some deposition in eddies and slack water pools until subsequent annual flood events move the sediment to the ocean. Depending on the severity of the color change and volume of the deposits, this could represent a weak to moderate contrast from the existing conditions, as further described in the paragraph below. Impacts would decrease the farther downstream the viewing point is from the dams.

The primary drawdown period for the J.C. Boyle Dam, which is upstream of the aesthetics Area of Analysis, would occur between January 1 and January 31 of the drawdown year. Drawdown of Copco No. 1 Reservoir would likely commence on November 1 of the year prior to drawdown, but no significant sediment release is expected until after January 1. Drawdown would be completed by March 15 of the drawdown year. Drawdown of Iron Gate Reservoir would also start January 1, with water levels controlled through the spring (Section 2.7 *Proposed Project*). Copco No. 2

Dam does not impound a significant volume of sediment, and drawdown of this reservoir would occur after Copco No. 1 Reservoir is drained to grade. Due to naturally high levels of turbidity in the river during winter flows, increased turbidity from the Proposed Project would not be noticeable for most of the drawdown period. In addition, impacts would occur for a period of less than six months. Therefore, visual impacts from increased turbidity and reduced clarity related to sediment discharges would be less than significant.

Long-term Changes in Visual Water Quality
Existing summer algal blooms in the Lower Klamath Project reservoirs adversely impact water quality, salmonids, recreation, and aesthetics (Section 3.2 *Water Quality*, Section 3.3 *Aquatic Resources*, Section 3.4 *Phytoplankton and Periphyton*). More than 66 percent of recreational survey respondents indicated that water quality detracted from their experience at least a little at both Copco No. 1 and Iron Gate reservoirs; 91 percent indicated the same concern about the Hell's Corner Reach. Algae was the primary water quality concern cited by respondents (PacifiCorp 2004b). The Proposed Project would reduce the occurrence and severity of algal blooms (Potential Impact 3.4-2). The removal of the dams is expected to reduce the river's summer algae concentrations, which result in changes to both water clarity and coloration. Improvements in water quality, such as water clarity or fish viewing opportunities, could result in some improvement in scenic resources. These improvements would be more noticeable from on-river and riverside viewpoints, and much less noticeable from river canyon roadway and community viewpoints. These improvements to water quality would be beneficial.

Significance
No significant impact from short-term changes in water quality including increased turbidity and reduced clarity

Beneficial due to long-term changes in visual water quality from reduced algal blooms

Potential Impact 3.19-4 Visual changes resulting from reservoir drawdown and restoration including temporarily bare/unvegetated banks.
Substantial areas of bare sediment and rock would be exposed in previously inundated areas after reservoir drawdown and dam removal. Much of these areas would remain relatively bare, consisting mostly of grass and small forbs, during the summer and first wet season after dam removal, while larger vegetation becomes reestablished. Because much of the sediment would be eroded during reservoir drawdown, and because the river is bedrock-controlled, the river channel would not appear to be to significantly entrenched or flowing through mud, but rather, is expected to appear very similar to conditions before the river was impounded, though lacking in vegetation. Some slumping of the remaining sediment is anticipated, followed by drying, cracking, and hardening of the sediment prior to the establishment of vegetation. Existing wetland vegetation on the reservoir shorelines may also die off, though some of it would be relocated to repopulate the newly formed and exposed banks (Appendix B: *Definite Plan – Appendix H*).

As proposed in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*), manual revegetation would occur quickly following reservoir drawdown while the sediment deposits are still wet. In the short term, all exposed areas would be hydroseeded. Woody vegetation would also be planted in the year immediately following drawdown. Planting areas would be divided into zones (e.g., upland, riparian) that would have different species composition. Based on monitoring results, reseeding and replanting would occur again, as needed, for the following five years. Monitoring, revegetation, and invasive species control would occur annually until vegetation is reestablished and reservoir management goals are met (Appendix B: *Definite Plan – Appendix H*).

Until the restoration is complete, some areas could appear barren and/or sparsely vegetated. In addition, some tree-dominated wet areas that are currently near the reservoir edges may experience die-offs, but these areas account for less than 10 percent of the shoreline areas (see Potential Impact 3.5-22 and Figures 3.5-4 and 3.5-5). Revegetation of herbaceous species in barren and/or sparsely vegetated areas is anticipated to be achieved in the short term (from less than one to three years). However, it should be noted that this is not necessarily consistent with restoration of natural-appearing vegetation patterns below and above the reservoir line. Natural-appearing mature vegetation patterns with woody riparian vegetation may require 10 to over 50 years to develop. Although the condition is considered temporary, some adverse scenery impacts would be extensive and long-term, perhaps requiring 30 years for the river corridor habitats to fully recover from dam removal (PWA 2009). However, much of the aesthetics primary Area of Analysis is grassland, which would revegetate rapidly (from less than one to three years). Woody vegetation would begin to grow and add variability to the landscape within a few years, decreasing the contrast with undisturbed areas over time.

Based upon the proposed Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*), the aesthetics primary Area of Analysis would be in a visible state of transition for four to five years, followed by several more years where contrast from adjacent natural woodlands, where they exist, would be evident. The exposure of previously inundated areas would be considered a moderate contrast from the existing condition under the VRM rating system, because it would attract attention and dominate the landscape encompassing a large area surrounding the river. It would likely be visible from various key observation points around each of the existing reservoirs. However, much of the vegetation around the reservoirs is grassland, which would have less contrast with the restoration areas. In addition, a moderate contrast is still consistent with the Class III objectives. It is expected that within five years, the contrast would be moderate or less.

Therefore, while aesthetic impacts due to barren areas within the reservoir footprints would be significant and unavoidable in the short term until vegetation in previously inundated areas has established, the long-term visible contrast from adjacent natural woodlands, where they exist, would be less than significant.

Significance

Significant and unavoidable in the short term due to reservoir drawdown

No significant impact in the long term due to reservoir drawdown

Potential Impact 3.19-5 Visual changes resulting from the removal of Lower Klamath Project dams and associated facilities and improvements to or construction of new infrastructure.

Demolition Impacts

Under existing conditions, many of the Lower Klamath Project facilities do not blend with the natural landscape and can dominate views due to their form, line, color, size, or locations, particularly those that appear taller from a distance than other natural features. Because, the Lower Klamath Project facilities are inconsistent with the VRM classification for the surrounding area, their removal would result in a landscape that would appear more similar to the surrounding characteristic natural landscape. Figures 3.19-9 and 3.19-11 show photo-simulations of the removal of Iron Gate Dam and Copco No. 1 Dam, respectively. As discussed above, the dams themselves are generally not visible for any scenic highway and the topography of the area makes the dams themselves generally not visible from most vantage points. Accordingly, any dam-related landscape disturbances that are not fully restored to natural conditions by revegetation do not have the potential to cause significant impacts. The aesthetic impacts of removing the Lower Klamath Project dam complexes would be beneficial.

Some of the Lower Klamath Project facilities are considered to be historic structures (FERC 2007), including the Copco No. 1 Powerhouse and Dam; Copco No. 2 Powerhouse; and, the Copco No. 2 wooden stave penstock (see also Table 4.3-1, Table 4.3-3, and Table 4.3-5). However, these particular structures are not visible from any scenic highways or river sections. Potential impacts to historic resources are discussed in more detail in Section 3.12.5 *[Historical Resources and Tribal Cultural Resources] Potential Impacts and Mitigation Measures* but, for purposes of potential impacts to aesthetics, removal of these structures will have no impact.

Improvements/New Recreation Facilities

The Proposed Project includes replacement of the 24-inch diameter water supply pipeline for the City of Yreka, which crosses under the Klamath River near the upstream end of Iron Gate Reservoir. There are a number of residential, commercial, and industrial developments in the vicinity of the City of Yreka water supply pipeline (see Section 2.7.7 *City of Yreka Water Supply Pipeline Relocation*). In addition, Daggett Road Bridge is located approximately 2,000 feet upstream of the current pipeline. Due to the other development nearby, a new bridge or aerial pipeline would be seen as a new feature but would not conflict with or degrade the existing visual quality or character of the site or its surroundings. The aesthetic impact would be less than significant.

In addition, at least six bridges would need to be replaced due to structural deficiencies and/or in order to raise them above the new 100-year flood elevation. There are also culverts and roads that would need to be upgraded with new erosion and drainage control improvements (Appendix B: *Definite Plan*). However, these improvements would result in only minor visual changes to existing structures. New bridges would be built in the same general location as the ones being removed and would be sized and oriented similarly. Associated construction activities would be small-scale and temporary, consistent with normal road and infrastructure maintenance activities. Therefore, they would not degrade the existing visual character of the sites or their surroundings and the impact is less than significant.

The Proposed Project also includes removal of eight recreational facilities on Copco No. 1 and Iron Gate reservoirs and modification of three other facilities. In addition, KRRC has developed a Draft Recreation Plan (Appendix B: *Definite Plan – Appendix Q*) that seeks to identify recreation opportunities, in coordination with stakeholders, that would offset the removal of reservoir recreation opportunities and the reduction in whitewater boating days associated with the Proposed Project. New river-based opportunities may include: (a) new routes and roads for river access; (b) two small to medium river recreation facilities that would accommodate 20 campsites, day use amenities, and access to the river for fishing and boating; and (c) a new trail between J.C. Boyle Dam and the Iron Gate Fish Hatchery (see also Section 2.7.8.3 *Recreation Facilities Management*).

The areas in which recreation facilities that currently exist but are proposed to be removed are located will be restored through regrading and revegetating those areas, which would minimize aesthetic impacts. Construction of new facilities could have long-term aesthetic impacts depending on the final design and location of the new facilities. New recreation facilities are anticipated to be modest in size and spread throughout the Primary Area of Analysis. Therefore, they would have minimal potential to be inconsistent with the aforementioned aesthetics significance criteria. In addition, a Draft Recreation Plan will be developed by KRRC working with appropriate agencies through the FERC process, and KRRC also proposes that KRRC and the appropriate state and local agencies work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference to licensees to be 'good citizens' of the communities in which the project area is located and thus to comply, where possible, with state and local requirements. With these expected processes and opportunities for public and/or agency input, it is unlikely that new recreation facilities will be constructed that are inconsistent with the aesthetics significance criteria; however, overseeing development and implementation of terms and conditions relating to aesthetics of new recreation facilities does not fall within the scope of the State Water Board's water quality certification authority. Because the State Water Board cannot ensure implementation of measures in the Final Restoration Plan that would minimize potential aesthetic impacts, the visual impacts of new recreation facilities is considered in this Draft EIR as significant and unavoidable.

Significance

No impact in the long term due to removal of the Lower Klamath Project dams and associated facilities

No significant impact in the long term due to improvements to and construction of new infrastructure

Significant and unavoidable in the long term for new recreation facilities

Note that the residence shown in the foreground would also be removed under the Proposed Project Source: 2012 KHSA EIS/EIR.

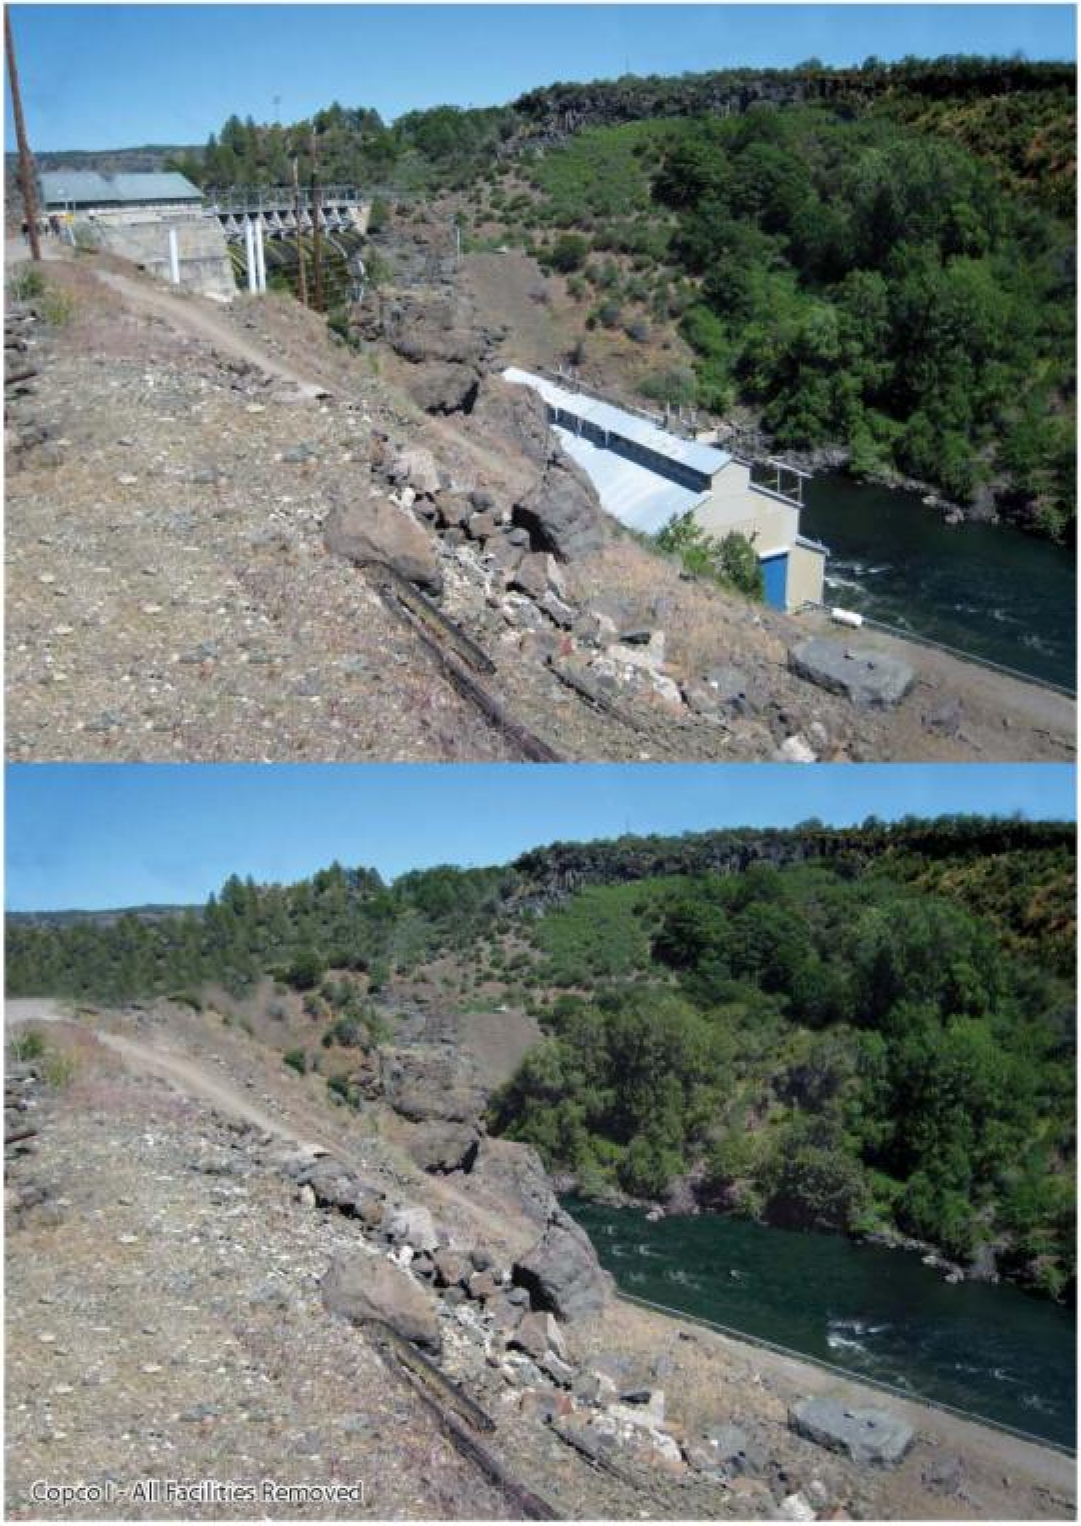

Figure 3.19-10. Copco No. 1 Dam Before Removal (top) and a Simulation of what the Facility Could Look Like After Full Removal (bottom) Except for Landform/Vegetation Restoration Details Were Not Known at the Time of Simulation. Source: 2012 KHSA EIS/EIR.

Potential Impact 3.19-6 Short-term visual impacts of construction activities/equipment.

Removal of the Lower Klamath Project dams and associated facilities would be completed in stages over one year, with primary deconstruction activities occurring between May and September (Table 2.7-1). During the deconstruction, the aesthetics primary Area of Analysis would have large construction vehicles and equipment, temporary structures (e.g., trailers, portable toilets, security fencing, temporary power supply, fueling stations), temporary access roads, equipment storage areas, material stockpiles, piles of demolition materials (rock, concrete, steel), and other common construction items that would detract from the natural surroundings. Proposed construction activities are anticipated to range from weak (the element can be seen but does not attract attention) to strong (the element demands attention, would not be overlooked and dominates the landscape) contrasts, depending on the amount of vehicles, equipment, and materials in any given area. During ongoing construction activities, portions of the primary Area of Analysis near those activities would be inconsistent with the applicable VRM classification. Some scenic resources, such as trees, rocks, and vegetation in the immediate vicinity of the dams would need to be removed but areas will in general be restored to a natural appearance, including through revegetation.

During construction some material stockpiling areas may be visible but may not stand out because the color and form of the materials may blend in to the surrounding landscape. However, in most instances temporary stockpiling of dam fill materials, along with larger vehicles and construction equipment, would cause a moderate to strong contrast as the color and form are anticipated to stand out substantially from the existing landscape. Stockpile areas and most equipment will not be readily visible from most key observation points. In addition, after construction, all vehicles, equipment, and stockpiles would be removed and the area would be restored to relatively natural conditions (regraded, covered with topsoil and hydroseeded). There will be no long-term visual impacts from construction activities.

Dust emissions from dam removal activities may also temporarily impact views and enjoyment of the river. The majority of fugitive dust generally settles out of the atmosphere within 300 feet of the source, with larger particles traveling less distance and smaller particles traveling a longer distance (USEPA 1995). Because the recreational facilities that would be impacted by construction and demolition activities would be closed, and most dust settles quickly, aesthetic impacts from fugitive dust would be minimal and less than significant.

The Proposed Project involves the replacement of the City of Yreka water pipeline where it crosses the Klamath River. In addition, at least six bridges would need to be replaced due to structural deficiencies and/or in order to raise them above the new 100-year flood elevation. There are also culverts and roads that would need to be upgraded with new erosion and drainage control improvements (Appendix B: *Definite Plan*). The Proposed Project also involves removal of eight recreational facilities on Copco No. 1 and Iron Gate Reservoirs and modification of three other facilities. In addition, KRRC has developed a Draft Recreation Plan (Appendix B: *Definite Plan – Appendix Q*) that may result in construction of new recreation facilities. Construction activities associated with these portions of the Proposed Project would be small-scale and temporary, consistent with normal road and infrastructure maintenance activities and small construction projects. Construction activities and equipment would be seen during construction but would be temporary and would occur in already heavily disturbed areas. Therefore, they would not degrade the existing visual character of the sites or their surroundings. Similar to the other short-term potential visual impacts from construction this is considered less than significant.

Overall, because the construction activities would occur over a period of less than a year and during that time most nearby recreational facilities would be closed, the activities would not be visible to a substantial number of people, in addition to generally not being visible from any scenic vista. Furthermore, the immediate vicinities of the dams and most other construction activities are already heavily disturbed and the long term impacts will be beneficial. The short term visual impacts from construction activities are considered less than significant.

Significance
No significant impact due to construction activities

Potential Impact 3.19-7 The Project's construction or security lighting could result in new sources of substantial light or glare that would adversely affect nighttime views in the area.
Temporary lighting would be erected for nighttime construction activities during dam demolition, and security lighting might be required during deconstruction. During peak construction periods (April through November of dam removal year 2, Table 2.7-8), nighttime construction activities could occur regularly. Temporary lighting could cause glare that would adversely affect nighttime views in the area, particularly for overnight visitors and residents near the Copco No. 1 Reservoir. Because the area is rural with very little existing night lighting, and because construction lighting would be relatively intense, the impact on nighttime views would be a significant impact that would occur temporarily, until dam deconstruction was complete. No new permanent sources of light or glare would result from the Proposed Project.

The Proposed Project currently does not include measures that would reduce impacts to nighttime views cause by temporary construction lighting. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements. It would be appropriate for any such terms to include measures to reduce nighttime light and glare on surrounding residences during construction. However, overseeing development and implementation of measures to reduce impacts to nighttime views does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable good citizen agreements that will be finalized and implemented, at this time these agreements are not finalized and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the final FERC terms and conditions for the Proposed Project would reduce potential impacts to nighttime views to less than significant, because the State Water Board cannot ensure implementation of any associated measures, it is analyzing the impact in this Draft EIR as significant and unavoidable.

Significance
Significant and unavoidable

3.20 Recreation

This section describes the environmental setting for recreational resources, as well as potential environmental impacts and associated mitigation measures under the Proposed Project. Water quality, aquatic resources, and phytoplankton and periphyton[169] are discussed in this section only in terms of their relationship to recreation opportunities. For a detailed discussion of these resources, see Section 3.2 *Water Quality*, Section 3.3 *Aquatic Resources*, and Section 3.4 *Phytoplankton and Periphyton* of this EIR. Potential impacts to wild and scenic river segments are discussed in this section, as well as in Section 3.14 *Land Use and Planning*.

As part of the NOP scoping process, the State Water Board received several comments regarding potential recreation impacts due to Lower Klamath Project dam removal. Several commenters noted that reservoir recreational activities, including fishing, would be reduced due to dam removal, particularly at Copco No. 1 Reservoir. Many other comments anticipated an increase in river-related fishing and recreation following dam removal. Several commenters noted that Iron Gate Fish Hatchery is important for enhancing recreational fishing opportunities. Finally, one commenter questioned the future disposition of PacifiCorp properties within and adjacent to the former Lower Klamath Project reservoirs. Additional summary of the recreation comments received during the NOP public scoping process, as well as the individual comments themselves, are presented in Appendix A. Issues raised by the comments have been considered in the discussion below.

3.20.1 Area of Analysis

The Area of Analysis for recreation includes recreation areas and associated access along the Klamath River corridor from the California-Oregon border to the Klamath Estuary. Outside of the Area of Analysis for recreation, areas within and directly adjacent to the Klamath Basin, including those in Oregon, are also described to provide an overview of regional recreation opportunities and to provide a larger context for the recreational facilities that would be impacted under the Proposed Project. River reach designations are presented in Figures 2.2-2 and 2.2-3.

[169] *Phytoplankton* are defined as aquatic microscopic organisms, including algae, bacteria, protists, and other single-celled plants, that obtain energy through photosynthesis and float in the water column of still or slowly flowing waters like lakes or reservoirs. *Periphyton* are defined as aquatic organisms including algae and bacteria that live attached to underwater surfaces such as rocks on a riverbed. See Section 3.4 *Phytoplankton and Periphyton* for additional definitions related to algae.

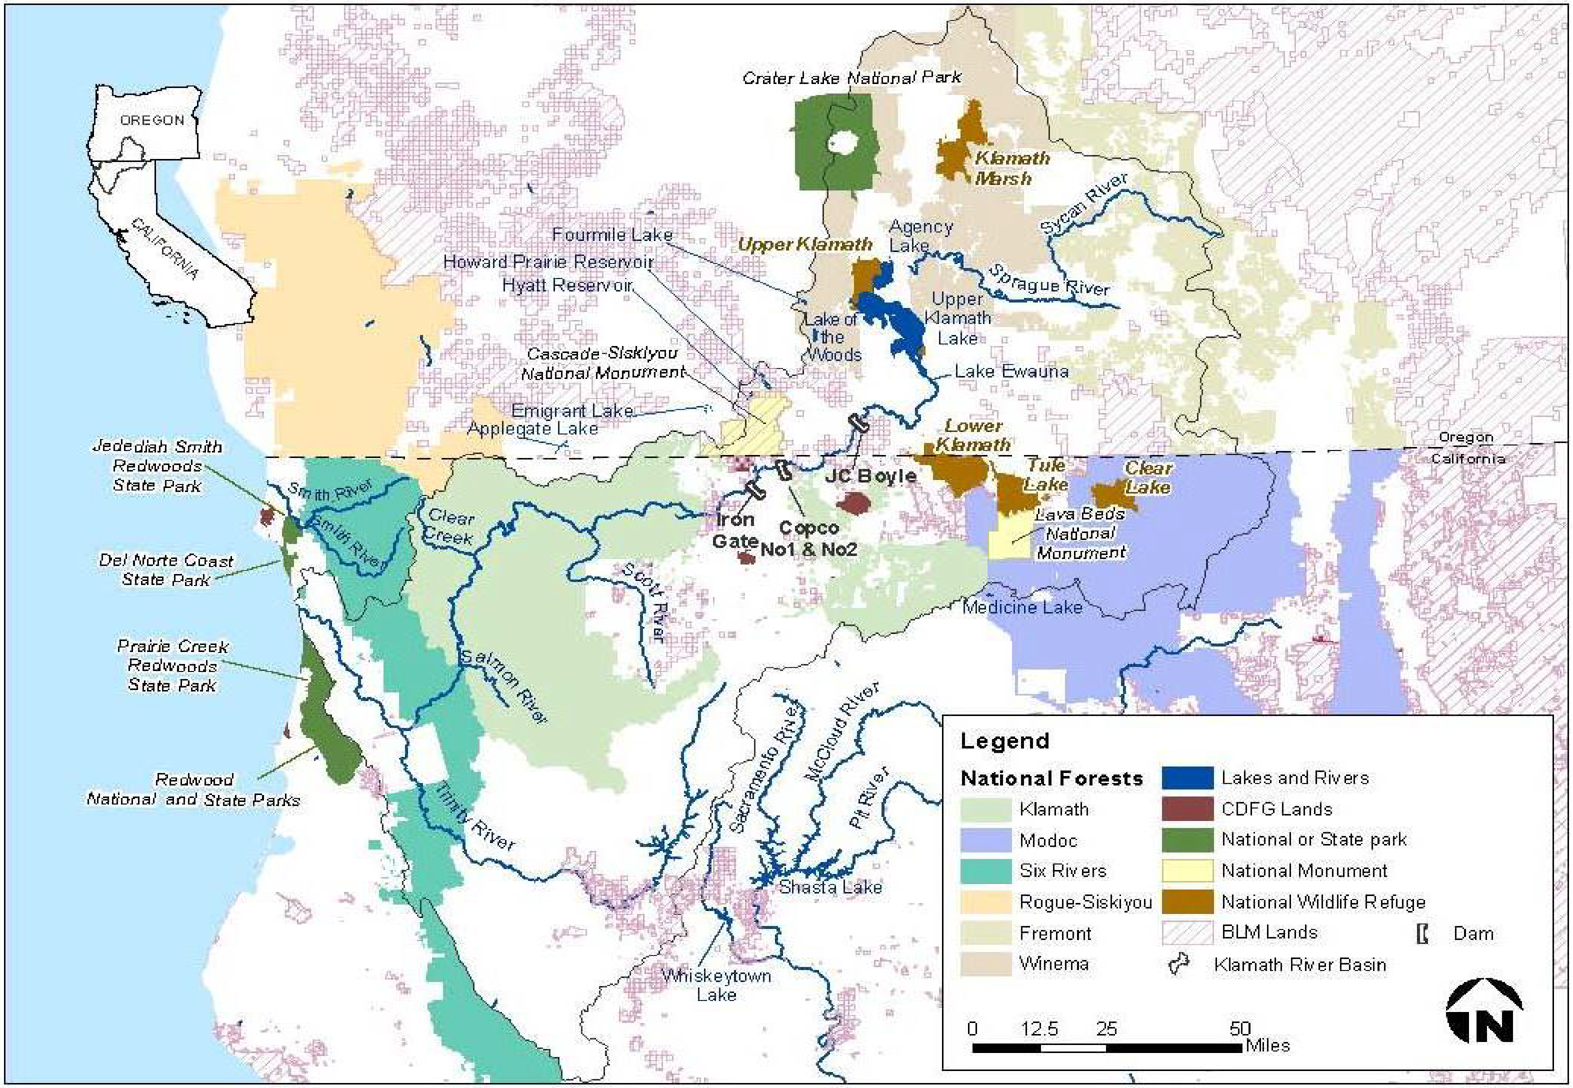

Figure 3.20-1. Area of Analysis for Klamath River Corridor and Regional Recreation Opportunities.

3.20.2 Environmental Setting

3.20.2.1 Regional Recreation

The recreational setting within the Klamath Basin is characterized by an expansive rural landscape that offers a myriad of outdoor recreational opportunities. Rivers, streams, and lakes are common throughout the mountainous landscape of the Klamath Basin, and grasslands exist in the high plateau areas of the region. Within the Klamath Basin, there are four national forests (Klamath, Fremont-Winema, Six Rivers, and Modoc), one joint national and state park (Redwood), one national park (Crater Lake), two national monuments (Lava Beds and Cascade - Siskiyou), and five National Wildlife Refuges (NWRs) (Klamath Marsh, Tule Lake, Clear Lake, Upper Klamath, and Lower Klamath), where the latter make up the Klamath Basin NWR System (Figure 3.20-1). These areas provide sightseeing, camping, hiking, fishing, boating, hunting, wildlife viewing, snow sports, off-highway vehicle uses, and other recreational opportunities. There are 297 miles of wild and scenic (under Section 2(a)ii of the Wild and Scenic Rivers Act [WSRA]) rivers in the Klamath Basin, which include segments of the Klamath, Scott, and Salmon rivers and Wooley Creek. There are also extensive public and private recreational opportunities along the Klamath River and within its reservoirs. Federal and state agencies, including the USDA Forest Service, BLM (including the Northern California District, and the Lakeview and Medford districts in Oregon), USFWS, the National Park Service (NPS), and CDFW, are responsible for managing associated lands located in Klamath and Jackson counties in Oregon, and Siskiyou County in California. Table 3.20-1 provides a summary of the opportunities offered on public lands within and adjacent to the Klamath Basin.

Table 3.20-1. Public Lands Offering Recreational Opportunities in the Area of Analysis for Recreation.

River-based Regional Recreation

A number of rivers cross the region, including four rivers designated as wild and scenic under the WSRA (Sprague, Sycan, Smith, and Trinity rivers). Portions of the Klamath River and its tributaries (further described below in Section 3.20.2.4 *Wild and Scenic River Conditions*), are designated as wild and scenic or have been deemed suitable and eligible for listing. Designated tributaries of the Klamath River include the Salmon River, Scott River, and Wooley Creek. These rivers provide a variety of recreational opportunities, including sightseeing, fishing, and whitewater boating. Figure 3.20-1 shows the location of these rivers relative to the Klamath River. Table 3.20-2 provides a summary of the rivers, the fish species caught, and the typical types of fishing methods (e.g., boat, bank, fly). Table 3.20-3 summarizes the whitewater boating opportunities in the region. These three tables show that there are a number of recreational opportunities outside of the Proposed Project area but within the region. The Oregon Wild and Scenic Rivers, in particular, have outstanding recreational and/or scenic values along the length of the designated segments. The California Wild and Scenic Rivers are classified as wild, scenic, and recreational along the length of the designated segments (NPS 2017).

Table 3.20-2. Rivers Providing Recreational Fishing Opportunities in the Region.

River	Fish Species Caught[1]	Common Types of Fishing
McCloud River	Native trout	Fly fishing, bank fishing
Pit River	Native trout; brown trout; smallmouth bass; rough fish	Fly fishing, bank fishing
Rogue River	Chinook salmon, steelhead	Drift boat, powerboat, fly fishing
Salmon River	Chinook salmon, steelhead, resident trout	Fly fishing, bank fishing
Scott River	Chinook salmon, steelhead, resident trout	Fly fishing, bank fishing
Smith River	Chinook salmon, steelhead	Drift boat, powerboat, fly fishing, bank fishing
Trinity River	Chinook salmon, steelhead, sturgeon, American shad, lamprey	Drift boat, powerboat, fly fishing, bank fishing
Upper Sacramento	Chinook salmon, native and stocked trout, American shad	Fly fishing, bank fishing
Klamath River	Redband trout, salmon	Fly fishing, bank fishing, drift boat

Source: FERC 2007

[1] Information is based on species caught within the 2003–2004 time period.

Table 3.20-3. Rivers with Whitewater Boating Opportunities in the Region.

River	Generalized Use Levels	Boating Class Type[1]	Miles of Boatable Whitewater	Factors Affecting Use Levels
Clear Creek	Low	III–V	7	Difficult access
Klamath River (upstream of CA/OR State line)	Moderate	III–IV+	31	Remote, not suited for beginner or intermediate boaters, unless accompanied by a commercial outfitter
Klamath River (downstream from Iron Gate Dam)	Moderate	II–V	122	Most skill levels, easy access, 186 miles support multi-day floats, shoreline camping, scenery, many outfitters, commercial use
North Umpqua River	Moderate	II–IV	32	Easy access, most skill levels, scenery, boatable year-round, shoreline suitable for camping
McCloud River	Moderate	II–IV	35	Proximity to I-5, most skill levels, low flows in summer
Pit River	Low	IV–V	34	Fragmented/short runs with long stretches of flat water between, remote location
Rogue River	High	II–V	100+	Easy access, most skill levels, scenery, boatable year-round, shoreline suitable for camping, many commercial outfitters
Salmon River	Moderate	II–V	44	Requires advanced/expert boating skills, commercial use
Scott River	Low	III–V	20	Recommended for expert boaters only
Smith River	Low	II–V	100+	Requires advanced/expert boating skills, low summer flows
Upper Sacramento River	Low	III–V	36	Proximity to I-5, average solitude
Trinity River	Moderate	II–V	100+	Most skill levels, easy access, commercial use

Reservoir- and Lake-based Regional Recreation

Numerous opportunities for reservoir and lake-based recreation are available in the vicinity of the Proposed Project. Table 3.20-4 provides a summary of some of the comparable lakes and reservoirs in the region, including facilities and use levels. Within Klamath County and Jackson County in Oregon and Siskiyou County in California, there are more than 85 boatable lakes, containing approximately 40 boat ramps (Boat Escape 2017). The region also has more than 180 high-elevation and wilderness lakes in Siskiyou County (FERC 2007). In addition to boat ramps, these lakes provide nearly 2,300 developed campsites within a two-hour drive from the Lower Klamath Project reservoirs. Some reservoirs in the region are also stocked with trout or warm water fish such as perch or bass. Angling occurs at the many lakes and reservoirs in the region and many are known for having excellent fisheries.

Table 3.20-4. Comparison of Lower Klamath Project Reservoirs with Lakes and Reservoirs in the Region.

Lake or Reservoir	Distance from Nearest Subject Reservoir (road miles)	Surface Water (acres)	Number of Developed Campsites	Number of Developed/ Improved Boat Launches	Number of Developed Picnic Areas	Generalized Use Levels
Lower Klamath Project Reservoirs						
J.C. Boyle	N/A	420	16	2	4	Low

Key:
- mi: miles
- N/A: not available

A small number of developed recreation facilities exist in the Upper Klamath Basin. The following paragraphs provide brief descriptions of each facility and the recreational opportunities available, to provide further context for the regional recreational setting.

Agency Lake is connected to the northern arm of Upper Klamath Lake. Although Agency Lake has no marina, there are two public boat launches and it has a fishery that features trophy redband trout. Other popular recreational activities at the lake are sightseeing, including wildlife viewing of waterfowl (and waterfowl hunting), otter, mink, deer, and bald eagles (Southern Oregon Directory and Guide 2017). The BLM's Wood River Wetland Management Area is on Agency Lake. As shown in Table 3.20-4, a number of campgrounds surround the lake.

Upper Klamath Lake is the largest freshwater body of water in Oregon. In the northern portion of the lake, Pelican Bay is known for its population of redband trout and is an extremely popular destination for fly-fishing. The bay is also a popular location for canoeing and kayaking, as well as sightseeing and wildlife viewing. Other popular activities in Upper Klamath Lake include sailing and waterfowl hunting. As shown in Table 3.20-4, there are numerous campgrounds and boat launches surrounding the lake.

The Link River segment of the Klamath River, an approximately 1-mile stretch downstream from Link River Dam (Figure 2.4-3), has only one developed recreational facility, the Link River Nature Trail. This 1.4-mile trail is for pedestrian use only and follows a gated access road on the west side of the Link River Bypass Reach. The Link River Nature Trail is popular for sightseeing, hiking, walking, jogging, trout fishing, and bird watching (FERC 2007).

The Keno Impoundment/Lake Ewauna (Figure 2.4-3) provides various recreational opportunities, including fishing, picnicking, boating, camping, sightseeing, and wildlife viewing. In the fall, waterfowl hunting is a popular activity at Keno Impoundment/Lake Ewauna. Although most of the land adjacent to the reservoir is privately owned, Lake Ewauna has several public access areas, including the City of Klamath Falls Veterans' Memorial Park/Boat Launch, Miller Island Boat Launch, the Klamath Wildlife Viewing Area, and the Keno Recreation Area and Campground (PacifiCorp 2004). Table 3.20-5 provides a summary of the facilities and estimated annual visitation and capacity as assessed by PacifiCorp as part of relicensing studies for the Klamath Hydroelectric Project (PacifiCorp 2004).

Table 3.20-5. Keno Impoundment/Lake Ewauna Developed Recreation Facilities.

Site Name	Facilities	2001/2002 Est. Annual Use (User Days[1,2])	Est. Facility Use vs. Capacity
Klamath Falls Veterans' Memorial Park/Boat Launch (OR)	Boat launch, day-use area	42,500	Exceeding capacity
Miller Island Boat Launch and Klamath Wildlife Viewing Area (OR)	Boat launch, wildlife viewing trail, and a portable toilet	7,300	Approaching capacity
Keno Recreation Area and Campground (OR)	Campsites (26), day-use area, restrooms, boat launch and boarding dock	6,000	Below capacity

Source: PacifiCorp 2004, FERC 2007
Notes:
1 User days are defined as one visitor to a recreation area for any reason in a 24-hour period.
2 Data for PacifiCorp Klamath Hydroelectric Project Facility use was collected by PacifiCorp in 2001 and 2002. No more recently collected data exists or is available.

The Klamath Falls Veterans' Memorial Park provides a boathouse and boat launch ramp on the northern shoreline of Keno Impoundment/Lake Ewauna and is managed by the City of Klamath Falls, Department of Parks and Recreation. Along the northwestern end of the lake, the Klamath Wingwatchers Lake Ewauna Nature Trail provides opportunities for bird watching and hiking. This 1.8-mile trail connects Veterans' Memorial Park to the Link River trail, along the Link River to the north. Another trail is currently under construction on the northeastern side of the lake (Klamath Birding Trails 2017).

The Miller Island Boat Launch is on the east shore of Keno Impoundment/Lake Ewauna, approximately six miles south of Klamath Falls, and is managed by the Oregon Department of Fish and Wildlife. The facility is accessed by Miller Island Road, which runs three miles through the Klamath Wildlife Area and Miller Unit, and provides an entrance station area, parking area, wildlife viewing trail, and a portable toilet. The Keno Recreation Area and Campground on the southwestern shore of the Keno Impoundment/Lake Ewauna provides a campground, day-use area, and boat launch. The campground has 26 developed campsites, restrooms, and a recreational vehicle (RV) dump station. Recreational opportunities in this area include camping, fishing, picnicking, sightseeing, and boating. The Keno Recreation Area consists of upper and lower use areas, with the upper area adjacent to the campground and the lower area adjacent to the boat launch (FERC 2007).

3.20.2.2 Klamath River-based Recreation

Upper Klamath River and the Hydroelectric Reach

Klamath river-based recreational facilities are only considered upstream to Keno Dam (i.e., inclusive of the Upper Klamath River). Upstream of Keno Dam, due to the flat topography, the influence/slackwater of Keno Reservoir extends almost to Upper Klamath Lake (FERC 2007).

Whitewater Boating Opportunities

In Oregon, the Upper Klamath River provides approximately five miles of river suitable for Class III whitewater boating, including a flatwater paddle upstream of J.C. Boyle Reservoir, however, not much boating use is reported for this reach. The reach is rated Class III difficulty and flows acceptable for whitewater boating opportunities range from 1,000 to 4,000 cfs. The J.C. Boyle Bypass Reach includes about five miles of the Klamath River downstream from J.C. Boyle Dam and upstream of the J.C. Boyle Powerhouse. This reach provides Class III to IV+ rapids, and acceptable whitewater boating flows range from 1,300 cfs to 1,800 cfs; however, this reach is typically dewatered with only 100 to 300 cfs base flow. Therefore, the majority of the year there is almost no boating use on this stretch of the river (FERC 2007).

The Spring Island boater access is adjacent to (downstream from) the J.C. Boyle Powerhouse and is managed by BLM. This site provides car-top whitewater boat launching and shoreline fishing access. The Klamath River Campground, managed by BLM, is about three miles downstream from the J.C. Boyle Powerhouse. The campground has three developed campsites and the shoreline which can be used for fishing and boater access.

Table 3.20-6 provides a summary of acceptable flow ranges for whitewater boating and other flow-dependent recreational activities in the Klamath River (from the Upper Klamath River to the ocean).

Table 3.20-6. Acceptable Flow Ranges for Various River-Based Activities for Reaches of the Klamath River.

River Reach (Length of Reach)	Activity	Low Value (cfs)[1]	High Value (cfs)[1]
Upper Klamath River (5.0 miles)	Whitewater Boating – Standard	1,000	4,000
	Play Boating	1,100	1,800
	Fishing	200	1,500
J.C. Boyle Bypass Reach (4.3 miles)	Whitewater Boating – Standard	1,300	1,800
	Fishing	200	1,000
Hell's Corner Reach (16.4 miles)	Whitewater Boating/Kayaking[2]	1,000	3,500
	Whitewater Boating/Commercial Rafting[2]	1,300	3,500
	Fishing[3]	200	1,500
Copco No. 2 Bypass Reach (1.3 miles)	Whitewater Boating	600	1,500
	Fishing	50	600
Iron Gate to Scott River (47 miles)	Whitewater Boating/Fishing	800	4,000
Scott River to Salmon River (76 miles)	Boating	800	7,000
	Fishing	800	4,000

River Reach (Length of Reach)	Activity	Low Value (cfs)[1]	High Value (cfs)[1]
Salmon River to Trinity River (23.1 miles)	Whitewater Boating/Fishing	800	10,000
Trinity River to Ocean (43.4 miles)	Whitewater Boating/Fishing	1,800	18,000

Source: Appendix R of USBR 2012b
Notes:
[1] Values were determined by the Secretarial Determination Recreation Sub-team (2010) from relicensing documents (PacifiCorp 2004; FERC 2007) and consultation with USDA Forest Service and BLM representatives.
[2] Flows are within the desirable range during the daily peak hydroelectric operations period (between 10:00 AM and 2:00 PM).
[3] Flows are within the desirable range for at least 4 hours during the daily non-peak hydroelectric operations period (either between 5:00 AM and 11:00 AM or between 3:00 PM and 9:00 PM).
Key:
cfs: cubic feet per second

Within California, whitewater boating opportunities are provided on the Hell's Corner Reach of the Klamath River Hydroelectric Reach, and the Copco No. 2 Bypass Reach. The Hell's Corner Reach from J.C. Boyle Reservoir to Copco No. 1 Reservoir extends about 16.4 river miles. Several public fishing and boat access areas exist along this reach, as summarized in Table 3.20-7. A 2002 recreation survey indicated that whitewater boating is the most common activity among respondents between J.C. Boyle Dam and Copco No. 1 Reservoir (PacifiCorp 2004).

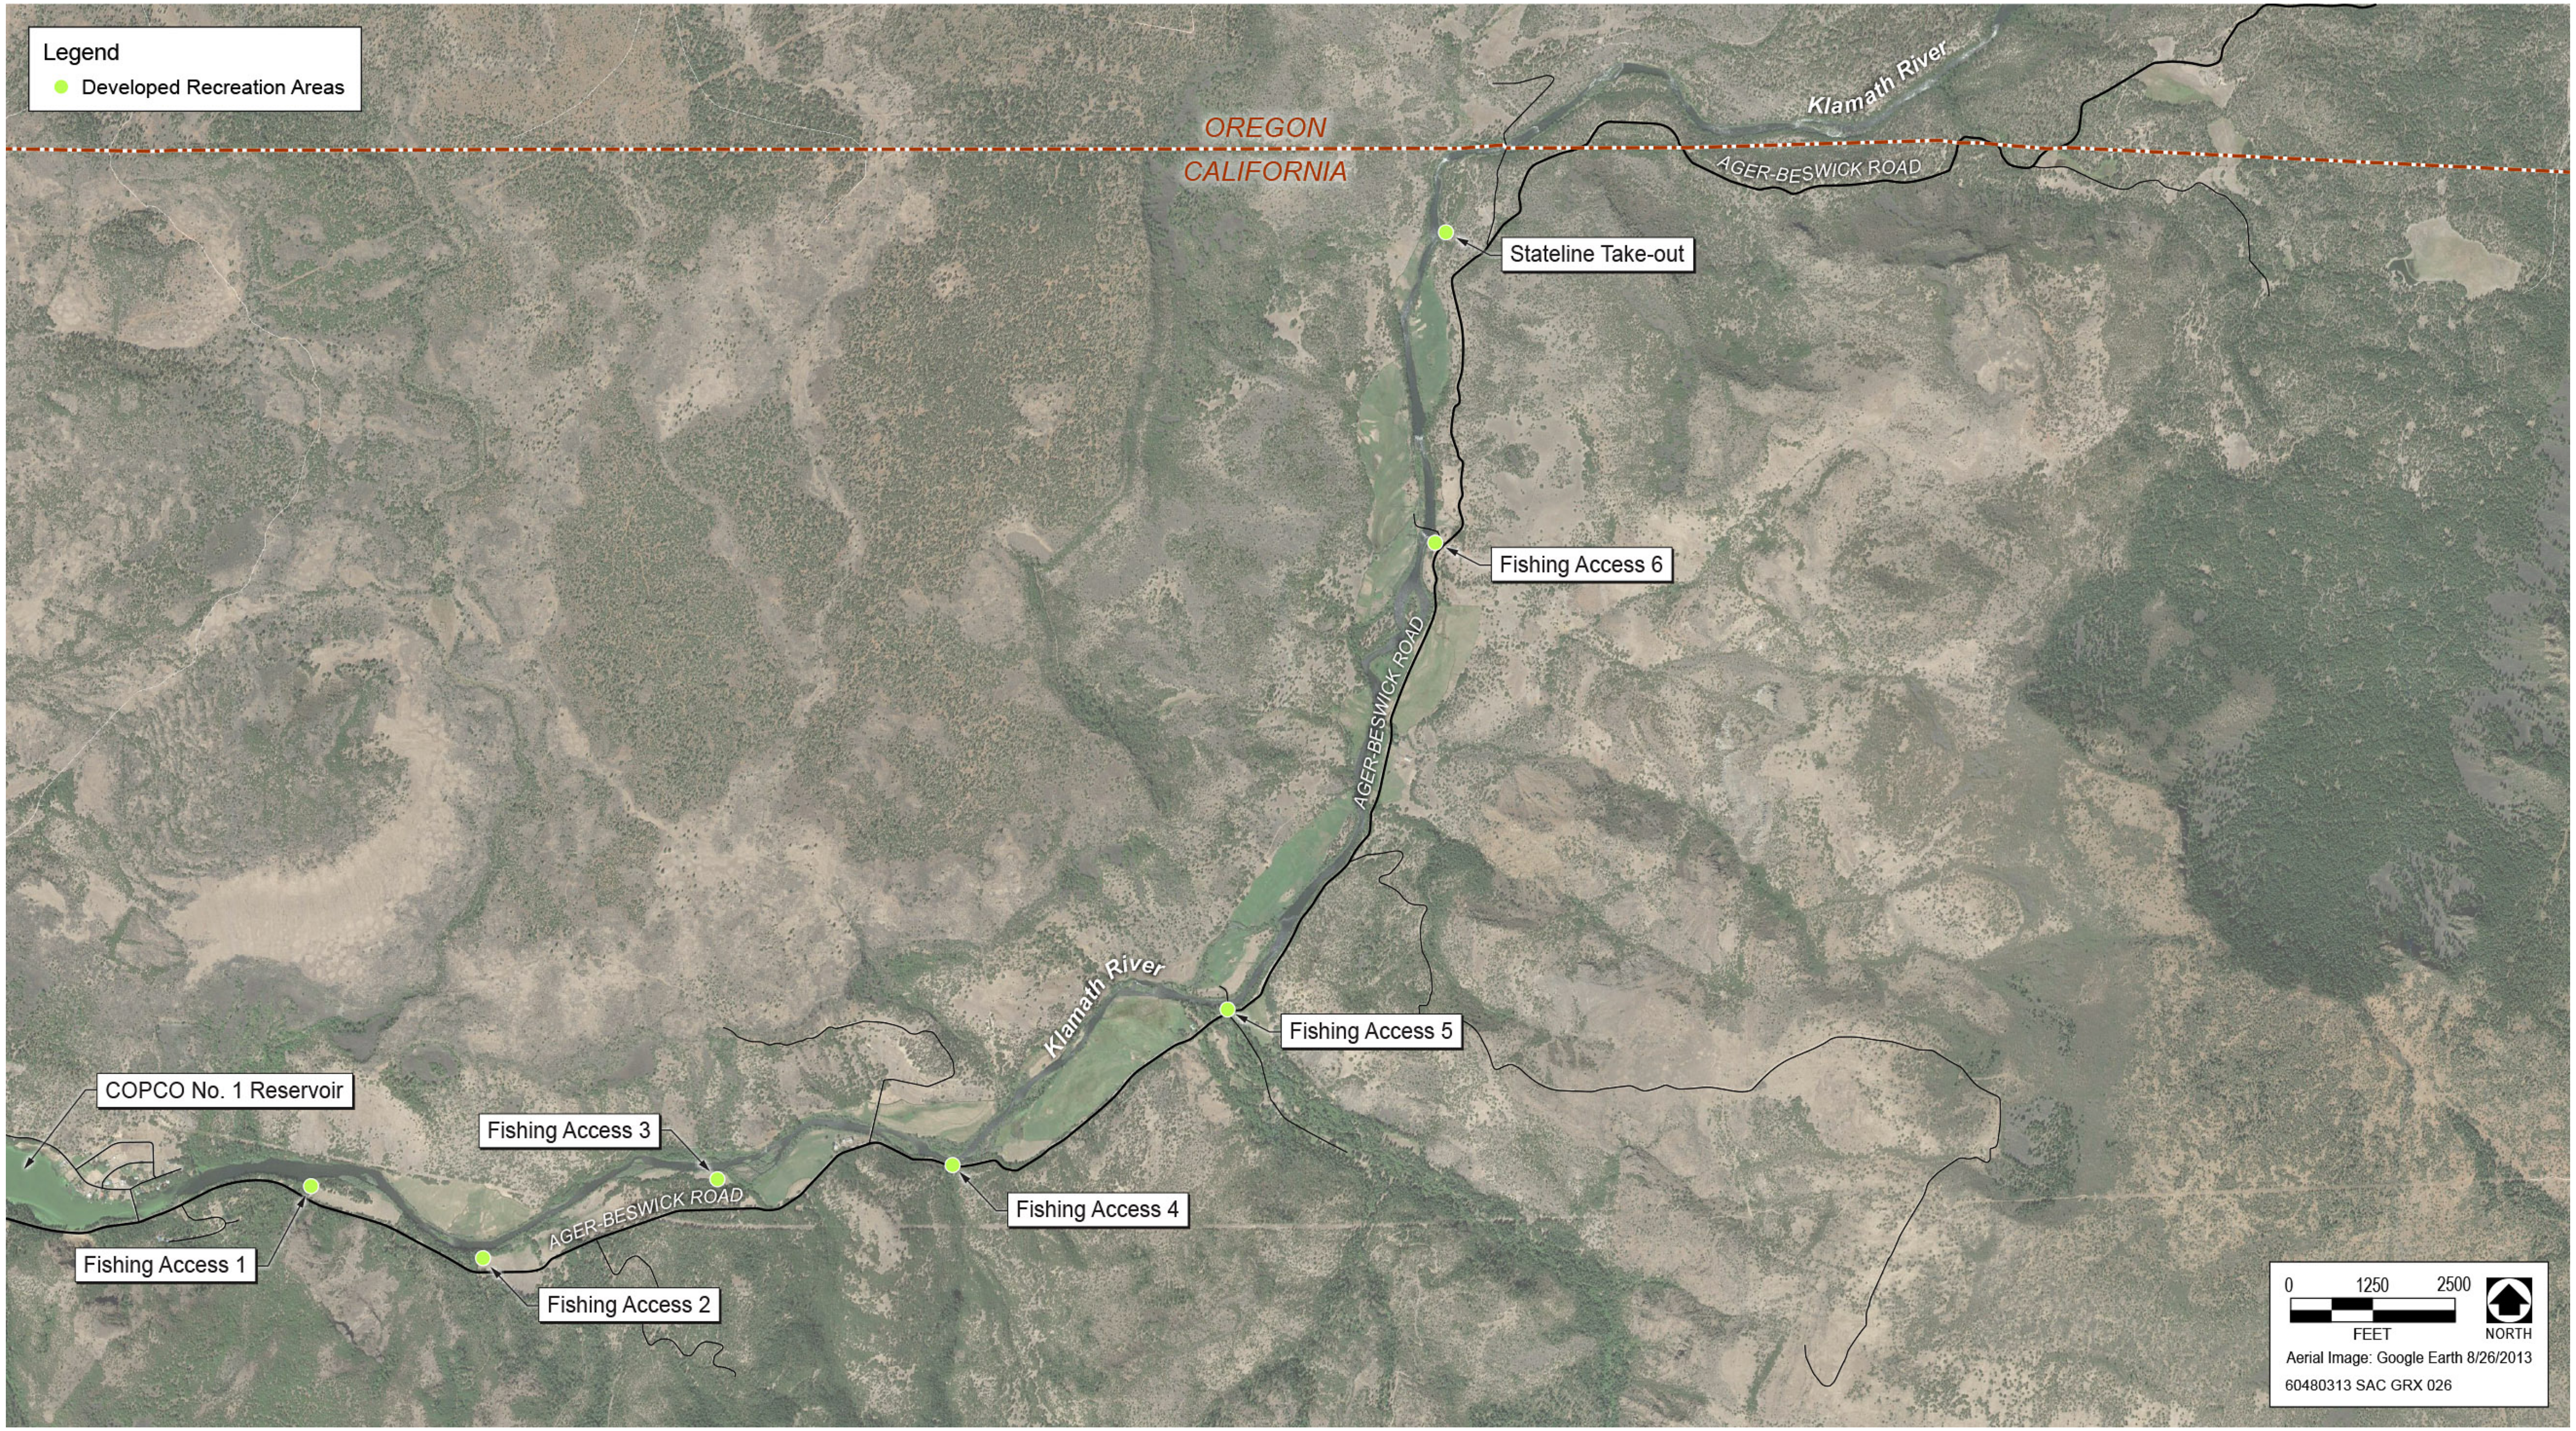

Figure 3.20-2a. California Stateline to Copco No. 1 Reservoir Recreation Area. Data source: PacifiCorp 2004. Map from AECOM (unpublished).

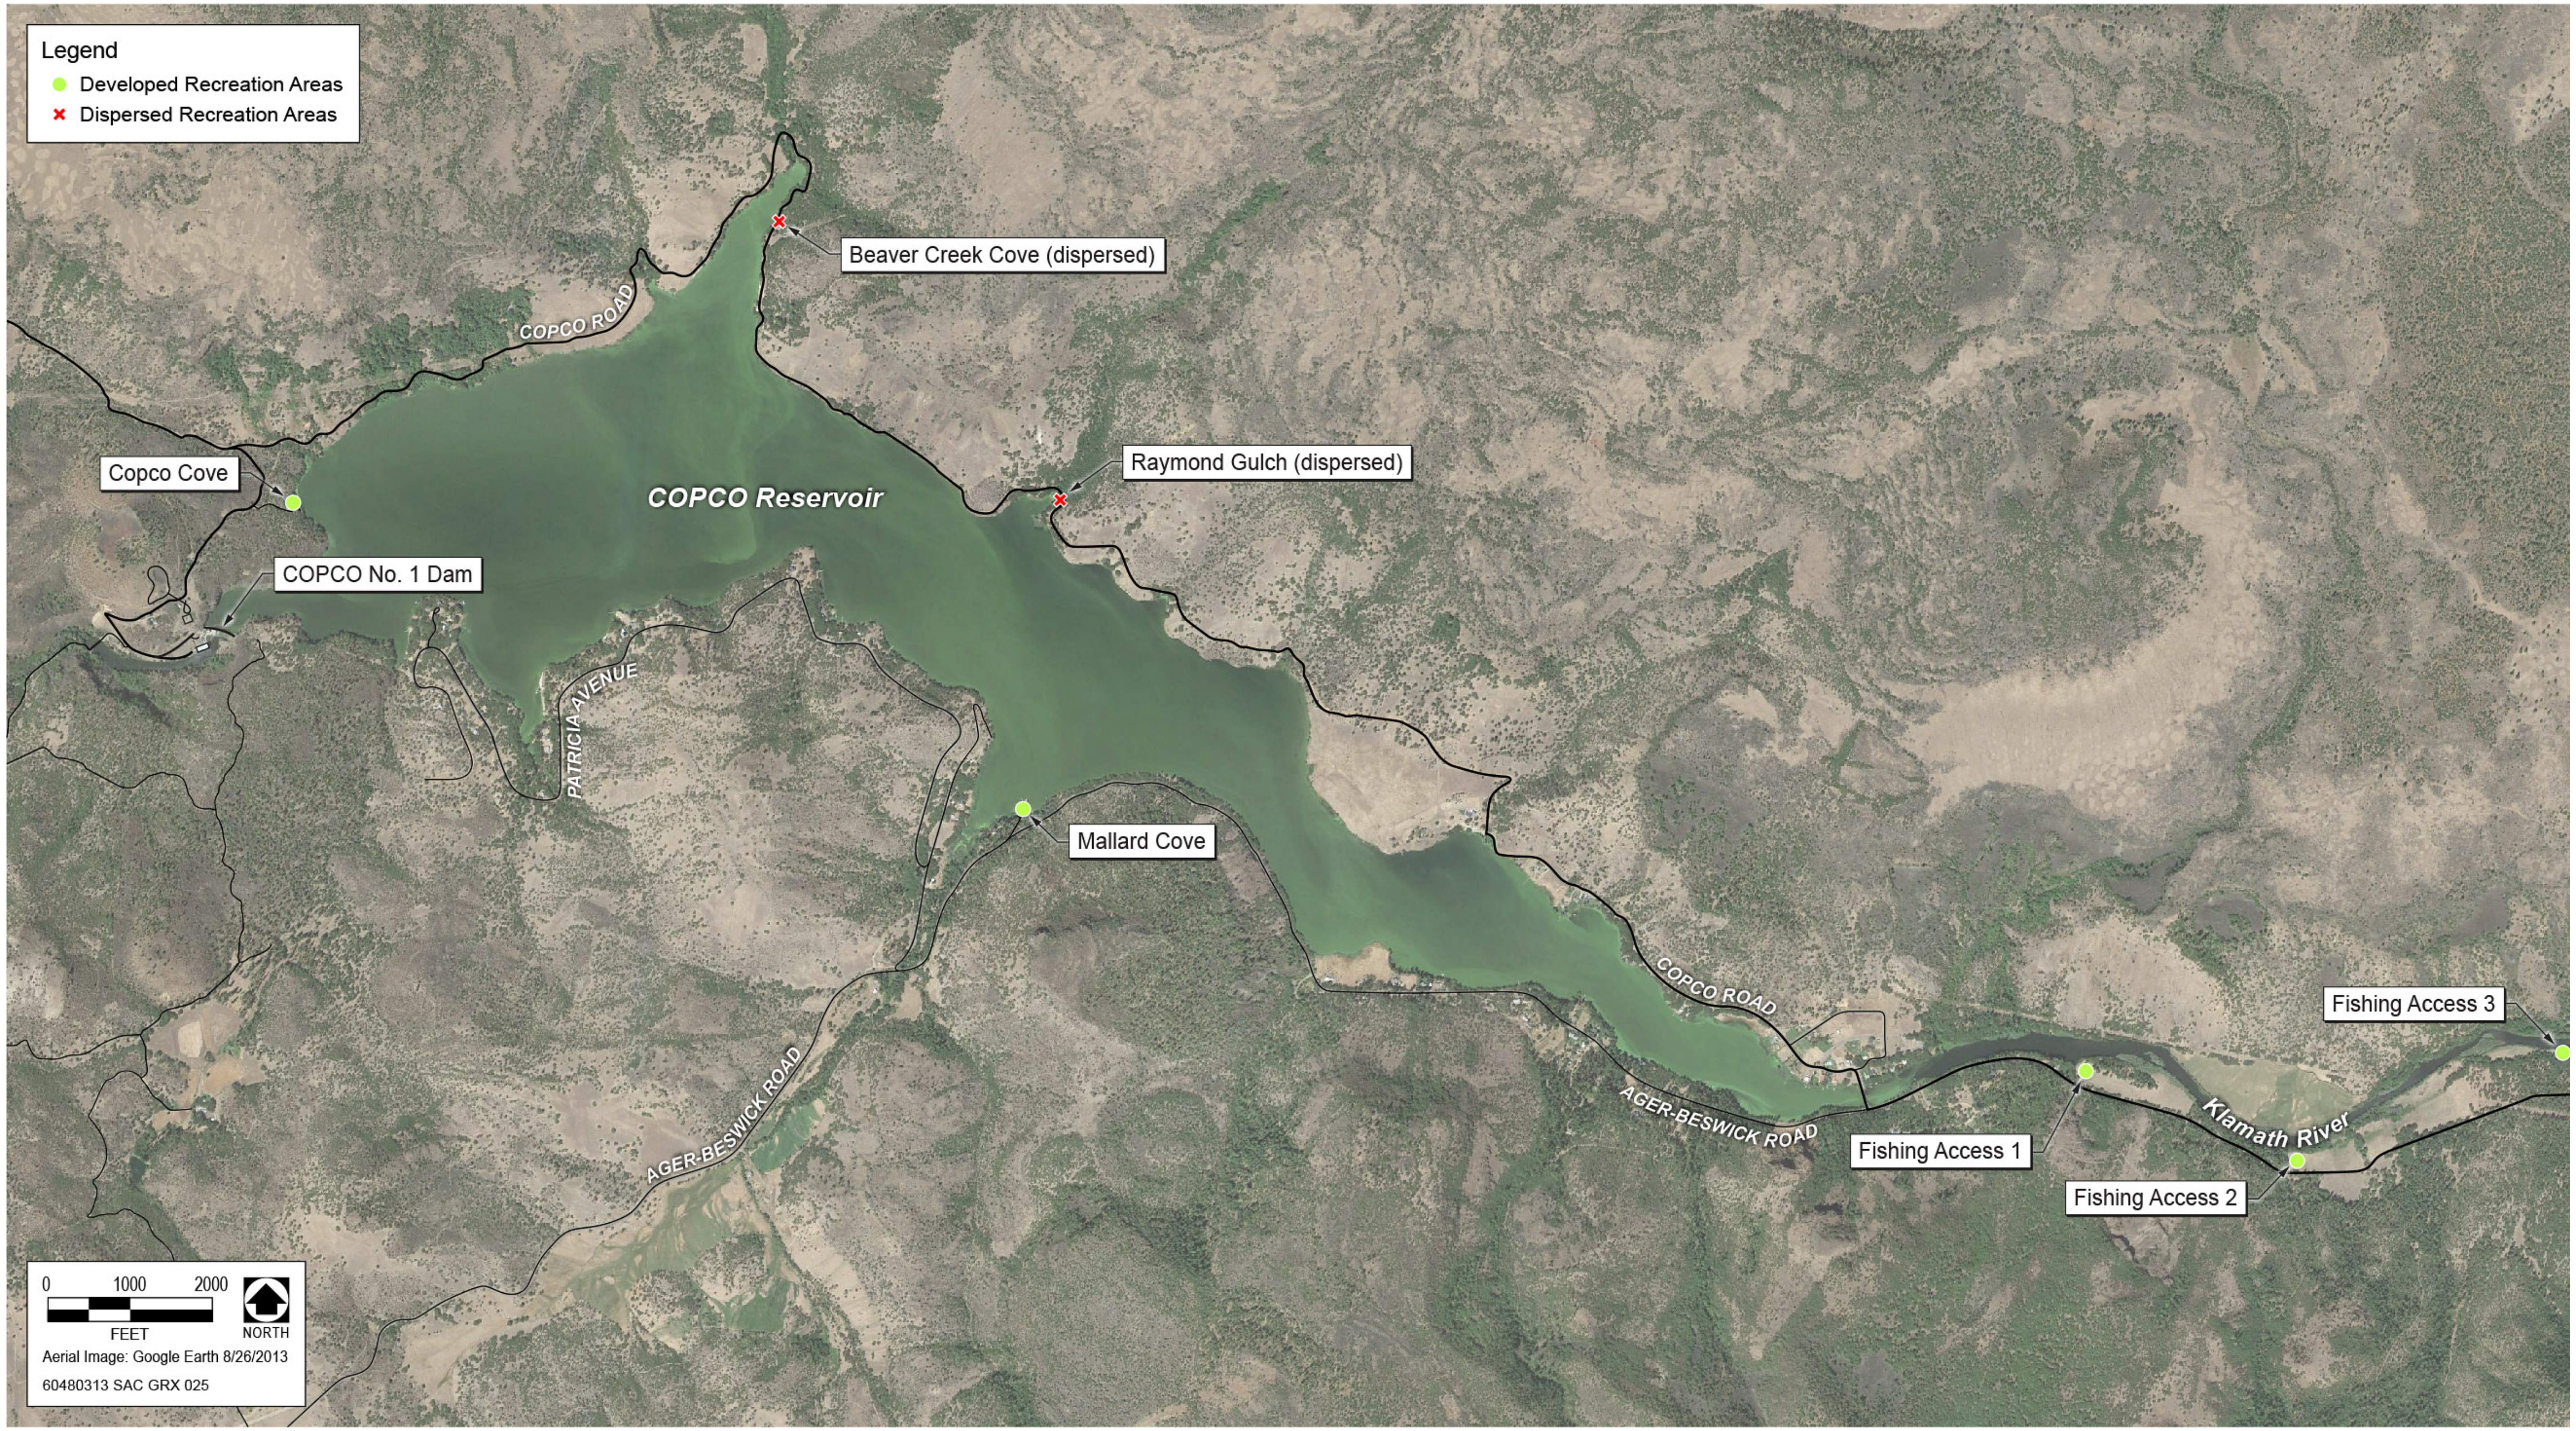

Figure 3.20-2b. Copco No. 1 Reservoir Recreation Area. Data source: Reclamation 2011. Map from AECOM (unpublished).

Table 3.20-7. Hell's Corner Reach Developed Recreation Facilities.

Site Name	Facilities	2001/2002 Est. Annual Use (Recreation days)	Est. Facility Use vs. Capacity
Spring Island Boater Access	Launch area, shoreline fishing access, restrooms	5,200	Below capacity
Klamath River Campground	Campsites (3), shoreline fishing and boating access, restrooms	1,000	Below capacity
Stateline Take-out	Boat put- in/take-out, shoreline fishing access, restrooms	2,700	Approaching capacity
Fishing Access Sites 1–6	Shoreline fishing access, parking	3,600	Below capacity

Source: PacifiCorp 2004, FERC 2007

The State line take-out access area of the Hell's Corner Reach, at the Oregon/California State line, includes upper and lower areas and is co-managed by BLM and PacifiCorp. The facility provides shoreline fishing and boat launching access. The fishing access sites provide access to the Klamath River in six locations between the State line take-out access area and Copco No. 1 Reservoir.

BLM manages whitewater boating use in the Hell's Corner Reach, a 16.4-mile reach from below J.C. Boyle Reservoir to the Fishing Access Site 1 take-out (see Figure 3.20-2a). This reach provides Class III to IV+ rapids during daily peaking flows from the PacifiCorp hydropower operations (between 10:00 AM and 2:00 PM), and acceptable whitewater boating flows range from 1,300 cfs to 3,500 cfs for commercial rafting and heavier loaded boats. Acceptable minimum flows for kayaking and private boaters are 1,000 cfs. Outside of the daily peaking flows, flow rates within this reach do not meet the acceptable range to create or enhance whitewater boating opportunities.

The average estimated annual whitewater boating use from 1994 through 2009 on this reach was 4,414 recreation days, peaking in the mid-1990s at around 6,000 recreation days per year. Whitewater boating use occurs typically during April through October, with about 80 percent of the commercial rafting use occurring during July through September. Commercial boating use accounted for about 93 percent of the whitewater boating use on this reach (DOI 2011).

Commercial boating use is allowed by permit only. There is a set commercial capacity of 10 outfitters or 200 clients per day on this reach. There is no limit for private boating capacity, although BLM has established 250 persons per day as the overall whitewater boating carrying capacity of the reach. Factors that constrain the carrying capacity of the reach are vehicle congestion at the take-out locations near Copco No. 1 Reservoir and the limited size and number of areas that are available to scout rapids (FERC 2007).

The Copco No. 2 Bypass Reach is approximately 1.3 miles long, extending from Copco No. 2 Dam to the Copco No. 2 Powerhouse and whitewater boating opportunities are limited due to lack of flow. However, the reach could provide Class IV whitewater opportunities at acceptable flows ranging from 600 to 1,400 cfs (Appendix S.

Fishing Opportunities
In Oregon, fishing is allowed from September 30 until June 16 on the Klamath River downstream from Link River Dam. The highest use in this area occurs from late winter through spring; this area is mainly used by Klamath Falls residents. At lower flow times, anglers use the river at a few sites where there is access for bank fishing through thick riparian vegetation. Catch records indicate that although angler success is consistently low, there is a greater percentage of larger fish caught in the upstream reach than between J.C. Boyle Dam and the state line. Table 3.20-6 summarizes flows acceptable for fishing opportunities in the various reaches of the Klamath River.

PacifiCorp conducted a visitor use survey in 2002 to obtain information on existing visitor demand, needs, and recreational activities within the area between J.C. Boyle Reservoir and Iron Gate Dam. The results of the survey indicated that 33 percent of visitors to the area participate in bank fishing, both along the river and reservoirs. Survey respondents also indicated that fishing for trout on river reaches in this area is considered very good, and one of the two most popular reaches for fishing opportunities includes the J.C. Boyle Bypass Reach downstream from J.C. Boyle Dam. Opportunities for trout fishing also exist downstream of J.C. Boyle Powerhouse (Hell's Corner Reach). This reach (between J.C. Boyle Powerhouse and the state line) is popular with anglers, and catch records indicate good angler success, although fish size is typically smaller than fish caught below Keno Dam and rarely exceeds 16 inches (FERC 2007).

Recreational opportunities downstream from Hell's Corner Reach, between the California/Oregon state border and Iron Gate Dam, are quite popular for angling. In 1974, a 6-mile reach of the Klamath River, from the California/Oregon state line to Copco No. 1 Reservoir (not including tributaries), was designated as Wild Trout Waters by the State of California and is managed under the Wild Trout Program (CDFG 2010) (see also Section 3.3 *Aquatic Resources*). Demand for recreational angling is high in this area. However, the Klamath River between the Copco No. 1 and Iron Gate developments has limited public access and no documented fishing activity.

In California, the Lower Klamath Project dams impound three waterbodies on the Klamath River: Copco No. 1, Copco No. 2, and Iron Gate reservoirs. Since Copco No. 2 is small with a surface area of only about 40 acres and contains no recreational facilities, the discussion focuses on Iron Gate and Copco No. 1 reservoirs. In addition to these reservoirs, there is a stretch of un-impounded river between the California-Oregon state line, and Copco No. 1 Reservoir. There is also a small (approximately 1.5-mile) stretch of river in between Copco No. 2 Dam and Iron Gate Reservoir. Figures 3.20-2(a), (b), and (c) show the locations of these waterbodies, and Section 3.20.2.3 *Lower Klamath Project Reservoir-based Recreation* describes recreational opportunities at each of these areas.

Middle and Lower Klamath River
The USDA Forest Service (Klamath and Six Rivers National Forests) manages the majority of the Klamath River corridor from downstream from Iron Gate Dam to the confluence with the Trinity River. Other areas downstream from Iron Gate Dam are also managed by the NPS, BLM, tribes, and private landowners. Table 3.20-8 summarizes the river-based recreational opportunities available on the Klamath River downstream of Iron Gate Dam.

Table 3.20-8. River-Based Recreation Opportunities in the Middle Klamath River, Between Iron Gate Dam and the Confluence with the Trinity River.

Reach	Length (miles)	Current Recreation Opportunities
Iron Gate Dam to Shasta River	13	Sightseeing, fishing (especially from boats), tubing and swimming, whitewater boating (rare), waterplay
Shasta River to Scott River	34	Sightseeing, fishing, canoeing, whitewater boating, locational playboating, waterplay
Scott River to Indian Creek	36	Sightseeing, fishing, canoeing, whitewater boating, waterplay
Indian Creek to Salmon River	40	Sightseeing, fishing, whitewater boating, canoeing, hiking, waterplay
Salmon River to Trinity River	40	Sightseeing, fishing, waterplay

Source: PacifiCorp 2004

There are two privately developed recreation facilities located along the Middle Klamath River a few miles downstream of Iron Gate Dam. The R Ranch Klamath River Campground is located a few miles east of Cottonwood and I-5 and 2.5 miles downstream from Iron Gate Dam along 1.7 miles of the Middle Klamath River. This campground contains 156 campsites with a large lodge/recreation center and provides opportunities to fish, hunt, and view natural scenery and wildlife. And the Klamath Ranch Resort Blue Heron RV Park is located along the Klamath River 1.5 miles downstream of Iron Gate Dam. This campground features 26 campsites, several accessory structures, a fly-fishing school casting pond, historic restaurant, and boat launch.

There are several other private land areas near the I-5 corridor, in Seiad Valley, at Happy Camp, and near the mouth of the Salmon River at Somes Bar. In general, these areas have several homes and associated, sparsely populated, rural development. These areas have considerable opportunities to camp, swim, picnic, or relax along this portion of the Klamath River. There are also some opportunities for sightseeing, hiking, walking, or biking along the river. In addition, there are some popular short hikes from the river up the tributaries, such as Ukonom and Clear Creek. Land-based recreation points along the river are generally near developed access points for boaters and anglers and a few developed USDA Forest Service and private campgrounds (PacifiCorp 2004).

In addition, there are two National Forest Scenic byways located along this segment of the river and within the Klamath and Six Rivers National Forests. The “State of Jefferson” National Forest Scenic Byway is located primarily on California State Highway 96 (State Highway 96) between Shasta River to Happy Camp, and the “Bigfoot” National Forest Scenic Byway is located on Highway 96 from Happy Camp to California State Highway 299 (State Highway 299). There is also an “All America Road,” the Volcanic Legacy Scenic Byway, which goes from Lassen National Park in California and through the project area via Highways 97, 140, and 62 on its way to Crater Lake National Park in Oregon. These byways provide excellent views for sightseers within the Klamath and Six Rivers National Forests and access to numerous other recreational activities (America’s Scenic Byways 2017).

Downstream of the Trinity River confluence, the Lower Klamath River flows through the Yurok, Hoopa, and Resighini Indian Reservations and Redwood National Park, as well as through public lands managed by the BLM and privately-owned lands. A number of private RV and tent campgrounds are along the river in Redwood National Park, and just outside of the park in the City of Klamath. These campgrounds provide opportunities for bank fishing, camping, and picnicking. Other recreation opportunities in the area are associated with Redwood National and State Parks, which includes Jedediah Smith, Del Norte Coast, and Prairie Creek Redwood state parks and Redwood National Park, which offer hiking, hunting, wildlife viewing, and other recreational opportunities. (See Table 3.20-1 for a summary of the facilities associated with these parks.)

Public Health Issues

As discussed in Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*, concentrations of chlorophyll-*a* and *Microcystis aeruginosa* have exceeded World Health Organization guidelines for protection from adverse effects in recent years, in both Copco No. 1 and Iron Gate reservoirs, as well as reaches of the Klamath River downstream from Iron Gate Dam. In 2005, 2008, 2009, 2010, 2012, 2013, 2014, 2016, and 2017, the North Coast Regional Board, Karuk Tribe, Yurok Tribe, USEPA, and other local, state, and federal agencies issued warnings to residents and recreational users of the reservoirs and river to use caution near these algal blooms due to possible health effects of exposure to *Microcystis aeruginosa* and its microcystin toxin (Kann and Corum 2006, Kann and Corum 2009, North Coast Regional Board 2009, 2010, 2012a, 2013, 2014, 2016, 2017a). Effects range from mild, non-life-threatening skin conditions to permanent organ impairment and death, depending upon exposure time and intensity (FERC 2007). As identified in comments received during the scoping period for the 2012 KHSA EIS/EIR, as well as in PacifiCorp's recreation survey in 2002, these water quality issues and public health warnings have resulted in reduced recreational activity in affected river segments in recent years.

Whitewater Boating Opportunities

Extensive whitewater boating opportunities exist downstream from Iron Gate Dam. Depending on the river segment and level of flow, there are opportunities for play, standard, and big water boating on Class II and III waters (American Whitewater 1998). These runs are boatable in rafts, kayaks, inflatable kayaks, and open canoes. Table 3.20-6 summarizes the acceptable flow ranges for all reaches within the area of effect, including downstream from Iron Gate Dam.

Although not as challenging as the Hell's Corner Reach upstream, there are a few rapids that are sometimes rated Class IV, including Hamburg and Upper Savage on the Otter's Playpen run, Rattlesnake on the day-use run below Happy Camp, and Dragon's Tooth between Ferry Point and Coon Creek Access. There is also a well-known kayak playboating wave known as the "School House Wave" between Skehan Bar and Gottville. This wave is typically available during low to moderate summer flows and is popular with local kayakers from the Mount Shasta, Klamath Falls, and Ashland areas (PacifiCorp 2004). There is also a Class V-VI rapid at Ishi Pishi Falls (Somes Bar) that boaters are strongly advised to portage around due to its cultural significance to local tribes (American Whitewater 2017).

The primary whitewater boating season is in summer (June through August), when water temperatures are warm; however, the Klamath River can be boated in most months of the year (PacifiCorp 2004). There is less whitewater rafting downstream from the Trinity

River confluence after the river turns northwest into strong prevailing winds. There are fewer developed river access points along this reach than in the reaches upstream. This reach is located within the boundaries of the Yurok Tribe Indian Reservation. Data collected by the USDA Forest Service and BLM indicate that substantially more whitewater boating occurs on the Klamath River downstream of Iron Gate Dam than in the Klamath River upstream to J.C. Boyle Dam. From 1994 through 2009, the average annual number of user days was 14,392 per year. However, whitewater boating in this portion of the Klamath River has decreased somewhat in recent years. Total user days from 2000 through 2003 ranged from 13,976 to 15,349 per year, whereas from 2005 through 2009, total user days ranged from 11,751 to 15,279 per year (DOI 2011).

Fishing Opportunities

The Klamath River downstream from Iron Gate Dam has high quality angling opportunities extending nearly 200 miles to the Pacific Ocean and is open to fishing year-round. This reach, designated a wild and scenic river (see Section 3.20.2.4 *Wild and Scenic River Conditions* below), attracts and supports several fishing outfitter services that focus on salmon, steelhead, and trout fisheries. A review of outfitters conducted as part of the Secretarial Determination process identified over 50 outfitters providing sport fishing, boat fishing, and/or fly-fishing trips on the Klamath River. Twenty-seven river access sites within the Klamath National Forest provide access for fishing in this section of the river. Use at the sites varies; however, most are rated as light usage (Klamath National Forest 2017). Tables 3.20-9 and 3.20-10 provide recent use data for Chinook salmon and steelhead fishing on the Klamath River. As shown in Table 3.20-9, angler success for Chinook salmon varied annually, but was generally greater in the first half of the decade than in the latter half. The USDA Forest Service reported that the decline in fish production in the past few decades triggered a similar decline in the guide and resort industry, as well as sport fisheries (FERC 2007).

Table 3.20-9. Estimated Number of Recreational Salmon Angler Days[1] and Chinook Salmon Harvest on the Klamath River (excluding the Trinity River), 2001–2015.

Year	# Angler Days	Chinook Salmon Harvest (# Fish)		
		Adults	Grilse (Jacks)	Total
2001	28,251	9,621	1,365	10,986

2008	21,192
03-08Avg	17,155

Source: NMFS 2011

Downstream from the Trinity River confluence, angling in the Klamath River is dependent on the annual status of the fall-run Chinook salmon run, so the number of businesses that offer angling guide services varies from year to year with the Chinook salmon population size. The main run of Klamath River Chinook salmon peaks in late fall and is normally over by mid-January each year; the steelhead season generally starts in November and runs through March (see also Section 3.3 *Aquatic Resources*).

Anglers fish from boats and the bank. Most of the boat fishing occurs from drift boats or rafts. Fishing regulations allow anglers to keep up to five trout per day and most of the fishing activity occurs in summer and fall. Quotas and limits on salmon and steelhead have varied over the years, and regulations may depend on whether the fish are wild or from a hatchery. Most anglers catch and release steelhead (PacifiCorp 2004).

3.20.2.3 Lower Klamath Project Reservoir-based Recreation

As there are no reservoirs located on the Klamath River downstream of Iron Gate Dam, the following discussion of reservoir-based recreation focuses on the Lower Klamath Project reservoirs located in the Hydroelectric Reach from J.C. Boyle Reservoir to Iron Gate Dam.

Hydroelectric Reach

J.C. Boyle Reservoir

J.C. Boyle Reservoir has a surface area of approximately 420 acres and is about 3.6 miles long. Developed public recreational facilities at the reservoir include Pioneer Park, Sportsman's Park, and Topsy Campground (Table 3.20-11). See Appendix B: *Definite Plan - Appendix C,* Figure 5.1-1, Sheets 2-3, for locations of these recreational facilities.

Table 3.20-11. J.C. Boyle Reservoir Developed Recreation Facilities.

Site Name	Ownership	Facilities	2001/2002 Est. Annual Use	Est. Facility Use vs. Capacity
Pioneer Park	PacifiCorp	Picnic areas, boat launches, interpretive signs, restrooms	16,700	Below capacity
Topsy Campground	BLM	Campsites (16), an RV dump, two day-use areas, a boat launch with boarding dock, an accessible fishing pier, restrooms	5,600	Below capacity
Sportsman's Park	Klamath County	Shooting ranges, dirt racetracks, archery courses, a model aircraft flying field, off-highway vehicle area, restrooms	12,600	Below capacity

Source: PacifiCorp 2004, FERC 2007

Pioneer Park is owned and operated by PacifiCorp and it lies off Oregon State Highway 66 (State Highway 66) east and west of Spencer Bridge. Pioneer Park is a day-use area that provides picnic areas, boat launches, interpretive signs, and two restroom facilities. It has an improved boat ramp on the east shore just off State Highway 66, and a picnic area and unimproved boat launch on the west shore. Popular activities at this location include sightseeing, boating, fishing, swimming, and picnicking (PacifiCorp 2004).

Topsy Campground is managed by BLM. The campground is south of State Highway 66 off Topsy Grade Road, a gravel road maintained on an as-needed basis by BLM, private owners, timber companies, and PacifiCorp. This site features a campground with 16 sites, an RV dump, two day-use areas, a boat launch with boarding dock, an accessible fishing pier, and two restroom facilities. The campground is available to the public and BLM charges fees for day-use and camping at this facility (PacifiCorp 2004).

Sportsman's Park, approximately 0.25-mile east of the reservoir, is a multi-use recreation area owned by Klamath County and leased long term to Klamath Sportsman's Park Association. The park does not provide developed reservoir access, but it does provide river access for fishing. The park contains shooting ranges, dirt racetracks, archery courses, and a model aircraft flying field. The park also has facilities for self-contained RVs and some tent camping. Annual membership passes and single-day passes for use of the park are available to the general public for a fee (PacifiCorp 2004, Sportsman's Park 2017).

In California, the Lower Klamath Project dams impound three waterbodies on the Klamath River: Copco No. 1, Copco No. 2, and Iron Gate reservoirs. In addition to these reservoirs, there is a stretch of un-impounded river between J.C. Boyle Reservoir and Copco No. 1 Reservoir. Figures 3.20-2(a), (b), and (c) show the locations of these reservoirs, and the following sections describe recreational opportunities at each of these areas.

Copco No. 1 Reservoir

Copco No. 1 Reservoir, with a surface area of approximately 1,000 acres and about 4.5 miles long, has two publicly available day-use facilities—Mallard Cove and Copco Cove—that are owned and operated by PacifiCorp. These facilities provide day-use access to the reservoir, and although they are not official campgrounds, camping occasionally occurs at both locations. Copco No. 1 Reservoir currently provides a recreational fishery for non-native fishes including largemouth bass, trout, catfish, crappie, sunfish, and especially yellow perch (Hamilton et al. 2011). Table 3.20-12 summarizes the existing facilities and estimated use during 2001/2002 at both of these areas.

Table 3.20-12. Copco No. 1 Reservoir Developed Recreation Facilities.

Site Name	Facilities	2001/2002 User Days[1,2]	Est. Facility Use vs. Capacity
Mallard Cove	Picnic area, restrooms, boat launch with boarding dock	7,600	Below capacity
Copco Cove	Picnic area, restrooms, boat launch with boarding dock	1,250	Below capacity

Source: PacifiCorp 2004, FERC 2007

Notes:

[1] User days are defined as one visitor to a recreation area for any reason in a 24-hour period. Estimated use was during the 2001/2002 study period (PacifiCorp 2004).

[2] Although annual user data from 2001/2002 represent the most comprehensive information available, these data were collected prior to data characterizing seasonal blue-green algae blooms in Iron Gate Reservoir became available (see also Section 3.4.2.3 *Hydroelectric Reach*) and prior to the freshwater CyanoHABs Program that began posting of public health advisories for California reservoirs that exceed algal toxin thresholds.

Mallard Cove, on the south shore of Copco Reservoir, is accessed off Ager-Beswick Road and includes day-use facilities, two restrooms, and a boat launch with boarding dock. Copco Cove, on the western shoreline of Copco Reservoir, off of Copco Road, has a small picnic area, two restrooms, and a boat launch with boarding dock (PacifiCorp 2004).

Additionally, homes on Copco Lake provide private recreational access, including docks for fishing, boating, swimming and birdwatching.

Copco No. 2 Reservoir

Copco No. 2 Reservoir is relatively small (with a surface area of approximately 40 acres and about 0.3-mile long) and has a narrow configuration with steep and difficult shoreline access. Copco No. 2 Reservoir has no recreational facilities and no public access (FERC 2007).

Iron Gate Reservoir

Iron Gate Reservoir has a surface area of approximately 944 acres and is 6.8 miles long. The reservoir has the highest concentration of recreation sites of all the developments associated with the PacifiCorp facilities. The developed facilities at Iron Gate Reservoir are owned and managed by PacifiCorp and include a trail (Fall Creek Trail), five combination day-use and campground areas (Jenny Creek, Camp Creek, Juniper Point, Mirror Cove, and Long Gulch), three day-use areas (Fall Creek, Overlook Point, and

Wanaka Springs), and a fish hatchery and associated day-use area (Iron Gate). Recreational opportunities include sightseeing, swimming, fishing, boating, and day and overnight use. Iron Gate Reservoir currently provides a recreational fishery for non-native fishes including largemouth bass, trout, catfish, crappie, sunfish, and especially yellow perch (Hamilton et al. 2011). Summer and weekend use is high at the reservoir due to the popularity of bass tournaments, waterskiing, and camping. Table 3.20-13 summarizes the developed recreation facilities at the reservoir and PacifiCorp's estimated annual recreation visitation and capacity during the 2001/2002 study period.

The Fall Creek Day-Use Area is at the upper end of the reservoir and includes a picnic area, boat launch access, and restroom facilities. This small day-use area is adjacent to the CDFW Fall Creek Fish Hatchery and provides access to Fall Creek Trail. Fall Creek Trail is a short (0.1-mile) trail located adjacent to the Fall Creek Fish Hatchery where visitors can hike up to Fall Creek Falls.

Wanaka Springs Day-Use Area provides picnic areas, a fishing dock, restroom facilities, and some informal camping occurs in the area.

Table 3.20-13. Iron Gate Reservoir Developed Recreation Facilities.

Site Name	Facilities	2001/2002 Est. Annual Use (User days)[1]	Est. Facility Use vs. Capacity
Fall Creek Day-Use Area and Fall Creek Trail	Picnic area, boat launch access, restrooms, hiking trail	4,150	Below capacity
Overlook Point	Restrooms	1,900	Below capacity
Wanaka Springs Day-Use Area	Fishing dock, restrooms	4,150	Exceeding capacity
Jenny Creek Day-Use Area and Campground	Campsites (6), restrooms	3,700	Approaching capacity
Camp Creek Day-Use Area and Campground	Campsites (13), boat launch, boarding and fishing docks, swimming area, a RV dump station, sports field, interpretive display restrooms	15,250	Exceeding capacity
Juniper Point Day-Use Area and Campground	Campsites (9), a fishing dock, restrooms	4,700	Exceeding capacity
Mirror Cove Day-Use Area and Campground	Campsites (10), a boat launch, restroom	11,140	Exceeding capacity
Long Gulch Day-Use Area and Campground	Picnic sites, boat launch, restrooms	5,200	Below capacity
Iron Gate Fish Hatchery	Picnic area, picnic shelter, visitor center/interpretive kiosk, restrooms, trail to river	2,200	Below capacity

Sources: PacifiCorp 2004, FERC 2007

[1] Although annual user data from 2001/2002 represent the most comprehensive information available, these data were collected prior to data characterizing seasonal blue-green algae blooms in Iron Gate Reservoir became available (see also Section 3.4.2.3 *Hydroelectric Reach*) and prior to the freshwater CyanoHABs Program that began posting of public health advisories for California reservoirs that exceed algal toxin thresholds.

Overlook Point is on the west side of the reservoir, approximately 0.75-mile upstream of Iron Gate Dam. The facility has picnic sites on moderately steep topography, providing a good view of the reservoir and surrounding landscape.

Jenny Creek Day-Use Area and Campground includes six day-use/campsites and a restroom facility. Jenny Creek is on the north side of the reservoir and provides a creekside setting for picnicking and bank fishing.

Camp Creek Day-Use Area and Campground is along a narrow reach on the north side of Iron Gate Reservoir. The surrounding hilly, semi-arid landscape and the reservoir provide pleasant views. Camp Creek Campground has several campsites designed primarily for RV campers, with a large overflow RV/tent camping area. The facility also has picnic sites, a sports field, and boat docks/fishing piers.

Juniper Point Day-Use Area and Campground has several picnic areas (occasionally used as campsites), a fishing dock, and restroom facilities.

Mirror Cove is a day-use area and campground centrally located on the west side of the reservoir. The area offers several picnic sites (occasionally used as campsites), a boat launch, and restroom facilities. This particular location is popular for group camping and is used extensively by local water-ski clubs. This boat launch is the nearest access to a competitive water-ski course placed in the western area of the reservoir.

Long Gulch Day-Use Area and Campground is on the east side of the reservoir directly across from Overlook Point. Facilities at this location include picnic sites, restroom facilities, and a boat launch. Land along an adjacent ridge is occasionally used for dispersed camping and day-use (PacifiCorp 2004).

Immediately downstream of Iron Gate Dam, the Iron Gate Fish Hatchery is operated by CDFW and includes a public day-use area adjacent to the hatchery and an undeveloped boat launch across the river from the hatchery. The day-use area includes a picnic area, a picnic shelter, visitor center/interpretive kiosk, restroom facilities, a trail to the river, and seasonal interpretive tours. Fishing is prohibited in this area as well as within 3,500 feet downstream from the dam.

Visitor Use and Perception

PacifiCorp conducted a visitor survey in 2004 to assess recreational use and visitor perceptions of recreational facilities, including the Lower Klamath Project reservoirs. The majority of visitors surveyed (approximately 60 percent of total) were from Klamath County and Jackson County, Oregon. The remaining visitors were from California (approximately 40 percent of total), approximately half of which came from Siskiyou County (approximately 20 percent of total). When asked to indicate all activities participated in while visiting the Lower Klamath Project reservoirs, more than half of the visitors' surveys included resting/relaxing as one of the activities. When surveyed on their perception of crowding at the reservoirs, the mean score of respondents was 3.2 (on a 9-point scale from 1—not crowded to 9—extremely crowded), indicating that visitors did not feel overly crowded while participating in recreation activities. Further, approximately 39 percent of respondents had changed their visits to the Lower Klamath Project reservoirs from other lakes in the area to avoid crowding. When surveyed regarding management options of the reservoirs, survey respondents indicated opposition to the collection of user fees at either day-use sites or facility campgrounds (PacifiCorp 2004).

In response to the survey question "Has water quality ever affected your visit to the Klamath River area?" approximately two-thirds of recreational users of the Lower Klamath Project reservoirs had negative perceptions of water quality, commenting on its color, turbidity, and odor. The source of visitor concerns was primarily the brown, foamy water in free-flowing reaches and regular, extensive phytoplankton [algae] blooms that occur throughout the reservoirs. Visitors reported that the phytoplankton [algae] produces bad odors, fouls fishing lines, and reduces the area available for fishing, swimming, and wading (FERC 2007).

3.20.2.4 Wild and Scenic River Conditions

Two segments of the mainstem Klamath River are designated wild and scenic rivers, one in Oregon and one in California (Figure 3.20-3). The reach in Oregon, between the J.C. Boyle Powerhouse and the Oregon-California state line was designated a wild and scenic river in 1994. As this section is not in California, it is not analyzed in this EIR.

In California, the entire river beginning 3,600 feet downstream of Iron Gate Dam to the Klamath Estuary (i.e., Middle and Lower Klamath River) is designated a wild and scenic river segment by both the State of California and the federal government. Wild and scenic river segment boundaries include variable-width linear corridors which typically include not more than 320 acres per linear mile (averaging up to approximately 0.5 mile in width along the river corridor). However, some protections for designated outstanding remarkable values can extend beyond the boundaries.

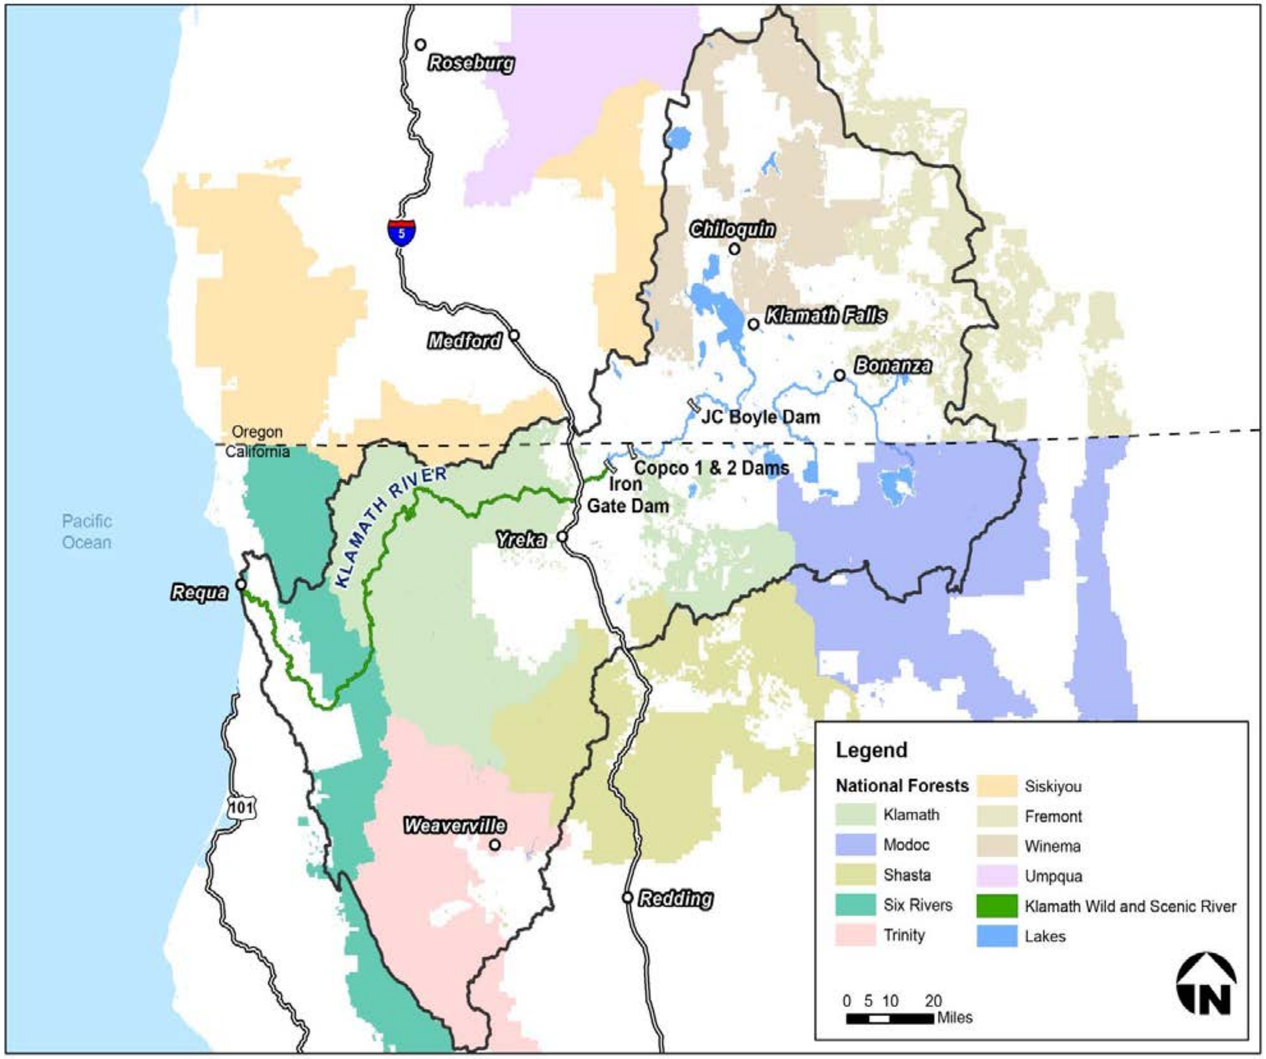

Figure 3.20-3. Klamath Wild and Scenic River Corridor.

California Klamath River Wild and Scenic River Segment

The segment of the Klamath River in California, as well as portions of three tributaries (Salmon and Scott rivers and Wooley Creek), were added to the National Wild and Scenic River System in 1981 through Section 2(a)(ii) of the WSRA. The wild and scenic river portion of the mainstem Klamath River in California is classified as recreational with portions of the tributaries classified as scenic and wild. At the time of listing, the anadromous fishery, including salmon and steelhead, was considered to have the outstandingly remarkable value for the entire 286 miles of the designated segment, which includes the tributaries. For the purposes of evaluating the potential impacts of the Proposed Project on the wild and scenic qualities of this river segment, the following subsections summarize the conditions of the river at the time of the wild and scenic river designation, as well as changes to the condition of the river since the time of the designation that have affected its wild and scenic character.

Scenic Character

Scenery within the wild and scenic river segment of the Klamath River in California is dominated by natural settings. This segment's characteristic river flows, water appearance, anadromous fish, and riparian vegetation within a forested river canyon are the primary scenic aspects. Since 1981, flow regimes have varied moderately in response to water resource competition within the Klamath Basin. During summer months, these variations have typically been caused by water diversions (Van de Water et al. 2006). Copco No. 1 and Iron Gate reservoirs serve as the major sources of large seasonal phytoplankton blooms with the first documented toxic bloom in 2004 (see also Section 2.6 *Project Background* and Section 3.4.2.3 *Hydroelectric Reach*), which when transported into downstream reaches of the Middle and Klamath River reduce water clarity, cause discoloration, and result in surface scums that impair the historic scenic character of the river downstream from Iron Gate Dam. Extensive seasonal periphyton mats that colonize bottom surfaces in the Middle and Lower Klamath River , (see also Section 3.4.2.4 *Middle and Lower Klamath River*) can also result in water coloration, cloudiness, and limitations on depth of view. The level of reduced water clarity, discoloration, limitations on depth of view, and resulting scenic quality effects is dependent on viewer location. Views from on-river, in-river, or riverside viewpoints are most likely to display substantial changes to scenic quality indicators, while these changes are less likely to be noticed as viewed from nearby river canyon roadways and communities.

Similarly, seasonal and project-induced changes in flow and resulting scenic quality changes are more likely to be observed by on-water, in-water, and riverside viewpoints than nearby river canyon roadways and community viewpoints. The scenic quality of the river changes with different flow levels; more banks and mid-channel rocks are visible during low flows. The lowest monthly mean flows on the Klamath River occur in the summer (July and August), which also tends to coincide with the highest visitorship rates. Monthly mean flows below Iron Gate Dam (USGS Gage #11516530) in July and August have generally ranged from around 700 cfs to 1,100 cfs, with a few exceptions in drought years and wet years (USGS 2017). With the exception of 17 months between 1991 and 2004, flows have not dropped below 700 cfs since the dam was built; since 2004, flows have not dropped below 800 cfs (Van de Water et al. 2006 and USGS 2017).

Recreation

Before and since the wild and scenic designation, the flows released from Iron Gate Dam have greatly influenced the downstream Klamath River summer recreation season's whitewater boatability, challenge levels, safety hazards, potential for equipment damage, and the opportunity to access and experience the river's full range of rapids and channels. Exceptionally low summer time flow releases are especially adverse to wild and scenic river boating activities on the Klamath River. Table 3.20-14 compares flows at the time of the 1981 designation to flow conditions required for whitewater boating and recreational fishing (see Table 3.20-6 for optimal flow ranges) (Van de Water et al. 2006).

Table 3.20-14. Comparison of 1981 Flows to the Acceptable Range for Whitewater Boating and Fishing.

Month	Flows (cfs)	Whitewater Boating	Fishing
January	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
February	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
March	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
April	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
May	1,000	In acceptable boating flow range/optimal playboating range	In optimal range
June	710	Does not meet minimum boatable flow or playboating opportunities	Does not meet minimum fishing flow
July	710	Does not meet minimum boatable flow or playboating opportunities	Does not meet minimum fishing flow
August	1,000	In acceptable boating flow range/optimal playboating range	In optimal range
September	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
October	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
November	1,300	In acceptable boating flow range/optimal playboating range	In optimal range
December	1,300	In acceptable boating flow range/optimal playboating range	In optimal range

Key:

cfs: cubic feet per second

Although precise estimates of available recreation days in 1981 are not available, commercial recreational whitewater boating activity on the Klamath River within the Klamath National Forest, increased by approximately 34 percent between 1981 and 2005 (Van de Water et al. 2006). However, commercial activity on the Lower Klamath River has decreased somewhat since 2005 from a recorded 10,695 user days to 8,230 user days in 2009. Private recreational whitewater boating activity has followed a similar pattern, with the greatest number of user days between 1995 and 2005 (ranging from

4,193 to 5,230) and decreasing since 2005 to a low of 3,525 user days in 2009 (DOI 2011).

Water Quality

Water quality influences recreational use and it is one of the criteria considered in a Wild and Scenic River designation. Water quality issues have existed since the time of wild and scenic river designation and there is evidence indicating that these issues may have increased since that time (Kann and Corum 2009, Asarian and Kann 2011, Asarian and Kann 2013). Data collected in the past five years provides further evidence water quality issues continue to persist (Watercourse Engineering, Inc. 2012, 2013, 2014, 2015, 2016). Water quality issues in the Klamath River, including phytoplankton blooms and microcystin toxin from blue-green algae [cyanobacteria], affect river recreation users (also see discussions in Section 3.20.2.2 *Klamath River-based Recreation*, and Section 3.20.2.3 *Lower Klamath Project Reservoir-based Recreation*). Monitoring of blue-green algae [cyanobacteria] species that produce algal toxins conducted by the Karuk Tribe between 2005 and 2007 at 16 nearshore stations in the Klamath River downstream of Iron Gate Dam indicate that nearly 60 percent of samples taken between June and September exceeded the moderate risk level as defined by the World Health Organization (Kann and Corum 2009). Sampling conducted in 2007 shows that microcystin toxin is found as far downstream as the Yurok Reservation, near the river mouth (Kann 2006). In recent years, high levels of microcystin concentrations have continued to be measured during summer months in Copco No. 1 and Iron Gate reservoirs with the microcystin concentrations exceeding the state recommended threshold in recreational waters in most years since 2008 (North Coast Regional Board 2009, 2010, 2012a, 2013, 2014, 2016, 2017a). Microcystin concentrations in the reservoirs and much of the Klamath River exceeded the “Danger Tier II” threshold in August/September 2017 (North Coast Regional Board 2017). In addition, the entire length of the Klamath River’s wild and scenic river section in California currently does not meet North Coast Regional Board water quality objectives for temperature during certain times of the year (North Coast Regional Board 2017b; Watercourse Engineering, Inc. 2012, 2013, 2014, 2015, 2016; Asarian and Kann 2013). Water temperature in the Klamath Basin varies seasonally, with mean monthly temperatures in the river immediately downstream from Iron Gate Dam peaking at approximately 20 to 22.5°C (68 to 72.5°F) in July and August (Asarian and Kann 2013). Daily mean and daily maximum water temperatures during summer typically increase with distance downstream from Iron Gate Dam due to meteorological controls until between Seiad Valley and Orleans, then, as the Klamath River approaches the coast, the daily mean and daily maximum water temperatures decrease with distance downstream due to the influence of cooler coastal air temperatures as well as incoming flow from cooler tributaries such as the Salmon and Trinity rivers (Basdekas and Deas 2007, Asarian and Kann 2013). A detailed description of existing water quality is provided in Section 3.2.2 *Environmental Setting* and Appendix C.

Fisheries

The Klamath River was designated a wild and scenic river from3,600 feet downstream of Iron Gate Dam to the mouth because of its free-flowing condition and its outstandingly remarkable anadromous fisheries, including that of salmon and steelhead trout. Even at the time of designation, decreasing salmonid trends in the Klamath River system were identified as being affected by various factors, including dam construction and operations related to hydropower generation in the Klamath River (Snyder 1931; DOI 1980; see also Section 3.3.2.1 *Aquatic Species*). Such factors have resulted in increased summer water temperatures, changed the natural flow regime, decreased dissolved oxygen levels in portions of the river, and blocked access to more than 350 miles of anadromous salmonid spawning, incubation, and rearing habitat.

Fisheries and the associated fisheries wild and scenic river conditions in the Klamath River are also affected by the coarse sediment deficit resulting from sediment trapping in the Lower Klamath Project developments, which has resulted in coarsening of the channel bed and a reduction in the size and frequency of mobile coarse sediment deposits in a limited downstream channel extent. Because tributaries downstream of Cottonwood Creek supply most of the coarse sediment to the mainstem Klamath River under both unimpaired and current conditions, the effects of reservoir sediment trapping are limited to the reach between J.C. Boyle Reservoir and approximately the Scott River. As discussed for fisheries resources in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project*, reduced coarse sediment delivery to this reach has reduced the amount and quality of spawning gravel deposits and disrupted the geomorphic processes that create and maintain aquatic habitats (Buer 1981, PacifiCorp 2004). Although the reach downstream of Iron Gate Dam was historically a prime spawning area, by 1981 the reach produced few salmon and the riffles within the reach contained cobbles too large for salmon to move. Prior to the construction of Iron Gate Dam and the 1981 wild and scenic river designation, the reach between Iron Gate Dam and Shasta River was scoured by daily peak flows from Copco No. 1 and Copco No. 2 operations (Van de Water et al. 2006).

Given the findings of the 2006 study, it appears that much of the riverbed coarsening had occurred prior to the wild and scenic river designation (Van de Water et al. 2006). However, impacts from dams progress over time so continued sediment depletion (by the retention of sediment behind the dams) is expected to continue to worsen spawning habitat below Iron Gate Dam (Ligon et al. 1995, Kondolf 1997, Grant et al. 2003).

River flows also affect fisheries' population and abundance. Table 3.20-14 shows the monthly flows at the time of the Klamath River's wild and scenic river designation. Flows are a key component of cumulative effects from water management on the aquatic environment. The flow regime downstream from Iron Gate Dam affects aquatic resources through instream flow influences on physical habitat (depth, velocity, substrate, and cover) and on water quality that may affect the prevalence of disease pathogens (Bartholow et al. 2005). See Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* for a discussion of the Klamath River flows under the Proposed Project.

Estimates of abundance for anadromous fisheries in California at the time of the wild and scenic river designation are not available for all species. Table 3.20-15 provides estimates of abundance at the time of designation, or as near as possible to the time of designation for those species for which data is available. As discussed in Section 3.3.2.1 *Aquatic Species*, the abundance of anadromous fisheries has decreased since the time of the wild and scenic river designation. Specific units of coho salmon in the Klamath River were listed as threatened under the ESA in 1997. Similarly, green sturgeon was listed by NMFS as a Species of Concern in 2005 and designated as threatened under the ESA in 2010. The resident (i.e., non-anadromous) Lost River and shortnose suckers endemic to the Upper Klamath Basin of southern Oregon and northern California were designated as endangered in 1988 after the wild and scenic river designation.

Table 3.20-15. Estimated Abundance of Fish Species at the 1981 Wild and Scenic River Designation.

Species	Estimated Abundance
Fall Chinook salmon	Natural spawners – 4,000 (1981)
	Iron Gate hatchery spawners – 21,595 (1981)
Coho salmon	3,400 (1984)
Summer Steelhead	110,000 (average 1977–1991)
Winter Steelhead	20,000 (average 1977–1991)

Source: Van de Water et al. 2006

Wildlife

Wildlife populations have not been systematically surveyed on the Klamath River. Baseline data were not collected in 1981; therefore, population numbers or trends are not available for most species in specific areas like the wild and scenic river corridor.

Riparian vegetation provides habitat for feeding, breeding, and sheltering for willow flycatchers, western pond turtles (a species of special concern in California), and various other wildlife species along the Klamath River. There is no reference condition for the riparian vegetation in 1981 (Van de Water et al. 2006). The Proposed Project area and the area within the Klamath River corridor includes a large number and diversity of wildlife species. Surveys conducted by PacifiCorp in 2002 and 2003 identified five amphibian species, numerous bird species, including 19 species of birds of prey, and numerous mammal species, including black-tailed jackrabbit, mule deer, and California ground squirrels. See Section 3.5 *Terrestrial Resources* for further discussion of wildlife populations within the Klamath River corridor.

Eligible and Suitable Wild and Scenic River Section on the Klamath River

In 1990, BLM found the 5.3-mile section of the Klamath River from the California-Oregon state line to the slack water of Copco No.1 Reservoir to be eligible and suitable for wild and scenic river designation under Section 5(d)(1) of the WSRA. The river segment is free-flowing and possesses outstandingly remarkable scenic, recreational, fish, and wildlife values. This river segment is not a designated wild and scenic river and is not protected under the WSRA and its Section 7(a) requirements. The BLM is required, within its authorities, to protect this suitable river segment's free-flowing character, water quality, and outstandingly remarkable river values. This segment of the Klamath River is also listed on the Nationwide Rivers Inventory (NPS 2009). If a river is listed in the Nationwide Rivers Inventory, the federal agency involved with the action must consult with the land managing agency in an attempt to avoid or mitigate adverse effects of any proposed water resources projects. This consultation is required pursuant to a directive from the Council on Environmental Quality.

3.20.3 Significance Criteria

Criteria for determining significance on recreational opportunities are based on Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgement. As the Appendix G checklist questions for recreational impacts are limited, two additional criteria were added for this EIR as there is potential for impacts on a variety of users and uses under the Proposed Project.

Impacts from the Proposed Project would be considered significant if any of the following criteria are met:

- Changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people.
- Significant increase in the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facilities would occur or be accelerated.
- Construction of new or expansion of existing recreational facilities which might have an adverse physical effect on the environment.
- Affect identified resource values in a wild and scenic river segment (i.e., scenic, recreational, fish, and wildlife) such that the long-term wild and scenic river designation or eligibility for listing would be compromised.

3.20.4 Impact Analysis Approach

The impact analysis for recreational resources considers the potential implications of the Proposed Project on changes to river- and reservoir-based recreation opportunities, activities, and settings within the Area of Analysis. Short-term and long-term effects on access, flow-dependent recreational activities, recreational fishing, and other recreational activities associated with the existing Klamath River corridor and reservoir recreational facilities within the Area of Analysis are described. The relocation of the City of Yreka's water supply pipeline is not expected to result in any impacts to recreational resources; therefore, it is not addressed in this section of the EIR.

3.20.4.1 Recreational Setting, Facilities, and Access

Likely changes to recreational use and access were assessed qualitatively, including changes from reservoir-based recreational opportunities to more river-based opportunities in the areas where the Lower Klamath Project dams, recreational facilities, and/or PacifiCorp facilities would be removed. The short-term effects analysis includes a discussion of potential areas where recreational access would be restricted during construction activities. The assessment of long-term effects considers potential changes in the recreational setting and experience, changes in water quality and reservoir area revegetation for Klamath River-based recreational opportunities, as well as potential impacts on regional recreational facilities due to increased use.

3.20.4.2 Whitewater Boating Opportunities

Optimal and acceptable flows for whitewater boating opportunities along reaches of the Klamath River were assessed as a part of the technical review completed for the Proposed Project. The range of acceptable flows resulted from the Final Technical Report, Klamath Hydroelectric Project (PacifiCorp 2004). Flow values that fall within these ranges are considered acceptable flow levels for the various activities (see Table 3.20-6).

Hydrologic modeling was used to assess changes in the availability of acceptable flows under the various alternatives. The modeling results for each water year type were subjected to a statistical analysis (paired T-tests) to determine whether the difference in number of days meeting the acceptable range of flows following dam removal (both on an annual and monthly basis) would be statistically significant. A qualitative approach was used to assess the effects of the identified alternatives on whitewater boating access and existing whitewater boating opportunities.

3.20.4.3 Recreational Fishing Opportunities

The results of the hydrologic modeling were used to: determine whether changes in flow would affect recreational fishing opportunities (i.e., the number of days with optimal flows for recreational fishing); qualitatively assess potential changes in fisheries populations and abundance; and determine effects of changes from reservoir-based fishing opportunities to river-based opportunities.

3.20.4.4 Other Recreational Opportunities

The analysis also includes an assessment of other recreational activities, such as sightseeing, swimming/wading/tubing, fish and wildlife viewing, and camping that occur within the river corridor and a qualitative discussion of the effects of the various alternatives on these activities. The discussion here covers both anticipated short-term effects, such as construction-related effects, and long-term effects, such as changes in reservoir-based swimming opportunities.

3.20.4.5 Wild and Scenic Rivers

Evaluation criteria for each of the four protected resources specified in the WSRA Section 7 (a) (i.e., scenic, recreational, fish, and wildlife) have been developed to assess the effects of the Proposed Project as compared with conditions at the date of the Klamath River's designation into the National Wild and Scenic Rivers System (see Section 3.20.2.4 *Wild and Scenic River Conditions*). The type (positive or negative) and duration (short term or long term) of the effects are described, and the magnitude of these effects is analyzed. The effects are characterized as unchanged, beneficial, or adverse (or similar conclusion), by value (i.e., scenic, recreational, fisheries, and/or wildlife), for that resource.

Scenery was evaluated using the following criteria:

- Water flow character (river flows and accompanying river width, depth, and channel inundation or exposure)
- Water appearance (clarity, turbidity, depth of view, color, prominence of phytoplankton and periphyton)
- Fish and wildlife viewing
- Riparian vegetation
- Natural appearing landscape character (the visual effects of facilities and structures as viewed from within the designated wild and scenic river corridor)

Recreation was evaluated using the following criteria:

- Whitewater boating
- Recreational fishing
- Other recreational activities (water play, swimming, camping)
- Recreational setting (water quality related aesthetic odors, tastes, contacts, and public health and safety aspects)

Fishery was evaluated using the following criteria:

- Stream flow regime
- Water temperature
- Water quality (physical, biological, and chemical)
- Aquatic habitat (geomorphic condition, sediment transport regime, and substrate quality)
- Fish species population conditions, specifically:
  - Anadromous salmonid fish species
  - Resident fish species
  - Species traditionally used and culturally important to Native Americans

Wildlife was evaluated using the following criterion:

- Changes in habitat for affected species

3.20.5 Potential Impacts and Mitigation

Potential Impact 3.20-1 Effects on existing recreational facilities and opportunities due to access restrictions, noise, dust, and/or sediment release resulting from construction activities.

Construction activities associated with dam removal would result in temporary loss of access to recreational facilities at the Lower Klamath Project reservoirs and associated reservoir-based recreational opportunities. Access could remain restricted for an additional period following completion of dam removal as restoration activities are conducted on the former reservoir area and existing recreational areas are modified to accommodate the new river channel. However, as described above in Section 3.20.2.1 *Regional Recreation*, a number of reservoirs, lakes, and rivers are present within and adjacent to the Klamath Basin and provide similar opportunities for recreational activity. Therefore, temporary impacts on recreational access in the vicinity of Iron Gate and Copco No. 1 reservoirs would be less than significant.

As described in Potential Impact 3.9-1 and Potential Impact 3.23-1, the use of heavy vehicles and equipment during dam removal activities, and to a much lesser degree during restoration, would result in increases in dust and ambient noise in the vicinity of the Proposed Project. These activities will primarily occur over a period of approximately one and a half years; however, in any one location, there will generally be less than six months of nuisance generating activities (see Table 2.7-1). These increases could indirectly result in a decrease in the quality of recreational experiences at nearby facilities that would not have restricted access during construction (e.g., river access, trails, and private parks not directly affected by construction and reservoir drawdown). Specific effects related to dust and noise during construction are discussed in detail in Potential Impact 3.9-1 and Potential Impact 3.23-1, respectively.

With regard to recreational activities, increases in ambient noise and air pollutants could impede visitors' ability to rest and relax, and disrupt bird and wildlife viewing opportunities. These effects would last for the duration of demolition activity and during initial restoration activities. However, as shown in Figures 3.20-2(a-c), the majority of recreation facilities and access points at the Lower Klamath Project reservoirs and along the Hydroelectric Reach are located a fair distance away from the Lower Klamath Project dams and would continue to provide opportunities for recreation until drawdown is completed. Because noise and dust impacts decrease with increasing distance from the source, impacts at these recreational facilities will be minimal. Further, as described in Section 3.20.2.1 *Regional Recreation*, numerous other recreational facilities are available outside the area of affect, but within the vicinity of the Iron Gate and Copco No. 1 reservoirs that provide similar recreational opportunities (Table 3.20-4). Therefore, these temporary noise and dust impacts would be less than significant.

As discussed in Potential Impact 3.2-3, drawdown of the reservoirs would result in short-term increases in turbidity (also expressed as suspended sediment concentration) downstream from the Lower Klamath Project reservoirs. Elevated turbidity would be most pronounced immediately downstream from Iron Gate Dam to Bogus Creek and it would become less noticeable farther downstream due to dilution from tributary flows entering the Klamath River. Modeling of suspended sediment concentrations during drawdown indicates suspended sediment concentrations would decrease to 60 to 70 percent of the initial value by Seiad Valley (RM 132.7) and to 40 percent of the initial value downstream of Orleans (approximately RM 59). Turbidity in the Klamath River is anticipated to flush through the system relatively quickly, but elevated turbidity is conservatively anticipated to occur for six to ten months following drawdown based on modeling of suspended sediment concentrations (USBR 2012a). Sediment jetting would occur during drawdown maximize erosion of accumulated sediments during this period and potentially reduce turbidity after drawdown concludes, and immediate revegetation will occur to further minimize the potential for prolonged increases in turbidity. Turbidity in the Klamath River is expected to resume natural background levels by the end of post-dam removal year 1 regardless of the water year type based on modeling of suspended sediment concentrations (USBR 2012a) (see Potential Impact 3.2-3 for more details).

The increase in turbidity would reduce visibility for boaters, swimmers, and fishermen during the sediment flushing period and could result in reduced public participation for these activities (e.g., swimmers might be less likely to enter the river, and fishermen might be less successful due to the reduced water clarity). Increased turbidity would also affect swimmer safety considerations if swimmers are unable to see the river bottom or navigate around obstacles, such as large boulders or logs beneath the water surface. However, impacts would be temporary; following completion of reservoir drawdown activities, water quality and clarity would be expected to improve as sediments are flushed downstream and into the Pacific Ocean. Due to naturally high levels of turbidity in the river during winter flows, increased turbidity from the Proposed Project would not be noticeable for most of the drawdown period. In addition, turbidity impacts primarily would occur for a period of approximately six to ten months, with turbidity decreasing with distance downstream of Iron Gate Dam due to dilution from tributary flows entering the Klamath River. Turbidity would likely be only slightly above or similar to natural background turbidity in the Klamath River downstream of Seiad Valley (RM 132.7) by mid-May following drawdown based on a comparison of model SSCs during drawdown and natural background SSCs, except during dry water year types when turbidity may remain above natural background turbidity until after September (USBR 2012a). While opportunities for fishing and swimming in the vicinity of the Klamath River, including the area where Copco No. 1 and Iron Gate reservoirs are located, would be reduced during the drawdown period when these recreational activities would typically be low, opportunities for fishing and swimming in the Klamath

River downstream of Seiad Valley (RM 132.7) during the deconstruction period would be similar or slightly reduced compared to existing conditions since turbidity would only be slightly above or to similar to natural background turbidity levels during most water year types. Additionally, opportunities for fishing and swimming would remain available in tributaries of the Klamath River during both drawdown and deconstruction. As such, the Proposed Project would not result in changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people; therefore the impacts are less than significant.

Sediment release could also decrease the quality of water-contact-based recreational opportunities if sediment released downstream resulted in longer-term deposition in pools, eddies, slack water, and beaches and decreased the availability of these areas for recreational activity. As discussed in Potential Impact 3.11-5, modeling was conducted to determine the potential for such deposition following dam removal activities. The results of the modeling indicate that following dam removal activities, short-term deposition of fine and coarse sediment would occur primarily between Iron Gate Dam and Cottonwood Creek and average river bed elevation would change (i.e., increase or decrease) by up to 1 foot (see Figure 3.11-15). The Proposed Project was developed to allow reservoir drawdown to occur during winter months when precipitation, river flows, and turbidity are naturally highest. Suspended sediment concentrations would be highest during the period of greatest reservoir drawdown (January through mid-March of dam removal year two), as erodible material behind the dams is mobilized downstream (see also Potential Impacts 3.2-3 and 3.11-6). During normal to dry water years, suspended sediment concentrations would begin to decline in late March and would continue declining through early summer. If it is a wet year, it may take longer to drain the reservoirs and the high concentrations may extend until June. Suspended sediment concentrations would return to near background conditions for all water year types within the first year following removal (see also Potential Impact 3.2-3). Therefore, it is unlikely that sediment release would decrease the availability of pools, eddies, or beaches for recreational activity, even temporarily, and impacts on the quality of water contact-based recreational opportunities would not be- significant.

Overall, the impacts of construction and restoration activities are limited in temporal and geographic scope and so would not result in changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people. Nor would they result in a significant temporary increase in the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facilities would occur or be accelerated. Tables 3.20-2, 3.20-3, and 3.20-4 show that there are numerous alternative recreational facilities and access outside the area of affect, but within the vicinity. Most of these facilities experience low to moderate use levels and they can accommodate additional users. Recreational users who are temporarily displaced would be able to use these other areas, but they are unlikely to overload the other areas because those areas have sufficient capacity to accept them. Therefore, impacts will be less than significant.

Significance

No significant impact

Potential Impact 3.20-2 Long-term changes to or loss of reservoir-based recreation activities and facilities due to removal of Iron Gate and Copco No. 1 reservoirs. The removal of Iron Gate and Copco No. 1 reservoirs under the Proposed Project would eliminate existing opportunities for reservoir-based recreation activities, such as power boating, waterskiing, lake swimming, and flat-water boat angling. Copco No. 2 Reservoir is very small and has no recreational facilities or access. As discussed in Section 3.20.2.3 *Lower Klamath Project Reservoir-based Recreation*, Iron Gate and Copco No. 1 reservoirs are popular recreational areas for sightseeing, fishing, camping, swimming, boating, and wildlife viewing, and they attract visitors primarily from the surrounding communities in Klamath and Jackson counties, Oregon and Siskiyou County, California. As indicated in the responses to visitor use surveys conducted by PacifiCorp (2004), the reservoirs are popular recreation areas in part because they are uncrowded relative to other lakes in the area and do not require user fees. Some activities associated with reservoir recreation could still be possible in the restored river channel (e.g., swimming and wading). However, due to increased flows, certain reservoir-based recreation such as swimming opportunities and flat-water boating may be limited in the restored river channel during certain times of year and in wet water years.

Thus, under the Proposed Project there would be a long-term loss of local reservoir-based recreational activities at Iron Gate and Copco No. 1 reservoirs, but there would be no change from existing conditions in reservoir-based recreational activities at Copco No. 2 since it has no recreational facilities or access.

However, a number of other lakes and reservoirs are in the vicinity of the Lower Klamath Project reservoirs and provide similar opportunities for recreation in an uncrowded setting (Table 3.20-4). Specifically, Fourmile Lake, Agency Lake, Applegate Reservoir, and Medicine Lake, located from 26 to 46 miles away from the Lower Klamath Project reservoirs, each have generally low-use levels as well as similar or greater surface area, a greater number of developed campsites, and a similar number of improved boat launches compared with Iron Gate and Copco No.1 reservoirs (PacifiCorp 2004). As described in Section 3.20.2.1 *Regional Recreation* (in particular, see Table 3.20-4), there are more than 85 boatable lakes in Klamath and Jackson Counties in Oregon and Siskiyou County in California that are within 100 miles of the Lower Klamath Project reservoirs and provide similar facilities and activities. The Lower Klamath Project reservoirs only account for less than 1.5 percent of the surface area of the regional lakes, 2.2 percent of the developed campsites and 1.1 percent of the boat launches. The percent of picnic areas was not calculated, because Table 3.20-4 only includes day-use only picnic areas and does not include day-use areas that are also associated with overnight facilities. In addition, there are a multitude of other recreational facilities in the region; Table 3.20-1 lists public lands, but there are private facilities as well. Also, approximately two-thirds of recreational visitors to the Lower Klamath Project reservoirs had negative perceptions of water quality, stating concerns of bad odors and phytoplankton (e.g., blue-green algae) blooms, which restrict areas available for fishing, swimming, and wading (PacifiCorp 2004). Therefore, the loss of Iron Gate and Copco No.1 reservoirs under the Proposed Project would not result in a long-term loss in regional lake-based recreational activities that would affect a large area or a substantial number of people.

With respect to local recreational facilities and access points, the Proposed Project would completely remove most of the existing recreational sites at Iron Gate, Copco No. 1, and J.C. Boyle reservoirs, which primarily provide fishing, boating, and day-use access to the three reservoirs. Several existing recreational sites also provide camping facilities for overnight use. Decommissioning of these facilities would include removal of structures, concrete and pavement, regrading and revegetation of associated parking areas, access roads, and other improvements (Appendix B: *Definite Plan – Appendix Q*). Facilities at Fall Creek and Jenny Creek Day-Use Areas at Iron Gate Reservoir, Topsy Campground at J.C. Boyle Reservoir, and the Iron Gate Fish Hatchery Day-Use Area downstream of Iron Gate Reservoir, would remain, where possible, and be upgraded or enhanced (Appendix B: *Definite Plan – Appendix Q*). In addition, most existing river access facilities would be retained and upgraded.

The Proposed Project includes a Recreation Plan (see Appendix B: *Definite Plan – Appendix Q* for the Draft Recreation Plan) that would be used to identify new recreation opportunities that offset the proposed removal of reservoir recreation sites as well as the reduction in whitewater boating days resulting from the Proposed Project (see Potential Impact 3.20-5 for a discussion of whitewater boating). KRRC has started an ongoing stakeholder outreach process seeking input from potentially impacted recreation users, operators, managers and administrators, including tribes, state and federal agencies, county agencies and chambers of commerce, local residents, recreation businesses, and public interest groups. The stakeholder outreach process would continue through the development of the Final Recreation Plan, which is scheduled for completion by KRRC in June 2019. The Draft Recreation Plan includes potential recreation opportunities identified in the USBR (2012) Detailed Plan as well as those identified through recent stakeholder outreach efforts. The Draft Recreation Plan also outlines preliminary criteria for screening opportunities, including whether each recreation opportunity would: *"directly address the recreation impacts generated by the KHSA;"* and *"directly address or offset changes in the localized reservoir recreation or Hells Corner boating near where the impacts are occurring."* In addition, the Proposed Project includes the transfer of approximately 8,000 acres of real property (Parcel B lands; see also Section 2.7.10 *Land Disposition and Transfer*) located in Klamath County, Oregon, and Siskiyou County, California, to the respective states (or a designated third party) for public interest purposes, including river-based recreation, open space, active wetland and riverine restoration, and public education.

The Proposed Project would result in the loss of the locally popular fishery for non-native fishes including largemouth bass, trout, catfish, crappie, sunfish, and yellow perch (Hamilton et al. 2011). Fishing is popular in Copco No. 1 and Iron Gate reservoirs, especially for yellow perch, with one fishing guide (Shaffer 2005) considering the reservoirs the best yellow perch fishery in California. Without the Lower Klamath Project dams, fishing for non-native warm water species would be lost at the Lower Klamath Project reservoirs. While the yellow perch fishery in the reservoirs is considered by Shaffer (2005) to be the best in California, it does not constitute a unique recreational resource since there are other yellow perch fishing opportunities near the Copco No. 1 and Iron Gate reservoirs in northern California and southern Oregon, including Emigrant Lake (Ashland Daily Tidings 2009). Additionally, fishing tournaments like the largemouth bass tournaments (e.g., Rogue Valley Bassmasters) in Iron Gate Reservoir would no longer occur under the Proposed Project (Hamilton et al. 2011). However, yellow perch fishing and bass tournaments occur in dozens of lakes in northern California and southern Oregon, including some of those listed in Table 3.20-4, because these non-native fish occur over large areas of the Western United States. Thus, Copco No. 1 and Iron Gate reservoirs do not constitute a unique recreational resource with respect to perch, largemouth bass, and other warm water fishing. Steelhead, trout, and salmon fisheries would be enhanced by the Proposed Project, since Lower Klamath Project reservoir habitat would be replaced by riverine habitat that supports these cold water species. Lastly, the loss of warm-water fishing in Iron Gate and Copco No. 1 reservoirs does not represent the loss of a recreational resource that would affect a large number of people. Therefore, fishing-related impacts from the Proposed Project would be less than significant.

Given that a number of other lakes and reservoirs in the vicinity of the Lower Klamath Project provide similar opportunities for reservoir-based recreation in an uncrowded setting, KRRC's proposal to retain and enhance most existing river access facilities within the Area of Analysis for recreation, and Parcel B land transfer under the Proposed Project that would potentially allow for additional future river-based recreation opportunities, the Proposed Project would be highly unlikely to result in a loss of rare or unique recreational facilities affecting a large area or substantial number of people. In addition, the KRRC has prepared a Draft Recreation Plan (Appendix B: *Definite Plan – Appendix Q*) that includes stakeholder outreach, identification of potentially new or modified recreational facilities as well as evaluation and screening criteria, which will further reduce any potential impacts.

Significance

No significant impact

Potential Impact 3.20-3 Significant increase in the use of regional recreational facilities due to loss of Iron Gate and Copco No. 1 reservoirs, such that substantial physical deterioration or acceleration of deterioration of the regional facilities would occur.

The Proposed Project would result in the loss of reservoir-based recreational facilities at Iron Gate and Copco No. 1 reservoirs, but this impact is not significant for the reasons discussed in Potential Impact 3.20-2. While the Proposed Project also includes the creation of additional recreational facilities and opportunities, the types of river-based recreational opportunities available following dam removal activities, including camping in a river setting as opposed to camping in a lake/reservoir setting, may not appeal to the same recreational users who currently visit and recreate at Iron Gate and Copco No. 1 reservoirs. In other words, while new recreation opportunities would exist along the restored river corridor, there could be a change in user type.

A number of other lakes and reservoirs are in the vicinity of the Lower Klamath Project reservoirs and provide similar opportunities for recreation in an uncrowded setting for people specifically seeking lake or reservoir-based recreation (Table 3.20-4). Specifically, Fourmile Lake, Agency Lake, Applegate Reservoir, and Medicine Lake, are located from 26 to 46 miles away from Iron Gate and Copco No.1 reservoirs, and each exhibits generally low use-levels as well as similar or greater surface area, number of developed campsites, and number of improved boat launches. Within Klamath County and Jackson County, Oregon, and Siskiyou County, California, there are more than 85 boatable lakes, containing nearly 40 boat ramps (Boat Escape 2017). There are also more than 180 high-elevation and wilderness lakes in Siskiyou County (FERC 2007). In addition to boat ramps, these lakes provide nearly 2,300 developed campsites within less than a two-hour drive from Iron Gate and Copco No. 1 reservoirs (Table 3.20-4). The Lower Klamath Project reservoirs only account for less than 1.5 percent of the surface area of the regional lakes, 2.2 percent of the developed campsites and 1.1 percent of the boat launches. In addition, there are a multitude of other recreational facilities in the region; Table 3.20-1 lists public lands, but there are private facilities as well. Given the number and proximity of these regional lakes, as well as other lakes and reservoirs summarized in Table 3.20-1, the loss of Iron Gate and Copco No. 1 reservoirs under the Proposed Project would not be a significant impact because it would not result in a substantial increase in the use of regional lake and reservoir recreational facilities such that deterioration of those facilities would occur or be accelerated.

Significance

No significant impact

Potential Impact 3.20-4 Effects on the environment due to construction of new or expansion of existing recreational facilities.

As described previously, the Proposed Project involves the development and implementation of a plan to construct new recreational facilities and river access points along the restored river channel between the California-Oregon border and Iron Gate Dam following dam removal activities. Replacement of recreation facilities would not necessarily be "like for like", but rather would be designed to accommodate similar levels, if different types of use. This would require the creation of new gravel roads and other improvements for vehicle and visitor access to and use of the new river-based recreation sites, which could result in construction-related impacts to the environment, including potential impacts to water quality and historical and/or tribal cultural resources.

While new recreation facilities are part of the Proposed Project, the final location, size, and design of the facilities are still under development and will be the subject of subsequent approvals. It is thus too soon to conduct a meaningful environmental analysis of the replacement facilities. However, construction and operation of new recreational facilities would undergo any environmental review necessary for the subsequent approvals, and any impacts of the construction and operation of the facilities would be mitigated, if feasible, to levels that comply with all applicable laws, regulations, and environmental standards. Because this component of the Proposed Project would not be approved until a later date, for the purposes of this EIR the impacts of this component are not significant.

Significance

No significant impact

Potential Impact 3.20-5 Changes to or loss of river conditions that support whitewater boating.

Dam removal activities would not affect whitewater boating access locations, as access areas are at established places along the Klamath River channel, outside of the Lower Klamath Project reservoirs and would not be affected by dam removal activities. As discussed in the impact analysis above and in Potential Impact 3.11-6, drawdown of the reservoirs would not result in substantial changes to the floodplain or river channel. Thus, no impacts to land-based recreational facilities would be expected. Therefore, there would be no adverse impacts on whitewater boating access downstream of Iron Gate Dam. However, in the reaches between the existing dams, particularly in the Hell's Corner Reach, whitewater boating access would likely be temporarily affected due to dam removal activities and sedimentation, as discussed previously. However, these short-term impacts on whitewater boating access locations would be less than significant.

The average number of days providing acceptable river flows in specific reaches each month was modeled for specific recreational activities as part of the 2012 KHSA EIS/EIR under the KBRA Flows (see Appendix S). However, flow requirements in the Klamath River have changed since the modeling for the 2012 KHSA EIS/EIR was performed, with 2013 BiOp Flows replacing the KBRA Flows as detailed in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* and Appendix S.

Differences in the monthly flow ranges between the 2013 BiOp Flows and the KBRA Flows result in changes to the previously-modeled number of days with acceptable flows for whitewater boating during certain months. The greatest differences would occur during summer and fall in the Klamath River reaches between Keno and Iron Gate dams due to variations in the amount of time flows would be within the acceptable range for whitewater boating between the 2013 BiOp Flows and the KBRA Flows. Whitewater boating requires a minimum flow of 1,000 cfs to 1,300 cfs in the Keno, J.C. Boyle Bypass, and Hell's Corner reaches of the Klamath River. In July through September, KBRA Flows would exceed 1,000 cfs during wet water years, with KBRA Flows exceeding 1,300 cfs during wet water years in July. However, the 2013 BiOp Flows would remain below 1,000 cfs during all water year types between July through September, so the number of days whitewater boating could occur between July and September in the Keno, J.C. Boyle Bypass, and Hell's Corner reaches of the Klamath River would be zero under the 2013 BiOp Flows. Conversely, in October the average number of days of whitewater boating would increase under the 2013 BiOp Flows relative to the KBRA Flows since the 2013 BiOp Flows exceed 1,000 cfs in 30 percent of years, but the KBRA Flows are always below 1,000 cfs. Overall, the average number of days supporting whitewater boating for all water year types between Keno and Iron Gate dams would decrease under the 2013 BiOp Flows compared to under the KBRA Flows, since decreases in July through September are expected to be greater than an increase in October (see Appendix S for more detail). Downstream of Iron Gate Dam, the differences between the 2013 BiOp Flows and the KBRA Flows would not significantly alter the previously modeled average number of days whitewater boating could occur because the flow variations would occur within the range of acceptable flows for whitewater boating. Thus, the average annual number of days estimated by the previous modeling downstream of Iron Gate Dam is generally representative of trends and conditions under the 2013 BiOp Flows (see Appendix S for more detail).

Model results under the KBRA Flows indicate that the changes in the availability of flows within the acceptable flow ranges for whitewater boating and fishing opportunities would be negligible for the reaches downstream from Iron Gate Dam. As previously discussed, whitewater boating opportunities under the Proposed Project with 2013 BiOp Flows would be similar to model results under the KBRA Flows downstream of Iron Gate Dam. Dam removal activities would likely improve access and create new opportunities in the reservoir reaches, which would benefit whitewater boating opportunities in this area. Given negligible changes in flows and improvements in access, impacts in reaches downstream from Iron Gate Dam would not be significant.

The reaches of the Klamath River that are currently inundated by the existing Copco No. 1 and Iron Gate reservoirs would be converted to free-flowing riverine reaches over the long term, and depending on the river channel and access, could provide additional opportunities for whitewater boating in these reaches. However, river flows following dam removal activities were not modeled for areas currently inundated by reservoirs. While it could be expected there would be additional opportunities for whitewater boating in these reaches, no records exist of the condition or suitability of the presently inundated areas for whitewater boating activities. With details of the condition of these areas lacking, it is too speculative to determine the quality and quantity of whitewater boating opportunities that could be realized due to dam removal activities in areas currently inundated by reservoirs. Accordingly, this analysis does not rely on the creation of whitewater boating opportunities in these reaches.

In contrast, for the Copco No. 2 Bypass Reach, model results indicate there would be a substantial increase in whitewater boating opportunities during the July through September time period. Comparison of the monthly range of KBRA Flows utilized in the modeling with the 2013 BiOp Flows indicates that the whitewater boating opportunities during the July through September time period would still increase under 2013 BiOp Flows, but the magnitude of the increase may be more than modeled under the KBRA Flows for the 2012 KHSA EIS/EIR. The flows would be more likely to be within the range of acceptable flows for whitewater boating in the Copco No. 2 Bypass Reach (i.e., 600 cfs to 1,500 cfs) under 2013 BiOp Flows than the modeled KBRA Flows, especially during July (see Appendix S for more detail). The increase in the number of days with acceptable flows for whitewater boating would be a long-term beneficial effect on whitewater boating in the Copco No. 2 Bypass Reach.

In the J.C. Boyle Bypass Reach, modeling done in 2012 under the KBRA Flows show an increase in the average annual number of days with acceptable flows for whitewater boating during the July through September time period after implementation of the Proposed Project. Under the Proposed Project with 2013 BiOp Flows there would be no increase in the whitewater boating opportunities in the J.C. Boyle Bypass Reach. Similar to baseline conditions, Klamath River flow between July and September would remain below the minimum flow necessary for whitewater boating in this reach (i.e., 1,000 cfs) under the 2013 BiOp Flows, so the average annual number of days with acceptable flows for whitewater boating under the Proposed Project would be similar to the model results for the No Project scenario (see Appendix S for more detail). With the Proposed Project operating under the 2013 BiOp flow regime, there would be no impact on whitewater boating in the J.C. Boyle Bypass Reach.

The Hell's Corner Reach is located partially in California and partially in Oregon. This stretch of river would be impacted by removal of the J.C. Boyle Dam, which is part of the Proposed Project and is located in Oregon. Since potential impacts to flows in the Hell's Corner Reach were brought up as an issue during the Lower Klamath Project scoping process, and because the impacts would also occur in California, a discussion and analysis is included in this EIR. Currently, the Hell's Corner Reach is the only Class IV+ rapids in the region with late summer flows. Whitewater rafters can boat on the Hell's Corner Reach from April through October due to hydroelectric peaking power and flows historically generated by J.C. Boyle Powerhouse to meet high power demand periods. This typically occurs for four hours, between 10 a.m. and 2 p.m. each day. It also happens approximately 15 to 20 days per month in July, August and September. Additionally, flow peaking occurs on a predictable schedule, which is highly favorable for commercial boating operations. The vast majority of rafting is performed by permitted commercial outfitters, due to the technical difficulty of the run and lack of access to scouting points. There are 10 outfitters, which take up to 200 clients down the river per day, primarily between July and September, and BLM has set an overall carrying capacity of 250 people per day on this stretch of river (DOI 2011).

In the Hell's Corner Reach, there would be loss of acceptable flows for whitewater boating opportunities with the Proposed Project as compared to existing conditions. The minimum flow necessary for whitewater boating in this reach is estimated to be between 1,000 cfs and 1,300 cfs. Klamath River flow in the high demand months of July to September are expected to remain below 1,000 cfs under the 2013 BiOp Flows based on an evaluation of flow exceedance curves at Keno Dam. Flow accretion from groundwater springs may cause some increase in the flow between Keno Dam and the Hell's Corner Reach, but the flow exceedance curve at Keno Dam is still expected to be representative of flow conditions within the Hell's Corner Reach under the Proposed Project with 2013 BiOp Flows. Flow in the Hell's Corner Reach would be below the minimum flow necessary for whitewater boating between July and September, eliminating opportunities for whitewater boating during this time under the Proposed Project. For the month of October, some whitewater boating opportunities would exist during wetter years, with the Proposed Project operating under but there would be a significant reduction compared to existing (see Appendix S for more detail).

There are a number of alternative rafting opportunities in the region that are available all summer, including the Klamath River downstream of Iron Gate Dam, Trinity River and Rogue River. However, due to the lower late summer flows, the higher-class rapids are not available, typically from July until the fall rains start. From spring through early summer, there are ample whitewater rafting opportunities for all skill levels in the region (see Table 3.20-3). However, whitewater boating opportunities within the Hell's Corner Reach would be eliminated during July through September and significantly reduced in October.

The Proposed Project would result in the loss of a unique opportunity in the region to raft Class IV+ rapids for three months during the late summer and early fall. This would affect up to 250 people per day during that time, as well as 10 commercial outfitters. However, the resource is not lost completely due to the following: (1) alternative Class IV+ whitewater boating opportunities during other times of the year; and (2) ample alternative nearby rafting opportunities in the late summer, albeit with lower class ratings. However, the impact to whitewater boating opportunities in the Hell's Corner Reach (within the upper portion of the Hydroelectric Reach) would be significant and unavoidable.

Significance

No significant impact in the Middle and Lower Klamath River

Significant and unavoidable in the Hell's Corner Reach (within the upper portion of the Hydroelectric Reach)

Potential Impact 3.20-6 Changes to or loss of other river-based recreation including fishing.

No significant impacts to river-based recreational facilities upstream of the Hydroelectric Reach would occur as a result of the Proposed Project, because any changes to flow and water quality would occur within and downstream of this reach. However, as discussed in Potential Impact 3.3-7 through 3.3-11 in Section 3.3.5.9 *Aquatic Resource Impacts*, removal of the dams would help eliminate barriers to volitional fish passage in the Klamath River upstream of the Lower Klamath Project, which would beneficially affect recreational fishing at these upstream locations.

In general, river-based recreational facilities downstream of the Hydroelectric Reach would not be physically affected by dam removal activities, since there would be little change to the 100-year floodplain extent under the Proposed Project (see also Potential Impacts 3.6-3 and 3.20-1). However, along the Middle Klamath River from Iron Gate Dam (RM 193.1) to the confluence with Humbug Creek (RM 174.0), the 100-year floodplain extent would change slightly due to dam removal and this would potentially impact existing recreational facilities. At the Blue Heron RV Park, the Fish Hook Restaurant (see Site "FS-2" in Appendix B: *Definite Plan – Appendix C, Figure 7.7-1 Sheet 1*) is within the 100-year floodplain extent under current conditions and would remain within the (altered) 100-year floodplain extent following dam removals. The R Ranch office at the Klamath Campground (see Site "FS-3" in Appendix B: *Definite Plan – Appendix C, Figure 7.7-1 Sheet 2*) is also within the 100-year floodplain extent under current conditions and would remain within the (altered) 100-year floodplain extent following dam removals. Thus, there would be no change or loss to these facilities under the Proposed Project. The Blue Heron RV Park office structure (see Site "FS-1" in Appendix B: *Definite Plan – Appendix C, Figure 7.7-1 Sheet 1*) is not within the 100-year floodplain extent under current conditions and would be within the (altered) 100-year floodplain extent following dam removals. While there would be an increased potential for flooding at this office structure, this would not represent a change or loss of a rare or unique recreational facility affecting a large area or substantial number of people and therefore impacts to recreation would be less than significant. In addition, the Proposed Project includes implementation of the Downstream Flood Control Project Component, as described in Section 2.7.8.4 *Downstream Flood Control* and in Appendix B: *Definite Plan.* Thus, under the Proposed Project, KRRC would move or elevate legally-established structures, where feasible, to reduce the risks of exposing people and/or structures to damage, loss, injury, or death involving flooding, which would further reduce the potential for flooding impacts to this structure.

Downstream of Humbug Creek (RM 174.0), there would be no significant effect on flood elevations (Potential Impact 3.6-3) and therefore there would be no impacts to river-based recreational facilities, including to the Klamath National Forest Tree of Heave Campground near the confluence of Humbug Creek (Figure 7.7-1 in Appendix B: *Definite Plan – Appendix C*).

Over the long term, removal of the Lower Klamath Project dams is also expected to result in water quality improvements within the Hydroelectric Reach and in the Middle and Lower Klamath River downstream of Iron Gate Dam (see Potential Impacts 3.2-1, 3.2-11, 3.2-12, and 3.2-13), which could improve visitor perceptions and attract a greater number of visitors to existing recreational facilities.

Dam removal activities are expected to result in long-term improvements in water quality, notably by decreased prevalence of microcystin toxin during summer phytoplankton blooms in the Lower Klamath Project reservoirs and in the Middle and Lower Klamath River. As discussed in Section 3.2.2.7 *Chlorophyll-a and Algal Toxins* and Section 3.20.2.4 *Wild and Scenic River Conditions*, microcystin toxin has been associated with public health risks for recreational bathing waters. Health warnings issued in 2005, 2008, 2009, 2010, 2012, 2013, 2014, 2016, and 2017 by the USEPA, the North Coast Regional Board, and other agencies warned recreation visitors to use caution due to the potential health effects of contact with waters containing elevated microcystin concentrations. In addition, 91 percent of recreational survey respondents indicated that water quality detracted from their experience at least a little within the

Hell's Corner Reach (PacifiCorp 2004). These adverse effects related to water quality negatively influenced the quality of the recreational experience for visitors and also resulted in safety risks to the recreational visitors. As existing conditions for water-contact-based recreational activities are considered adverse due to water quality, improved water quality conditions would result in long-term beneficial effects.

As discussed in Section 3.3.5.9 *Aquatic Resource Impacts*, dam removal activities are anticipated to result in increased abundance of recreational fish species from increased access to suitable habitat, and improved habitat conditions. The increased fisheries populations and abundance would beneficially affect recreational fishing opportunities. More specifically, the increased abundance and extent would allow for enhanced fishing opportunities and could decrease the number of closures of entire fishing seasons over the long term. These effects on recreation-based fisheries would be long-term and beneficial.

The Proposed Project would improve river access and create new fishing opportunities in the Hydroelectric Reach through implementation of the Recreation Facilities Plan (see Potential Impact 3.20-2), which would benefit fishing opportunities in this area. Given negligible changes in flows and improvements in access, impacts in reaches downstream from Iron Gate Dam would be less than significant. There would be a slight reduction in length of time available for fishing in the Copco No. 2 Bypass Reach, which would primarily occur during May due to the availability of acceptable flows (Table 3.20-5). In the Hell's Corner Reach, there would be a reduction in the availability of acceptable flows during April; however, the impacts would be minor overall and outweighed by other beneficial effects (Figure 3.20-4).

Significance

No significant impact for the Middle Klamath River between Iron Gate Dam (RM 193.1) and Humbug Creek (RM 174.3)

Beneficial for the Hydroelectric Reach, the Middle Klamath River downstream of Humbug Creek (RM 174.3), and the Lower Klamath River

Potential Impact 3.20-7 Effects on Wild and Scenic River resources, designations, or eligibility for listing.

The following section provides an assessment of the effects of the Proposed Project on each of the four resources specified in the Wild and Scenic River Act Section 7(a) (i.e., scenery, recreation, fish, and wildlife river values). The evaluation criteria presented in Section 3.20.4.5 *Impact Analysis Approach* were used to assess the effects of the Proposed Project as compared with conditions present at the time of wild and scenic river designation or eligibility listing, as well as changes to the condition of the river since the time of the designation or eligibility listing that have affected its wild and scenic character.

Potential impacts to scenery on designated California Klamath Wild and Scenic River segment.

As previously discussed in Section 3.20.2.4 [*Recreation] Environmental Setting – Wild and Scenic River Conditions*, the historic scenic character of reaches downstream from Iron Gate Dam has been impacted by reduced water clarity and discoloration resulting from large seasonal phytoplankton blooms in the Lower Klamath Project reservoirs that are subsequently transported into the Middle and Lower Klamath River. The Proposed

Project would eliminate the major sources of seasonal phytoplankton blooms to the Klamath River downstream of Iron Gate Dam (see also Section 3.4.2.3 *[Phytoplankton and Periphyton] Hydroelectric Reach,* Section 3.4.2.4 *[Phytoplankton and Periphyton] Middle and Lower Klamath River,* and Potential Impact 3.4-2), enhancing water appearance in the wild and scenic river segment of the Klamath River in California by eliminating or substantially reducing seasonal algal surface scums in the Middle and Lower Klamath River and increasing water clarity during summer low-flow periods.

As discussed in Potential Impact 3.2-3, drawdown of the reservoirs would result in short-term increases in turbidity (also expressed as suspended sediment concentration [SSCs]) downstream from the Lower Klamath Project reservoirs. Elevated turbidity would be most pronounced immediately downstream from Iron Gate Dam to Bogus Creek and it would become less noticeable farther downstream due to dilution from tributary flows entering the Klamath River. Modeling of SSCs during drawdown indicates SSCs would decrease to 60 to 70 percent of the initial value by Seiad Valley (RM 132.7) and to 40 percent of the initial value downstream of Orleans (approximately RM 59). Sediment jetting would occur during drawdown maximize erosion of accumulated sediments during this period and potentially reduce turbidity after drawdown concludes, and immediate revegetation would occur to further minimize the potential for prolonged increases in turbidity. Turbidity in the Klamath River is anticipated to flush through the system relatively quickly, but based on modeling of SSCs elevated turbidity is conservatively anticipated to occur for six to ten months following drawdown, with turbidity completely resuming natural background levels by the end of post-dam removal year 1 regardless of the water year type (USBR 2012a) (see Potential Impact 3.2-3 for more details). Although removal of the dams would result in increases in SSCs (Potential Impact 3.2-3) and decreased water clarity, the SSC increases would be short term and as such would not affect scenic value such that the long-term wild and scenic river designation or eligibility for listing would be compromised. In the long term, improved water appearance from on-river, in-river, and/or riverside viewpoints would improve the wild and scenic character of the Klamath River below the Lower Klamath Project.

With respect to periphyton colonization in the California Klamath wild and scenic river segment, although increased nutrient transport and recycling following dam removal could favor enhanced periphyton growth downstream from Iron Gate Dam, dam removal would also restore more frequent river sediment movement (Potential Impact 3.11-6) and increased flow variability during storm flow downstream of Iron Gate Dam, which could result in increased scouring of periphyton during late spring storm events (Potential Impact 3.4-5). The magnitude of the effect of bed turnover and scouring on periphyton would decrease with distance downstream, with increased scour occurring from Iron Gate Dam to approximately the Shasta River (RM 179.5), or the upper portion of the California Klamath River wild and scenic river segment. Information about water appearance at the time of California Klamath River wild and scenic river designation is sparse; however, it is likely that the existing trend of increasing periphyton blooms with their associated water coloration, cloudiness, and limitations on depth of view was already underway at the time of wild and scenic river designation (Van De Water et al. 2006). Although there would be negative water clarity impacts on scenic quality due to elevated SSCs during reservoir drawdown, the increases would be temporary and as such would not affect scenic value in a manner that would compromise the long-term wild and scenic river designation or eligibility for listing. Instead, the long-term effect of the Proposed Project would improve the scenic value of the California Klamath River wild and scenic river segment.

As discussed in Section 3.3.5.9 *Aquatic Resource Impacts*, removal of the Lower Klamath Project dams is expected to increase the long-term abundance, productivity, population spatial structure, and genetic diversity of fall-run Chinook salmon (Potential Impact 3.3-7), spring-run Chinook salmon (Potential Impact 3.3-8), coho salmon (Potential Impact 3.3-9), steelhead (Potential Impact 3.3-10) and Pacific Lamprey (Potential Impact 3.3-11) in the Klamath River. The expected restoration of the anadromous fish populations would largely be the result of the increased access to anadromous fish habitat within the Upper Klamath Basin, along with water quality improvements downstream from the Lower Klamath Project. The increased population of fish species and increased water clarity would improve scenic fish viewing value. Increased fish viewing would be most prominent during fish migration, spawning, or holding periods, when the fish concentrate at particular reaches, pools, riffles, and falls. Fish and wildlife viewing impacts to scenic quality would be long-term and beneficial for the California Klamath River wild and scenic river segment.

Specific effects on river-dependent wildlife populations and scenic viewing opportunities are unknown. As discussed in Section 3.5.5.5 [*Terrestrial Resources] Potential Impacts and Mitigation – Wildlife Corridors and Habitat Connectivity*, riparian habitat in the Iron Gate Dam to Shasta River reach of the California Klamath River wild and scenic river segment would potentially be improved by dam removal activities because proportional increases in wildlife presence related to the increase in abundance of anadromous fish in the river and scenic wildlife viewing are expected. Therefore, effects on river-dependent wildlife populations and scenic viewing opportunities would be long-term and beneficial.

Removal of the Lower Klamath Project may result in an increase in riparian vegetation immediately downstream from Iron Gate Dam due to more regular transport of riverbed sediments (Potential Impact 3.11-5) and sediment deposition that has the potential to create new surfaces for riparian plants to colonize (Potential Impact 3.5-5). Improved riparian vegetation would increase the presence and scenic variety of the vegetation within the Klamath River wild and scenic river segment in California. This would likely increase overall scenic riparian vegetation aspects of scenic quality over conditions present at the California Klamath River wild and scenic river segment's 1981 date of designation, as updated by existing conditions, and result in long-term beneficial effects.

The California Klamath River wild and scenic river segment is downstream from the Lower Klamath Project; therefore, removal of the dams and associated facilities would not result in any changes to the overall landscape character in the designated segment of the river. However, as discussed above, water appearance in the wild and scenic river segment is expected to improve due to elimination or reduction of large seasonal phytoplankton blooms transported into the Middle and Lower Klamath River (Potential Impact 3.4-2), as is the quality of the riparian vegetation (Potential Impact 3.5-4). These improvements would result in a more natural landscape character for the California Klamath River wild and scenic river segment and result in a long-term positive scenic quality effect from both near river and distant viewpoints.

Potential impacts to recreation on designated California Klamath Wild and Scenic River segment.

During dam removal years 1 and 2, release of sediment deposits stored within the reservoir footprints could decrease the quality of and opportunity for water contact activities. However, initial reservoir drawdown would occur in the coldest high flow months of winter and early spring when recreation use of the Lower Klamath Project reservoirs is at its lowest. Further, the increases in SSCs (Potential Impact 3.2-3) and decreased water clarity during dam removal would be short term so these would not affect the scenic value in a manner that would compromise the long-term wild and scenic river designation or eligibility for listing. In the long term, dam removal activities would improve water quality and also improve water contact-based recreation activities. For the California Klamath River wild and scenic river segment, dam removal activities would not affect recreational activities access downstream from the dams, and dam removal activities would result in improved water quality downstream from the dams in the long term; thus, there would be long-term beneficial effects on recreational activities in these areas as compared to the 1981 conditions and existing conditions.

Whitewater boating opportunities relating to river flow following removal of the Lower Klamath Project would likely be similar to 1981 conditions and current conditions of the California Klamath River wild and scenic river segment. As discussed in Potential Impact 3.20-5, following removal of the dams, changes in the availability of flows within the acceptable flow ranges for whitewater boating and fishing opportunities would be negligible for the reaches downstream from Iron Gate Dam following dam removal. Whitewater boating opportunities under the Proposed Project with 2013 BiOp Flows would be similar to results previously modeled under the KBRA Flows downstream of Iron Gate Dam. Therefore, no adverse impacts to flow-related whitewater boating opportunities would occur for the California Klamath River wild and scenic river segment. Dam removal activities would also result in long-term improvements to water quality conditions over existing conditions and the 1981 conditions. With improved water quality, the whitewater boating recreation experience would also improve. Therefore, long-term water quality-related whitewater boating impacts would be beneficial for the California Klamath River wild and scenic river segment.

As discussed in Potential Impact 3.20-6, removal of the Lower Klamath Project would not result in substantial increases or decreases in the number of days with acceptable flows for recreational fishing. However, as described in Potential Impacts 3.3-7 through 3.3-11, the geographic extent of the Klamath River fish habitat would be substantially expanded compared to 1981 and existing conditions. Moreover, the long-term improvements to water quality conditions are expected to reduce fish disease and increase the likelihood of fish survival. Increased fish populations could result in expansion of fishing seasons or increases to quotas and bag limits. Thus, recreational fishing effects from implementing the Proposed Project would be long-term and beneficial for the California Klamath River wild and scenic river segment.

There could be short-term impacts to recreational fishing during Lower Klamath Project reservoir drawdown. While it is not possible to accurately predict short-term deposition patterns in the mainstem Klamath River channel at a fine spatial scale (e.g., individual pools or other slack-water areas that may serve as fishing holes), general sediment transport and depositional patterns observed in the Klamath River and other analogous river channels indicate that dam-released sediment that may temporarily deposit in pools and other slack water areas (e.g., eddies) and at tributary confluences in the reach from

Iron Gate Dam to Cottonwood Creek would be highly erodible during subsequent flow events, leading to a short residence time (i.e., likely one year or less except during dry years) (Potential Impact 3.11-5). Thus, the potential for clogged fishing holes or less accessible shorelines that are temporarily blocked by sediment deposits of limited extent would be short-term and as such would not affect recreational value in a manner that would compromise the long-term wild and scenic river designation or eligibility for listing.

Further, In the short term, new beaches and riparian areas may become established, increasing the variety of shoreline settings. Most of these effects would be temporary and many aspects of the wild and scenic river segment's recreation setting would be considerably improved in the long term once the Klamath River stabilizes. The improved water quality conditions following completion of drawdown activities would improve the recreational setting overall (i.e., with improved clarity during swimming and fishing and reduced malodors and tastes [Bartholow et al 2005]). With regard to public health, improved water quality, and in particular a reduction in the potential for seasonal exposure to high levels of algal toxins (greater than 8 µg/L microcystin) generated by nuisance blooms in the Lower Klamath Project reservoirs and transported into the Middle and Lower Klamath River (Potential Impact 3.2-12) would also reduce potential human health risks associated with water-contact-based activities. Therefore, effects on the recreational setting would be long term and beneficial for the California Klamath River wild and scenic river segment.

Potential impacts to fisheries on designated California Klamath Wild and Scenic River segment.

Changes in flow regimes can affect fishery resources. Section 3.6.2.1 [*Flood Hydrology] Environmental Setting* discusses historic flow rates and discharge statistics for each of the reservoirs. The proposed drawdown rates for the Lower Klamath Project reservoirs are consistent with the historic discharge rates from the reservoirs and would be adjusted depending on the water year; therefore, flow rates downstream from the dams are not anticipated to increase substantially above historic rates, if at all. As such, conditions during the reservoir drawdown period (i.e., dam removal years 1 and 2) are expected to remain largely unchanged as compared to stream flow regimes at the time of the 1981 wild and scenic river segment designation.

Following removal of the Lower Klamath Project, the Klamath River would return to a natural flow regime in the Middle Klamath River immediately downstream of Iron Gate Dam. Restoration of the natural flow regime and upstream sediment supply would improve water quality conditions, likely reducing the occurrence of myxozoan parasites (*Ceratomyxa shasta* and *Parvicapsula minibicornis*) that are known to negatively affect salmonids. Increased spawning gravel from upstream sources could enhance spawning habitat following dam removal. Restoring natural sediment mobility processes could also help scour periphyton (e.g., *Cladophera* spp.) (Potential Impact 3.4-5), and deposited sand and gravel would be a less favorable substrate for the periphyton because of greater particle mobility during high-flow events than the existing armored substrate. A reduction in periphyton would reduce the habitat for the fish pathogen's alternate host (Section 3.3.5.5 *Fish Disease and Parasites*). Further, as discussed above, removal of the reservoirs would eliminate habitat for populations of blue-green algae that produce toxins that can result in acute and chronic effects on fish, including increased mortality, reduced fecundity, reduced feeding, and habitat avoidance (see Section 3.3.5.7 *Algal Toxins*). Thus, stream flow regime effects would be long term and beneficial for the California Klamath River wild and scenic river segment.

Removal of the Lower Klamath Project would improve water quality conditions over existing conditions and the 1981 conditions. As described in 3.2.5.1 *[Water Quality] Water Temperature* and 3.3.5.4 *[Aquatic Resources] Water Temperature*, following dam removal, the seasonal temperature regime downstream from Iron Gate Dam would be more suitable for salmon. As part of its relicensing procedure, PacifiCorp modeled changes in water temperature that could result following removal of the Lower Klamath Project dams. The modeling results show that from Iron Gate Dam to Clear Creek, water temperatures in the spring and early summer would be as much as 5°C warmer, but they would be cooler in later summer and fall than under existing conditions. Water temperatures currently remain greater than 20°C in dry years with little variability in July and August. Although summer temperatures would likely be more variable following dam removal, the median temperatures would be substantially lower than current conditions. Summer and fall water temperatures would therefore be more conducive to salmon rearing, migrating, and spawning than the conditions that likely existed in 1981 (Van de Water et al. 2006). Water temperature effects of dam removal would therefore be long-term and beneficial for the California Klamath River wild and scenic river segment.

Information about habitat conditions at the time of wild and scenic river segment designation is sparse; however, it is likely that existing trends of river coarsening, increasing habitat for periphyton, and reduced recruitment and maintenance of riparian vegetation were already underway at the time of wild and scenic river segment designation due to PacifiCorp facilities and operations. The Proposed Project would reduce those trends in the long term, and restore natural sediment transport processes, which were no longer in place by 1981. Following the initial drawdown period and flushing of reservoir sediment downstream, aquatic habitat conditions would be expected to improve compared with conditions in 1981, as well as existing conditions, in the long term. Therefore, effects on aquatic habitat conditions would be long-term and beneficial for the California Klamath River wild and scenic river segment.

As discussed in as described in Potential Impacts 3.3-7 through 3.3-11, dam removal would result in beneficial long-term effects on anadromous salmonids. Dam removal would restore connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and would create additional spawning and rearing habitat within the Hydroelectric Reach. While, sediment released during dam removal could be sufficient to cause substantial smothering of spawning gravels, pool infilling, gill abrasion, and changes to holding and migration patterns in the Klamath River reaches immediately downstream of Iron Gate Dam, these impacts would be temporary, as sediment is expected to be flushed through the river system relatively quickly, and would not affect survivability of fish species in a manner that would compromise the long-term wild and scenic river designation or eligibility for listing. Removal of the Lower Klamath Project would also eliminate fish barriers and expand fish access to upstream spawning areas.

As discussed in Section 3.3.5.8 *Aquatic Habitat*, removal of the Lower Klamath Project would improve conditions for native resident fish species, including culturally important fish species (e.g., Chinook salmon, coho salmon, steelhead, and lamprey), by restoring connectivity between the Lower and Upper Klamath River, and by returning a natural flow regime to the reaches where the reservoirs currently exist, thereby improving water quality. Dam removal would also likely result in diminished non-native fish habitat and populations, reducing competition for space and resources with native resident fish (see

Potential Impact 3.3-17). Therefore, effects on the conditions for native resident fish species, including species traditionally used and culturally important to Indian Tribes, would be beneficial and long term in the California Klamath River wild and scenic river segment.

Potential impacts to wildlife on designated California Klamath River Wild and Scenic River segment.
Riparian vegetation in the California Klamath River wild and scenic river segment downstream from the Iron Gate Dam would benefit from dam removal activities In the long term, especially in the reach between the Iron Gate Dam and the Shasta River confluence (Potential Impact 3.5-4). Special status species that utilize riparian habitat, such as the willow flycatcher (Potential Impact 3.5-12) and Western pond turtle (Potential Impact 3.5-16) would benefit in the long term from successful riparian habitat recovery from Iron Gate Dam downstream to the Klamath River's confluence with the Shasta River.

In addition to improving riparian habitat, the Proposed Project would result in improvements in fish resources in the long term following dam removal, thus providing increased forage for wildlife species that depend upon fish as a food source. The area currently blocked by dams would provide additional available habitat for anadromous fish (see above discussion). Increased fish abundance would also create greater foraging opportunities for riparian and riverine species such as bald eagle, river otter, osprey and black bear (see also Potential Impact 3.5-24). Therefore, there would be a long-term, beneficial effect on habitat for special status species in the California Klamath River wild and scenic river segment. Because wildlife viewing is an important component of recreational opportunities within the Area of Analysis, impacts to recreation would also be long-term and beneficial.

Potential impacts to eligible and suitable California Wild and Scenic River section.
In addition to the designated wild and scenic river segment, the Klamath River reach from the California-Oregon state line to the upstream end of Copco No. 1 Reservoir was found to be "eligible and suitable" for wild and scenic river designation, though it has not yet been designated into either the National or the State Wild and Scenic River System. The potential outstandingly remarkable values include scenic, fish, wildlife, recreation (whitewater boating and fishing), and historic. This candidate wild and scenic river reach is included in the Area of Analysis for recreation.

Short-term negative impacts on water quality, scenic, recreation, fishery, and wildlife river values would be likely to occur due to high SSCs anticipated during drawdown of the upstream J.C. Boyle Reservoir (see Potential Impact 3.2-3). Short-term impacts would also occur as a result of restricted access and use of river-based recreation facilities and opportunities within the Limits of Work during dam removal years 1 and 2. However, these temporary impacts would not affect river values in a manner that would compromise the long-term wild and scenic river eligibility for listing. In the long term, dam removal under the Proposed Project would eliminate hydropower peaking and return this section of the Hydroelectric Reach to a more natural condition than under existing conditions. Overall, dam removal activities under the proposed Project that return this section of the Hydroelectric Reach to a more natural condition would result in long-term beneficial effects to this candidate wild and scenic river reach's free-flowing condition, water quality, scenic, wildlife, fishery, and recreation river values and the long-term wild and scenic river designation or eligibility for listing would be not be compromised.

Significance

No significant impact in the short term for the designated California Klamath River wild and scenic river segment.

No significant impact in the short term for the eligible and suitable California Klamath River wild and scenic river section

Beneficial in the long term for the designated California Klamath River wild and scenic river segment.

Beneficial in the long term for the eligible and suitable California Klamath River wild and scenic river section

3.21 Hazards and Hazardous Materials

This section describes the environmental setting for hazards and hazardous materials, as well as potential environmental impacts and associated mitigation measures for the Proposed Project. The discussions in the following subsections focus primarily on the transport, use, and disposal of hazardous materials, school proximity to hazardous materials, contaminants and contaminated sites, nearby airports, emergency response plans, and wildfires.

The State Water Board received comments expressing the following concerns related to hazards and hazardous materials: water in the Lower Klamath Project reservoirs would no longer be available for use in fire suppression; and construction-related traffic, including hauling of hazardous materials and waste, would occur on the single access route for the Copco No. 1 Dam area, which could affect the safety of other road users such as school busses, residents, pedestrians, livestock and dogs. Additional details regarding the public comments received during the NOP public scoping process can be found in Appendix A.

3.21.1 Area of Analysis

The Area of Analysis for hazards and hazardous materials includes lands within the Project Boundary (Figure 2.2-4). This area includes the area in the immediate vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams and reservoirs, and areas identified as construction/demolition and staging areas. The construction/demolition and staging areas are described in specific detail in this EIR in Section 2 *Proposed Project* and in Sections 5.3, 5.4, and 5.5 of Appendix B: *Definite Plan*. Consideration of hazards and hazardous materials also includes considering routes proposed to be utilized for the transportation of construction debris (see Section 3.22 *Traffic and Transportation*).

3.21.2 Environmental Setting

This section describes the environmental setting associated with the exposure to various potential hazards and hazardous materials. For discussion of other related hazards, the table below describes topics and where these other hazards are discussed.

Table 3.21-1. Hazards-related Discussion Found Elsewhere in this EIR.

Hazard	Section No.	Topic(s)
Water Quality	3.2	Water Quality
Flooding	3.6	Flood Hydrology
Vehicle and Toxic Emissions	3.9	Air Quality
Geologic	3.11	Geology and Soils
Emergency Response	3.17	Public Services
Emergency Response	3.22	Transportation and Traffic

3.21.2.1 Transport/Releases of Hazardous Materials

California Health and Safety Code Section 25501(n) defines hazardous material as any material "that, because of its quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment."

Hazardous substances include, but are not limited to, hazardous materials, hazardous waste, and, any material which a handler or regulatory agency has a reasonable basis for believing would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment.

California Code of Regulations (CCR), Title 22, Division 4.5, Chapter 11, Article 2, Section 66261.10, identifies a hazardous material as a substance (or combination of substances) that may cause or significantly contribute to an increase in mortality or an increase in serious, irreversible, or incapacitating illness, or that may pose a substantial hazard to human health or the environment when improperly treated, stored, transported, or disposed of, or otherwise managed. Hazardous wastes are hazardous substances that no longer have practical use, such as materials that have been discarded, discharged, spilled, or contaminated, or are being stored until they can be disposed of properly. The Department of Toxic Substances Control (DTSC) (DTSC 2018a) further defines hazardous wastes as wastes from manufacturing processes, manufacturing industries, unused commercial chemical products or products containing mercury (CCR, Title 22, Division 4.5, Chapter 11, Article 4, Section 66261.31-33). Hazardous wastes can also be characterized as defined in Article 3 of Chapter 11 of the hazardous waste regulations (CCR, Title 22, Chapter 11, Article 3, §§ 66261.21–66261.24) according to four properties:

- toxicity (or the degree to which a substance can damage an organism),
- ignitability (or the capability of a material to be ignited or set on fire),
- corrosiveness (the ability of a material to eat away or disintegrate another material), and
- reactivity (the stability of a material).

The Hazardous Waste and Substances Sites List, also known as the Cortese List, is a planning document used by the state, local agencies, and developers to comply with CEQA requirements in providing information about the location of hazardous materials release sites. Government Code section 65962.5 requires the California Environmental Protection Agency (CalEPA) to maintain an updated Cortese List. DTSC is responsible for a portion of the information contained in the Cortese List. Other state and local government agencies are required to provide additional hazardous material release information for the Cortese List. Below are the data resources that provide information regarding the facilities or sites identified as meeting the Cortese List requirements (CalEPA 2017).

- List of Hazardous Waste and Substances sites from DTSC EnviroStor database.
- List of Leaking Underground Storage Tank Sites by county and fiscal year from State Water Board GeoTracker database.
- List of solid waste disposal sites identified by State Water Board with waste constituents above hazardous waste levels outside the waste management unit.
- List of Active Cease and Desist Orders and Cleanup and Abatement Orders identified by the Regional Water Quality Control Boards.
- List of hazardous waste facilities subject to corrective action pursuant to section 25187.5 of the Health and Safety Code, identified by DTSC.

Hazardous wastes that are to be transported off site would utilize local roads to reach Interstate 5 so that they can be disposed of at required facilities (see 3.22 Traffic and

Transportation for additional information). Likewise sources of hazardous materials, such as fuels and lubricants, welding materials, and explosives to be used during construction activities, will travel primarily from Interstate 5 along local roads to the work areas. This transport of materials could result in the potential for an increased risk in release of these hazardous substances into the environment.

There is an existing transfer station near the City of Yreka that accepts Class II sanitary landfill materials such as construction and demolition wastes, mixed municipal wastes, metals, and mixed municipal recyclable materials. Wastes are currently hauled 45 miles to the Dry Creek Landfill in White City Oregon. The Class I Anderson Landfill in Anderson, California, located 122 miles from Hornbrook, California, is permitted to accept hazardous waste, including treated wood waste. Existing capacity is available for wastes generated by the Proposed Project, as described in Section 3.18.2.4 *Solid Waste*.

USEPA is the primary federal agency responsible for the implementation and enforcement of hazardous materials regulations. In most cases, enforcement of the federal laws and regulations is delegated to state and local environmental regulatory agencies. California implements federal regulations through the DTSC, which identifies the Siskiyou County Environmental Health Department as the Certified Unified Program Agency. The Certified Unified Program Agency works closely with lead agencies through project review to ascertain the impacts from hazardous materials.

3.21.2.2 School Proximity

No schools are within a quarter mile of the dam demolition or equipment staging areas (see Figure 3.21-1). The closest existing schools to Iron Gate Dam are Bogus Elementary School, 5.4 miles away; Willow Creek Elementary School, 5.5 miles away; and Hornbrook Elementary School, 6 miles away. Distances from Copco No. 1 and Copco No. 2 to the nearest schools are similar to or greater than distances from Iron Gate Dam.

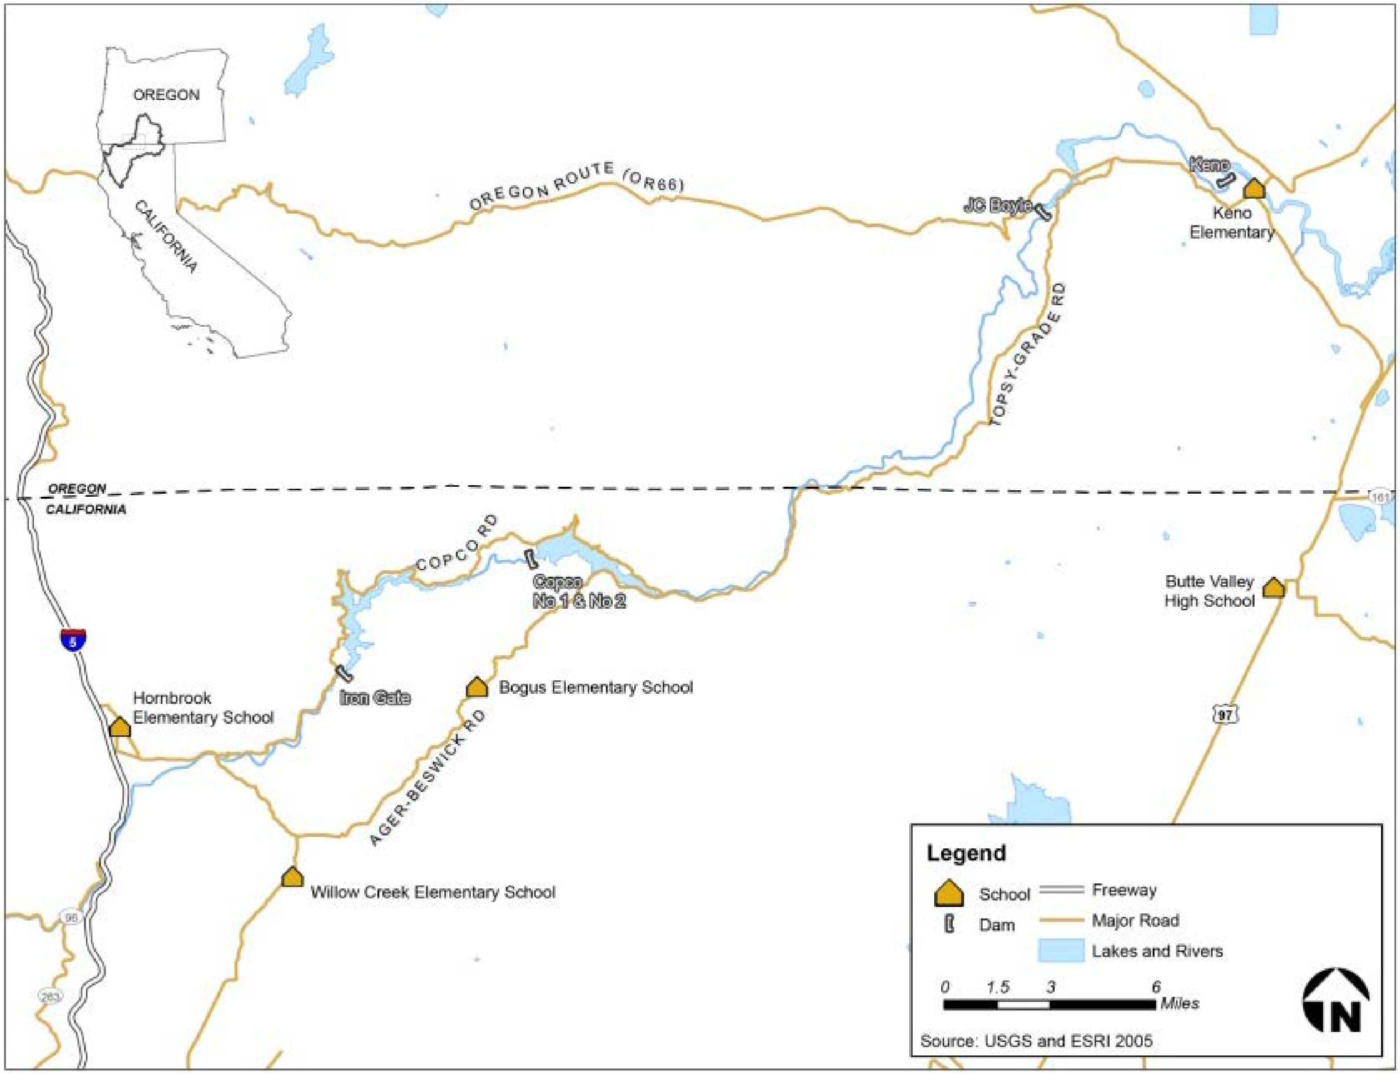

Figure 3.21-1. School Sites Near the Project Area.

3.21.2.3 Contaminants/Contaminated Sites

A comprehensive search of commercial databases was performed by Environmental Data Sources, Inc. (EDR 2010) to identify potential sites that may be contaminated with hazardous substances in the vicinity of the Proposed Project and to identify sites where soil and/or groundwater contamination may be present. Four Hazardous, Toxic, and Radioactive Waste (HTRW) sites, within the 2012 KHSA EIS/EIR Area of Analysis for hazards and hazardous materials, were identified by the 2010 EDR search. Two of the listings indicated the presence of underground and aboveground storage tanks at the Copco Lake Store and the "Pacific Power – Iron Gate," respectively; but there was no evidence of spills. The third listing referenced health limit exceedances in water samples from the Copco Lake Municipal Water Company for radium-228, arsenic (total), bromodichloromethane, dichloroacetic acid, and total haloacetic acids between 2004 and 2006, and for aluminum in water samples collected since 2004. The fourth listing resulted from a minor spill of non-PCB transformer oil at the Copco No. 2 Powerhouse, which was remediated and no longer is a site of concern. The spill is also listed in the California Hazardous Material Incident Reporting System and the Emergency Response Notification System databases. The EDR listing indicated that a bushing failed in 1999 at a transformer adjacent to the Klamath River releasing transformer oil. Most of the oil was contained, and less than one quart reached the Klamath River.

In addition to the four sites described above, the EDR research identified 162 "orphan sites," which are those sites that could not be mapped or "geocoded" due to inadequate address information along the two corridors of the Klamath River. Seven of the orphan sites are identified within the 2012 KHSA EIS/EIR Area of Analysis: Two are National Pollutant Discharge Elimination System-permitted facilities and one is a Waste Discharge Requirements-regulated facility; these do not present concerns related to HTRW. Two sites indicated the presence of underground and aboveground storage tanks at Iron Gate Dam; one site, listed on the Emergency Response Notification System, is the Copco No. 2 Powerhouse minor spill described above; and the remaining two sites were listed on the California Facility and Manifest Database and the leaking underground storage tank databases. No additional information was available in the State Water Board's GeoTracker database or the DTSC's EnviroStor database. No additional information on the presence of HTRW at the Proposed Project site is available.

An updated search of DTSC's Cortese List and search for sites with reported hazardous material spills, leaks, ongoing investigations, and/or remediation near the Proposed Project vicinity was performed using EnviroStor and GeoTracker (DTSC 2018b, State Water Board 2018). The updated search of site listings within these databases identified the Laubacher Ranch (Ager-Beswick Road, Montague, CA) as a leaking underground gasoline storage tank cleanup site undergoing remediation. The site is located adjacent to the Klamath River approximately four miles upstream from Copco No. 1 Reservoir. This case was completed/closed as of September 2017. (DTSC 2018b).

A review of the California Office of Emergency Services (CalOES) hazardous spill database was also reviewed for any incidents in the vicinity of the project facilities and the results are summarized in Table 3.21-2. (CalOES 2017). None of these indicated a need for further reporting.

Table 3.21-2. Hazardous Materials Spill Report.

CalOES 2018	Accessed 10/17/2018	Substance Type	Date
Control #	Reporting Party		
06-2856	PacifiCorp	Non-PCB Transformer Oil	5/12/2006
06-2940	NRC	Oil sheen in Klamath River	5/16/2006
12-4295	PacifiCorp	Oil from ski boat sank in Iron Gate Reservoir	7/24/2012
12-7480	Private Citizen	Septic sewage into creek. 20738 Ager Beswick Rd	12/7/2012
16-1355	PacifiCorp	Oil from vehicle crash into Iron Gate Reservoir.	3/4/2016
16-1563	Private Citizen	Diesel from leaking tractor. 15629 Klamath Rd	3/12/2016
17-1030	PacifiCorp	Oil from vehicle rolled into Iron Gate Reservoir	2/3/2017
17-2111	CALFIRE Yreka	Oil from boat fire	3/14/2017
18-1265	PacifiCorp	Oil from equipment spill, Fall Creek Rec Boat Ramp	2/26/2018

As reported in the 2012 KHSA EIS/EIR:

- In 2009, at the Copco No. 1 warehouse, soil known to be contaminated by petroleum products was removed from a former lube rack area. The final report and site cleanup was approved by a letter from Siskiyou County in 2010.
- In 2009, a former landfill site at Copco No. 2 Dam was removed per Siskiyou County review and approval.
- Copco No. 2 Dam's fueling facility has two aboveground storage tanks (1,000-gallon gasoline and 500-gallon diesel). No known spills or cleanups occurred at this facility.

No additional information was found related to these hazardous material issues at Copco No. 1 and No. 2 dams during the updated database searches (DTSC 2018b, State Water Board 2018).

The Lower Klamath Project dams and associated facilities include painted structures, equipment, and metalwork that may contain potentially hazardous materials. Window caulking, electrical wiring and components, building materials, and some coatings may contain asbestos. Surrounding soils may contain heavy metal contaminants where coatings have flaked off of the painted structures, equipment, and metalwork. There are no known reports that indicate building components and/or soil surrounding the facilities have been tested (Appendix B: Detailed Plan).

Certain closed systems, such as transformer bushings, cannot be tested until time of disposal. Thus, small quantities of polychlorinated biphenyls (PCBs) may be present in hydraulic fluids, soils, and in transformers and other electrical equipment, including older fluorescent light fixtures. Old light switches may contain mercury. The dams and hydroelectric facilities within the Proposed Project area may also include items such as transformers, batteries, bushings, oil storage tanks, bearing and hydraulic control system oils, lead bearings, soils or other material contaminated with lead from the use of lead-based paints or plumbing and 700 tons of creosote-treated wood in the wooden stave penstock at Copco No. 2 Dam (see also Appendix B: *Definite Plan – Appendix O3*).

Phase 1 and Phase 2 Environmental Site Assessments are currently underway (Appendix B: *Definite Plan*).

3.21.2.4 Nearby Airports

The Proposed Project is not located in the vicinity of any private or public use airport or airfield. Siskiyou County operates five public use, general aviation airports: Butte Valley, Happy Camp, Scott Valley, Weed, and Siskiyou County. A private emergency medic flight service operates between Medford, Oregon and Redding, California. Each airport is owned and operated by their respective city. The Siskiyou County Airport, located in Shasta Valley—11 miles east of Yreka—is home to a USDA Forest Service Fire Attack Base in the summer months (Greendot 2016). The USDA Forest Service also operates Happy Camp Airport at Happy Camp. The closest public airport to project facilities is Siskiyou County Airport, which is more than 10 miles south of Iron Gate Dam in Montague. Pinehurst State Airport in Oregon is located approximately nine miles north of Copco No. 1 Reservoir. The closest commercial airport in California to the proposed project is Redding Municipal Airport, located in Redding, approximately 130 miles south of the project site.

In addition to public use airports, a number of private airstrips are operated in Siskiyou County. Six private airstrips are listed for the area: Lefko, Round Mountain, Coonrod Ranch, Triple Ranch, McCloud, and Longbell Ranch. The closest private airstrip to the Proposed Project is Coonrod Ranch Airstrip, located approximately 25 miles south.

3.21.2.5 Emergency Response Plans

The Governor's Office of Emergency Services (CalOES) coordinates preparedness for and response to natural disasters such as earthquakes, fires, and floods by activating the California Standardized Emergency Management System (SEMS) used by all California public safety agencies. Section 3.17 *Public Services* contains a description of the various agencies (fire, police, medical) that would respond in case of an emergency within the Area of Analysis. Each of these agencies has their own defined emergency response capabilities. Developing an emergency response plan would be one of the elements required by SEMS.

Siskiyou County began the emergency response planning process in the 2010 Siskiyou County Multi-Jurisdictional Hazard Mitigation Plan (Plan). The Plan identified natural hazards within Siskiyou County and outlined the history, future vulnerability, and future damage potential for each hazard. The Plan's goal is to identify mitigation projects that will reduce the vulnerability and damage potential of each hazard. The Plan addresses earthquake, flood, wildfire, landslide/other earth movement, drought, severe weather/storm, dam failure, and volcano/lahar/ash fall hazards. For additional information visit http://www.co.siskiyou.ca.us/content/oes-hazard-mitigation-plan (accessed April 10, 2018).

As part of the County's plans for emergency evacuation, Siskiyou County has instituted a rapid emergency notification service called CodeRED®. CodeRED® employs internet mapping capability for geographic targeting of calls, coupled with a high-speed telephone calling system capable of delivering customized pre-recorded emergency messages directly to homes and businesses, live individuals, and answering machines. This service can be used in case of fires, chemical spills, evacuations, lock downs, downed power lines, lost individuals, natural disasters, abductions, water system problems, bomb threats, or other emergencies (County of Siskiyou 2018b).

No hospitals and only one fire station (Copco Lake Fire Department Station 210) at Copco No. 1 Reservoir, are within the Area of Analysis. The nearest hospitals are Fairchild Medical Center in the City of Yreka, California (18 miles southwest of Iron Gate Dam), Ashland Community Hospital in Ashland, Oregon (35 miles north-northwest of Iron Gate Dam), and Sky Lakes Medical Center in Klamath Falls, Oregon (52 miles east-northeast of Copco). Other emergency responders are discussed in Section 3.17 Public Services.

3.21.2.6 Wildfires

Wildland fires represent a substantial threat to rural residences, timber, and other infrastructure or improvements located within the Klamath River watershed, particularly during the hot, dry summer months in areas where topography, land use, access, and heavy fuel loading contribute to hazardous conditions. During implementation of the Proposed Project, wildland fires may be started by natural processes, primarily lightning, or by human activities, including construction activities.

CALFIRE has established a fire hazard severity classification system to assess the potential for wildland fires[170]. The zones depicted on CALFIRE maps take into account the potential fire intensity and speed, production and spread of embers, fuel loading, topography, and climate (e.g., temperature and potential for strong winds).

The Proposed Project area along the Klamath River in Siskiyou County has been classified as having either high or very high wildfire hazard, with very high hazard land concentrated from the eastern portion of Copco No. 1 Reservoir to the Oregon border. (CALFIRE 2007). Under state regulations, areas within these very high fire hazard zones must comply with specific building and vegetation management requirements intended to reduce property damage and loss of life within these areas. Public Resources Code (PRC) 4291 requires a 100-foot defensible zone around each structure. It is these defensible spaces that CALFIRE notes (CALFIRE 2016) are the most effective way of reducing wildfire hazards to structures. Success only occurs under the combined efforts of strong fire suppression with aggressive and robust fire prevention activities (CALFIRE 2018).

Appendix B: *Definite Plan –Appendix O1 Fire Management Plan* contains a list of applicable fire suppression agencies and applicable regulations. The Fire Management Plan requires coordination with multiple city, county, state, and federal fire suppression agencies including USDA Forest Service, Bureau of Land Management (BLM), the Oregon Department of Forestry (ODF) Klamath-Lake District (KLD), Cal Fire - Siskiyou Unit (Cal Fire SU), local districts of Klamath and Jackson Counties in Oregon and Siskiyou County in California, and local city and volunteer fire stations. Fire safety and suppression resources are available from the various agencies in the event of a fire. In California, responsibility for wildfire prevention and suppression is shared by federal, state, and local agencies. Federal agencies are responsible for lands in Federal Responsibility Areas (FRAs). The State of California has determined that non-federal

[170] More information about CALFIRE's classification system is available online at: http://www.fire.ca.gov/fire_prevention/fhsz_maps_siskiyou (Accessed December 21, 2018).

lands in unincorporated areas with watershed value are of statewide interest and have classified those lands as State Responsibility Areas (SRAs), which are managed by CALFIRE. CALFIRE enforces their respective state laws and regulations and coordinate fire support with the local agencies. There are no Local Responsibility Areas (LRAs) (e.g., incorporated areas) near the Proposed Project area and less than two square miles of FRA's (see Figure 3.21-2). The Fire Management Plan (page 29) notes that KRRC's contractor would contact the CALFIRE SU Prevention Specialist during development of detailed, site-specific fire management plans and would be in frequent contact with the pertinent fire suppression agencies during construction to discuss fire hazards, prevention, suppression, and contingency plans.

Siskiyou County is located in the CALFIRE Siskiyou Unit. The CALFIRE Siskiyou Unit encompasses 1.2 million acres of ecologically diverse wildlands. Most of the large fires in the CALFIRE Siskiyou Unit over the past 50 years have been wind-driven fires. Lightning, equipment use, and debris burning have historically been the determined primary ignition sources for these large fires (CALFIRE 2016).

As discussed in Section 3.17 *Public Services*, the Proposed Project area is located within the Shasta Valley Battalion (Battalion 2) of the CALFIRE Siskiyou Unit. Battalion 2 consists of two CALFIRE stations: one in the City of Yreka and one in the community of Hornbook; both stations provide fire protection services year-round. Paradise Craggy serves as the fire lookout for the Shasta Valley Battalion and is staffed with only emergency personnel during high-fire danger days and during and after lightning storms (CALFIRE 2016).

Fuel types consist of grass, brush, and timber that cover flat, rolling hills, and mountainous terrain. Battalion 2 includes a substantial wildland urban interface that includes many dispersed houses within the wildland areas. Much of the fire prevention efforts by Battalion 2 are focused on reducing the potential for large fire losses through public education and enforcement of Public Resources Code Section 4291, which requires up to 100 feet of fuel reduction around structures (CALFIRE 2016).

As shown in Table 3.21-3, approximately 10,624 acres burned between 2010-2015 in the CALFIRE Battalion 2 Unit SRA. In past years many of the Battalion's fires have started in LRA land and have threatened to burn SRA land. These fires were found to have the same causes as the SRA fires. (CALFIRE 2016). Wildfires originating in Oregon (such as the Oregon Gulch Fire in 2014) in the vicinity of the Klamath River also pose hazards to structures and public health within and adjacent to the Proposed Project area. Of note, from the below tables, the Oregon Gulch Fire burned 9,464 acres in California, meaning only 1,160.55 acres burned as a result of lightening fires the remaining six years. The next two largest categories for acres burned are from debris burning and equipment.

Table 3.21-3. 2010–2015 Battalion 2 Fire Causes.

Shasta Valley Battalion 2010-2015 Causes	Number by Cause	Acres Burned
Undetermined	38	31.6
Lightning Fires	55	10,211.68
Campfire	7	0.22
Smoking	3	0.21
Debris Burning	65	2.5
Debris Burning with Escape	18	130.93
Arson	13	3.15
Equipment	22	223.45
Playing With Fire	3	0.30
Vehicle	9	10.05
Railroad	0	0
Electrical Power	5	7.4
Miscellaneous/Other	16	3.06
Totals	**254**	**10,624.55**

Source: CALFIRE 2016

CALFIRE Incident Information (CALFIRE 2018) noted the following wildfires that occurred in the general area of the Proposed Project between 2010 and 2018.

Table 3.21-4. 2010–2018 Incident Information.

2010–2018 Incidents	Date of Incident	Acres Burned
Dutch Fire	July-August, 2010	371
Oregon Gulch Fire	July, 2014	9,464 in CA
Bogus Fire	June, 2017	56
Klamathon Fire	July, 2018	38,008
Iron Gate Fire	October, 2018	15

Source: CALFIRE 2018

During the dry season, areas surrounding the Proposed Project are at risk for fires, particularly at the interface between residential development and open space. The fire threat is high to very high in the areas surrounding the Proposed Project (CALFIRE 2007). The Klamathon Fire that started in July 2018 and burned 38,008 fires resulted in 82 structures destroyed, 12 structures damaged, one fatality and three injuries. Fire suppression is dependent on both air drops and ground crews, requiring a readily available source of water for helicopter fire suppression and ground crews fighting fires in the vicinity of the wildfire. The use of fire retardant, from fixed wing aircraft, is replenished from nearby airports or other places that aircraft can land and not dependent on sources of water.

Fire protection in the area of analysis is provided by federal agencies, the state forestry and fire prevention agencies, and a variety of city, county, and volunteer fire stations. Federal agencies include the USDA Forest Service, which is responsible for wildland fire protection on National Forest lands and providing assistance to other federal entities when requested, and the BLM, which is responsible for wildland fire protection on land managed by the BLM and for providing assistance to other federal, state, and local agencies when requested.

Fire protection at the state level is provided by CALFIRE in California, who, in conjunction with county and volunteer fire departments, is also responsible for fire protection throughout the unincorporated areas of the state. As discussed above, there are two CALFIRE stations in the vicinity of the Lower Klamath Project; Yreka, and Hornbrook. In Oregon, the Oregon Department of Forestry responds to wildland fires in the state resource areas and on federally managed lands. The Oregon Department of Forestry works with the BLM and the USDA Forest Service to prevent and fight wildfire on the federally managed lands as well.

City-operated fire stations include the Yreka Fire Department and the Mount Shasta Fire Department. There are also county fire stations throughout the Proposed Project area, including the Copco, Happy Camp, Seiad Valley, Etna, Fort Jones, Montague, Butte Valley, McCloud, Dunsmuir, and Mount Shasta fire departments (CPF Fire Department Directory 2017). The nearest fire stations to the Proposed Project area are the Copco Fire Department, Keno Rural Fire Protection District Station (in Oregon east of Keno Dam), Yreka Fire Department, and the Colestin Rural Fire Protection District (in Oregon northwest of Iron Gate Dam). The Colestin Rural Fire Protection District and the Hilt Fire Company in Northern California operate as one agency out of geographic necessity. Legally, however, they are two separate entities. The Hilt volunteer fire department jurisdiction includes the California side of the Colestin Valley, and also part of northern Siskiyou County, down to the Hornbrook boundary (Colestin Rural Fire District 2017). Each of these stations would have their own localized source of water for keeping their equipment full, but most would dependent on the reservoirs, the Klamath River, or other streams and sources for refilling at sources closer to a particular fire.

According to Appendix B: *Definite Plan –Appendix O1 Fire Management Plan*, the Fire Management Plan would include, among other items, details on: (1) establishing effective communication links between fire protection services and all personnel on the Proposed Project site; (2) compliance with all applicable regulations and federal and state guidelines (including CALFIRE 1999); (3) assessing weather conditions; (4) identifying all fire suppression infrastructure and emergency resources; (5) coordinating with nearby fire protection services; (6) routinely checking all fire abatement equipment and water storage on site; (7) establishing an up-to-date map of current helicopter fire suppression resources throughout the construction period; and (8) construction, utilizing, and maintaining proposed dry hydrants.

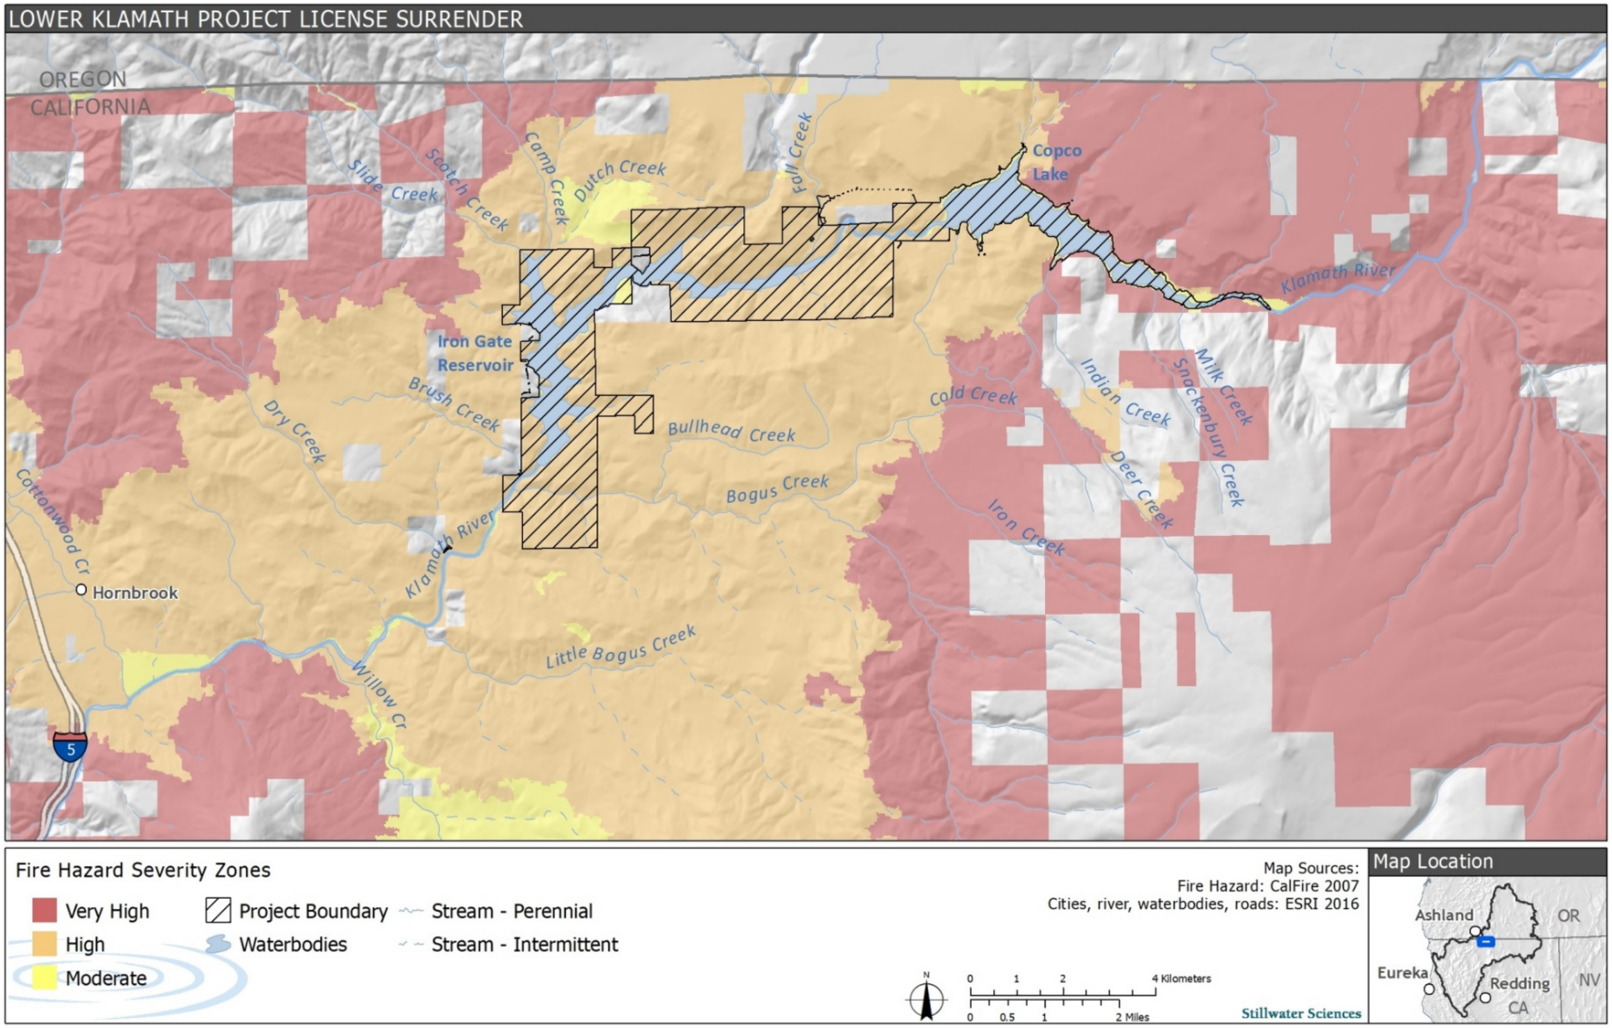

Figure 3.21-2. Map of CALFIRE Fire Hazard Severity Zones with Proposed Project Boundary Depicted (Source: CALFIRE 2007).

3.21.3 Significance Criteria

Criteria for determining significance of hazards and hazardous materials is informed by Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and based on professional judgment. Effects of hazards and hazardous materials are considered significant if the Proposed Project would result in one or more of the following:

- Substantial exposure to hazardous materials, where substantial is defined as quantities of hazardous, or acutely hazardous, materials that would be harmful to the public or the environment.
- A substantial safety hazard for people residing or working in the Area of Analysis due to an increase in the risk of air traffic accidents.
- Impaired implementation of, or physical interference with, an adopted emergency response plan or emergency evacuation plan that would result in harm to the public or to the environment.
- A substantial increase in the risk of loss, injury or death involving wildland fires.

3.21.4 Impact Analysis Approach

The approach to impact analysis for hazards and hazardous materials includes an evaluation of the Proposed Project's transport, use, disposal and potential release of hazardous materials within the context of existing environmental setting. This section also describes the proximity of Proposed Project activities to schools, evaluates the existing known and unknown contaminants and contaminated sites within the Area of Analysis for hazards and hazardous materials, identifies airport locations, evaluates emergency response plans, and addresses wildfire hazards.

The analysis of the Proposed Project primarily focuses on the short-term construction-related activities and impacts that would cause the removal of existing hazardous materials. An increased need for emergency services is likely during construction activities and, as described in Section 3.22 *Transportation and Traffic*, project-related equipment and debris hauling may conflict with the ability to provide required emergency services. Consideration has been provided for the potential for accidental release of hazardous materials during routine transport along roadways that would be shared with public vehicles, where the latter could include school busses when school is in session (September to June). The analysis of wildfires considers the potential increase for wildfires during construction activities and as a result of restoration activities, as well as potential long-term impacts related to the loss of the reservoirs for future fire-fighting purposes.

The potential for aquatic species and human exposure to inorganic and organic contaminants due to sediment release associated with dam removal under the Proposed Project is discussed in Section 3.2.5.7 *Inorganic and Organic Contaminants*.

Local regulations pertaining to impacts analyzed in this section include Siskiyou County General Plan policies (i.e., Policies 30 Wildfires, 41.9 Adequate access) and solid waste regulations such as the Countywide Source Reduction and Recycling Element and Siskiyou County Code of Ordinance Title 5, Chapter 1 Garbage and Refuse Disposal. Other local regulations that may indirectly pertain include those of the Siskiyou County Environmental Health Department, and the Siskiyou County Air Pollution Control District.

3.21.5 Potential Impacts and Mitigation

Potential Impact 3.21-1 Proposed construction-related activities could result in substantial exposure to hazardous materials through the routine transport, use, or disposal of hazardous materials.

The Proposed Project would not result in the long term routine transport, use, or disposal of hazardous materials since the Proposed Project is the removal of existing dams and their associated hydroelectric facilities, and, once completed, the Proposed Project would not involve the continued use, transport or disposal of hazardous materials. However, in the short term, construction-related dam removal would involve routine transport, use, and disposal of general construction waste materials (e.g., concrete, rebar, building waste, power lines; see also Appendix B: *Definite Plan – Sections 5.3–5.5*) and some hazardous materials (e.g., treated lumber, asbestos, lead, PCBs, fuels, gases, etc.) would be encountered, used, transported and disposed of during those construction activities.

The Proposed Project Phase 1 Environmental Site Assessment for hazardous materials is underway but has not yet been completed. A Phase 2 Environmental Site Assessment for hazardous materials would be undertaken, as needed. Existing information regarding hazardous waste associated with the Lower Klamath Project dams and its facilities indicates that creosote or other treated wood is present, including 700 tons of treated wood waste from the wooden-stave penstock at Copco No. 2 Dam, as well as batteries, possible PCBs from transformers and other electrical equipment, asbestos-containing materials in building materials, fuels and oils, flammable and combustible liquids, flammable and nonflammable gases, corrosives, concrete dust (if it generates high pH waste), and soils or other material contaminated with lead from the use of lead-based paints or plumbing (see additional detail in Appendix B: *Definite Plan – Appendix O3*).

Demolition and disposal of structures containing the aforementioned hazardous materials, or others determined as part of Phase 1 investigations (and Phase 2, as needed), under the Proposed Project could result in exposure to quantities of hazardous, or acutely hazardous, materials that would be harmful to the public or the environment due to accidental releases and thus could result in a significant impact. Operation of construction equipment in close proximity to aquatic environments could involve equipment failures that would also result in the public or the environment being exposed to hazardous materials due to petroleum spills. Because the Proposed Project is located in a sensitive environment (i.e., along the Klamath River) and consists of substantial demolition activities, the increased amount of construction-related activity relative to existing conditions would increase the risk of exposing the public or the environment to quantities of hazardous, or acutely hazardous, materials that would be harmful. This would be a significant impact.

The Proposed Project includes an assessment of roads, intersections, bridges and culverts (Appendix B: *Definite Plan – Appendix K*) within the Area of Analysis for hazards and hazardous materials and proposes a number of improvements to help reduce the potential for accidental release of hazardous materials during transport of these materials to and from the dam sites. The proposed replacements and upgrades to transportation structures, as well as proposed construction-related traffic management, including signage, flaggers, and traffic coordination (Appendix B: *Definite Plan –*

Appendix O2), would reduce the risk of traffic accidents that could result in exposure to quantities of hazardous, or acutely hazardous, materials that would be harmful to the public or the environment.

Further, existing federal and state regulations require the KRRC and its construction contractors to undertake a number of measures related to hazardous materials. KRRC is developing a dam safety program that would ensure that removal of the Proposed Project would be undertaken in a manner that minimizes risk to people, structures, infrastructure, and the natural resources of the Klamath River Basin (Appendix B: *Definite Plan – Section 3*). Such removal would fully comply with FERC's dam safety requirements, and it would be consistent with FERC Engineering Guidelines (FERC 2017). In addition, the below list of state and federal regulations include requiring, for example, that the KRRC and its contractors keep an inventory of hazardous materials at each dam facility and the intention for final disposition of these materials. The KRRC and its contractors are required to describe the storage, spill prevention, and cleanup measures, including the deployment and maintenance of spill cleanup materials and equipment at each facility/site to contain any spill from Proposed Project activities. Onsite containment for storage of chemicals classified as hazardous is required to be away from watercourses and include secondary containment and appropriate management as specified in California Code of Regulations, Title 27, Section 20320.

The KRRC and its contractors are also required to comply with the terms and conditions in the State Water Board's *National Pollutant Discharge Elimination System (NPDES) General Permit for Storm Water Discharges Associated with Construction and Land Disturbance Activities* (Construction General Permit; State Water Board Order 2009-0009-DWQ, as amended by State Water Board Orders 2010-0014-DWQ and 2012-0006-DWQ), and ongoing amendments during the life of the Proposed Project.), Hazardous materials, substances, and waste within the Area of Analysis for hazards and hazardous substances are regulated by several other federal and state laws and policies, some of which are listed below. Compliance with required regulations would substantially minimize the potential impact of hazardous materials on the public and the environment during the routine transport, use, or disposal of hazardous materials.

Federal Regulations

- Resource Conservation and Recovery Act (42 USC 6901 et seq.)
- Hazardous Materials Transportation Act (49 USC Section 1801 et seq.)
- Clean Water Act (33 USC 1251 et seq.)
- Comprehensive Environmental Response Compensation and Liability Act and
- Superfund Amendment Reauthorization Act (SARA) (43 USC 9601 et seq.)
- 40 CFR 260-279 Federal Regulations on hazardous waste management
- 40 CFR 301 et seq. Emergency Planning and Community Right to Know Act
- Toxic Substances Control Act (15 USC 2601 et seq.)

State Regulations

- California Hazardous Waste Control Law (California Health and Safety Code [HSC] Section 25500 et seq.)
- Carpenter-Presley-Tanner Hazardous Substances Account Act (HSC Section 25300 et seq.)

- Unified Hazardous Waste and Hazardous Materials Management Regulatory Program (HSC Section 25404 et seq.)

The Proposed Project also includes Appendix B: *Definite Plan – Appendix O3 Hazardous Materials Management Plan*. The Hazardous Materials Management Plan states that all hazardous materials removed within the Project Boundary would be either returned to the vendor, recycled, or managed and disposed of as hazardous waste at an approved hazardous waste facility in accordance with applicable regulations. Transformer oils would be tested for PCBs if no data exist. Any tanks that contain hazardous materials would be decontaminated prior to disposal. Universal hazardous waste (e.g., lighting ballasts, mercury switches, and batteries) would be handled per applicable federal and state universal waste regulations. The Hazardous Materials Management Plan notes that any additional hazardous materials noted during the Phase 1 site visits and Phase 2 investigations would be included in an updated Hazardous Materials Management Plan and the contractor would sample and test for asbestos, lead and PCB's at all structures to be removed. The Hazardous Materials Management Plan is required to comply with, among other regulations, California Health and Safety Code, title 27, division 20, chapter 6.95, sections 25500 through 25545, and California Code of Regulations title 19, division 2, chapter 4.

Overseeing development and implementation of the Final Hazardous Materials Management Plan falls within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to be consistent with the water quality certification from California, at this time the Hazardous Materials Management Plan is not finalized. Therefore, implementation of Mitigation Measure HZ-1 is required to reduce the short-term, construction-related risk of exposing the public and/or the environment to harmful quantities of hazardous, or acutely hazardous, materials during their transport, use, and disposal under the Proposed Project to less than significant.

Mitigation Measure HZ-1 – Hazardous Materials Management.
No later than six months following issuance of the FERC license surrender order, and prior to the start of pre-dam removal activities and any construction activities, the KRRC shall submit a Final Hazardous Materials Management Plan (Final Hazardous Materials Management Plan) to the State Water Board Deputy Director for review and approval. The State Water Board has authority to review and approve any final Hazardous Materials Management Plan through its water quality certification under Clean Water Act Section 401. The State Water Board has issued a draft water quality certification[171] which sets forth monitoring and adaptive management requirements for any Hazardous Materials Management Plan to meet, as Condition 11. Additionally, the Oregon Department of Environmental Quality has issued a water quality certification[172] that sets forth water quality monitoring and adaptive management conditions for points upstream of California.

[171] The State Water Board's draft water quality certification is available online at: https://www.waterboards.ca.gov/waterrights/water_issues/programs/water_quality_cert/docs/lower_klamath_ferc14803/lkp_dwqc.pdf (Accessed December 19, 2018).
[172] The Oregon Department of Environmental Quality's final water quality certification is available online at: https://www.oregon.gov/deq/FilterDocs/ferc14803final.pdf (Accessed December 21, 2018).

Consistent with the above, the Final Hazardous Materials Management Plan shall include any modifications to the proposed Hazardous Materials Management Plan developed in coordination with State Water Board staff that provide the same or better level of protection regarding procedures for proper disposal or abatement of hazardous materials encountered during Proposed Project activities; proper storage, containment, and response to spills caused by the Proposed Project; and proper removal and disposal of septic tanks as part of the Proposed Project.

The Final Hazardous Materials Management Plan shall also describe how the elements of the KRRC's proposed Health and Safety Plan (Appendix B: *Definite Plan – Appendix O4*), the Spill Prevention, Control, and Countermeasure Plan (Appendix B: *Definite Plan – Appendix O4*), the Emergency Response Plan (Appendix B: *Definite Plan – Appendix O4*), and the Traffic Management Plan (Appendix B: *Definite Plan – Appendix O2*) are coordinated together, and as such, adequately protect water quality with respect to hazardous materials management.

The KRRC shall implement the Final Hazardous Materials Management Plan upon receipt of State Water Board Deputy Director approval and any changes to the Hazardous Materials Management Plan must be approved by the State Water Board Deputy Director prior to implementation.

The KRRC shall provide monthly reporting to the State Water Board detailing the volumes of hazardous materials and wastes that were cleaned up and disposed of from site construction activities and any other modifications to the proposed Hazardous Materials Management Plan developed in coordination with State Water Board staff.

Significance

No significant impact with mitigation

Potential Impact 3.21-2 Proposed construction-related activities could result in substantial exposure to hazardous materials through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.

See also discussion under Potential Impact 3.21-1. A reasonably foreseeable condition that could result in an upset involving the release of hazardous materials into the environment would occur from such natural events, such as earthquakes, floods or fires or from accidents during construction activities. Fuel storage tanks used for construction could rupture or spill and hazardous materials could be carried away by floodwaters. Proposed Project workers, the public sharing the roads with construction vehicles, and/or the environment could be exposed to harmful levels of hazardous materials due to accidental releases during construction activities. Accidental release of hazardous materials (from vehicle fuels, solid waste, materials and supplies) could also occur during transport as a result of vehicular accidents due to increased construction-related traffic and/or as a result of inadequacies in the capacity, design or traffic control of the roads that would be used for construction-related activities (Figure 3.22-1). Any of these situations under the Proposed Project would result in a significant impact.

Appendix B: *Definite Plan – Appendix O2 Traffic Management Plan*, *Appendix O3 Hazardous Materials Management* and *Appendix O4 Emergency Response Plan* complement one other with respect to pre-planning and response efforts to minimize the risk of potential upset and accident conditions involving the release of hazardous materials. Since the responsibility of finalizing these plans fall on the KRRC and the construction contractors, Mitigation Measure HZ-1 assures that the contractor(s) are aware of the federal and state requirements and submit updated plans that are geared towards their strategies and methods for addressing this issue.

With implementation of Mitigation Measure HZ-1, impacts due to potential upset and/or accidental release of hazardous materials that result in substantial exposure to the environment during the proposed short-term, construction-related activities would result in a less than significant impact.

Significance

No significant impact with mitigation

Potential Impact 3.21-3 Proposed construction-related activities could result in substantial exposure to hazardous materials through emissions or handling of substances or waste within one-quarter mile of an existing or proposed school.
Hazardous emissions and acutely hazardous materials generally can have a greater impact than other types of hazardous materials, especially if they are present within one-quarter mile of a school. There are no hazardous emissions proposed from a manufacturing process under the Proposed Project. Short-term operational emissions due to construction-related activities under the Proposed Project are discussed in Section 3.9 *Air Quality and Section 3.10 Greenhouse Gases*. Hazardous materials and wastes are addressed in Potential Impacts 3.21-1 and 3.21-2.

Existing schools are more than five miles away from construction-related activities (Section 3.21.2.2 *[Hazards and Hazardous Materials] Environmental Setting – School Proximity*), thus the Proposed Project would not involve handling of hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of a school.

Significance

No significant impact

Potential Impact 3.21-4 The Proposed Project could be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, could result in substantial exposure to hazardous materials.
The Proposed Project is not located on a site which is currently included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5. However, no Phase 1 or 2 reports have been submitted to make the determination of whether portions of the Proposed Project Area should be included on the lists. The type of use and activities and the length of time these activities have been occurring within the Proposed Project Area suggest the possibility that contaminated sites/soils exist on site. Therefore, the risk remains that contaminants exist on the site that could result in a substantial exposure that would be harmful to the public or the environment. The Proposed Project could also result in a significant impact if the project involved activity in areas that contained contaminated substances that would result in substantial exposure to the public or the environment. Crucial to this analysis would be the analysis of what contaminants exist on the site. This is typically ascertained by completion of a Phase 1 Environmental Analysis and, when necessary, a follow up with a Phase 2 Environmental Analysis.

Appendix B: *Definite Plan – Appendix O3*, Table 1 identified contaminated soils as a type of hazardous material that could be present at each dam location. As noted in Section 3.21.2.3 *Contaminants/Contaminated Sites*, there are several sites that may be contaminated with hazardous substances in the vicinity of the Proposed Project. Thus, the Proposed Project could result in an impact from known and unknown contaminants if, during construction activities, these materials are not handled and disposed of properly (i.e., according to state and federal regulations). For instance, dioxins and dioxin-like substances, including PCBs, are persistent in the environment and accumulate in the food chain. Human exposure to dioxins has been associated with a range of toxic effects. They are also a known human carcinogen. PCBs are found in industrial oils, old electric transmission lines, and substations. PCBs are currently listed as a potential type of hazardous waste present at the Copco No. 1, Copco No. 2, and Iron Gate dams (Appendix B: *Definite Plan – Section 5*). If these contaminants are present in the soil in substantial quantities there is the potential for exposure at levels that would be harmful to the public or the environment. This would be a significant impact.

Based on the age of the structures at Iron Gate Dam, the concrete in the structures may contain fly ash, which has raised concerns in the past about the presence of mercury or other toxic substances. Without proper protections, these contaminants can leach into groundwater and potentially migrate to drinking water sources, posing public health concerns. While USEPA recognizes the beneficial uses of fly ash and considers it safe when it is encapsulated in concrete or other building materials (USEPA 2016), construction activities include drilling and cutting into the large quantities of concrete slated for removal under the Proposed Project (i.e., greater than 100,000 yd^3) (Table 2.7-3, Table 2.7-4, and Table 2.7-7) could result in dust that releases toxic substances and would be harmful to the public or the environment. This would be a significant impact.

In addition to the measures included in the Proposed Project, Mitigation Measure HZ-1 would be necessary to ensure that adherence to existing regulations are included in contractor bid documents. This includes that the findings of the Phase 1 and Phase 2 Environmental Site Assessment reports would need to be added to the Hazardous Materials Management Plan and Health and Safety Plan. With implementation of Mitigation Measure HZ-1, potential impacts due to exposure to hazardous materials during the proposed construction-related activities would be less than significant.

Significance

No significant impact with mitigation

Potential Impact 3.21-5 The Proposed Project could result in, for a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, a substantial safety hazard for people residing or working in the project area due to a risk of traffic accidents.

Potential Impact 3.21-6 The Proposed Project could result in, for a project within the vicinity of a private airstrip, a substantial safety hazard for people residing or working in the project area due to a risk of traffic accidents.

The below analysis applies for both Potential Impacts 3.21-5 and 3.21-6.

The Proposed Project could result in a substantial safety hazard from air traffic accidents if it was located near an airport's area of influence or resulted in height obstructions that would result in air traffic accidents. Siskiyou County Airport is more than 10 miles south of Iron Gate Dam in Montague. Pinehurst State Airport in Oregon is located approximately nine miles north of Copco No. 1 Reservoir. There are no public or private airports within two miles of the Lower Klamath Project nor would any activities of the surrounding airports or airfields adversely affect the Proposed Project area. The 2001 Siskiyou County Airport Land Use Compatibility Plan does not extend as far north as the Proposed Project. There is also no aspect of the Proposed Project that would adversely affect any nearby airports or private airstrips. (see also Section 3.21.2.4 *Nearby Airports*). Overall there would be no impact.

Significance

No significant impact

Potential Impact 3.21-7 Proposed construction-related activities could impair implementation of, or physically interfere with, an adopted emergency response plan or emergency evacuation plan.

The Proposed Project would not directly conflict with any adopted emergency response plan or emergency evacuation plan. However, the Proposed Project could result in short-term construction-related impacts consisting of an increase in traffic on narrow rural roads from commuting workers, hauling of large equipment and disposal of wastes. This additional traffic could result in interference to emergency response vehicles as well as create a situation requiring additional need for emergency response due to personal and vehicular accidents, natural and worksite caused fires, and accidental releases of hazardous materials. This would be a significant impact. To prevent or reduce impacts to emergency response, a carefully orchestrated plan that avoids interfering with off-site emergencies as well as accommodates the need for emergencies resulting from the Proposed Project needs to be developed and disseminated amongst both workers and responders.

The Proposed Project (Section 2.7.8.11 *Emergency Response*) contains a brief description of an Emergency Response Plan (for details see Appendix B: *Definite Plan–Appendix O4*). According to that document, construction contractors would be required to develop a Final Emergency Response Plan to develop and implement procedures to help prevent incidents, to ensure preparedness in the event incidents occur, and to provide a systematic and orderly response to emergencies. The Final Emergency Response Plan needs to be closely coordinated with the contractor's Health and Safety Plan, Spill Prevention and Response Plan, Traffic Management Plan, and Fire Management Plan. Procedures documented in the Final Emergency Response Plan would apply to all personnel working on site. Prior to commencing construction activities, the contractor's Health and Safety lead would review emergency response procedures with all personnel assigned to the site to the extent necessary.

Applicable emergency scenarios include, but are not limited to, the following:

- Medical emergency
- Fire management
- Traffic incident
- Hazardous material spill management

- Downstream hydraulic change planning (e.g., flooding-related hazards)
- Dam or tunnel failure
- Catastrophic emergency (e.g., earthquake, high wind event, etc.)
- Security threat

Each type of emergency and its associated plan requirements are discussed in more detail in Appendix B: *Definite Plan – Appendix O4* Emergency Response Plan.

An increased need for emergency services may occur during peak construction activities under the Proposed Project, and, as described in Sections 3.17 Public Services and 3.22 *Transportation and Traffic*, this may conflict with the ability of entities to provide those services. As discussed in Section 3.21.2 *Environmental Setting* (as well as Section 3.22 *Transportation and Traffic*), there is the possibility that the combination of existing and project-related traffic may cause conflicts within the existing road system, preventing the level of emergency response that is available under existing conditions, particularly given the rural nature of the Area of Analysis for hazards and hazardous materials. This would be a significant impact. To reduce potential impacts all construction workers would require the knowledge and resources to adequately respond to emergencies, where emergency preparation and work should be overseen by a designated health and safety manager. In addition, responding agencies/departments should be made aware of the activities during the construction period so that they can implement their existing regulatory framework, establish an emergency contact process, and undertake inspections as needed throughout project implementation.

The draft Traffic Management Plan (Appendix B: *Definite Plan − Appendix O2)* further notes that the KRRC's contractor would perform a risk assessment of all intersections and roadways as part of the final Traffic Management Plan. Implementation of Recommended Measure TR-1 would require additional components beyond those listed as part of the Proposed Project (i.e., the final versions of the Traffic Management Plan and Emergency Response Plan) and these components would be necessary to adequately implement an Emergency Response Plan that addresses short-term construction-related impacts, consisting of an increase in traffic on narrow rural roads from commuting workers, hauling of large equipment and disposal of wastes, to the point that the potential impact would be less than significant.

Overseeing development and implementation of the final Traffic Management Plan and Emergency Response Plan, including measures described in Recommended Measure TR-1, does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable good citizen agreements that will be finalized and implemented, at this time the Traffic Management Plan and Emergency Response Plan are not finalized and the State Water Board cannot require their implementation. Accordingly, the State Water Board anticipates that implementation of the final Traffic Management Plan and Emergency Response Plan, including the aforementioned additional details in Recommended Measure TR-1 and any modifications developed through the FERC process that provide the same or better level of protection for transportation and traffic would reduce impacts to less than significant. However, because the State Water Board cannot ensure implementation of the final Traffic Management Plan and Emergency Response Plan, it has determined the impact in this Draft EIR to be significant and unavoidable.

Significance

Significant and unavoidable

Potential Impact 3.21-8 Proposed construction-related activities and/or removal of the Lower Klamath Project reservoirs could substantially increase the public's risk of loss, injury, or death associated with wildland fires.

The short-term potential for the public's increased risk from wildfires would occur during implementation of the Proposed Project if construction activities are not conducted consistent with adequately developed fire management and emergency response plans. As described under Potential Impact 3.21-7, providing all construction workers with the knowledge and resources for preventing and suppressing fires and requiring that all emergency preparation and work activities are overseen by a designated 'Safety Officer' would reduce the potential for short-term construction-related impacts of the Proposed Project to increase risk associated with wildland fires. The Proposed Project would be subject to a number of regulations and guidance documents, implemented by the various fire suppression services. Public Resources Code section 4423 et seq. include a number of requirements related to construction activities. CALFIRE's Industrial Operations Fire Prevention Guide (CALFIRE 1999) includes additional guidance.

Currently the Proposed Project includes versions of the Fire Management Plan and the Emergency Response Plan (Emergency Response Plan), leaving some of the details to the KRRC or selected contractor to provide. The Proposed Project Fire Management Plan (see Appendix B: *Definite Plan – Appendix O1*) responds to the above requirements and other fire prevention and response methods including fire precaution, pre-suppression, and suppression measures consistent with the policies and standards in the affected jurisdictions and provisions. The Fire Management Plan contains additional details, including the following bulleted items:

- Designate a Safety Officer
- Comply with all federal, state, and local regulations
- Assure fire suppression tools and water pumping systems on site
- Assure spark arresters on all equipment and vehicles
- Establish ongoing communication with fire suppression agencies
- Manage all work areas to reduce fire risk

Implementation of the proposed Fire Management Plan would result in a less than significant short-term construction-related impact because the measures contained within would substantially decrease the risk of wildland fires and hence the risk of loss, injury or death involving these fires.

Removal of the reservoirs as a source of water for fire suppression could substantially increase the public's risk of loss, injury, or death associated with wildfires if other sources of water are not readily available, and could result in an increased source of wildfire fuel in the form of dead trees around the former reservoir shorelines. Each of these potential impacts is discussed further below.

The Proposed Project would result in the removal of one readily available water source for wildfire services or increased emergency response times if other sources of water are not as readily available. Under the Proposed Project, removal of the Copco No. 1, Copco No. 2, and Iron Gate reservoirs would remove a long-term water source for fire suppression crews after the reservoirs are removed. The removal of the reservoirs could increase turn-around time for helicopters or ground crews refilling with water for fire abatement purposes. However, the initial response times for existing aircraft with fire retardant would not be changed by the loss of the reservoirs. Following dam removal, helicopters and ground crews would still be able to extract water from the Klamath River (both the current channel and the channel reaches to be exposed in the current reservoirs following drawdown), Lake Ewauna, and Upper Klamath Lake. Retrieving water directly from the Klamath River is consistent with how wildfires are suppressed along the Klamath River downstream of Iron Gate Dam under current conditions. Ground crews would be adversely affected unless access to Klamath River water continues to be supported under the Proposed Project. Loss of the reservoirs would not affect the use of fire retardant, which is loaded onto aircraft at regional airports (i.e., Redding, Montague, Klamath Falls) and then applied directly to wildfire sites.

With respect to Klamath River access, most helicopter water tanks require three feet of water depth to fill properly, so only deeper pools in the Klamath River would be able to be used by helicopters. CALFIRE uses the closest available water source that is suitable for fire-fighting, where suitability is determined by local conditions including water flow, depth of pool (2- to 3-foot minimum), amount of debris in pool, shoreline vegetation, and surrounding terrain. Rotor blade length and the length of bucket lines are also determinants, since there must be a safe amount of space to enter and exit the pool site. Individual pilots use their discretion to determine the closest and safest locations from which to withdraw water.

Analysis of aerial photos (Google Maps 2018) suggests the presence of pools with suitable conditions for helicopter filling in the currently free-flowing reaches of the Middle and Upper Klamath River, particularly in the reaches between Copco No. 1 and J.C. Boyle reservoirs and downstream of Iron Gate Dam. While source water would be available in the Klamath River in pools located in the river reaches exposed following reservoir drawdown, the travel time involved in accessing the newly formed pools would be greater than that for the existing Lower Klamath Project reservoirs because retrieval of water from relatively smaller, more narrow, river pools is more difficult than dipping directly from the broad water surface of a lake or reservoir, and only one helicopter at a time would have access to a given river pool versus multiple helicopters that can draw at one time from a large reservoir. Thus, response and travel times between water fills for helicopter crews would be expected to increase with the loss of the reservoirs. Wildfires can spread at a rapid speed, and involve high risks. Any amount of additional response time compared with existing conditions could result in a substantial increased risk of loss, injury, or death involving wildland fires and this would be a significant impact.

To compensate for the loss of reservoir water supply, the Proposed Project includes providing alternate water supply through dry hydrants that would be accessible to ground crews following removal of the dams. Flows in the Klamath River and tributaries are not expected to substantially change post-dam removal, as compared to current flows, and firefighting ground crews could still use the river as a water supply as long as physical access to water is provided. A dry hydrant is a passive, unpressurized system, with a screened intake placed in the channel above the channel bed. An above-ground fire hose is used to connect the intake to truck-mounted pumps (Figure 3.17-1). Placement of the dry hydrant must be in a location of satisfactory depth (during dry conditions), flow rate, and channel stability. The Definite Plan states that dry hydrants are commonly used as water supply for fighting fires in rural areas, and typical dry hydrants and fire truck pumps can supply over 1,500 gallons per minute, which is sufficient for rapid filling of typical water tankers and firefighting apparatus (Appendix B: *Definite Plan – Appendix O1*).

To assist ground-based firefighting efforts, the Fire Management Plan proposes the development of eight sites near the Copco No. 1 Reservoir and four sites near the Iron Gate Reservoir for installation of permanent dry hydrants from which water trucks and fire engines could draw directly from the Klamath River and larger tributaries (Figures 3.17-2 and 3.17-3). The Proposed Project also includes an evaluation of the potential for riverine pool features to be used for helicopter water filling and development of an associated map of resources that can be used by air-based firefighting crews.

The proposed dry hydrants are likely to be of limited use for firefighting compared with existing conditions because only ground crews can access them (i.e., they are of no use to aerial crews that can access the reservoirs under existing conditions). Hook-ups to the dry hydrants would require standard specifications and existing CALFIRE pumper trucks would require special equipment such as hard suction lines (a flexible hose would collapse) to successfully draft from the dry hydrants. The ground crews would need to be able to get close to the river to draft from the dry hydrants because firetrucks typically can only lift water over short vertical distances (i.e., 10 to 14 feet, with a maximum 15-foot height from the intake) and drafting from bridges may require too much lift. Decreased response time associated with dry hydrants as compared with aerial crew access of reservoir water via helicopters would be a significant impact since it would increase the risk of loss, injury, or death involving wildland fires. Direct withdrawal from the river using a boat ramp, pumping stations equipped with pumps connected to wells or deep pools in the river, above-ground storage tanks with ready access for transferring water to pumper trucks, are likely to be better options than the dry hydrants proposed by KRRC because these alternatives would be easier to use and thus would reduce ground crew response time. Section 3.17 *Public Services* includes Recommended Measure PS-1 that requires the KRRC or the Contractor's Safety Officer for the Proposed Project to submit a final Fire Management Plan after reaching agreement with CALFIRE Siskiyou Unit on a long-term water source replacement for helicopter and ground crews (including construction and utilization of proposed dry hydrants, dip ponds or other alternatives).

Loss of the Lower Klamath Project reservoirs could also increase the relative amount of dead woody vegetation compared with existing conditions, which would increase the fuel load by removing the reservoir shorelines and potentially affecting adjacent shallow groundwater levels. The potential for this effect would be limited to an approximate 300-foot wide band around the current reservoir shorelines, where root zones are within five to ten feet of groundwater. As noted in Section 3.5.2.1 *Vegetation Communities,* trees located outside of this 300-foot wide band would not be dependent on reservoir water as a significant source of water to tree roots. Conifers surrounding the reservoirs are considered drought-tolerant and would not be affected by the loss of the reservoirs but would remain as an existing fire hazard with or without the project. Riparian vegetation adjacent to tributary streams within the Area of Analysis for hazards and hazardous materials would continue to possess a source of water following dam removal since tributary stream flows would not be affected by the Proposed Project. In contrast, tree-dominated wet habitats surrounding the reservoir (i.e., Montane Riparian and Palustrine Forested Wetland [Section 3.5.2.1 *Vegetation Communities* and Appendix G]) would be likely to transition to upland habitats once the reservoirs are drawn down, and existing trees such as Oregon Ash and bigleaf maple may become snags or ultimately fall to the ground. While this increase in the relative amount of dead woody vegetation compared with existing conditions would increase the public's risk of loss, injury or death associated with wildland fires within the Area of Analysis, there is a relatively small proportion of these wet habitat types within the 300-foot buffer surrounding the Lower Klamath Project reservoirs (Figure 3.5-4 and 3.5-5). Montane Riparian and Palustrine represent three percent and six percent, respectively, of the vegetation in the 300-foot buffer surrounding Copco No. 1 and 2 reservoirs; Montane Riparian and Palustrine represent one percent and four percent respectively, of the vegetation in the 300-foot buffer surrounding Iron Gate Reservoir. This affected area, where woody vegetation may die off from loss of the reservoirs as a source of water, is limited in extent and would not substantially increase the risk of loss, injury or death involving wildland fires as a result of the loss of the reservoirs.

The measures included in the Fire Management Plan would reduce the potential for short-term, construction-related impacts of exposing people or structures, either directly or indirectly, to risk of loss, injury, or death involving wildland fires both during and immediately after the dams are removed, and there would be no significant impact. However, in the long term, the loss of the reservoirs, which are currently part of the existing conditions, would result in a substantial decrease in fire protection involving wildland fires due to longer response times and limitations on access to Klamath River water for fighting fires within the Area of Analysis for public services. While the proposed dry hydrants would provide a source of water to ground crews for firefighting, they do not offer the same degree of access as helicopter use of the reservoirs for wildfires occurring in the vicinity of the Lower Klamath Project, for which the reservoirs are the closest and safest source of water for aerial crews. One option that would assist in mitigating this impact would be to include appropriately placed dip ponds within the Proposed Project's restoration areas.

Recommended Measure PS-1 requires the KRRC and/or its Contractor(s) to develop, in consultation with the CALFIRE Siskiyou Unit, an updated Fire Management Plan that identifies long-term water sources for helicopter and ground crews (including construction and use of proposed dry hydrants, dip ponds, or other alternatives). Overseeing development and implementation of terms and conditions relating to fire management does not fall within the scope of the State Water Board's water quality certification authority. The State Water Board anticipates that in the absence of the reservoirs, the identification and use of alternative water sources (e.g., dip ponds, river pools suitable for helicopter drafting, dry hydrants) for both ground and helicopter crews that are developed through the FERC process would significantly ameliorate response times and provide a level of protection to substantially reduce the public's risk of loss from wildfires, thereby reducing impacts to less than significant in many instances. However, where suitable replacement water sources cannot be identified in close proximity to a fire in a location for which the reservoirs would otherwise have been the nearest water source, long-term impacts to the public's risk of loss from wildfires remain significant and unavoidable.

Significance

No significant impact in the short term

Significant and unavoidable impact in the long term

3.22 Transportation and Traffic

This section describes the environmental setting for traffic and transportation, as well as potential environmental impacts and associated mitigation measures under the Proposed Project. The discussions in the following subsections focus primarily on regional and local roadways that provide access to Proposed Project facilities, traffic safety and road conditions, as well as public transit and non-motorized travel. Impacts evaluated herein focus primarily on the increased construction-related activities that the Proposed Project would create regarding traffic and transportation. While this section considers the sporadic activities that would occur throughout this period, the transportation and traffic focus is on the four- to six-month period during the peak of the construction-related activity, when removal activity would occur concurrently at each of the three California dams. Once the construction-related activity is completed, there will be no additional traffic generated by or directly related to the Proposed Project.

The State Water Board received a comment expressing safety concerns about Copco Road's serving as the primary access route to the Copco No. 1 Dam area and about the potential impacts of construction activities and traffic on the safety of other road users, including school busses, residents, pedestrians, livestock and dogs. The commenter expressed concern that Copco Road could be damaged during construction activities. The State Water Board did not receive other comments related to transportation and traffic and service systems during the NOP public scoping process (see Appendix A).

3.22.1 Area of Analysis

The Area of Analysis for transportation and traffic includes roadways in Siskiyou County, California, that would be used by construction vehicles and workers for, and could potentially be affected by, the Proposed Project. The Area of Analysis includes major access roads from Interstate 5 easterly to where Ager Beswick Road crosses the Oregon border. These roads are generally rural with low-density development. Most of the surrounding private property outside of the Proposed Project is undeveloped or used as grazing land for cattle, with the exception of several small communities in the vicinity of Copco No. 1 and Iron Gate reservoirs. Figure 3.22-1 depicts California roadways within the Area of Analysis for transportation and traffic that are analyzed in this chapter, and excludes other local roads that feed into this network because those local roads would not be used for transportation of construction equipment or workers and would not be affected by the Proposed Project The portion of Interstate 5 that may be affected by the Proposed Project is only partially depicted in Figure 3.22-1, but it is fully analyzed herein.

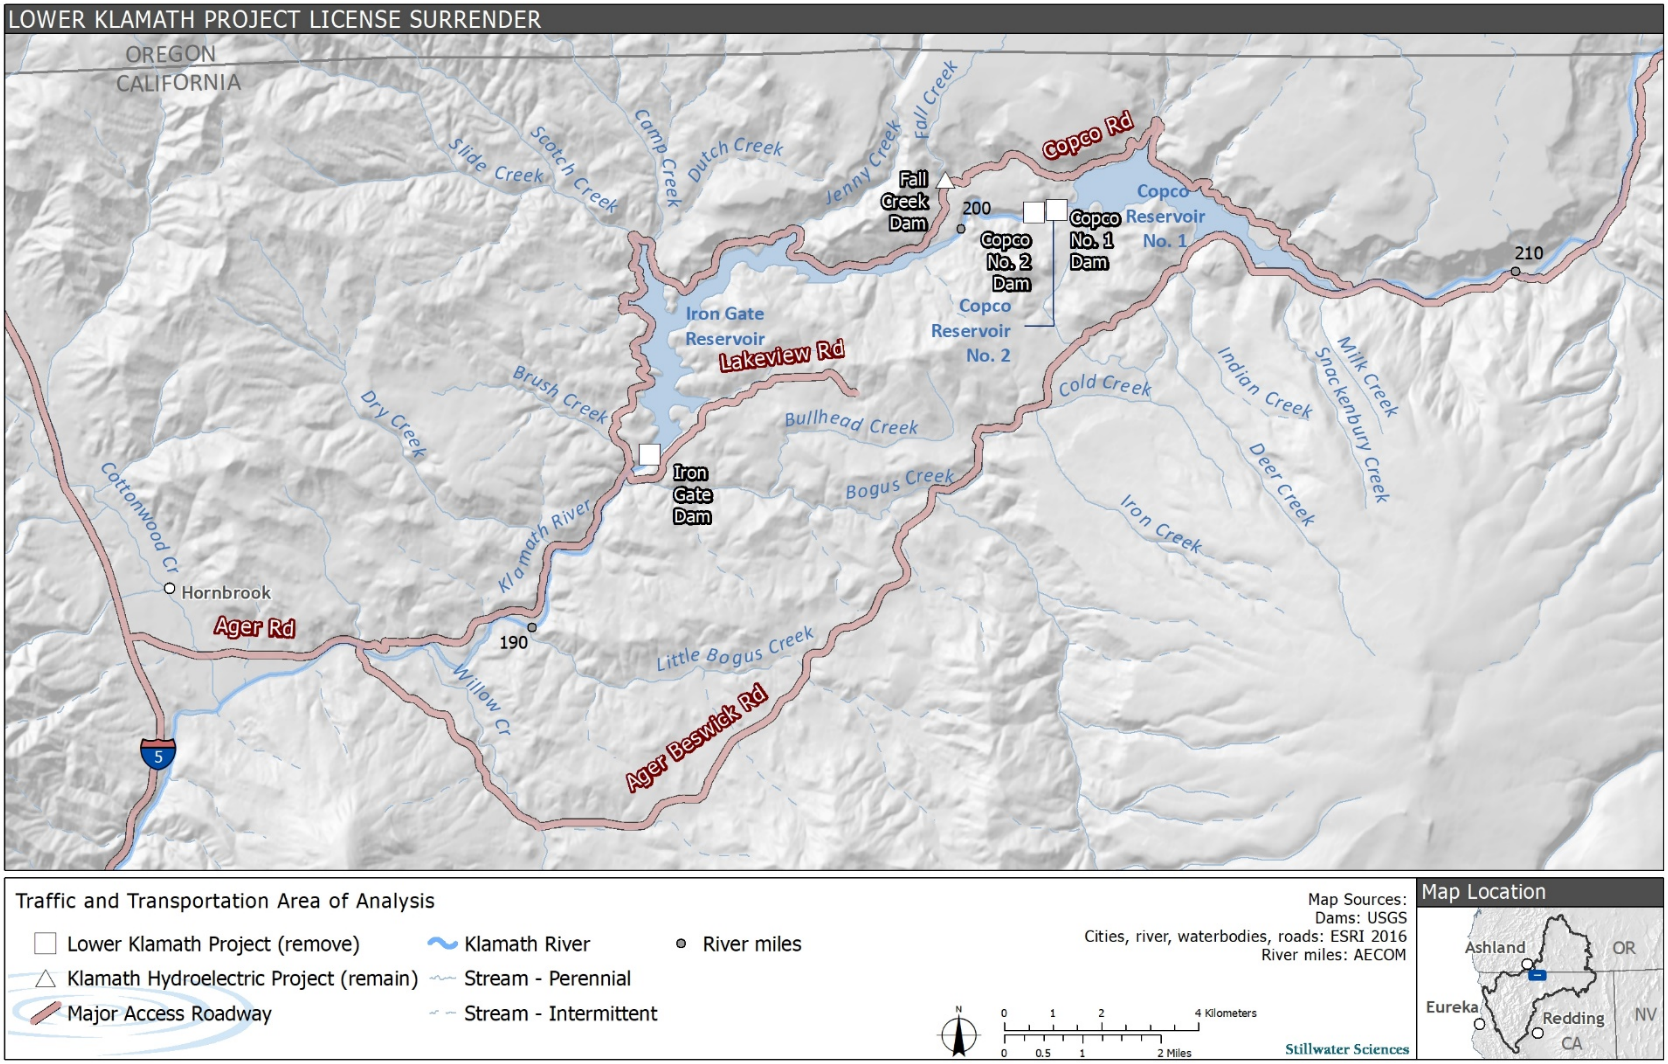

Figure 3.22-1. Traffic and Transportation Area of Analysis.

Table 3.22-1 lists the dam sites within the Area of Analysis for transportation and traffic, along with the corresponding regional and local roads that access each site. Under the Proposed Project, equipment hauling and waste disposal for J.C. Boyle Dam would occur only in Oregon (Appendix B: *Definite Plan*) and so traffic impacts associated with J.C. Boyle Dam are not analyzed herein.

Table 3.22-1. Major Local and Regional Access Roads within the Traffic and Transportation Area of Analysis.

Dam Site	Interstate Access Road	Regional Access Road	Local Access Road
Copco No. 1	I-5 (in California)	Copco Road	Ager-Beswick Road
Copco No. 2	I-5 (in California)	Copco Road	Ager-Beswick Road
Iron Gate	I-5 (in California)	Copco Road	Lakeview Road

3.22.2 Environmental Setting

This section describes the environmental setting associated with transportation and traffic within the Area of Analysis. For discussion of other related environmental resources areas, see Sections 3.9 *Air Quality*, 3.10 *Greenhouse Gas Emissions*, 3.14 *Land Use and Planning*, 3.17 *Public Services* and 3.21 *Hazards and Hazardous Materials*.

3.22.2.1 Traffic Flow

Roadways

Roadways in the Area of Analysis for transportation and traffic are classified as principal arterials, major collectors, minor collectors, and rural local roads. These roadway classifications are defined by the Siskiyou County Local Transportation Commission as follows:

- Principal arterials constitute routes whose design provides for high overall travel speeds with minimum interference to through movement. These routes serve long distance movements indicative of statewide or interstate travel. Principal arterials provide an integrated network that connects communities, regions, and other states.
- Major collectors provide service to larger towns not directly served by the arterial system, and to other traffic generators of equivalent intra-county importance, such as major recreational areas, schools, airports, and commercial activity centers. Additionally, they link these locations with nearby larger towns or cities and with higher classification routes.
- Minor collectors provide service to the remaining smaller communities within the county and link the locally important traffic generators with these rural areas.
- Rural local roads primarily provide access to adjacent land, and provide travel over relatively short distances as compared to arterials and collectors. Local roads constitute the remaining roadway mileage not classified as principal arterial, minor arterial, or collector roadways in Siskiyou County.

Primary access routes in the Area of Analysis for transportation and traffic that are likely to be affected by Proposed Project-related traffic are listed below and shown in Table 3.22-1 and Figure 3.22-1, above.

A discussion of road ownership and maintenance responsibilities is included in Section 3.14 *Land Use and Planning* (see also Figure 3.14-2).

Interstate 5 (I-5) is a major north/south interstate highway (principal arterial) that runs the length of California and is owned/maintained by Caltrans. This is a main regional access road for project facilities. I-5 is approximately 8 miles west of Iron Gate Dam. I-5 has four lanes through Siskiyou County. I-5 would be utilized for mobilization of construction equipment and as a haul route for carrying exported demolition materials. The alignment and pavement is in very good condition (Appendix B: *Definite Plan*). It would also serve as a route for workers commuting to the Proposed Project. Caltrans (2018a) traffic volume data from 2016 indicate that I-5 at Henley Way/Copco Rd (Exit 789) had 20,900 Annual Average Daily Traffic (AADT) in its peak month, and averaged 17,200 AADT.

Copco Road, some portions of which may be identified as "Juniper Road," "Ager Road," or "Iron Gate Lake Road" in some maps or documents, is a county-owned two-lane major collector in Siskiyou County that runs from I-5 to its intersection with Ager Road, where it then becomes a minor collector for the remainder of its length (Fehr and Peers 2011). Copco Road runs east from I-5 to Iron Gate Dam, where it turns north and parallels Iron Gate Reservoir to the Klamath River. From this point, Copco Road parallels the northern side of the Klamath River and Copco No. 1 Reservoir. Copco Road provides primary access to both Copco No. 1 and Copco No. 2 dams. Copco Road is a paved, two-lane road in generally good pavement condition between I-5 and Ager Road with few pavement cracks or ruts and is approximately 27 feet wide. Copco Road maintains this character from its intersection with I-5 east to a point about 10 miles from Copco No. 2 dam, near the Juniper Point Picnic Area. The condition of other portions of Copco Road are poorer that the segment between I-5 and Ager Road. For example, the section between the intersection of Copco Road with Ager Road and the Juniper Point Picnic Area contains intermittent pavement surfacing that has not been as well maintained as the portions to the west of Ager Road. (Additional information regarding the condition of roads in the vicinity of the Proposed Project is available in Appendix B: *Definite Plan – Appendix K*.) The final three miles, from Camp Creek Road near the Juniper Point Picnic Area to Copco No. 1 dam, are gravel and narrow, and less than 18 feet wide in some locations. The posted speed limit on Copco Road from I-5 to the Juniper Point Picnic Area is generally 55 mph with a few sharp curves, especially in the portions that run along the Iron Gate Reservoir. Posted speed limit is then reduced to 35 mph. Copco Road would be a primary access and hauling route for carrying exported demolition materials and for workers commuting to construction areas.

Roadways that could be accessed from Copco Road toward the Proposed Project include Ager Road, Ager-Beswick Road, Lakeview Road, Fall Creek Road, and other two-lane roads that provide access to residential and recreational areas. Copco Road, at its intersection with Ager Road, has approximately 485 AADT; Copco Road near Iron Gate Dam has approximately 216 AADT (Fehr and Peers 2011). Roadways described below connect to these road segments. Many sections of the local roads are posted for 25-35 mph or do not have posted speed limits.

Ager Road is a two-lane major county-owned collector that intersects Copco Road approximately three miles east of I-5 (Fehr and Peers 2011). Ager Road travels south to an intersection with Ager-Beswick Road.

Ager-Beswick Road is a county-owned two-lane minor collector that runs along the southern side of the Klamath River (Fehr and Peers 2011). It is accessed from Ager Road east of the downstream end of the Proposed Project or via a one-lane bridge that crosses from Copco Road over Copco No. 1 Reservoir at the upstream (easterly) end of the Proposed Project.

Lakeview Road is a rural local road that accesses Iron Gate Dam. Lakeview Road intersects with Copco Road at the entrance to the Iron Gate Recreation Area. A one-lane bridge crosses the river at this intersection, linking it to Lakeview Road. Lakeview Road is a gravel road that leads up to the top of Iron Gate Dam. It is approximately 24 feet wide and has a steep embankment on the east side, without a guardrail. Lakeview Road connects to an unnamed bridge access road. The narrow, gravel access road leads onto the top of Iron Gate Dam. For the purposes this analysis, Lakeview Road would be considered an unpaved access road except when discussing the bridge.

Fall Creek Road is a rural local road that intersects with Copco Road and provides access to Fall Creek Dam.

Unpaved access roads include a small network of one-lane, gravel access roads leading from Copco Road to each of the dams. These roads, the majority of which are owned by PacifiCorp, are no wider than 15 feet and are no longer than half a mile. Most of the traffic along these roads consists of PacifiCorp's technicians accessing the facilities, recreational users, or local residents. See Figure 2.7-2 and Appendix B: *Definite Plan − Appendix K* for additional details on locations and conditions of these roads.

Regional Transportation Plan

The Siskiyou County Local Transportation Commission (SCLTC) is the designated Regional Transportation Planning Agency for Siskiyou County. The County is within the jurisdictional boundaries of California Department of Transportation (Caltrans) District 2, located in Redding. The SCLTC, along with Caltrans District 2, fulfills the transportation planning responsibilities for Siskiyou County. One of the main responsibilities of the SCLTC is the preparation and approval of the Regional Transportation Plan. The 2016 Regional Transportation Plan serves as the planning blueprint to guide transportation investments in Siskiyou County involving local, state, and federal funding over the next twenty years. This assures that proper planning for traffic flow, including assessing road conditions and multimodal transportation needs, is implemented.

The 2016 Regional Transportation Plan includes:

- A Policy Element (Chapter 3) describing the transportation issues in the region, identifies and quantifies regional needs expressed within both a short- and long-range framework, and maintains internal consistency with the financial element fund estimates.
- An Action Element (Chapter 4) that identifies plans to address the needs and issues for each transportation mode in accordance with the policy element.

- A Financial Element (Chapter 5) that identifies the current and anticipated revenue sources and financing techniques available to fund the planned transportation investments describes in the action element. The intent is to define realistic financing constraints and opportunities.

The County's Regional Transportation Plan incorporates a number of local and state planning efforts to implement the County's policy to support the development and maintenance of an efficient, safe and effective road system. The 2016 Regional Transportation Plan incorporated information from the following plans and studies.

- Siskiyou County Regional Transportation Plan (2010)
- Siskiyou County Circulation Element Goals (1988)
- Siskiyou County General Plan (1988)
- Ten-Year State Highway Operation and Protection Plan (SHOPP Plan) (2015)
- Siskiyou County Unmet Transit Needs (2015)
- STIP Fund Estimate, CTC (Jan 2016)
- California Strategic Highway Safety Plan (2015)
- Siskiyou County Coordinated Public Transit-Human Services Transportation Plan (2014)

Level of Service

Operation of the roadway system typically is described in terms of Level of Service (LOS). LOS is a quantitative indication of the level of delay and congestion experienced by motorists. LOS is designated by the letters "A" through "F." LOS A corresponds to the lowest level of congestion, where individuals are virtually unaffected by the traffic stream, and LOS F corresponds to the highest level of congestion and the forced breakdown of flow.

The 2016 Siskiyou County Transportation Plan (Greendot 2016) provides AADT thresholds for general classes of roadways and projected volumes from the present to the year 2035. By comparing AADT for measured roads within the Area of Analysis for transportation and traffic with the capacities of those roadways, Greendot (2016) indicates acceptable LOS determinations for those roadways (Table 3.22-2).

Table 3.22-2. Maximum Daily Volume Thresholds for Roadway Classes.

Classification	Level of Service (LOS)* (vehicle trips)				
	A	B	C	D	E
4-Lane Major Freeway	25,400	41,600	58,400	71,000	79,200
2-Lane, Class I Highway	1,200	3,700	7,600	13,600	21,000
2-Lane, Class II Highway	1,700	4,100	8,200	16,600	21,200
Rural Principal Arterial (2 lane)	2,600	5,900	10,300	16,900	20,200
Rural Minor Arterial (2 lane)	1,200	3,300	6,400	11,000	15,500
Rural Major Collector (2 lane)	1,300	3,900	7,500	12,600	16,900
Rural Minor Collector (2 lane)	1000	3,000	5,500	8,750	11,200
Rural Local Road	600	2,000	3,500	4,900	5,500

* Based on the 2010 Highway Capacity Manual, which provided maximum peak hour flows. The values in this table were converted to daily travel using the peak period percent (approximately 10 percent) for these facilities (Greendot 2016).

Conditions on I-5 are at LOS A, which represents free flow. The major access roadways in the Area of Analysis that are likely to be affected by Project-related traffic are at LOS A most of the time (Greendot 2016), with occasional delays expected from high recreational traffic on particular days (e.g., Memorial Day, Fourth of July), and seasonal delays from road conditions (e.g., ice and downed trees).

3.22.2.2 Traffic Safety

Road widths, surface materials, vehicle speed limits, etc., are discussed briefly in Section 3.22.2.1 *Traffic Flow*. Additional information in Appendix B: *Definite Plan – Appendix K* includes an evaluation of sight stopping distance, intersection and roadway geometry, and road conditions. Google Earth Street View (2018), as well as county transportation planning documents that discuss road conditions, traffic accident data, etc. (Greendot 2016; Fehrs and Peers 2011) were also incorporated into the evaluation of traffic safety. The delivery of off-road construction equipment, including cranes, large excavators, loaders, and large capacity dump trucks would be by special tractor-trailer vehicles operating under “wide load” restrictions and at appropriate speeds. Intersection and infrastructure field observations are included in Appendix B: *Definite Plan – Appendix K*.

3.22.2.3 Road Conditions

The existing roads in the transportation and traffic Area of Analysis are owned by PacifiCorp, the Federal Government, Siskiyou County or private entities (Figure 3.14-2). PacifiCorp is currently responsible for maintaining approximately 14.5 miles of roads within lands it owns. Transfer of PacifiCorp land, including roads, within the Parcel B lands would be to the State of California or a designated third-party transferee (see also Section 2.7.10 *Land Disposition and Transfer*).

Roads (including bridges and culverts) in the traffic and transportation Area of Analysis have been utilized to provide rural residential and extensive recreational uses. Roadways originally may have been built for the construction and management of the dams and reservoirs and appear to have served adequately for that purpose (see Appendix B: *Definite Plan – Section 7.4 and Appendix K)*. However, the conditions of the roadways at the time that the dam removal activity is proposed are dependent on what road maintenance activities occur between now and then. According to Appendix B: *Definite Plan – Section 7.4 and Appendix K*, several roads (including bridges and culverts) near the Lower Klamath Project dam facilities are currently inadequate (narrow lanes, bridges of varying conditions, culverts that may be undermined). Recent (2017) surveys have identified the roadways, bridges, and culverts that may require improvements over their current conditions in order to withstand construction-related traffic under the Proposed Project. These roadways, bridges, and culverts are listed below.

Road and Bridge Improvements/Replacements

- Copco Road from I-5 to Ager Road—some pavement rehabilitation.
- Copco Road from Ager Road to Lakeview Road—poor condition, some pavement rehabilitation.
- Copco Road Bridge – potential erosion protection to abutments/ pier.

- Dry Creek Bridge—to be replaced, strengthened or provided with a temporary crossing.
- Copco Road between Lakeview Road and Daggett Road—poor condition, some pavement rehabilitation.
- Jenny Creek Bridge—to be replaced post-construction.
- Copco Road from Daggett Road to Copco Access Road—some road surface rehabilitation during construction.
- Fall Creek Bridge—to be replaced.
- Copco Access Road—grading and clearing required.
- Barge Access to Copco Lake—minor access improvements for barge/crane, boat ramp extension.
- Ager Beswick Road—minor access improvements for barge/crane, boat ramp extension at Mallard Cove.
- Daggett Road—some road surface rehabilitation during construction.
- Daggett Road Bridge—to be replaced, strengthened or provided with a temporary crossing.
- Lakeview Road between Copco Road and Disposal Site—some road surface rehabilitation during construction.
- Lakeview Road Bridge—to be replaced, strengthened or provided with a temporary crossing.
- Powerhouse Access Road—some road surface rehabilitation during construction
- Upstream Left Abutment Access Road—to be re-established then reclaimed post-construction.
- Access Road from Long Gulch Recreational Facility to Lakeview Road - some road surface rehabilitation during construction.
- Access Road from Overlook Point Recreational Facility to Copco Road - some road surface rehabilitation during construction.

Culvert Replacements

- Copco Road at Beaver Creek, East Fork Beaver Creek, Raymond Gulch, West Fork Unnamed Creek, Scotch Creek, 200 feet east of Scotch Creek, small cross-culverts between Brush Creek And Scotch Creek, Camp Creek
- Patricia Avenue at East and West Forks Unnamed Creek
- Deer Creek
- Indian Creek
- Daggett Road at Fall Creek

The proposed improvements to existing roads, bridges and culverts to support short-term construction activities are described in more detail in the following Appendix B: *Definite Plan* locations:

- *Sections 5.2.2, 5.3.2, 5.4.2 and 5.5.2* discuss construction access assessments and related transportation improvements and maintenance.
- *Section 7.4 and specifically Table 7.4.1* describes post-construction transportation improvements and maintenance.

- *Appendix K* contains specifics of the road infrastructure assessment.

The KRRC proposes to develop final designs for planned road, bridge, and culvert improvements during the detailed design phase or as part of a contractor bid document for the Proposed Project (Appendix B: *Definite Plan*). Development of final designs would enable agencies that must approve road, bridge, and culvert improvements to determine the necessity and scope of additional environmental review of those improvements.

3.22.2.4 Emergency Access

The location of the Proposed Project is generally rural, with limited access to vehicular emergency services. As such, rural users realize that response times for emergency access are much longer than in more urban settings. Sections 3.21 *Hazards and Hazardous Materials* and 3.17 *Public Services* of this EIR describe the actual service providers and ability to respond; the Traffic and Transportation analysis is limited to accessibility by emergency service vehicles.

Most roads that already experience truck traffic for hauling boat trailers or other large vehicles/equipment are generally adequate for emergency vehicle use, as has occurred in the past. Roads with residences or farms have experienced construction-sized vehicles and equipment for construction and maintenance. Emergency response times are affected by weather, road conditions, and the amount of other traffic using the road system at the same time. Existing limitations on bridge width and conditions may also affect emergency access and response times.

3.22.2.5 Public Transit

Transit Service

Siskiyou Transit and General Express (STAGE) is the county's public transit service provider. STAGE is the only regional service that connects the downtown areas of Dunsmuir, Weed, Mt. Shasta, Grenada, McCloud, Yreka, Montague, Fort Jones, Greenview, Etna, Klamath River, Horse Creek, Hamburg, Seiad Valley, and Happy Camp. See Table 3.22-3 for destination information. Service is very limited, sometimes running only one or two times a week. The Hornbrook route branches into the Area of Analysis for traffic and transportation and, as of 2016, runs twice a week. The Hornbrook route follows I-5 north into Hornbrook, turns east on Copco Road, and then turns south (before reaching Iron Gate Dam) at Ager Road, heading towards Montague.

In addition, Greyhound Lines provides service within the region in Weed, near the College of the Siskiyous. This location is accessible via the STAGE bus transit service. As with STAGE, this service is limited and is along a major U.S. highway.

Table 3.22-3. Siskiyou Transportation and General Express Routes (STAGE).

STAGE Routes	Destinations
Northbound I-5	Dunsmuir, McCloud, Mt. Shasta, Weed, Gazelle, Grenada, Cove Trailer Park, Yreka
Southbound I-5	Yreka, Cove Trailer Park, Grenada, Gazelle, Weed, Mt. Shasta, Dunsmuir
Montague/Scott Valley/Hornbrook	Yreka, Montague, Hornbrook, Scott Valley (Fort Jones, Etna)
Lake Shastina	Weed, Mt. Shasta, Dunsmuir, Lake Shastina
Happy Camp/Orleans	Yreka
Yreka Northbound	Various destinations within Yreka, Karuk
Yreka Southbound	Various destinations within Yreka, Karuk

Source: Greendot 2016

Air Transportation

Siskiyou County operates five public use, general aviation airports: Butte Valley, Happy Camp, Scott Valley, Weed, and Siskiyou County. A private emergency medic flight service operates between Medford, Oregon and Redding, California. In addition, United Parcel Service (UPS) Ground and Air Freight Services are available at the Montague/Yreka Rohrer Field and the Dunsmuir Municipal Airport. Each airport is owned and operated by its respective city. The Siskiyou County Airport, located in Shasta Valley—11 miles east of Yreka—is home to a USDA Forest Service Fire Attack Base in the summer months (Greendot 2016). The closest public airport is Siskiyou County Airport, which is more than 10 miles south of Iron Gate Dam in Montague. No private or public airport or airfield is within two miles of the Proposed Project.

Rail Transportation

The rail line in Siskiyou County has been dormant from Weed to Oregon since 2008, yet remains historically significant. The rail line follows the Sacramento River and I-5 through the California Central Valley, Shasta and Siskiyou Counties, and into Oregon. Recent grants have allowed for rehabilitation and repair projects for sections of the track. Reopening the track will create additional transportation options for lumber and manufacturing goods from Oregon, which will subsequently result in decreased truck use to transport goods. The rail line is an important historic and cultural attraction in Dunsmuir where the rail line is actively used for passenger travel through Amtrak. Near the rail line in Dunsmuir, the Railroad Resort offers a hotel, restaurant, and museum in vintage train cars.

Amtrak provides rail service in Dunsmuir and Klamath Falls; both are stops along the “Coast Starlight” route, which connects Vancouver, BC, to San Diego, CA. Several stations along the “Coast Starlight” route provide a bus and rail connection to Amtrak’s nationwide network. The Dunsmuir Amtrak station is accessible via the STAGE bus transit service.

3.22.2.6 Non-Motorized Transportation

The road system briefly described in Section 3.22.2.1 *Traffic Flow* has a varying but relatively rare amount of non-motorized use compared to motorized use,. However, it is anticipated that there could be occasional non-motorized commute and recreational uses on the thoroughfares and localized use by residents and recreators on local roads close to all three dam facilities. Similar to motorized traffic, non-motorized transportation would be subject to seasonal fluctuations based on weather, occupation of residences, and seasonal activities including resource utilization and school sessions. Other recreational uses such as motorized and non-motorized boating are discussed in Section 3.20 *Recreation*.

3.22.3 Significance Criteria

Criteria for determining significance on transportation and traffic is informed by Appendix G of the CEQA Guidelines (California Code of Regulations, title 14, section 15000 et seq.) and based on professional judgment. Effects on transportation and traffic are considered significant if the Proposed Project would result in one or more of the following:

1. Substantial increase in traffic where substantial is defined as a quantity in excess of the capacity or design of the road improvement or impairs the safety or performance of the circulation system, including transit, roadways, bicycle lanes or pedestrian paths.
2. Substantial conflict with an applicable congestion management program, including, but not limited to LOS and travel demand measures, or other standards established by the county congestion management agency for designated roads or highways that would result in an increased risk of harm to the public.
3. Substantial increase in hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment) that would result in an increased risk of harm to the public.
4. Result in inadequate emergency access that would result in harm to the public.
5. Substantially conflict with public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities that would result in an increased risk of harm to the public.
6. Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks.

3.22.4 Impact Analysis Approach

The approach to impact analysis for transportation and traffic evaluates the existing transportation circulation within the Area of Analysis for comparison with projected circulation under the Proposed Project. The impact analysis for transportation and traffic focuses on short-term construction-related activities, which generally include the pre-construction period, the dam removal period (up to two years), and one to five years after dam removal, where the latter includes the majority of anticipated restoration and monitoring activities (Appendix B: *Definite Plan*). While this section considers the sporadic activities that would occur throughout this period, the transportation and traffic impact analysis focuses on the six-month period during the peak of the construction-related activity, when concurrent activity would occur in the removal of the three California dams and compares this to the summertime peak recreational activity that is currently occurring. Once the construction-related activity is completed there will be no traffic generated directly related to the Proposed Project. Therefore long-term impacts, those occurring after the construction-related activities are completed, were considered to be less than significant when roads and other infrastructure are left in a condition equal or better than pre-project.

The transportation analysis considers the increase in traffic related to these short-term construction activities and the potential conflicts with residents and property owners in the area, as well as any recreational or visitor traffic that may occur during the activity period. This analysis also considers school bus traffic. The majority of the dam removal activity is proposed in May through September (Table 2.7-1), when, for the majority of the time, school is not in session. The transportation analysis considers the capacity and design of the roads used during activity times.

The Proposed Project addresses such factors as traffic management, emergency response, fire management, structural analysis of the integrity of the roads, bridges and culverts and implementation of required improvements prior to and after construction activities (Appendix B: *Definite Plan –Appendix O*). These factors are all an integral part of analyzing the potential for transportation impacts associated with the construction-related activities as well as after the completion of the Proposed Project. Additional related analysis is also found in other sections of the EIR, as listed in Table 3.22-4.

Table 3.22-4. Transportation-related Discussion Found Elsewhere in this EIR.

Transportation Issues	Section No.	Topic(s)
Vehicle Emissions	3.9	Air Quality
Greenhouse Gas Emissions	3.10	Greenhouse Gas Emissions
Community Connectivity	3.14	Land Use and Planning
Emergency Response	3.17	Public Services
Emergency Response	3.21	Hazards and Hazardous Materials

The Siskiyou County Local Transportation Commission (SCLTC) is the designated Regional Transportation Planning Agency for Siskiyou County. The County is within the jurisdictional boundaries of California Department of Transportation (Caltrans) District 2, located in Redding. The SCLTC, along with Caltrans District 2, fulfills the transportation planning responsibilities for Siskiyou County. As noted in the Siskiyou County Regional Transportation Plan the primary local and regional issues continue to revolve around a lack of maintenance funding to maintain the integrity of existing facilities. A major concern for Siskiyou County is the continuing maintenance requirements of the existing road system. Delayed projects and the lack of funding results in additional deterioration of already poor pavement quality, higher costs due to inflation, and more expensive rehabilitation and reconstruction costs. (Greendot 2016). Chapter 3 of the Regional Transportation Plan contains objectives and policies to meet the specified goals in the Regional Transportation Plan. In addition, the major goal and objective of the Land Use and Circulation element of the County's general plan is "to protect the county's critical natural resources and still allow room for adequate growth and development. The Proposed Project would not conflict with the measures set forth in the Regional Transportation Plan or with the goal and objective of the Land Use and Circulation element of the County's general plan. The Regional Transportation Plan does not contain measures or programs that would conflict with the Proposed Project in a manner that would adversely affect the environment.

3.22.5 Potential Impacts and Mitigation

Potential Impact 3.22-1 Proposed construction-related traffic could potentially result in a substantial increase in traffic in excess of the capacity or design of the road improvements or impairs the safety or performance of the circulation system, including transit, roadways, bicycle lanes or pedestrian paths

Potential Impact 3.22-2 Proposed construction-related traffic could potentially conflict with an applicable congestion management program, including, but not limited to, level of service standards and travel demand measures or other standards established by the county congestion management agency for designated roads or highways that would result in increased risk of harm to the public.

The below analysis applies for both Potential Impacts 3.22-1 and 3.22-2.

As described in Section 3.22.2.1 *Traffic Flow*, roadways that would be utilized for dam removal activities are generally narrow, rural roads that have been used primarily for a small amount of residential use and the existing seasonal recreational use demand associated with the reservoirs.

Short-term impacts to local roads would be primarily limited to the pre-construction period, the dam removal period (May through September of the drawdown year; Table 2.7-1) and one to five years after dam removal during restoration and monitoring activities. The pre-construction and dam removal period would include the import and export of materials and equipment, as well as the construction workforce associated with all the elements of the Proposed Project. Dam removal itself would result in the highest projected construction intensity under the Proposed Project, and thus the greatest workforce and number of associated vehicle trips. Table 3.22-5 presents the projected size of the dam removal workforce that would be commuting daily to the site, and the duration of the activity for each of the dams, presented as both an average and a peak value. The size of the construction workforce at each site would vary, and the peak times for construction would be staggered across sites.

Table 3.22-5. Workforce Projections for Dam Removal for the Proposed Project.

Dam	Estimated Construction Workforce	Duration	Estimated Peak Workforce	Peak Period
J.C. Boyle*	30 people	9 months	45 people	Jun−Sep dam removal year 2
Copco No. 1	35 people	12 months	55 people	Apr–Nov dam removal year 2
Copco No. 2	30 people	6 months	40 people	Apr−Sept dam removal year 2
Iron Gate	40 people	10 months	80 people	Jun−Sep dam removal year 2

* J.C. Boyle Dam is included in this analysis as some of the traffic flow may use roads in California (e.g., I-5 to OR 66)
Source: Appendix B: *Definite Plan – Section 5*

Based on Table 3.22-5, the Proposed Project creates the greatest traffic-related impacts due to construction occurring at three or more dam sites simultaneously. For instance, while only the Copco No. 1 Dam is proposed to begin removal activities for the last two months of Year 1, concurrent activity at four dams is projected for six months (April-September) with an average workforce 135 people and peak activity occurring for four months (June-September) with a 220-person peak workforce. If just considering the three California dams, concurrent activity is projected with an average workforce of 105 people and peak activity workforce of 175 people. These numbers would equate to one-way trips to or from the Proposed Project. If construction schedules shift, projections of traffic impacts may also shift, however, there would likely be times of concurrent activities regardless of small shifts in the Proposed Project schedule.

Because recreational facilities at the reservoirs would be closed during the construction period, this analysis assumes that traffic associated with recreational use of the reservoirs would cease during the construction period. When the additional traffic flow from the short-term concurrent activities associated with dam removal is compared to the current traffic flow for recreational use of the reservoirs, the workforce traffic is similar to the current recreational use traffic. FERC (2007) identified the total annual recreational days for both Copco No.1 (8,850 days) and Iron Gate (51,795 days) reservoirs. If the recreational use were to be evenly distributed throughout a year, then there would be a total of 166 "recreational uses," or trips per day, at recreational facilities within the Proposed Project area. There is no information on the peak number of recreational trips from recreational use, however it is likely that recreational use peaks during summer months. If it is assumed that peak recreational trips are double the average, the peak number would be 332 trips per day. Using the more conservative (for the purpose of comparison of effects) assumption that peak recreational trips are 20 percent greater than the average, the peak number would be approximately 199 trips per day. It is also assumed that recreational use peaks between June and September, which coincides with the proposed peak workforce months for construction activity. Based on these assumptions and the average and peak numbers of the construction workforce set forth in Table 3.22-5, traffic flow during the dam removal period would be similar to what occurs currently for recreational uses (166 average trips and 199 peak trips for recreational use, and 105 average and 175 peak trips per day for dam removal). With the closure of reservoir recreational facilities during construction activities, the average number of daily workforce trips is expected to be less than the average daily reservoir-related recreational trips during Project construction.

Recreational use trips associated with recreation at areas within the Area of Analysis other than Copco No. 1 and Iron Gate reservoirs may still occur during construction periods, but because Copco No. 1 and Iron Gate facilities would be closed, it is expected that continued recreational use traffic would be dispersed away from the immediate vicinity of Copco No. 1 and Iron Gate and would not overlap with construction traffic. Additional discussion of alternative recreational opportunities is described in Section 3.20 *Recreation*.

Additionally, under the Proposed Project, estimated vehicle trips for imported materials and waste disposal would generate a short-term increase in traffic volumes (Table 3.22-6). The short-term construction-related import and export of materials and equipment combined with workforce-related vehicle trips added to the existing AADT would be lower than the existing road capacities listed in Table 3.22-2. It is also possible that, depending on the contractors that are selected to undertake the construction work for each of the Lower Klamath Project dams, there may be overlap of work crews and equipment movement between the three California dams and J.C. Boyle Dam in Oregon. Some traffic from J.C. Boyle Dam construction activities may enter California, increasing the number of estimated vehicle trips noted in Table 3.22-6, but any estimate of either of these examples would be speculative.

Table 3.22-6. Vehicle Trips (VT) for the Import/Export of Materials for the Proposed Project*.

Dam	Estimated VT Imported	Estimated VT Exported	Total VT	Peak Duration	VT per Day
Copco No. 1	1,720	706	2,426	7 months	15
Copco No. 2	Included in Copco No. 1 VT estimates	1,928	1,928+	6 months	14
Iron Gate	380	746	1,126	4 months	12
J.C. Boyle	200	1,024	1,224	4 months	13

* VT numbers consider both full and empty returns.
Source: Appendix B: *Definite Plan – Section 5, revised (S. Leonard, AECOM as KRRC Technical Representative, pers. comm., November 2018).*

As noted in Section 3.22.2.1 *Traffic Flow*, the two major roads used for access would be Interstate 5 and Copco Road. Copco Road has an ADT of 485 and a LOS A capacity of 1300 ADT. Adding 391 ADT from both worker trips (350 ADT) and waste movement (41 ADT), Copco Road would remain at a LOS A. Likewise for Interstate 5, with an AADT of 20,900 and LOS A capacity of 25,400 AADT, there is sufficient capacity for added traffic (391 ADT) to keep the LOS level at LOS A. These short-term additional trips would cease after the Proposed Project is completed.

The period between one and five years after dam removal, associated with restoration and monitoring activities, would also involve an increased level of traffic but this would be less than existing recreational traffic and minor in comparison to traffic occurring during pre-construction and dam removal activities.

The long-term effects of the Proposed Project would include a reduction in overall recreational use of the reservoirs and associated traffic, along with the potential for a minor increase in associated traffic for river-associated recreational use, such as river kayaking and fishing. Given the decrease in traffic related to the reduction of reservoir-associated recreational use, the small increase in river-associated recreational use would be less than significant, as discussed in more detail in Section 3.20 *Recreation*.

With the low amount of current residential and recreational uses, the existing roads, bridges and culverts may have served adequately in the past; however, expanded use, such as from proposed construction-related activities related to deconstruction of the dam facilities, though it may be for a short period, would require additional evaluation, according to Appendix B: *Definite Plan – Section 7.4*. Roadways, bridges, and culverts that may require improvements over their current conditions in order to withstand construction-related traffic under the Proposed Project are listed in Section 3.22.2.3 *Road Conditions*. The Proposed Project would include improvement of these facilities to a level that would enable them to accommodate traffic associated with the Proposed Project without being degraded below baseline conditions. Final designs for planned improvements would be developed during the detailed design phase or as part of a contractor bid document for the Proposed Project, and would inform decisionmakers regarding the necessity and scope of additional environmental review. In addition, the discussion of impacts and mitigation measures set forth in this EIR, including Mitigation Measures WQ-1, TER-1, TER-2, TER-3, TCR-1, TCR-2, TCR-3, TCR-4, and HZ-1, would assist those decisionmakers in determining how the impacts of road improvements can be mitigated.

Finally, as noted above, the Proposed Project would not conflict with the measures set forth in the Regional Transportation Plan or with the goal and objective of the Land Use and Circulation element of the County's general plan does not contain measures or programs that would conflict with the Proposed Project in a manner that would adversely affect the environment.

Overall, additional traffic related to pre-construction activities, dam removal, waste transportation, restoration and monitoring activities, and planned improvements to existing roads, bridges and culverts under the Proposed Project would replace, and be similar to existing recreational use levels and thus would not have substantial, short-term impacts on the LOS in the Area of Analysis. However the proposed activities could result in impairing the safety or performance of the circulation system for all users, resulting in a potentially substantial risk of harm to the public.

The Proposed Project includes a draft Traffic Management Plan (Traffic Management Plan) that identifies the key requirements that would be incorporated by the construction contractor into a final Traffic Management Plan. According to Appendix B: *Definite Plan – Appendix O2*, the Traffic Management Plan is a specialized program tailored to minimize impacts by applying a variety of techniques such as *Public Information, Motorist Information, Incident Management and Construction Strategies.* The major objectives of the Traffic Management Plan are to maintain efficient and safe movement of vehicles through the construction zone covered by activities in the Definite Plan and to provide public awareness of potential impacts to traffic on both haul routes and access roads to the four dam complexes. The Traffic Management Plan outlines the structure and key requirements that would be incorporated by the KRRC's contractor into a final Traffic Management Plan. The final Traffic Management Plan would be informed by KRRC's contractor's specific means and methods for construction, which could refine the approach to access and traffic management. KRRC proposes that the final Traffic Management Plan would meet applicable regulatory permit requirements, as well as applicable state and local ordinances, as appropriate. In addition, as described in Potential Impact 3.22-4, KRRC will also be finalizing an Emergency Response Plan, which is integrally related to the Traffic Management Plan. As such these two plans are discussed together below.

The Traffic Management Plan would be further developed by KRRC working with the appropriate agencies through the FERC process. Additional details to be added to the final Traffic Management Plan and Emergency Response Plan would include those items listed in the draft Traffic Management Plan and Emergency Response Plan (Appendix B: Definite Plan – Appendix O2 and O4). KRRC also proposes that KRRC and the appropriate state and local agencies would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be "good citizens" of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to traffic and transportation in the final Traffic Management Plan and Emergency Response Plan to provide implementation details consistent with all applicable regulatory permit requirements including the latest version of the Caltrans California Manual on Uniform Traffic Control Devices (Caltrans 2018b) and be coordinated with the noted agencies (Caltrans, Siskiyou County, California Highway Patrol, CALFIRE, and other emergency response agencies) as part of the detailed design phase and prior to start of construction. Recommended Measure TR-1 includes additional and feasible components beyond those listed as part of the Proposed Project that would reduce potential short-term construction-related impacts on performance of the circulation system and congestion. However, overseeing development and implementation of the final Traffic Management Plan and Emergency Response Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable "good citizen" agreements that will be finalized and implemented, at this time the Traffic Management Plan and Emergency Response Plan are not finalized and the State Water Board cannot require their implementation. Accordingly, the State Water Board anticipates that implementation of the final Traffic Management Plan and Emergency Response Plan, including the aforementioned additional details and any modifications developed through the FERC process that provide the same or better level of protection for transportation and traffic, would be expected to ensure that impacts are lowered to less than significant. Because the State Water Board cannot ensure the Traffic Management Plan's and Emergency Response Plan's implementation, it has determined the impact in this Draft EIR to be significant and unavoidable.

Recommended Measure TR-1 – Transportation and Traffic.

A. The KRRC and/or its contractor(s) shall develop a final Traffic Management Plan that provides:

1. Implementation details consistent with all applicable regulatory requirements including the latest version of the Caltrans California Manual on Uniform Traffic Control Devices (Caltrans 2018b) and coordination with the noted agencies (Caltrans, Siskiyou County Public Works and Sheriff's Departments, California Highway Patrol, CALFIRE, and other emergency response agencies) as part of the detailed design phase and prior to start of construction. Potential conflicts with bicycle and pedestrian use, as well as transit and school bus service, need to be addressed in the Traffic Management Plan. The final version of the Traffic Management Plan, after coordination with the above referenced agencies, shall be received by the State Water Board prior to the start of construction.
2. Each road, bridge, and culvert improvement project included in the Proposed Project, or any other road, bridge, or culvert improvement project that is identified as necessary for the Proposed Project, shall be constructed consistent with the latest version of the Caltrans Highway Design Manual (Caltrans 2018c) or equivalent, and shall not conflict with any applicable plan, ordinance, or policy regarding performance of the transportation system, traffic safety and/or congestion management within the Area of Analysis. Construction shall not begin until all final designs for road, bridge, and culvert improvement projects included in the Proposed Project have been received and approved, as necessary, by the county and other responsible agencies.
3. The KRRC shall be responsible for repairing and/or rehabilitating any Siskiyou County roadways within the traffic and transportation Area of Analysis that are damaged or otherwise adversely impacted by Proposed

Project activities, such that they are in a condition equal to or better than they were before dam removal activities.

B. The KRRC and/or its construction contractor(s) shall develop an Emergency Response Plan with details and procedures to be put in place to help prevent incidents, to ensure preparedness in the event incidents occur, and to provide a systematic and orderly response to emergencies through coordination with emergency response agencies, as described in Appendix B: *Definite Plan − Appendix O4*.

Significance

Significant and unavoidable impact

Potential Impact 3.22-3 Proposed construction-related traffic could result in substantially increasing hazards due to a design feature (e.g., sharp curves or narrow lanes) or incompatible uses (e.g., oversized construction equipment) that would result in an increased risk of harm to the public.

Roads, bridges, and culverts in the transportation and traffic Area of Analysis currently serve rural residential and extensive recreational uses (Section 3.22.2.3 *Road Conditions*). Some of the roadways originally may have been built for the construction of the Lower Klamath Project dams and appear to have served adequately for that purpose. However, the existing conditions of the roadways and other infrastructure are not adequate for all of the construction activities included in the Proposed Project, as described in Appendix B: *Definite Plan − Appendix K*. As described in Impacts 3.22-1 and 3.22.-2, the improvements may include five bridges (two of them over the Klamath River) that need to be replaced: four bridges for construction purposes, and one bridge post-construction because it is built on reservoir sediment. There are 13 or more culverts that need replacement. As described in Appendix B: *Definite Plan − Appendix K,* there are portions of 20.3 miles of road that would need partial road improvements. Some descriptions note that sections of roads are in poor condition but no improvements are proposed. These sections of roads may not be up to a standard for the transportation of construction equipment, adequate for emergency response, or in a condition adequate for future use after dam removal activities have been completed.

The Proposed Project includes general information regarding planned improvements to existing roads, bridges, and culverts to support short-term construction activities. While the general information suggests that none of the road, bridge, and culvert improvement projects would substantially increase traffic or transportation hazards due to a design feature or incompatible use, it notes that details of each improvement would be developed during the detailed design phase or as part of a contractor bid document for the Proposed Project (Appendix B: *Definite Plan*). The draft Traffic Management Plan (Appendix B: *Definite Plan − Appendix O2*) further notes that the KRRC's contractor would perform a risk assessment of all intersections and roadways as part of the final Traffic Management Plan.

Implementation of Recommended Measure TR-1 would require additional components beyond those listed as part of the Proposed Project (i.e., the final versions of the Traffic Management Plan and Emergency Response Plan) and these components would be necessary to reduce potential traffic and transportation hazards due to a design feature or incompatible uses to less than significant. Overseeing development and implementation of the final Traffic Management Plan and Emergency Response Plan, including measures described in Recommended Measure TR-1, does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable "good citizen" agreements that will be finalized and implemented, at this time the Traffic Management Plan and Emergency Response Plan are not finalized and the State Water Board cannot require their implementation. Accordingly, the State Water Board anticipates that implementation of the final Traffic Management Plan and Emergency Response Plan, including the aforementioned additional details in Recommended Measure TR-1 and any modifications developed through the FERC process that provide the same or better level of protection for transportation and traffic would be expected to ensure that impacts to less than significant. However, because the State Water Board cannot ensure implementation of the final Traffic Management Plan and Emergency Response Plan, it has determined the impact in this Draft EIR to be significant and unavoidable**.**

Significance

Significant and unavoidable impact

Potential Impact 3.22-4 The Proposed Project could result in inadequate emergency access that would result in harm to the public.

The analysis of adequate emergency response considers the needs for emergency access related to dam removal activities, as well as concurrent emergency access for residents and property owners in the area. An example of inadequate emergency access would be a delay that might occur from a fire truck traveling in the opposite direction of large construction equipment, or an ambulance responding to a traffic accident at the time that construction workers are traveling to the work site.

Under the Proposed Project, the types of emergency vehicles would be similar to the types of vehicles currently using roadways, and the construction activities and schedule (Table 2.7-1) would provide a similar degree, but different type, of vehicular traffic within the Area of Analysis that is beyond current traffic levels and types. The peak of construction-related traffic would generally be for a two-year period (Table 2.7-1). Changes to traffic types and patterns could increase the potential for traffic-related conflicts due to the Proposed Project (e.g., construction-related traffic) as well as other users of the road, whether they be residents, or motorized and non-motorized transportation users. (However, as described under Section 3.22.5 above, it is assumed that recreation-related trips would effectively be replaced by construction worker trips during the construction period, which helps to limit traffic increases resulting from the Proposed Project.) Changes in the level of traffic and types of traffic-related conflicts may affect both the response time and the frequency of calls requiring emergency response.

The Proposed Project includes an Emergency Response Plan that addresses transportation-related emergency concerns (e.g., emergency access and response), while a final Emergency Response Plan, with additional details, would be required from the construction contractor (Appendix B: *Definite Plan − Appendix O4*). The Proposed Project considers how emergency access and response would be provided during the time of construction activity and how it would be coordinated with the contractor's Health and Safety Plan, Spill Prevention and Response Plan and Fire Management Plan. (Appendix B: *Definite Plan − Appendices O1 through O4*.) Emergency response is also discussed in Section 3.17 *Public Services* and Section 3.21 *Hazards and Hazardous Materials*, which address impacts related to emergency response providers as well as the risk of increased hazards such as wildfires and adequate access for abating wildland fires. Implementation of Recommended Measure TR-1 would require additional details and procedures to be put in place to help prevent incidents, to ensure preparedness in the event incidents occur, and to provide a systematic and orderly response to emergencies through coordination with emergency response agencies, as described in Appendix B: *Definite Plan − Appendix O4*, which would render potential traffic and transportation impacts of the Proposed Project to levels similar to baseline conditions. However, because wildfires can spread at a rapid speed and involve high risks, any amount of additional response time compared with existing conditions could result in a substantial increased risk of loss, injury, or death involving wildland fires and this would be a significant impact.

Overseeing development and implementation of the final Emergency Response Plan, including the aforementioned additional details in Recommended Measure TR-1, does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable "good citizen" agreements that will be finalized and implemented, at this time the Emergency Response Plan is not finalized and the State Water Board cannot require its implementation. Accordingly, the State Water Board anticipates that implementation of the final Emergency Response Plan, including the aforementioned additional details in Recommended Measure TR-1 and any modifications developed through the FERC process that provide the same or better level of protection for transportation and traffic, would reduce impacts to less than significant. Since the State Water Board cannot ensure the Emergency Response Plan's implementation, it has determined the impact in this Draft EIR to be significant and unavoidable.

Significance

Significant and unavoidable impact

Potential Impact 3.22-5 Construction-related activities could potentially substantially conflict with public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities resulting in an increased risk of harm to the public.

Short-term impacts to public transit, bicycle, or pedestrian facilities would result in an increased risk of harm to the public if construction-related activities substantially decrease the safety of such uses utilizing the roadways within the Area of Analysis. The Proposed Project includes measures to minimize both vehicular and non-vehicular transportation-related conflicts through a Traffic Management Plan (as analyzed in Potential Impact 3.22-1 and 3.22-2). As described in Section 3.22.2.5 *Public Transit*, there is minimal public transit, including bus service, rail service, or airports in the Area of Analysis. Construction-related traffic conflicts could occur where there is an occasional bicyclist or pedestrian using the roadways or when public transportation, including school bus traffic, is using the same roads as construction-related traffic. There is no information available on existing pedestrian or bicycle facilities. A review of Google Earth and Street View (2018) indicated the general absence of sidewalks and bike paths, and no information is available on the amount of bicycle or pedestrian use. Bicyclist or pedestrian use would be subject to a decrease in the performance and safety of the roadways utilized by the Proposed Project during construction activities, resulting in a potentially substantial increased risk of harm to the public, which would be a significant impact.

The Proposed Project includes management strategies in the draft Traffic Management Plan that would identify areas where pedestrians and cyclists could potentially share roads with construction vehicles. KRRC's contractor will install appropriate signage to notify both construction vehicle drivers and non-motorized users of each other's potential presence on the roads. If an unacceptable level of risk to non-motorized users is deemed to persist, KRRC's contractor will arrange appropriate detours to allow continued movement for such users (Appendix B: Definite Plan – Appendix O2). The Traffic Management Plan would be further developed by KRRC working with the appropriate agencies through the FERC process. KRRC also proposes that KRRC and the appropriate state and local agencies would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be "good citizens" of the communities in which projects are located and thus to comply, where possible, with state and local requirements.

It would be appropriate for the recommended terms and conditions relating to traffic and transportation to include Recommended Measure TR-1 as part of the detailed design phase and prior to start of construction. Recommended Measure TR-1 includes additional components beyond those listed as part of the Proposed Project and would ensure that potential short-term construction-related impacts on the safety of all users of the roadways within the Area of Analysis would be less than significant.

Overseeing development and implementation of the final Traffic Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable "good citizen" agreements that will be finalized and implemented, at this time the Traffic Management Plan is not finalized and the State Water Board cannot require its implementation. Accordingly, the State Water Board anticipates that implementation of the final Traffic Management Plan, including any modifications developed through the FERC process that provide the same or better level of protection for Transportation and Traffic resource would reduce impacts to less than significant. However, because the State Water Board cannot ensure the Traffic Management Plan's implementation, it has determined the impact in this Draft EIR to be significant and unavoidable.

Significance

Significant and unavoidable impact

Potential Impact 3.22-6 The Proposed Project would not potentially result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks.

Impacts to air traffic could result if the Proposed Project requires a change in flight paths or an increase in flights, resulting in substantial safety risks. There are no airports within two miles of the work area or that would be affected by the Proposed Project. The location of the Proposed Project (away from existing airports) and the short-term duration of construction activities, would not require a change in flight paths or an increase in flights that would result in substantial safety risks. Helicopters may be used for hydroseeding during restoration activities or in response to an emergency (medical, fire), but this would not alter air traffic patterns at any nearby airport. As a result there would be no significant impact.

Significance

No significant impact

3.23 Noise

This section focuses on potential noise- and vibration-related impacts from implementing the Proposed Project. The State Water Board did not receive comments related to noise during the NOP public scoping process (Appendix A).

3.23.1 Area of Analysis

The Area of Analysis for noise and vibration effects associated with the Proposed Project includes areas in the vicinity of Copco No. 1, Copco No. 2, and Iron Gate reservoirs and along the haul routes in Siskiyou County, California (Figures 3.23-1 and 3.23-2). The Area of Analysis includes locations where there is a potential for noise and vibration impacts on sensitive receptors from construction, waste transportation, and construction worker commutes.

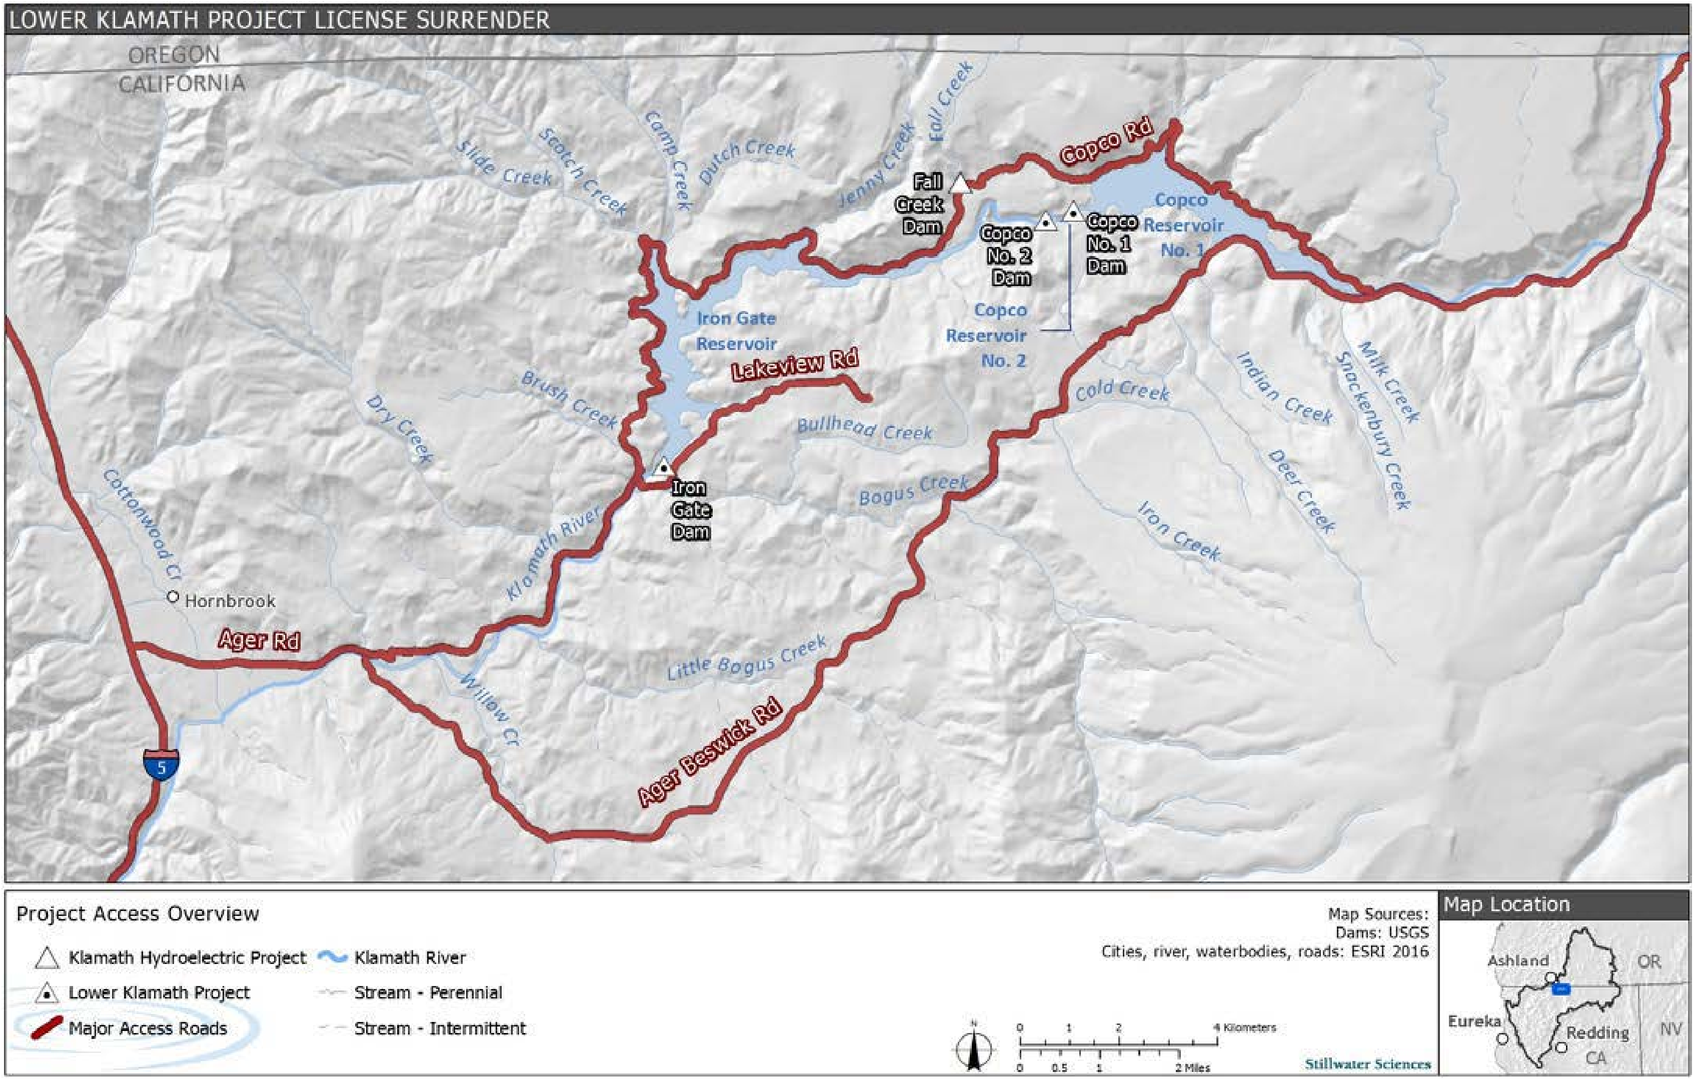

Figure 3.23-1. Proposed Project Access Overview.

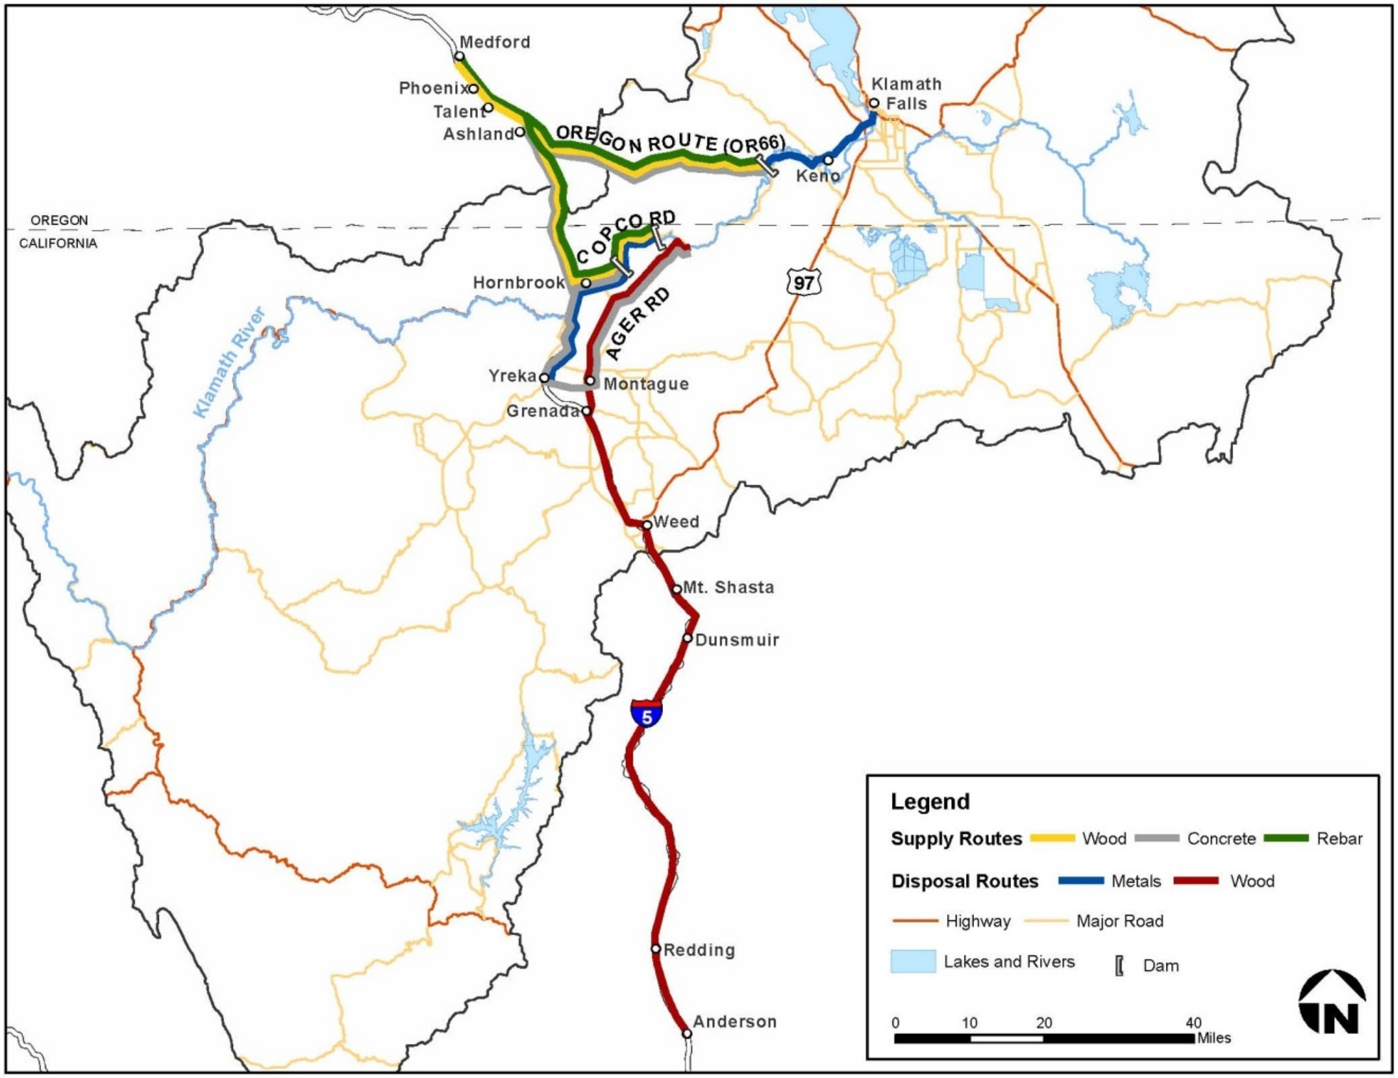

Figure 3.23-2. Primary Haul Routes from Lower Klamath Project Dam Sites.

3.23.2 Environmental Setting

This section provides a description of the environmental setting for noise and vibration in the Area of Analysis, including a brief overview of existing noise conditions in the Klamath Basin to set the stage for subsequent impact analyses.

3.23.2.1 Noise Characteristics

Excessive human exposure to noise can result in adverse physical and psychological responses (hearing loss and other health effects, anger and frustration); can interfere with sleep, speech, and concentration; or can diminish the quality of life. The perceived loudness of sounds depends on many factors, including sound pressure level and frequency content. Sound pressure level is recorded in decibels (dB). While the threshold of human hearing (near-total silence) is approximately zero dB, in typical noisy environments, the healthy human ear generally does not perceive noise-level changes of one to two dB; however, people can begin to detect three dB increases in noise levels. An increase of 5 dB is generally perceived as distinctly noticeable, and a 10-dB increase generally is perceived as a doubling of loudness.

A doubling of sound energy corresponds to an increase of three dB. In other words, when two sources at a given location are each producing sound of the same loudness, the resulting sound level at a given distance from that location is approximately three dB higher than the sound level produced by only one of the sources. For example, if one automobile produces a sound pressure level of 70 dB when it passes an observer, two cars passing simultaneously do not produce 140 dB; rather, they combine to produce 73 dB.

The perception of loudness is generally predictable and can be approximated through frequency filtering, using the standardized A-weighting network, or A-scale (expressed as dBA). The A-weighting approximates the frequency response of the average young ear when listening to most everyday sounds. When people make relative judgments of the loudness or annoyance of a sound, their judgments correlate well with the A-weighting sound levels of those sounds (California Department of Transportation [Caltrans] 2013). All noise levels reported in this analysis are in terms of A-weighting.

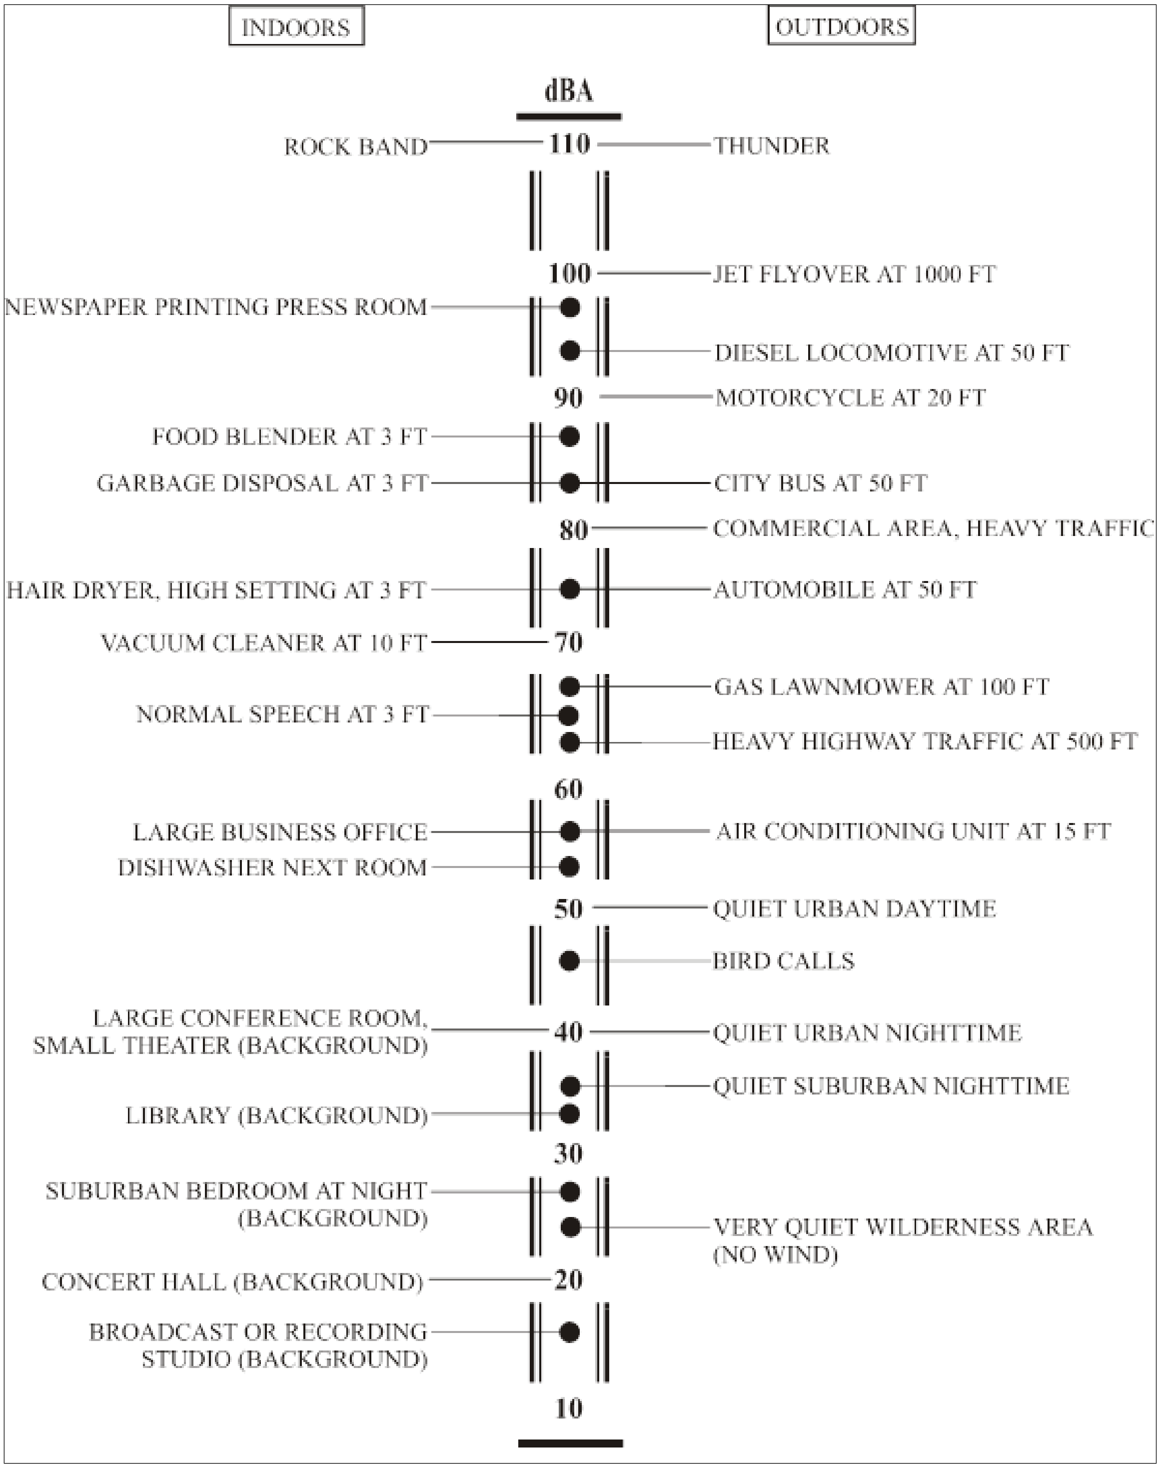

Figure 3.23-3. Decibel Scale and Common Noise Sources. Source: Caltrans 2013.

The following are the sound level descriptors commonly used and incorporated into this environmental noise analysis:

- Equivalent sound level (L_{eq}): An average of the sound energy occurring over a specified time period. In effect, the L_{eq} is the steady-state sound level containing the same acoustical energy as the time-varying sound that actually occurs during the same period. The one-hour, A-weighted equivalent sound level (L_{eq}[h]) is the energy average of A-weighted sound levels occurring during a one-hour period.

- Peak hour L_{eq}: The L_{eq} during the hour with the highest L_{eq}.
- Maximum sound level (L_{max}): The highest instantaneous sound level measured during a specified period.

Sound from a localized source (i.e., point source) expands (propagates) uniformly outward from the source in a spherical pattern. The sound level attenuates due to the following factors (Caltrans 2013):

- Distance between source and receptor;
- Atmospheric effects and refraction;
- Ground absorption;
- Terrain (shielding by natural and manmade features, noise barriers, diffraction, and reflection).

Generally, sound levels attenuate at a rate of six dB for each doubling of distance from a point source (FHWA 2011). Sound from non-point “line” sources (roadways and highways) attenuates at a rate of three dB for each doubling of distance from the linear source.

3.23.2.2 Existing Noise Conditions

Noise-sensitive receptor locations (e.g., rural residences, schools, hospitals, rest homes, churches, long-term care facilities, mental care facilities, residences, convalescent nursing homes, hotels, certain parks) were identified within the Area of Analysis for noise and vibration based on a review of current topographic, aerial, and land use maps. Existing conditions ambient noise levels were identified for both daytime and nighttime. To estimate ambient noise levels at selected receptor locations, the average daytime L_{eq} and nighttime outdoor L_{eq} noise levels from the USEPA’s *Information on Levels of Environmental Noise Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety* (USEPA 1974) were used. Daytime is defined as the hours between 7:00 a.m. and 10:00 p.m. and nighttime is defined as the hours between 10:00 p.m. and 7:00 a.m. (USEPA 1974). Noise levels for rural residential areas in the USEPA document are lower than the levels presented in the Siskiyou County General Plan (Siskiyou County 1978); thus, it is more conservative to analyze the impacts using the USEPA levels. The following describe the ambient noise and existing sensitive receptors near Copco No. 1, Copco No. 2, and Iron Gate dams.

Copco No. 1 Dam and Associated Facilities

Ambient Noise Condition

The closest noise-sensitive receptor to Copco No. 1 Dam and powerhouse is the Janice Avenue rural residential area, located approximately 2,200 feet to the east of Copco No. 1 Dam (Figure 3.23-5). The estimated existing daytime and nighttime outdoor L_{eq} at the Janice Avenue rural residential area are 40 and 30 dBA, respectively (USEPA 1974) (Table 3.23-1).

Figure 3.23-4. Copco 1 and 2 Noise Receptor (Closest Receptor to Copco No. 1 and Copco 2 No. Dams).

Table 3.23-1. Existing Noise Levels at Residential Receptors near Construction Sites.

Construction Site	Nearest Receptor Description[1]	Distance from Construction Site (feet)	Estimated Existing Daytime L_{eq} (dBA)[2]	Estimated Existing Nighttime L_{eq} (dBA)[2]
Copco No. 1 Dam	Residential Area on Janice Ave, east of Copco No. 1 Dam	2,200	40	30
Copco No. 2 Dam	Residential Area on Janice Ave, east of Copco No. 1 Dam	3,700	40	30
Iron Gate Dam	Residential Area on Tarpon Drive, southwest of Iron Gate Dam	4,500	40	30

Notes:

[2] Source: USEPA 1974
Key:
dBA = A-weighted decibels
L_{eq} = one-hour equivalent noise level

Existing Roadway Traffic Noise

Existing roadway traffic noise is present along Copco Road and Ager-Beswick Road, which are the proposed main off-site haul routes from the Copco No. 1 Dam and powerhouse construction site (Figure 3.23-1). The existing peak hour L_{eq} for the Proposed Project haul routes at 50 feet and 500 feet from the edge of the roadway is summarized in Table 3.23-2.

The existing roadway traffic noise is based on the following information. Peak daytime hour noise level results from Traffic Noise Model, Version 2.5 (TNM2.5) were used for generic receptors located 50 and 500 feet from the edge of the road (50 feet represents the minimum distance for a receptor along any roadway, and 500 feet is the maximum recommended receptor distance for traffic noise models) (Caltrans 2013). Also, field observations conducted in 2012 provided the basis for estimating existing 1-hr L_{eq} along Copco Road and Ager-Beswick Road. In 2012, the Federal Highway Administration (FHWA) TNM2.5 was used to estimate the existing daytime peak hour L_{eq}s along proposed haul routes (Appendix T). Peak-hour traffic was estimated by multiplying the average daily traffic by 10 percent based on a review of Caltrans 2009 average daily and peak hourly traffic data (Caltrans 2009). Average daily traffic values published by Caltrans (2009) were used to estimate the existing noise levels on Interstate 5 (I-5).

Table 3.23-2. Existing Daytime Peak Hour Leq along Proposed Haul and Commute Routes.

Haul Route/Commute Segment	Existing Daytime Peak hour Leq (dBA)[1]	
	50 feet	500 feet
Ager-Beswick Road	53	42
Copco Road	58	46
I-5 between OR-66 and Yreka	76	66

Notes:

Copco No. 2 Dam and Associated Facilities

Ambient Noise Condition

The closest sensitive receptor to Copco No. 2 Dam is the residential area on Janice Avenue described above for Copco No. 1 Dam (Figure 3.23-5). The receptor is approximately 3,700 feet to the east of Copco No. 2 Dam. The estimated existing daytime and nighttime outdoor L_{eq} at the residences on Janice Avenue, based on the USEPA information, are 40 and 30 dBA, respectively (USEPA 1974) (Table 3.23-1).

Existing Roadway Traffic Noise

Copco Road and Ager-Beswick Road are the proposed main off-site haul routes from the Copco No. 2 dam construction site (Figure 3.23-1). The existing peak hour L_{eq} for the Proposed Project haul routes at 50 feet and 500 feet from the edge of the roadway is summarized in Table 3.23-2. The existing roadway traffic noise is based on the same information as described for Copco No. 1 Dam facilities.

Iron Gate Dam and Associated Facilities

Ambient Noise Condition

The closest sensitive receptor to Iron Gate Dam is the fish hatchery complex (which includes staff residences as well as egg incubation, rearing, maintenance, and administration facilities), located approximately 1,200 feet downstream (Figure 3.23-6). However, PacifiCorp's residential properties, including the staff residences at the hatchery complex, would be unoccupied during Proposed Project construction activities and thus are not considered as a sensitive receptor for the purposes of this analysis. The next closest sensitive receptor to Iron Gate Dam is the rural residential land on Tarpon Drive, approximately 4,500 feet southwest of the dam, as shown on Figure 3.23-6. Based on the rural residential land use category, the existing daytime outdoor L_{eq} on Tarpon Drive likely is 40 dBA and the existing nighttime outdoor L_{eq} at this receptor is approximately 30 dBA (USEPA 1974) (Table 3.23-1).

Figure 3.23-5. Iron Gate Noise Receptors (Closest Sensitive Receptor to Iron Gate Dam).

Existing Roadway Traffic Noise

Existing traffic noise is assessed along Copco Road, located approximately 1,100 feet from Iron Gate Dam, as it would be the main off-site haul route from the Iron Gate Dam and powerhouse construction site (Figure 3.23-1). The existing peak hour L_{eq} for the Proposed Project haul routes at 50 feet and 500 feet from the edge of the roadway is summarized in Table 3.23-2. The existing roadway traffic noise is based on the same information as described for Copco No. 1 Dam facilities.

3.23.2.3 Airport Noise Levels

Siskiyou County owns four airports—in Weed, Fort Jones, Montague, and Dorris. The closest public airport to the Lower Klamath Project is Siskiyou County Airport in Montague, California, which is more than 10 miles south of Iron Gate Dam. No private or public airport or airfield is within two miles of the Lower Klamath Project. Airplanes and helicopters are proposed to be used during seeding as part of reservoir restoration activities (Section 2.7.4 *Restoration Within the Reservoir Footprint*), which would involve airport use. However, the airports themselves are not within the Proposed Project's Area of Analysis.

3.23.3 Significance Criteria

Significance criteria used for the determination of noise and vibration impacts are based on Appendix G of the CEQA Guidelines (California Code of Regulations title 14, section 15000 et seq.) and professional judgement. Noise and vibration effects are considered significant if the Proposed Project would result in one or more of the following conditions or situations:

- Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies;
- Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels;
- A substantial permanent increase in ambient noise levels in the Area of Analysis above levels existing without the Proposed Project; or
- A substantial short-term or periodic increase in ambient noise levels in the Area of Analysis above levels existing without the Proposed Project.

This section focuses on noise- and vibration-related impacts to humans. Construction-related noise disturbance and physical vibration (e.g., blasting and use of construction equipment) impacts on wildlife are addressed in Section 3.5 *Terrestrial Resources*.

3.23.3.1 Thresholds of Significance

Noise and vibration levels in the Area of Analysis are regulated by the Siskiyou County General Plan Noise Element (Siskiyou County 1978), which contains criteria for maximum allowable noise levels from construction equipment (Table 3.23-3). There are no other applicable federal, state, or local regulatory levels for noise or vibration in the Area of Analysis.

Table 3.23-3. Siskiyou County General Plan Maximum Allowable Noise Levels from Construction Equipment.

Equipment Type	Peak Noise Level at 100 feet (dBA)	Peak Noise Level at 50 feet (dBA)[1]

Source: Siskiyou County 1978

[1] Maximum allowable noise levels from construction equipment at 100 feet from Siskiyou County's General Plan were converted to noise levels at 50 feet (by adding 6 dBA to account for the halving of distance).

Noise

Although the Proposed Project does not involve highway construction, federal and state highway traffic noise criteria provide a basis for analyzing traffic noise impacts. The FHWA requires highway agencies to define a "substantial" noise increase as an increase of 5 to 15 dBA over existing noise levels (23 CFR Part 772). Caltrans defines a "substantial" increase in noise levels from traffic as a predicted increase greater than or equal to 12 dBA at the receptor over existing 1-hour equivalent noise levels (L_{eq}) (Caltrans 2006).

For the purpose of this analysis, an action would be significant if it resulted in any the following:

- Use of construction equipment that exceeds Siskiyou County maximum allowable noise levels from construction equipment; or
- A greater than 10 dBA increase in the daytime or nighttime outdoor one-hour L_{eq} at the receptor from onsite construction operations; or

- A greater than 12 dBA (in California) increase above existing one-hour L_{eq} for traffic-related noise.

The criteria above were based on the characteristics of noise, published studies on vibration effects, and established regulations.

Vibration

Vibration from construction projects is caused by general equipment operations, and is usually highest during pile driving, soil compacting, jack hammering, demolition, and blasting activities. A PPV of 0.3 in/sec or greater can damage old residential structures from continuous or frequent vibration sources (Jones and Stokes 2004). The annoyance level for vibration is 72 VdB in residential areas (FTA 2006).

For the purpose of this analysis, an action would be significant if it resulted in any the following:

- A peak particle velocity (PPV) greater than 0.3 inches per second (in/sec) at the receptor
- A vibration velocity level in decibels (L_v) greater than 72 VdB at the receptor

The criteria above were based on the characteristics of noise, published studies on vibration effects, and established regulations. Although Siskiyou County does not have local significance criteria for vibration levels, the significance criteria itemized above are expected to provide a conservative analysis of vibration levels.

3.23.4 Impact Analysis Approach

Evaluating potential noise and vibration impacts considers the baseline of existing conditions compared with the impacts of the Proposed Project. Noise and vibration levels were determined for proposed construction equipment (including blasting) and construction-related traffic using the methods described below[173]. A more detailed method description, analysis results, and data supporting the analysis are included in Appendix T.

Noise and vibration impacts were modeled in 2011 as part of the 2012 EIS/EIR analysis (Appendix T). Although there have since been some modifications to the Proposed Project schedule, the 2011 noise and vibration impact modeling is still relevant as the construction-related noise and vibration-generating activities for the Proposed Project are materially similar (see Section 3.22 *Transportation and Traffic*) to those modeled in 2011. Minor changes in proposed construction activities between the 2012 EIS/EIR analysis and the Proposed Project are primarily due to the timing associated with removing Iron Gate Dam, Copco No. 1 Dam, and Copco No. 2 Dam. The Proposed Project and the data modeled as part of the 2012 EIS/EIR are compared to the thresholds noted in Section 3.23.3.1 *[Noise] Thresholds of Significance* and analyzed in Section 3.23.5 *[Noise] Potential Impacts and Mitigation*.

Principles and methods described in FHWA's Roadway Construction Noise Model User's Guide (FHWA 2006) were the basis for predicting noise impacts associated with construction equipment (Appendix T). Table 3.23-4 presents noise levels of common

[173] Construction-related impacts are considered to be short-term impacts.

construction equipment operating at full power (L_{max}) measured 50 feet from the source, the percentage of time the equipment would be operated at full power (usage factor), and the L_{eq} over a single shift (Appendix T). For equipment whose L_{max} in the Roadway Construction Noise Model exceeds the maximum allowable noise levels from construction equipment in the Siskiyou County General Plan Noise Element (1978), the upper limits from Siskiyou County were used (Siskiyou County 1978).

Table 3.23-4. Construction Operations, Equipment Types, and Their Noise Levels.

Equipment Type	Usage Factor	L_{max} at 50 feet (dBA)	L_{eq} at 50 feet (dBA)
Air Compressor	40 percent	78	74
Backhoe	40 percent	78	74
Blasting	1 percent	94	74
Compactor	20 percent	83	76

Pumps	50 percent	77	74
Scraper	40 percent	84	80
Tractor[1]	40 percent	81	77

Source: Appendix T

[1] Maximum allowable noise levels from construction equipment at 100 feet from Siskiyou County's General Plan were converted to noise levels at 50 feet (by adding 6 dBA to account for the halving of distance).

Groundborne vibration is energy transmitted in waves through the ground. Groundborne vibration can cause building floors to shake, windows to rattle, hanging pictures to fall off walls, and in some cases can damage buildings. Vibration attenuates at a rate of approximately six to nine vibration decibels (VdB) for each doubling of distance from the source (FTA 2006). A conservative reduction rate of six VdB per doubling of distance was used in this study. This approach considers only the attenuation from geometric spreading and tends to provide for a conservative assessment of vibration level at the receiver's location.

The effects of construction-related noise and vibration on wildlife are evaluated in Section 3.5 *Terrestrial Resources*, and the analysis includes potential impacts as a result of noise disturbance greater than ambient conditions. Species-specific noise impacts on northern spotted owl included noise disturbance distances developed in coordination with the Arcata USFWS office using an estimation of auditory and visual disturbance effects (USFWS 2006) including a 1-mile buffer around all dams to account for the loudest noise disturbance distance associated with blasting, 0.5-mile buffer around all reservoirs to account for the loudest noise disturbance distance associated with helicopter use, and 0.25 mile buffer around all other areas within the Limits of Work to account for noise disturbance associated with heavy equipment.

The following source was assessed to determine the scope of existing local policies relevant to the Proposed Project:

- Siskiyou County General Plan Noise Element (Siskiyou County 1978).

The Siskiyou County General Plan Noise Element (1978) contains criteria for maximum allowable noise levels from construction equipment (Table 3.23-3). These criteria are discussed above in Section 3.23.3.1 *Thresholds of Significance* and the Proposed Project's potential conflict with these criteria is discussed below in Potential Impact 3.23-1.

3.23.5 Potential Impacts and Mitigation

This section summarizes the noise and vibration impacts that would be caused by the Proposed Project and recommends noise and vibration mitigation measures. The impact analysis for noise and vibration focuses on short-term construction-related activities, which include the pre-removal period, the dam removal period (zero to one years), and one to five years after dam removal, where the latter includes the majority of anticipated restoration and monitoring activities (Table 2.7-1 and Section 2.7.4 *Restoration Within the Reservoir Footprint*). While sporadic activities would occur throughout these periods and are analyzed herein, the following analysis is focused on the six-month period during the peak of the construction-related activity, when the three California dams would be removed. There would be no long-term noise and vibration impacts due to the Proposed Project as the Lower Klamath Project dam complexes would be removed.

Potential construction-related noise and vibration impacts on special-status wildlife species are evaluated in Section 3.5 *Terrestrial Resources,* including an analysis of potential short-term impacts to nesting birds (Potential Impact 3.5-12), willow flycatcher (Potential Impact 3.5-13), bald and golden eagles (Potential Impact 3.5-14), bats (Potential Impact 3.5-15), and northern spotted owl (Potential Impact 3.5-14).

Potential Impact 3.23-1 Use of standard construction equipment could exceed Siskiyou County General Plan criteria for maximum allowable noise levels from construction equipment.

For several specific types of construction equipment (specifically dozers, jackhammers, and tractors), the maximum allowable noise levels identified in the Siskiyou County General Plan Noise Element (Siskiyou County 1978) are lower than the typical noise levels produced by those equipment types according to the FHWA's Roadway Construction Noise Model User's Guide (FHWA 2006). This is summarized in Table 3.23-5. For the other 17 equipment types listed in the noise model, appropriate equipment noise levels consistent with FHWA 2006 were used. Given the maximum allowable noise levels identified in the Siskiyou County General Plan Noise Element (Siskiyou County 1978), any use of dozers, jackhammers, and/or tractors during the Proposed Project would constitute an exceedance of County maximum allowable noise levels and this would be a significant impact.

Table 3.23-5. Equipment Types for which Siskiyou County Maximum Allowable Noise Levels Exceed Typical Equipment Noise Levels.

Equipment Type	Siskiyou County Maximum Allowable Noise Level at 50 feet (dBA)[1]	Typical Equipment Noise Maximum Sound Level at 50 feet (dBA)[2]
Dozers	81	82
Jackhammers	81	89
Tractors	81	84

Source: Siskiyou County 1978, FHWA 2006

[1] Maximum allowable noise levels from construction equipment at 100 feet from Siskiyou County's General Plan were converted to noise levels at 50 feet (by adding 6 dBA to account for the halving of distance).

[2] Typical equipment noise levels at 50 feet are from FHWA 2006.

The Proposed Project includes a Noise and Vibration Control Plan (NVCP) (Appendix B: *Definite Plan – Appendix O5*) that would minimize short-term outdoor noise impacts, and which specifies that a Final NVCP, with additional details, would be required of the construction contractor. The proposed NVCP requires preparation and implementation of the Final NVCP and would be necessary to reduce potential noise impacts to the degree feasible. However the Final NVCP would not cause equipment noise levels from dozers, jackhammers, and tractors to comply with the Siskiyou County maximum allowable noise levels for these specific equipment types since the maximum allowable noise levels are lower than the typical noise levels produced by those equipment types according to the FHWA's Roadway Construction Noise Model User's Guide (FHWA 2006). Therefore, this impact would be significant and unavoidable.

Significance

Significant and unavoidable

Potential Impact 3.23-2 Construction activities at Copco No. 1 Dam could cause short-term increases in daytime and nighttime noise levels affecting nearby residents.

Noise disturbance associated with construction areas was evaluated to assess the potential to result in adverse physical and psychological responses (hearing loss and other health effects, such as anger and frustration), which can interfere with sleep, speech, and concentration; or diminish the quality of life. The Proposed Project would result in significant impacts if construction-related activities resulted in noise levels adversely affecting residents in the area.

The noise model (Appendix T) states that to comply with the Siskiyou County regulation, the maximum allowable noise level in the Siskiyou County General Plan Noise Element (1978) was used for equipment (specifically dozers, jackhammers, and tractors) whose maximum sound level (L_{max}) in the FHWA's Roadway Construction Noise Model User's Guide (FHWA 2006) exceeds the Siskiyou County regulation. This would cause the noise model (Appendix T) to slightly underestimate noise levels during construction. However, for the other 17 equipment types listed in the noise model, appropriate equipment noise levels consistent with FHWA 2006 were used.

The Proposed Project includes two shifts of construction workers to deconstruct each of the three California dams - Copco No. 1, Copco No. 2, and Iron Gate. At each dam the first work shift would be 6 a.m. to 4 p.m. and the second work shift would be 6 p.m. to 4 a.m. This would allow for 2-hour breaks between shifts for refueling and maintenance. Blasting would occur at each dam and would be restricted to 8 a.m. to 6 p.m. Note that the noise model (Appendix T) does not account for blasting during Shift 2 at Copco No. 1 Dam or during any work shift at Iron Gate Dam and thus underestimates the potential noise impacts. Both work shifts overlap with the daytime (defined as 7 a.m. to 10 p.m.) and nighttime (defined as 10 p.m. to 7 a.m.) (USEPA 1974). Table 3.23-6 lists the predicted average one-hour L_{eq} at Copco No. 1 Dam and Iron Gate Dam and at the receptors, the existing L_{eq} without the project, and the increase in noise level at the receptors that would occur as a result of the Proposed Project. (Copco No. 2 Dam removal was not analyzed as the line of sight to the closest receptor is assumed to be completely blocked, preventing noise disturbance at this receptor.) Significant increases in L_{eq} caused by the Proposed Project are shown in bold. Although the threshold of significance for this impact is "a greater than 10 dBA increase in the daytime or nighttime outdoor one-hour L_{eq} at the receptor from onsite construction operations," an increase of 9 dBA during Shift 2 at Copco No. 1 Dam was also identified as significant. This was meant to conservatively account for (1) the noise model's omission of blasting during Shift 2, and (2) the noise model's additional underestimation of construction noise due to use of Siskiyou County Maximum Allowable Noise Levels instead of typical noise levels for dozers, jackhammers, and tractors.

Table 3.23-6. Summary of Noise Levels from Construction Activities Compared to Existing.

Location[1]	**Time**	**Work Shift**	**Time of Day**[2, 3]	**L_{eq} (dBA)**			
				At Construction Site (50 feet)	**At Receptor with Proposed Project**	**Existing L_{eq} (dBA)**[4]	**Increase in L_{eq} Caused by Proposed Project**[5]

	7:00 p.m.–midnight	Shift 2	Nighttime	91	45	30	**15**

Source: Appendix T
Notes:
1 J.C. Boyle Dam removal was not analyzed because there are no receptors within one mile and it is located in Oregon. Copco No. 2 Dam removal was not analyzed because the line of sight to the closest receptor is assumed to be completely blocked.
2 Daytime is defined as between the hours of 7:00 a.m. and 10:00 p.m. Source: USEPA 1974.
3 Nighttime is defined as between the hours of 10:00 p.m. and 7:00 a.m. Source: USEPA 1974.
4 Source: USEPA 1974. Also see Table 3.23-1.
5 Bolded numbers indicate exceedances of significance threshold.

The predicted L_{eq} from all construction equipment on a peak construction day at Copco No. 1 Dam is approximately 91 dBA at 50 feet during the first shift (6 a.m. to 4 p.m.) and 88 dBA during the second shift (6 p.m. to 4 a.m.) (Appendix T). Attenuation due to distance, atmospheric effects, ground absorption, and terrain effects would reduce this construction site's L_{eq} by approximately 39 dBA at the nearest receptor. Compared to the daytime and nighttime existing outdoor noise levels of 40 and 30 dBA, the resulting increase at Copco No. 1 Dam ranges from 9 to 22 dBA, depending on the time of day (Table 3.23-6 and Appendix T). Work during both shifts exceeds the significance criteria at all times because of the high source noise level. This increase in outdoor noise levels would have a short-term significant noise impact on the residential area near Copco No. 1 Dam.

The Proposed Project includes a Noise and Vibration Control Plan (NVCP) (Appendix B: *Definite Plan – Appendix O5*) that would minimize short-term outdoor noise impacts, and which specifies that a Final NVCP, with additional details, would be required of the construction contractor. The proposed NVCP requires preparation and implementation of the Final NVCP and would be necessary to reduce potential noise impacts to the degree feasible. However, the Final NVCP would not be enough to reduce short-term construction-related noise impacts to less than significant levels at sensitive receptors. Therefore, noise impacts would remain significant and unavoidable for outdoor receptors during Copco No. 1 Dam deconstruction.

Significance

Significant and unavoidable

Potential Impact 3.23-3 Construction activities at Copco No. 2 Dam could cause short-term increases in noise levels affecting nearby residents.
As described in Potential Impact 3.23-2, the Proposed Project would result in significant impacts if construction-related activities resulted in noise levels adversely affecting residents in the area. The closest noise-sensitive receptor to Copco No. 2 Dam and Powerhouse is the Janice Avenue rural residential area, located approximately 3,700 feet to the east of Copco No. 2 Dam (Figure 3.23-4). The line of sight from the receptor to Copco No. 2 Dam is blocked by a hill. Due to the natural topography surrounding the dam and the distance between the dam and the receptor, noise from on-site construction activities at the Copco No. 2 Dam would be reduced by more than 65 dB (approximately 35 dB by the distance and an additional 30 dB due to the topography). This amount of noise reduction would reduce noise impacts to less than significant levels at sensitive receptors**.** Measures specified in the Final NVCP would further reduce noise levels.

Significance
No significant impact

Potential Impact 3.23-4 Construction activities at Iron Gate Dam could cause short-term increases in nighttime noise levels affecting nearby residents.
As described in Potential Impact 3.23-2, the Proposed Project would result in significant impacts if construction-related activities resulted in noise levels adversely affecting residents in the area. The Proposed Project includes two shifts of construction workers to deconstruct Iron Gate Dam. The first work shift would be 6 a.m. to 4 p.m. and the second work shift would be 6 p.m. to 4 a.m. This would allow for 2-hour breaks between shifts for refueling and maintenance. Blasting would occur at Iron Gate to break mass concrete at any of the facilities to be removed (including intake structures, control structures, fish handling facilities, and powerhouse). Blasting would not occur as part of excavation of the Iron Gate Dam embankment material. Blasting would be restricted to 8 a.m. to 6 p.m. It is noted that the noise model (Appendix T) did not account for blasting during any work shift at Iron Gate Dam. Both work shifts overlap with the daytime (defined as 7 a.m. to 10 p.m.) and nighttime (defined as 10 p.m. to 7 a.m.) (USEPA 1974). Table 3.23-6 lists the predicted average one-hour L_{eq} at Iron Gate Dam and at the receptors, the existing L_{eq} without the project, and the increase in noise level at the receptors that would occur as a result of the Proposed Project. Significant increases in L_{eq} caused by the Proposed Project are shown in bold.

The predicted L_{eq} from the Iron Gate facilities removal is approximately 91 dBA at 50 feet during both shifts (6 a.m. to 4 p.m. and 6 p.m. to 4 a.m.). The combination of existing noise and attenuation due to distance, atmospheric effects, ground absorption, and terrain effects would result in a L_{eq} of approximately 46 dBA at the nearest receptor (Iron Gate Hatchery and associated facilities) (Table 3.23-6) (Appendix T). The estimated noise level at the receptor exceeds the significance criterion for nighttime noise during all proposed night work (7 p.m. to 4 a.m. and 6 a.m. to 7 a.m.). Construction noise would cause a short-term significant noise impact on the residential area near Iron Gate Dam at night. Implementation of the proposed NVCP (as described in Potential Impact 3.23-1) would reduce this noise impact; however, it would not reduce nighttime outdoor noise impacts to less than significant levels at sensitive receptors. Thus, nighttime noise impacts would remain significant and unavoidable for outdoor receptors during Iron Gate Dam nighttime deconstruction.

Significance
Significant and unavoidable

Potential Impact 3.23-5 Reservoir restoration activities at Copco No. 1 and Iron Gate could result in short-term increases in noise levels affecting nearby residents. The Proposed Project would result in significant impacts if reservoir restoration activities resulted in noise levels adversely affecting residents in the area. Equipment, including planes, barges, trucks, and helicopters, would be used for reservoir restoration at the same time as and subsequent to dam deconstruction. This reservoir restoration activity would add to the noise levels generated by dam deconstruction activities in and around the dam sites described above. Hydroseeding methods include by barge along the reservoir bank, by helicopter along steep slopes, by airplane along uneven large areas, and by trailer-mounted blower for areas easily accessible by truck. Equipment noise from embankment restoration would cause a short-term significant noise impact on the residential areas near the Copco No. 1 and Iron Gate reservoirs and contribute to the noise levels generated by dam deconstruction in and around the dam sites. The Proposed Project includes development of a NVCP (Appendix B: *Definite Plan – Appendix O5*) to minimize noise impacts from construction activities. Implementation of the Final NVCP would reduce short-term outdoor noise impacts, but given that they would add to already significant noise levels (Potential Impacts 3.23-2 and 3.23-4), noise impacts would remain significant and unavoidable for outdoor receptors during the reservoir restoration activities.

Significance
Significant and unavoidable

Potential Impact 3.23-6 Blasting activities at Copco No. 1, Copco No. 2, and Iron Gate Dams could increase daytime vibration levels affecting nearby residents. The Proposed Project would result in significant impacts if blasting activities resulted in vibration levels adversely affecting residents in the area. Blasting at each dam is proposed to occur infrequently, would be restricted to the time between 8 a.m. and 6 p.m., and would be dependent on scheduling. The predicted vibration levels at sensitive receptors are summarized in Table 3.23-7. Significant increases in PPV or L_v caused by the Proposed Project are shown in bold. Blasting during the first shift at Copco No. 1 Dam is anticipated to result in PPV and L_v at the nearest receptor of 0.065 in/sec and 84 VdB, respectively. For reference, vibration levels without blasting are 0.002 in/sec and 53 VdB (Table 3.23-7) (Appendix T). Therefore, the first shift at Copco No. 1 Dam would exceed the significance criteria for L_v (L_v greater than 72 VdB at the receptor). Construction activities during the second shift at Copco No. 1 (in which no blasting would occur) are anticipated to result in PPV and L_v at the nearest receptor of 0.001 in/sec and 47 VdB, respectively. The vibration model (Appendix T) did not account for the proposed blasting at either of the other dams. Blasting at Copco No. 2 and Iron Gate is proposed to occur infrequently between 8 a.m. and 6 p.m. Therefore it is conservatively assumed that vibration levels at Copco No. 2 and Iron Gate dams during Shift 1 would also exceed the threshold of significance.

Table 3.23-7. Summary of Vibration from Construction Activities.

Location[1]	Time of Day[2]	PPV at Receptor (in/sec)	L_v at Receptor (VdB)[3]
Copco No. 1 Dam	Shift 1	0.065 (0.002 without blasting)	**84** (53 without blasting)
	Shift 2	0.001	47
Copco No. 2 Dam	Shift 1	**no data available**[4]	**no data available**[4]
	Shift 2	no data available, but no blasting proposed[4]	no data available, but no blasting proposed[4]
Iron Gate Dam	Shift 1	**no data available**[4]	**no data available**[4]
	Shift 2	no data available, but no blasting proposed[4]	no data available, but no blasting proposed[4]

Source: Appendix T

1 J.C. Boyle was not analyzed because there are no receptors within one mile and it is in Oregon

2 Shift 1 is 6:00 a.m. to 4:00 p.m. and Shift 2 is 6:00 p.m. to 4:00 a.m.

3 Bolded numbers indicate exceedances of significance threshold(s)

4 The Appendix T noise and vibration model did not include blasting at Copco No. 2 or Iron Gate dams.

Key:

in/sec = inches per second

Construction activities (including blasting) would result in significant human annoyance levels for daytime vibration impacts at receptors near each of the three dams. The Proposed Project includes a Noise and Vibration Control Plan (NVCP) (Appendix B: *Definite Plan – Appendix O5*) that would minimize short-term outdoor noise impacts, and which specifies that a Final NVCP, with additional details, would be required of the construction contractor. The proposed NVCP requires preparation and implementation of the Final NVCP and would be necessary to reduce potential noise impacts to the degree feasible. The Final NVCP would minimize short-term outdoor noise impacts during blasting activities, but would not reduce impacts to less than significant levels at sensitive receptors. Therefore, daytime vibration impacts to humans would remain significant and unavoidable for outdoor receptors during the blasting activities.

Significance

Significant and unavoidable

Potential Impact 3.23-7 Transporting waste to off-site landfills and construction worker commutes could cause increases in traffic noise along haul routes affecting nearby residents.

The Proposed Project would result in significant impacts if hauling or commuting activities resulted in noise levels adversely affecting residents along the haul routes. Noise effects from transporting waste and construction worker commutes were evaluated for receptors at 50 feet and 500 feet from the road. TNM2.5 modeling results showed only minor increases in existing L_{eq} for receptors 50 feet or more from all haul routes analyzed (Table 3.23-8). Transporting waste off-site and construction worker commutes would result in less than significant noise impacts for receptors 50 feet or more from all local roadways. The Proposed Project includes a Noise and Vibration Control Plan (NVCP) (Appendix B: *Definite Plan – Appendix O5*) that would minimize short-term outdoor noise impacts, and which specifies that a Final NVCP, with additional details, would be required of the construction contractor. The proposed NVCP requires preparation and implementation of the Final NVCP and would be necessary to reduce potential noise impacts to the degree feasible. Implementation of the Final NVCP would reduce short-term construction-related noise impacts along haul routes to less than significant.

Table 3.23-8. Summary of Construction-Related Traffic Noise from Off-site Hauling and Construction Worker Commuting for the Proposed Project.

Haul Route/Commute Segment	Peak 1-hour L_{eq} (dBA)		Increase in L_{eq} Caused by Proposed Project (dBA)[1]	
	50 ft	500 ft	50 ft	500 ft
Ager-Beswick Road	54	43	1	1
Copco Road	63	51	5	5
I-5: Between OR-66 and Yreka, CA	77	66	0	0

Source: Appendix T
Notes:
[1] The increase in L_{eq} may appear different when subtracting the existing 1-hour L_{eq} from peak 1-hour L_{eq} values due to rounding.
Key:
ft = feet

Significance
No significant impact

Potential Impact 3.23-8 Construction activities associated with the Downstream Flood Control project component (moving or elevating legally established structures with flood risk) could produce noise and vibration associated with construction activities.
Construction activities associated with the Downstream Flood Control project component (moving or elevating legally established structures located within the altered 100-year floodplain, where feasible) (Section 2.7.8.4 *Downstream Flood Control*) could produce noise and vibration associated with construction activities. The Downstream Flood Control project component includes moving or elevating structures that could be affected by changes to the 100-year flood inundation area as a result of dam removal. These activities would take place before or after the primary construction and deconstruction activities associated with the Proposed Project; therefore, noise from these activities would not add to the noise and vibration impacts. These construction activities are generally smaller efforts, compared to dam removal, and would not cause a substantial increase in noise to sensitive receptors. As a result, construction associated with the Downstream Flood Control project component would cause a less than significant noise and vibration impact to sensitive receptors.

Significance
No significant impact

Potential Impact 3.23-9 Construction activities associated with implementation of Mitigation Measure WSWR-1 (modify water intakes) could produce noise and vibration associated with construction activities.
Mitigation Measure WSWR-1 could produce noise and vibration associated with construction activities. It provides protection for downstream water intakes during the passage of eroded sediment, which may include installing temporary facilities (e.g., settling basins or groundwater wells). These activities would take place before or after the primary construction and deconstruction activities associated with the Proposed

Project; therefore, noise from these activities would not add to the noise and vibration impacts. These construction activities are generally smaller efforts, compared to dam removal, and would not cause a substantial increase in noise to sensitive receptors. As a result, construction associated with Mitigation Measure WSWR-1 would cause a less than significant noise and vibration impact to sensitive receptors.

Significance
No significant impact

Potential Impact 3.23-10 Construction activities associated with the deepening or replacement of existing groundwater wells adjacent to the reservoirs could produce noise and vibration affecting nearby residents.
Construction activities associated with deepening or replacing existing groundwater wells adjacent to the reservoirs (see Potential Impact 3.7-1) would take place before and/or after the primary construction and deconstruction activities associated with the Proposed Project (i.e., dam removal); therefore, they would not add to these noise and vibration impacts. Construction activities associated with the deepening or replacement of wells are generally smaller construction efforts that would not cause a substantial increase in noise to sensitive receptors. Therefore these activities would cause a less than significant noise and vibration impact to sensitive receptors.

Significance
No significant impact

3.24 Cumulative Effects

3.24.1 Introduction

3.24.1.1 Analysis Approach

CEQA requires a discussion of a project's cumulative impacts on the physical environment (CEQA Guidelines Section 15130). Cumulative impacts are defined as follows:

> *"Cumulative impacts" refers to two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts.*
>
> *(a) The individual effects may be changes resulting from a single project or a number of separate projects.*
>
> *(b) The cumulative impact from several projects is the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time."*

(CEQA Guidelines Section 15355).

Determinations of cumulatively considerable effects is required by CEQA Section 15065[a][3] *Mandatory Findings of Significance*, and CEQA Section 15130 guides the discussion of cumulative impacts. Three questions are useful to make determinations:

1. Does the Proposed Project make an adverse contribution to the impact in question?
2. Is the combined impact of the Proposed Project and other projects significant and adverse?
3. Is the Proposed Project's incremental effect cumulatively considerable?

CEQA states that when a project's contribution is not cumulatively considerable, then the EIR need only briefly describe supporting reasoning for this conclusion (CEQA Guidelines Section 15130[a][2]).

To perform the cumulative impact analysis, CEQA recommends relying on one of two approaches (CEQA Guidelines Section 15130[b]):

- List Approach: a list of past, present, and probable future projects producing related or cumulative impacts, or
- Projection Approach: a summary of projections contained in an adopted general plan or planning document, or in a prior environmental planning document, which has been adopted or certified, that describes or evaluates regional or area-wide conditions contributing to the cumulative impacts.

In this analysis, a list approach is used (Table 3.24-1) to analyze potential cumulative effects for each resource area, considering specific impacts of the Proposed Project in combination with potential impacts of other projects. When utilizing a list, the following factors should be considered: (1) the nature of each environmental resource being examined, and (2) the location of the project and its type (CEQA Guidelines Section 15130[b][1][B][2]). The list for the Proposed Project cumulative effects analysis includes the following planned, approved, or reasonably foreseeable project types that would result in related or cumulative impacts when considered in combination with the Proposed Project: riverine restoration projects; terrestrial resource management, conservation and restoration projects; water flow and water quality resource management projects; wildfire; forest and wildfire management projects; cannabis cultivation projects; other agricultural and rural residential projects; mining and mining withdrawal projects; infrastructure and energy projects; other rezoning and development projects; and recreation projects. This cumulative impact analysis focuses on projects that are not already considered in the analysis of potential impacts on environmental resources due to actions and elements included in the Proposed Project (Section 2). Past environmental conditions, including significant projects implemented before NOP issuance, are captured by the assessment of existing conditions in the *Environmental Setting* section of each resource area analysis. We note that the existing conditions included consideration of the NMFS and USFWS 2013 Joint Biological Opinion (2013 BiOp) flow requirements for the USBR Klamath Irrigation Project (NMFS and USFWS 2013), but the cumulative effects analysis considers the additional winter-spring surface flushing flows and deep flushing flows, as well as emergency dilution flows, that became a requirement in 2017 (U.S. District Court 2017). Additionally, measures PacifiCorp has committed to undertake as part of the KHSA upon certain triggers related to implementation of the Proposed Project are considered in this cumulative effects' analysis.

While wildfire is a natural occurrence, and an 'emergency' (CEQA Section 15359) rather than a foreseeable 'project' (CEQA Section 21065) under CEQA, with climate change more frequent and intense wildfires are reasonably foreseeable in California (Bedsworth et al. 2018). The area of the Proposed Project in Siskiyou County has been classified as having either high or very high wildfire hazard potential (CALFIRE 2007). Wildfires have the potential to result in relevant impacts (e.g., erosion and sediment deposition in streams) when combined with the Proposed Project, therefore this cumulative effects analysis considers increased frequencies and intensities of wildfires along with the list of 'projects' that could result in cumulative impacts (Table 3.24-1).

Significance criteria for cumulative effects vary by resource considered, and they are identical to those used to determine significance for Proposed Project impacts in each resource area. Classifications of significance differ from those used in resource areas, because of the mandatory requirement to assess cumulatively considerable effects (CEQA Section 15065[a][3]). The cumulative effects analysis concludes with a significance determination as follows (note that clarifying information is provided in non-bold font):

- ***Beneficial cumulative effects*** – when effects are cumulatively beneficial.
- ***No significant cumulative impact*** – when the combined impact of the Proposed Project and other projects would not be significant and adverse (and would also not be beneficial with sufficient certainty to describe it as such).
- ***Not cumulatively considerable*** – when the combined impact of the Proposed Project and other projects would be significant and adverse, but the incremental contribution of the Proposed Project would not be cumulatively considerable.
- ***Not cumulatively considerable with mitigation*** – when the combined impact of the Proposed Project and other projects would be significant and adverse, and the

incremental contribution of the Proposed Project requires mitigation to reduce it to less than cumulatively considerable.

- ***Cumulatively considerable*** – when the combined impact of the Proposed Project and other projects would be significant and adverse, and the incremental contribution of the Proposed Project is cumulatively considerable (and there is no feasible mitigation).

Table 3.24-1. List of Planned, Approved, or Reasonably Foreseeable Projects (Plus Wildfires) that Would Potentially Result in Related or Cumulative Effects When Combined with the Proposed Project (prepared September 2018).

Forest and Wildfire Management Projects					
USDA Forest Service — Klamath National Forest (Federal Lands)	Horse Creek Community Protection and Forest Restoration Project—reduce fuels, reduce safety hazards, and restore previously stocked units that were burned in the 2016 Gap Fire over 7325 acres and 103 lineal road miles	Happy Camp/Oak Knoll Ranger District of Klamath National Forest; this includes north, northwest, and northeast of the town of Horse Creek, CA up to the border of CA and OR and the Rogue-River Siskiyou National Forest	In late planning phase, 2017	USDA Forest Service 2017b	https://www.fs.usda.gov/project/?project=50586
USDA Forest Service — Klamath National Forest (Federal Lands)	Harlan—management for wildfire, including prescribed fire, strategic fuel breaks, and thinning; improve forest health and diversity, including resilience to insects and disease; maintain historic grassland and shrubland habitats; improve foraging habitat for elk and deer; protect cultural resources; and provide for safe public access to open roads; Water Board Waiver Category B	Goosenest Ranger District, Klamath National Forest; the project is located within the Horsethief Creek, Lough Lake, Lower Butte Creek, Prather Creek, and Upper Butte Creek 6th field watersheds; directly west and north of the community of Bray, CA, and approximately eight miles south of Macdoel in Siskiyou County	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service — Klamath National Forest (Federal Lands)	Lucky Penny—thinning of 1,500 acres of pine plantation within about a 2,300 acre project area to promote stand health, reduce fuel, and accelerate development of late-successional characteristics; Water Board Waiver Category A.	Goosenest Ranger District, Klamath National Forest; 20 miles northwest of Macdoel, CA	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
USDA Forest Service — Klamath National Forest (Federal Lands)	Pumice Vegetation Management Project—addresses deteriorating forest health conditions, increasing hazardous fuel conditions, and reduced ecological diversity, all caused by a century of fire exclusion and past management activities over an area of 9056 acres; Water Board Waiver Category B	Goosenest Ranger District, Klamath National Forest; Tamarack Flat (18010204130100) 7th field watershed; between Garner Mountain and Davis Rd (S. of four corners)	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Six Shooter Project—addresses the lack of young to mid-aged shrubs for big game, deteriorating forest health conditions, and increasing hazardous fuel conditions over an area of 15,067 acres; Water Board Waiver Category A, expected	Goosenest Ranger District, Klamath National Forest; the project is located within the Antelope Well, Dock Well, Hill 22, and Six Shooter Pass 7th field watershed	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Crawford Vegetation Management Project—thinning in stands for forest health and fuels reduction, with fuel treatments, including under-burning and pile burning on about 1,600 acres; Water Board Waiver Category B	Happy Camp Ranger District, Klamath National Forest	In progress; implementation expected in 2019	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Hancock Forest Management Access Road—construct 2,300 feet of temporary and 300 feet of permanent roadbeds for log hauling for forest use and management purposes	Happy Camp Ranger District, Klamath National Forest; Mill Creek 7th Field Watershed	In planning phase, 2018; implementation expected in 2020	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
USDA Forest Service—Klamath National Forest (Federal Lands)	Oak Fire Roadside Hazard Tree Proposal—reduce threats to public safety along 31 miles of National Forest Transportation System roads within the Oak Fire perimeter; Water Board Waiver Category A, expected	Happy Camp Ranger District, Klamath National Forest	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Seiad-Horse Risk Reduction Project—reduce safety hazards along roads and in concentrated stands, reduce fuels adjacent to private property, reduce the risk of future large-scale high severity fire losses of late successional habitat, and place large woody debris in streams for fish and wildlife habitat restoration in response to the 2017 Abney Fire, over an area of 10,800 acres	Happy Camp / Oak Knoll Ranger District of Klamath National Forest, Seiad Creek-Klamath River and Horse Creek-Klamath River 5th field watersheds—five miles North to Northeast of Seiad Valley, CA, in Siskiyou County	In planning phase, 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Callahan Complex Fuels Treatment on Private Land CE—fuel reduction on 200 acres of private land	Salmon River Ranger District, Klamath National Forest; private land in and around the community of Callahan, Siskiyou County	In planning phase, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Salmon August Reforestation Project—reforestation on 155 acres of lands burned during the 2017 Salmon-August Complex fire (1,093 acres); primarily restocking of conifer-dominated stands	Salmon River Ranger District, Klamath National Forest; located about five miles northwest of Sawyers Bar, CA, and within the Cherry Creek and Specimen Creek areas of the North Fork Salmon River Watershed	In planning phase, 2018; implementation expected 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
USDA Forest Service—Klamath National Forest (Federal Lands)	Salmon August Reforestation Project—Planting Unit 450-40 Only CE; to promote reforestation on lands burned during the 2017 Salmon-August Complex fire	Salmon River Ranger District, Klamath National Forest; located about 5 miles northwest of Sawyers Bar, CA, and within the Cherry Creek and Specimen Creek areas of the North Fork Salmon River Watershed	Completed in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Yellow Jacket Ridge—2,600 acres of precommercial thinning, release and fuels reduction in plantations and in natural stands	Salmon River Ranger District, Klamath National Forest	In planning phase, 2018; implementation expected 2019	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Craggy Vegetation Management—improve fire resiliency by reducing fuels and stand density in strategic areas (11,000-acre treatment area) to protect communities and promote forest health	Scott River Ranger District, Klamath National Forest; near Yreka, CA	In planning phase, 2018; implementation expected 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	East Fork Scott—improve conditions within the E Fork Scott watershed; treatments may include meadows, riparian areas, fuels reduction, mine reclamation, stand density reduction, and wildlife habitat improvements over 31,540 acres	Scott River Ranger District, Klamath National Forest; 10 miles NE of Callahan, Siskiyou County	In planning phase, 2018; implementation expected 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
USDA Forest Service—Klamath National Forest (Federal Lands)	Upper North Fork Salmon Fuels Reduction—treatment of 120 acres with high priority fuels reduction and prescribed fire on private land	Salmon River Ranger District, Klamath National Forest; private properties in the upper North Fork Salmon River drainage from Little North Fork to Taylor Hole; North Fork Salmon River 5th Field Watershed	On hold, 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Lover's Canyon—commercially thin about 863 acres, non-commercially thin about 1,103 acres, create fuel breaks on about 255 acres, and underburn about 2,223 acres over a total project area of 4,444 acres	Scott River Ranger District, Klamath National Forest; 15 miles west of Fort Jones, CA, within 7 drainages of the Lower Scott River Watershed	In planning phase, 2018; implementation expected 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Steamboat Oak Habitat Improvement—fuels reduction and oak woodland habitat improvement and retention for improved defensible space adjacent to the CALFIRE Deadwood Camp, improved wildlife habitat, increased fire resiliency, and overall forest health over an area of 45.5 acres	Scott River Ranger District, Klamath National Forest; 5 miles north of Fort Jones, CA, Siskiyou County; located on the ridge between Soares and Steamboat Gulch adjacent to the CALFIRE Deadwood Camp in the McAdams Creek Drainage	In planning phase, 2018; expected implementation 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
USDA Forest Service—Klamath National Forest (Federal Lands)	Yreka WUI Hazardous Fuels Reduction on Private Land—fuel reduction over 250 acres, additional acreage in future stages	Scott River Ranger District, Klamath National Forest; West of the city of Yreka, in the Middle Fork Humbug Creek, Greenhorn Creek, Yreka City—Yreka Creek, Long Gulch, and Rocky Gulch—Yreka Creek 7th field watershed	In planning phase, 2018; implementation expected 2019	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
USDA Forest Service—Klamath National Forest (Federal Lands)	Somes Bar Integrated Fire Management—remove fuels prior to prescribed burning in plantations 40 years and older, and mature natural stands while enhancing cultural and ecological plant species; shaded fuel breaks are proposed, and temporary roads are considered on a case by case basis over a project area of 5,570 acres	Scott River Ranger District, Klamath National Forest	In planning phase, 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf
TCRCD	California Fire Safe Council CWPP Implementation Phase I: OR Mountain area of Weaverville—mechanical chipping and thinning over 1.2 miles of roadside shaded break; 50 acres completed to date	OR Mountain area of Weaverville, including OR St and Dutch Ln	Work initiated in 2017	TCRCD 2018b	http://www.tcrcd.net/index.php/2014-02-05-08-30-03/forest-health

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
Cannabis Cultivation Projects					
City of Yreka	A City Council-initiated Ordinance entitled "Non-Medical Marijuana Cultivation Regulation and the Prohibition of Commercial Cannabis Activity, Manufacture, Testing, Dispensing, Sales, Distribution and Delivery within all Zoning Districts in the City of Yreka" (note that indoor cultivation is regulated, not prohibited)	City of Yreka limits	Adopted, 2017	Yreka Planning Commission 2017	http://ci.yreka.ca.us/sites/ci.yreka.ca.us/assets/files/P_C_Mintues_7_19_17.pdf
Humboldt Healing Collective; Aronsen Peter M Tr (owner)	Special Permit (SP) under Humboldt County Commercial Medical Marijuana Land Use Ordinance—existing outdoor cannabis cultivation; there are two points of water diversion and a rain catchment; includes 63,400-gallon water storage in hard tanks onsite on a 9,976-square-foot site	Willow Creek area, Humboldt County; North side of SH 299, 4.86 miles from the intersection of Titlow Road and SH 299	In planning phase, 2018	Humboldt County 2017a	https://humboldtgov.org/DocumentCenter/View/5523/summary-chart-of-projects-opened-by-the-Current-Planning-Division-in-the-previous-month?bidId=
Oak Knob, LLC	Conditional Use Permit for existing outdoor and mixed light cannabis cultivation—includes relocation of cultivation away from streamside, a new well and drip irrigation system on a 43,560-square-foot site; projected water use is 250,000 gallons/year; water is from an existing spring diversion, with storage in tanks, bladders, and a rainwater catchment pond; processing will occur offsite	Willow Creek area, Humboldt County; West side of SH 299, 12.42 miles from the intersection of SH 299 and Friday Ridge	In planning phase, 2018	Humboldt County 2017a	https://humboldtgov.org/DocumentCenter/View/5523/summary-chart-of-projects-opened-by-the-Current-Planning-Division-in-the-previous-month?bidId=

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
SJH Timber, Inc	Cannabis nursery in Trinity Alps Business Park—construction of two 3,000-sqare-foot greenhouses, and a 3,600-square-foot commercial building for sales, research and development, and storage	Trinity Alps Business Park, 271 Industrial Park Way, Weaverville, Trinity County, CA; outside 100-year floodplain of Weaver Creek	In planning phase, 2018	Trinity County 2018	http://www.trinitycounty.org/Agendas-Minutes-Staff-Reports
Various applicants	Variance from required 350-foot cannabis cultivation setback—there are several applications for the same variance	Lewiston, Hayfork, and other locations in Trinity County	In planning phase, 2018	Trinity County 2018	http://www.trinitycounty.org/Agendas-Minutes-Staff-Reports
Sungold Flat, LLC	SP to relax the 600-foot setback requirement from Six Rivers National Forest—an associated Zoning Clearance is concurrently being processed for 10,000 square feet of new commercial medical cannabis cultivation, and 20,000 square feet of Retirement, Remediation, and Relocation (RRR) cultivation referred to as Lorie Harbor; 30,000-square-foot total area	1570 Patterson Road, Willow Creek, Humboldt County, CA	In planning phase, 2018	Humboldt County 2018a	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_05102018-1077
Patterson Flat, LLC	SP to relax the 600-foot setback requirement from Six Rivers National Forest—the proposed cannabis cultivation area totaling 50,000 square feet is being permitted under three separate applications	1570 Patterson Road, Willow Creek, Humboldt County, CA	In planning phase, 2018	Humboldt County 2018b	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_04192018-1069

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
Sacred Earth Apothecary	SP for an existing commercial cannabis operation consisting of 7,000 square feet of outdoor cultivation and 2,111 square feet of mixed-light cultivation—5.1-acre parcel; water is supplied by the Willow Creek Community Services District, and estimated annual water usage is 65,000 gallons	1255 State Highway 96, Willow Creek area, Humboldt County, CA	In planning phase, 2018	Humboldt County 2018c	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_03222018-1055
Enchanted Earth, LLC Special Permit	SP to relax the 600-foot setback requirement from Six Rivers National Forest—an associated Zoning Clearance is concurrently being processed for 2,000 square feet of commercial medical cannabis cultivation	212 Enchanted Spring Lane, Willow Creek area, Humboldt County, CA	In planning phase, 2018	Humboldt County 2018d	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_01182018-1027
Green Star Ranch, Inc	SP for an existing 7000 sq-ft cannabis cultivation operation consisting of 2,000 square feet of mixed light and 5,000 square feet of outdoor with onsite relocation—water is provided by the Willow Creek Community Services District, and estimated annual water usage is 14,400 gallons; total onsite water storage is 300 gallons in a mixing-tank, and processing occurs onsite	2525 Patterson Road, Willow Creek, Humboldt County, CA	In planning phase, 2017	Humboldt County 2017b	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_12142017-1015

Applicant or Implementing Agency	Project/Program Name	Location	Timeframe	Reference	Website
Willow Creekside Farms	SP for an existing 10,000-square-foot medical cannabis cultivation operation—cultivation will consist of a 1,800-square-foot mixed-light greenhouse and an existing 8,200-square-foot outdoor cultivation area on a 10,000-square-foot site; total onsite storage capacity is 5,500 gallons in 4 storage tanks, and irrigation water is by the Willow Creek Community Services District	230 Creekside Lane, Willow Creek, Humboldt County, CA	In planning phase, 2017	Humboldt County 2017c	https://humboldtgov.org/AgendaCenter/ViewFile/Agenda/_09212017-975
Other Agricultural and Rural Residential Projects					
USDA Forest Service—Klamath National Forest (Federal Lands)	Bray and Horsethief Grazing Allotment Analysis—grazing management / reauthorization of grazing under the Rescissions Act of 1995, Water Board Waiver Category B	Goosenest Ranger District, Klamath National Forest, including: Bray, 13 miles SE of Macdoel, CA, and Horsethief, 10 miles SW of Macdoel, CA, 5th-field watersheds: Butte Creek, Antelope Creek-Red Rock, and Little Shasta River	In planning phase/public comment period, 2018; implementation expected in 2018	USDA Forest Service 2018a	https://www.fs.fed.us/sopa/components/reports/sopa-110505-2018-04.pdf

3.24.1.2 Geographic Scope

CEQA requires that a geographic scope of the area affected by the cumulative effect is defined, and a reasonable explanation for the geographic limitation used (CEQA Guidelines Section 15130[b][1][B][3]). The Areas of Analysis for the assessment of cumulative effects of the Proposed Project, in combination with other projects, are stated at the start of the cumulative effects' analyses for each resource area. The Areas of Analysis for some resource areas have clearly defined cumulative assessment boundaries, while others are more general in nature owing to the type and nature of the potential impacts.

3.24.1.3 Timeframe

CEQA requires consideration of past, present, and probable future cumulative effects (CEQA Guidelines Section 15130[b]). Cumulative effects may occur over a longer timeframe than project-specific effects, and the timeframe for the cumulative effects analysis varies by environmental resource and impact. The Proposed Project would be implemented over several years (Table 2.7-1). For several resource area impacts, the cumulative effects analysis timeframe is the duration of pre-dam removal activities (pre-dam removal years 1−3) and dam deconstruction (dam removal years 1 and 2). For other resource area impacts, long-term effects could occur after dam removal, so for these a longer timeframe is considered. The timeframes for long-term cumulative effects are based on the best available existing information and consider the inherent difficulties of long-term forecasting. Unless otherwise specified, the timeframe for cumulative effects analyses is the same as for Proposed Project-related resource effects. As with the analysis of Proposed Project impacts, the analysis of cumulative effects uses 2016 conditions (issuance of the Notice of Preparation) as the baseline for existing resource conditions. Unless otherwise specified, historical trends and the effects of past projects are part of the existing conditions.

3.24.1.4 Mitigation

An EIR must examine reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects (CEQA Guidelines Section 15130[b][1][B][5]). Additionally, no public agency can approve or carry out a project with an EIR that identifies significant impacts, unless the public agency makes one or more written findings for each of those significant effects (CEQA Guidelines Section 15091). This assessment of cumulative effects identifies feasible mitigation measures for effects of the Proposed Project determined to be cumulatively considerable.

3.24.2 Water Quality

The geographic scope for cumulative water quality effects is the same as the Area of Analysis for water quality, as described in Section 3.2.1 *[Water Quality] Area of Analysis*. The geographic scope includes the Klamath River from the Hydroelectric Reach[174] in the Upper Klamath Basin through the Lower Klamath River from its confluence with the Trinity River, the Klamath River Estuary, and the Pacific Ocean nearshore environment (Figure 3.2-1).

[174] Reaches of the Klamath River upstream of the Oregon-California state line (RM 214.1) are considered to the extent cumulative actions in those reaches influence water quality downstream in California.

Water quality existing conditions in the Area of Analysis are described in Section 3.2.2 *[Water Quality] Environmental Setting* and Appendix C *Water Quality Supporting Technical Information*. The spatial and temporal trends in water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-a and algal toxins, and inorganic and organic contaminants conditions for the Klamath River, from the Hydroelectric Reach through the Klamath River Estuary and the Pacific Ocean nearshore environment, are all detailed for the Area of Analysis. Section 3.2.2 *[Water Quality] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, water quality. Additionally, the reaches of the Klamath River listed as impaired on the Clean Water Act (CWA) section 303(d) list are presented in Section 3.2.3 *[Water Quality] Significant Criteria*, Table 3.2-3.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of water quality resource area effects (Section 3.2). The non-project activity types shown below have been evaluated for potential cumulative impacts on water quality and include those activities that would potentially alter water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-*a* and algal toxins, and inorganic and organic contaminants in the Klamath River within the water quality Area of Analysis. While wildfire is a natural occurrence, under climate change more frequent and intense wildfires are reasonably foreseeable (Bedsworth et al. 2018) and thus wildfires are also evaluated for potential cumulative impacts on water quality. The non-project activity types are included in Table 3.24-1).

Significance criteria for cumulative water quality impacts are the same as defined in Section 3.2.3 *[Water Quality] Significance Criteria*.

Potential Cumulative Impact 3.24-1 Long-term water quality effects of the Proposed Project in combination with restoration, flow enhancement, and water quality improvement projects.

Restoration, flow enhancement, and water quality improvement projects along the Klamath River and its tributaries (creeks and rivers) are anticipated to enhance water quality (e.g., water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-a and algal toxins), with improvements to stream channels, riparian habitat restoration, placement of off-channel habitat features, floodplain restoration, incorporation of large wood into tributaries to the Klamath River, and increases in stream flow (Table 3.24-1).

Restoration, flow enhancement, and water quality improvement projects would have a beneficial effect on water quality in the Klamath River. As an example, the Long Term Plan to Protect Adult Salmon in the Lower Klamath River is anticipated to improve nutrient, suspended sediment (i.e., organic matter concentrations), and chlorophyll-a and algal toxin conditions during August and September by increasing the Trinity River flows into the Klamath River and diluting (i.e., lowering) the nutrient, suspended sediment, and chlorophyll-a and algal toxin concentrations in the Lower Klamath River downstream of the Trinity River. Various grants for water quality improvement projects, through money received from the USEPA through Section 319(h) of the Clean Water Act and Timber Regulation and Forest Restoration Fund, reduce nonpoint source pollution (e.g., sediments, nutrients) and address TMDL implementation in the Klamath Basin. Waste discharge requirements, waivers, and NPDES permits are issued by the North Coast

Regional Water Quality Control Board for particular projects, and are renewed with updated BMPs on a regular basis, addressing a variety of water quality parameters (e.g., water temperature, dissolved oxygen, sediment, nutrients) throughout the Klamath Basin. A number of entities involved in the Upper Klamath Basin Watershed Action Team and the Watershed Stewardship Partnership (see Table 3.24-1) implement various projects throughout the Upper Klamath Basin that improve water quality through working with landowners, agencies, and other partners to conserve, enhance, and restore natural resources. Associated improvements in water quality in the Upper Klamath River, Lower Klamath Lake, Lost River, Klamath Irrigation Project, Upper Klamath Lake, Wood River, Sprague River, and Williamson River, will ultimately improve water quality in the Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary.

The conversion of the reservoir areas to free-flowing river reaches as part of the Proposed Project would have a beneficial effect on water temperature in the Hydroelectric Reach and the Middle Klamath River to the confluence with the Salmon River (Potential Impact 3.2-1) and chlorophyll-a and algal toxins in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary (Potential Impact 3.2-12). Long-term increases in suspended material (Potential Impact 3.2-6 and 3.2-7) and nutrients (Potential Impact 3.2-8) due to the lack of continued interception by the Lower Klamath Project dams under the Proposed Project would have no significant impact, since the increases were relatively small compared to background conditions. The beneficial effect of restoration, flow enhancement, and water quality improvement projects on suspended materials and nutrients would potentially further reduce the relatively small long-term increases from the Proposed Project and improve water quality conditions downstream of the restoration, flow enhancement, and water quality improvement projects. As a result, the combined effect of the Proposed Project and these restoration, flow enhancement, and water quality improvement projects would be beneficial for water quality, especially for water temperature and chlorophyll-a and algal toxins. The restoration, flow enhancement, and water quality improvement projects would increase the amount of cold water flowing in the river improving water temperature conditions for salmonids, while the Proposed Project would improve water temperature by returning more natural seasonal and daily variations. In combination with restoration, flow enhancement, and water quality improvement projects, the Proposed Project would help to offset the effects of climate change on late summer/fall water temperatures, where climate change is expected to increase these temperatures in the Klamath Basin on the order of 1.8–5.4°F between 2012 and 2061 (Bartholow 2005 Perry et al. 2011).

Increases in river flows from restoration, flow enhancement, and water quality improvement projects would also be beneficial for water quality by diluting chlorophyll-a and algal toxins concentrations, while the Proposed Project would decrease high seasonal chlorophyll-*a* concentrations and periodically high algal toxin concentrations by eliminating the reservoir environment that currently supports growth conditions for toxin-producing nuisance blue-green algal species such as *Microcystis aeruginosa.* In combination with restoration, flow enhancement, and water quality improvement projects, the Proposed Project would help to offset the effects of climate change on the frequency of algal blooms, where climate change is generally expected to affect water quality through increased runoff and the associated potential for algal blooms (Michalak 2016).

Overall, the Proposed Project, in combination with restoration, flow enhancement, and water quality improvement projects, would result in beneficial cumulative effects on water quality.

Significance

Beneficial cumulative effects

Potential Cumulative Impact 3.24-2 Short-term increases in suspended sediments under the Proposed Project in combination with the 2017 court-ordered flushing and emergency dilution flows.

Formal consultation of the NMFS and USFWS 2013 Joint Biological Opinion (2013 BiOp) (NMFS and USFWS 2013) for the USBR Klamath Irrigation Project was reinitiated in 2017 to improve management of *Ceratanova Shasta (C. Shasta)* infection among coho salmon in the Klamath River. Until formal consultation is completed and a new biological opinion (BiOp) is issued, USBR is required to manage *C. Shasta* by releasing additional winter-spring surface flushing flows and deep flushing flows, as well as emergency dilution flows (U.S. District Court 2017). The flushing and emergency dilution flow requirements are in addition to 2013 BiOp flow requirements, which remain in effect until formal consultation is completed. During the period when the Proposed Project would occur, the 2017 flow requirements (i.e., 2013 BiOp Flows plus the 2017 court-ordered flushing and emergency dilution flows) or the to-be-determined new BiOp flow requirements may be in effect since USBR's consultation with NMFS and USFWS on the 2013 BiOp Flows for the Klamath Irrigation Project is currently underway and is expected to be completed by August of 2019 (see also Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*). At this time, estimates of flows that will be required under the future Klamath Irrigation Project biological opinion are speculative, so they are not included in hydrologic modeling. Potential new BiOp flow requirements under the Proposed Project are speculative in part because the fish disease conditions that prompted the flushing and emergency dilution flow requirements would be reduced due to increased dispersal of spawners and carcasses, transport of bedload, and establishment of variable flows, even if infection is not eliminated (see Section 3.3.5.5 *Fish Disease and Parasites*). Thus, it is not clear whether flushing and emergency dilution flow requirements would continue under a new BiOp after dam removal. It is also not clear if the prior location of Iron Gate Dam would remain as the compliance point if the flushing and emergency dilution flows continued. However, the 2017 flow requirements are the most reasonable assumption for conditions until formal consultation is completed and a new BiOp is issued. This is different from the existing conditions flow requirements, since the flushing flow requirements were imposed after issuance of the Notice of Preparation.

The 2017 flow requirements for the USBR Klamath Irrigation Project are generally the same as the 2013 BiOp Flows analyzed under the individual resource sections for the Proposed Project, but they also include new flushing and emergency dilution flows based on the management guidance from *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* (Hillemeier et al. 2017; U.S. District Court 2017). The management guidance specifies surface and deep flushing flows downstream of Iron Gate Dam to dislodge and flush out polychaete worms attached to the streambed that host *C. Shasta*, and emergency dilution flows downstream of Iron Gate Dam to reduce disease conditions in the Klamath River, if specific disease criteria are exceeded. In the 2013 BiOp, Iron Gate Dam is the compliance point for flow requirements. Iron Gate Dam is assumed to be the compliance point for the 2017 court-ordered flushing and emergency dilution flows since the injunction specifies the flushing and emergency flows be modeled on the management guidance and the management guidance specifies the flows occur downstream of Iron Gate Dam. Surface flushing flows of at least 6,030 cfs for a 72-hour period are required to be met by USBR every year between November 1 and April 30 to scour riverbed sediments (i.e., scour fine sediment from approximately 20 to 30 percent of the surface of the streambed). USBR is also required to release deep flushing flows averaging at least 11,250 cfs over a single 24-hour period between February 15 and May 31 every other year to scour fine sediment from between gravels and cobbles (i.e., armor layer) on the streambed and potentially move individual armor layer particles, if such a flow does not occur naturally. Deep flushing flows were first required in 2017, so according to the court order they would be required again in 2019 and 2021. The timing of surface and deep flushing flows within the specified period is left to the discretion of USBR, but the USBR is required to coordinate with the parties[175] specified in the U.S. District Court case regarding the timing and magnitude of the flushing flows. Emergency dilution flows of 3,000 cfs (potentially increasing to 4,000 cfs) up to a maximum volume of 50,000 acre-feet may also be required to be released by USBR from Iron Gate Dam between April 1 to June 15, if fish disease thresholds in the Klamath River downstream of Iron Gate Dam are exceeded. USBR, as part of their management of the Klamath Irrigation Project, is required to reserve the 50,000 acre-feet in case release is needed.

This Potential Cumulative Impact examines whether the Proposed Project in combination with the 2017 flow requirements (i.e., 2013 BiOp Flows plus the court-ordered flushing and emergency dilution flows) potentially would have a short-term significant cumulative effect on suspended sediments, with the incremental contribution of the Proposed Project being cumulatively considerable. As discussed in Potential Impact 3.2-3, the Proposed Project would result in a significant and unavoidable short-term impact on suspended sediment by causing suspended sediment to be greater than 100 mg/L over a continuous two-week period (i.e., the suspended sediment significance criteria), especially during the reservoir drawdown period from November to March. This impact evaluates the potential change in significance to that impact in light of the 2017 flow requirements.

Modeling of reservoir drawdown flows during representative water years indicates that the flow at Iron Gate Dam under the Proposed Project would meet the annual surface flushing requirements in all water year types except dry, but reservoir drawdown flows would only meet the biennial deep flushing flows during the above normal water year and two of the three representative wet water years (Figures 3.24-1 and 3.24-2). In years that reservoir drawdown flows meet flushing flow requirements, drawdown flows would mobilize the streambed sediments in the Middle Klamath River downstream of Iron Gate Dam to the threshold expected for dislodging and flushing the polychaete worms involved in fish disease. Suspended sediment concentrations (SSCs) estimated as part of the Proposed Project (Potential Impact 3.2-3) would include the mobilization of these streambed sediments downstream of Iron Gate Dam, and there would be no cumulative increase in suspended sediment from the combination of the Proposed Project and the 2017 flow requirements because the latter would not be required.

[175] Parties refer to Yurok Tribe, Pacific Coast Federation of Fishermen's Associations, Institute for Fisheries Resources, Klamath Riverkeeper, Hoopa Valley Tribe, National Marine Fisheries Service, Klamath Water Users Association, Sunnyside Irrigation District, Ben DuVal, Klamath Drainage District, Klamath Irrigation District, and Pine Grove Irrigation District.

In years where reservoir drawdown flows would not meet the magnitude or duration of flushing flow requirements (Figures 3.24-1 and 3.25-2), surface and/or deep flushing flow releases may still be required. These flushing flows would mobilize more sand, silt, and clay sized sediment downstream of Iron Gate Dam than would occur under the Proposed Project, resulting in higher SSCs downstream of Iron Gate Dam. Additionally, the flushing flows would likely need to be released from Keno Dam under the Proposed Project since J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams would not be available to release these flows, so more sediment and increases in SSCs would potentially occur throughout the Hydroelectric Reach. Flushing flows may also increase SSCs by re-wetting and mobilizing some of the reservoir sediments that were not transported during reservoir drawdown. The flushing flows are within the range of flows modeled under the Proposed Project, so increases in SSCs under flushing flows would be within the range of SSCs modeled under the Proposed Project. While flushing flows would only occur for 72 hours (surface flushing) or 24 hours (deep flushing), they may prolong the duration of SSCs exceeding the significance criteria (i.e., 100 mg/L for a continuous two week period) compared to under the Proposed Project drawdown flows alone, if flushing flows occur when the drawdown flows are nearly or completely finished (November to March). The incremental increase in SSCs due to flushing flows are unlikely to increase the duration of SSCs above 100 mg/L for an entire two-week period since the duration of the flushing flows is 72 hours or less, but SSCs greater than 100 mg/L due to the Proposed Project that would last for less than two weeks may occur for two weeks or slightly more with the flushing flows. There are one to two months when flushing flows may increase SSCs outside of the Proposed Project reservoir drawdown period since surface flushing flows potentially would occur until April 30 and deep flushing flows potentially would occur until May 31. Thus, there would be the potential for a cumulative short-term increase in SSCs in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary from the combined effect of the Proposed Project and the 2017 flow requirements in water years when the Proposed Project reservoir drawdown flows do not meet the surface and/or deep flushing flow requirements.

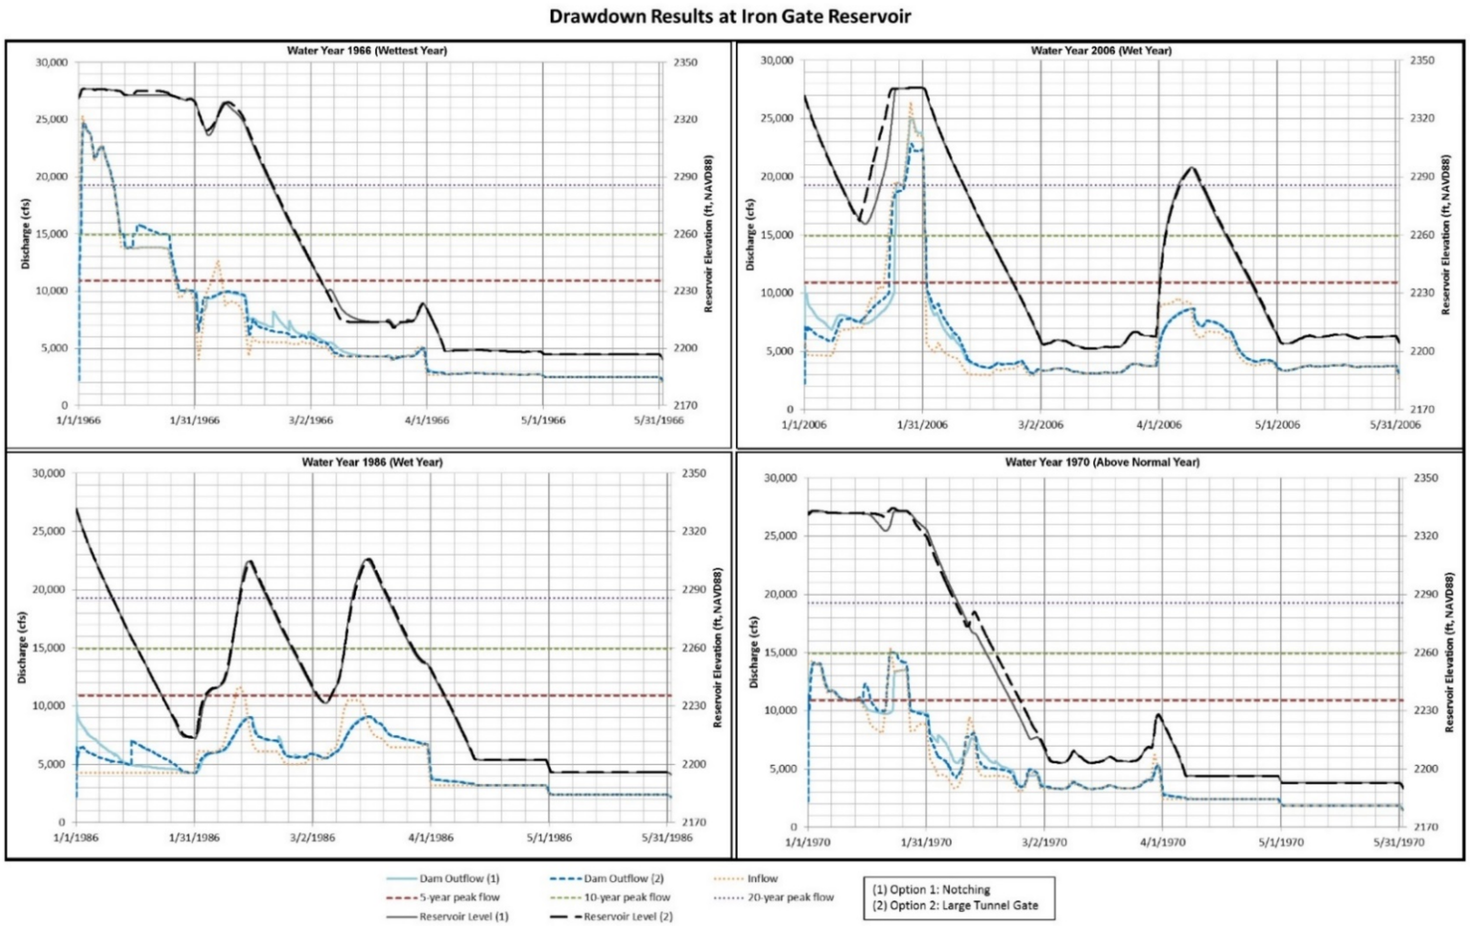

Figure 3.24-1. Proposed Project Modeled Drawdown Flow Downstream of Iron Gate Dam and Iron Gate Reservoir Elevation for Representative Wet and Above Normal Water Year Types. Dam Outflow Option 2 (Large Tunnel Gate) is included in the Proposed Project. Dam Outflow Option 1 (Notching) is presented in the Definite Plan for comparison purposes only; KRRC is not proposing notching as the preferred plan for dam demolition. Surface annual flushing flows of at least 6,030 cfs for 72 hours would occur between November 1 and April 30, while deep flushing flows of at least 11, 250 cfs for 24 hours would occur every other year starting in 2017 (i.e., odd numbered years) between February 15 and May 31.

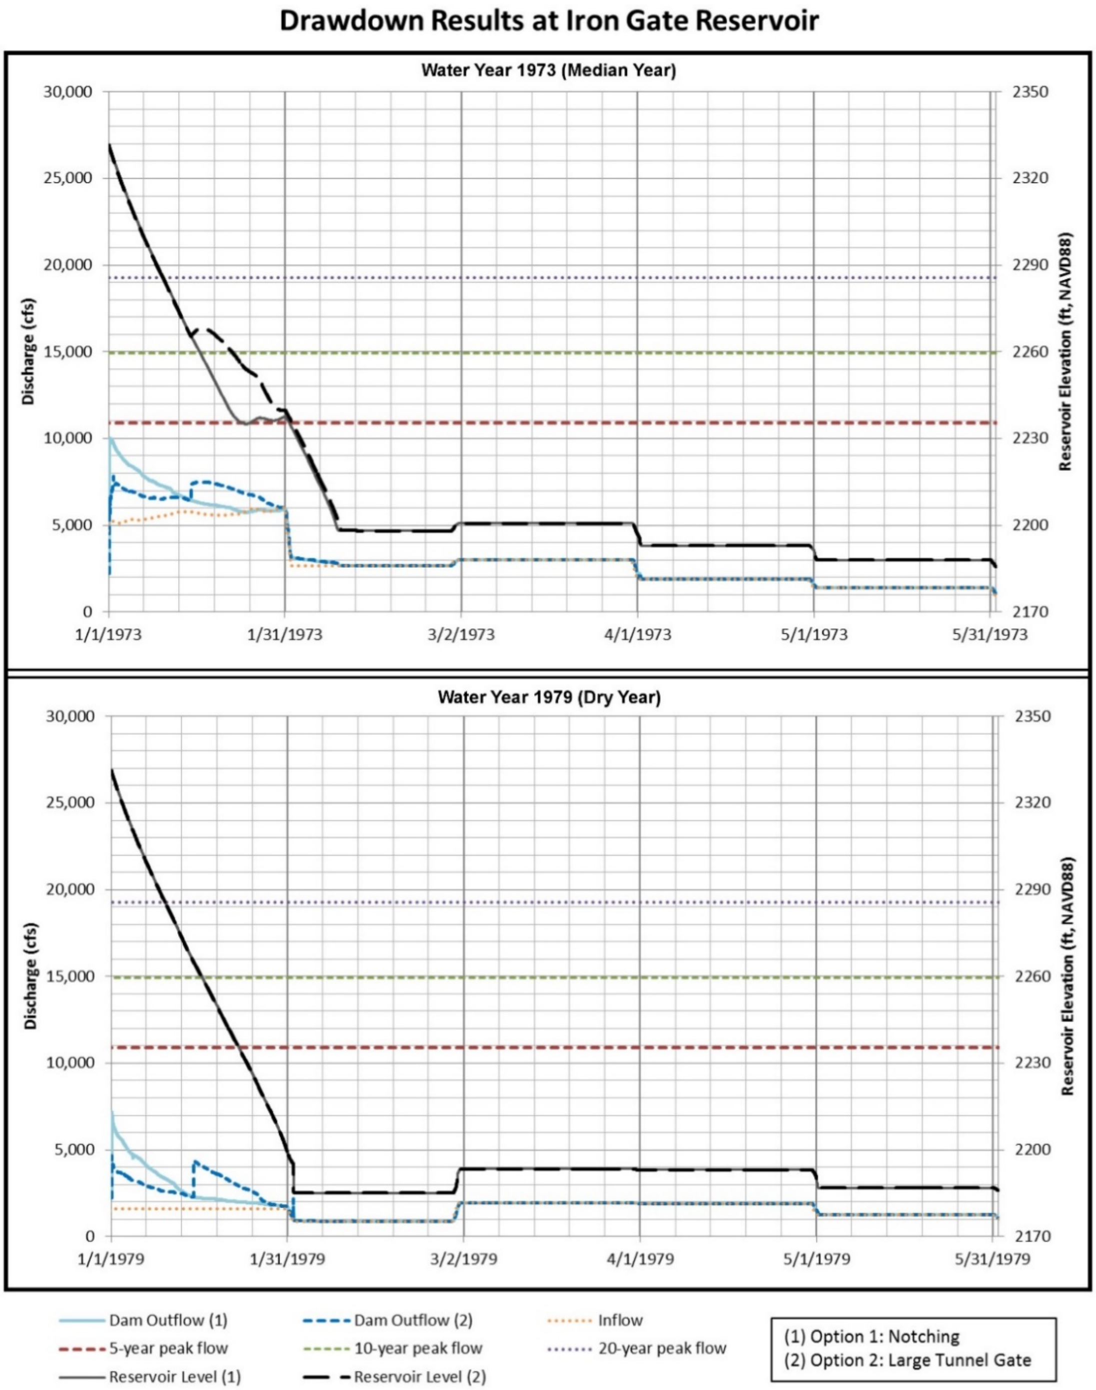

Figure 3.24-2. Proposed Project Modeled Drawdown Flow Downstream of Iron Gate Dam and Iron Gate Reservoir Elevation for Representative Median and Dry Water Year Types. Dam Outflow Option 2 (Large Tunnel Gate) is included in the Proposed Project. Dam Outflow Option 1 (Notching) is presented in the Definite Plan for comparison purposes only; KRRC is not proposing notching as the preferred plan for dam demolition. Surface annual flushing flows of at least 6,030 cfs for 72 hours would occur between November 1 and April 30, while deep flushing flows of at least 11, 250 cfs for 24 hours would occur every other year starting in 2017 (i.e., odd numbered years) between February 15 and May 31.

Emergency dilution flows may be required under the 2017 flow requirements between April 1 to June 15 regardless of reservoir drawdown flows from the Proposed Project, since emergency dilution flows are based on disease thresholds in the Klamath River downstream of Iron Gate Dam. If required, emergency dilution flows (3,000 to 4,000 cfs) are unlikely to increase SSCs and/or durations due to re-wetting and mobilization of remaining floodplain and reservoir sediment deposits, because they are below the thresholds recognized for coarse and fine particle entrainment (see USBR 2012). Additionally, it is unlikely that emergency dilution flows would be required in the months just following reservoir drawdown under the Proposed Project because periods of high SSCs (Potential Impact 3.2-3) and low dissolved oxygen (Potential Impact 3.2-9) in reaches of the Klamath River downstream of Iron Gate Dam during reservoir drawdown (November 1 to March 15) would limit periphyton establishment along the streambed following drawdown, which would also limit favorable habitat for the polychaete worm that hosts fish parasites (e.g., *C. shasta*) during April 1 to June 15 of the same year. Overall, exceedances of disease thresholds that would trigger emergency dilution flows would be unlikely In the short term, particularly in dam removal year 2, and thus there would be no cumulative impact due to an increase in SSCs from emergency dilution flows associated with the 2017 court-ordered flows.

Overall, the short-term combined impact of the Proposed Project and the 2017 flow requirements (i.e., 2013 BiOp plus court-ordered flushing and emergency dilutions flows) would result in a cumulative increase in the SSCs during water years when reservoir drawdown flows are less than the surface and/or deep flushing flows. The short-term cumulative increase in SSCs would not increase the magnitude of SSCs outside the range modeled for the Proposed Project, but the cumulative effect may increase the duration that SSCs exceed the significance criterion in the Klamath River if flushing flows occur when the drawdown flows are nearly or completely finished. Thus, the Proposed Project combined with the 2017 flow requirements would potentially have a short-term cumulatively considerable impact in the in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary.

There are no long-term cumulative water quality impacts from the Proposed Project's sediment and sediment-related (i.e., sediment-associated nutrients, oxygen demand, and inorganic and organic contaminants) impacts and the 2017 flow requirements (Potential Impacts 3.2-6, 3.2-7, 3.2-9, 3.2-11, 3.2-14, and 3.2-15). SSCs in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary are predicted to resume background levels by the end of post-dam removal year 1 under all water year types, especially with revegetation of the reservoir sediments immediately following dam removal which would stabilize the sediment from erosion due to rainfall (USBR 2012). As such, the combined impact of the Proposed Project and the 2017 flow requirements would not be cumulatively considerable.

Significance

Cumulatively considerable in the short term

No significant cumulative impact in the long term

Potential Cumulative Impact 3.24-3 Long-term water quality effects of the Proposed Project in combination with forest and wildfire management activities. In the water quality Area of Analysis, anticipated forest and wildfire management project activities include commercial and non-commercial thinning in stands for forest health and fuel reduction, using prescribed fire, creating strategic fuel breaks, implementing fuel treatments including under-burning and pile burning, revegetating areas to accelerate the development of mature forest, enhancing meadow conditions, improving water temperature and sediment conditions in streams, modifying road conditions, and increasing recreational opportunities. The main water quality parameters potentially adversely impacted by these activities would be water temperature, since vegetation removal allows more solar radiation to reach streams and the surrounding floodplain surfaces, and suspended sediment due to vegetation removal, prescribed burns, fuel treatments, and road construction and usage increasing erosion. The North Coast Regional Water Quality Control Board's Forest Activities Program issues waste discharge requirements and general waivers with terms and conditions to address the potential water quality problems potentially associated with a range of forest management activities on private and on US Forest Service lands (North Coast Regional Board 2018c). Reasonably foreseeable forest and wildfire management projects within or near the water quality Area of Analysis are included in Table 3.24-1.

The Proposed Project would have either a beneficial effect (Potential Impact 3.2-1) or result in no significant impact (Potential Impact 3.2-2) on water temperature in the Area of Analysis. Suspended sediment impacts from the Proposed Project would be significant and unavoidable in the short term due to increases in suspended sediment as reservoir sediments trapped behind the Lower Klamath Project dams are released (Potential Impact 3.2-3), but the other short-term and long-term impacts and potential impacts of the Proposed Project on suspended sediment in the Area of Analysis would be beneficial, not significant, or not significant with mitigation (Potential Impacts 3.2-4 through 3.2-6). Most notably, there would be no significant impact in the long term on suspended sediment concentrations from releases of reservoir sediments currently trapped by the Lower Klamath Project dams or the lack of continued interception and retention of suspended material behind the Lower Klamath Project dams. Suspended sediment concentrations in the Klamath River are expected to return to background levels by the end of post-dam removal year 1 and the long-term annual increase in suspended sediments downstream of Iron Gate Dam would be relatively small (approximately 3.4 percent) compared to the cumulative average annual sediment load from the Klamath Basin.

The Proposed Project and forest and wildfire management activities would not have a significant cumulative impact on water quality, since the cumulative magnitude of changes to water quality would not be anticipated to exceed the water quality significance criteria or impact designated beneficial uses. There would be no significant cumulative impact during drawdown of the Lower Klamath Project reservoirs and the Proposed Project impacts associated with drawdown (e.g., Potential Impact 3.2-3 and Potential Impacts 3.2-7, 3.2-9, 3.2-13, 3.2-14), because drawdown would occur during November through March when forest and wildfire management activities (e.g., prescribed burns or commercial logging) would be limited. Under the Proposed Project, dam removal also would result in a less than significant increase in inorganic (mineral) and organic (algal-derived) suspended material in the Klamath River due to the lack of continued interception and retention by the Lower Klamath Project dams (Potential Impact 3.2-5 and 3.2-6). While some forest and wildfire management activities would potentially increase water temperature and suspended sediment in streams due to removal of vegetation cover and temporary or permanent road construction and usage for tree removal (i.e., logging), other activities would potentially improve water quality conditions by revegetating areas, enhancing riparian cover along meadow streams, and decommissioning or downgrading roads to reduce suspended sediment delivery to streams. As a result, the net effect from the anticipated forest and wildfire management activities would be less than significant and there would be no significant cumulative impact from the Proposed Project and forest and wildfire management activities.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-4 Short-term and long-term water quality effects of the Proposed Project in combination with wildfires.

Wildfires regularly occur within the Klamath Basin with multiple fires occurring in 2016 through 2018 (see Table 3.24-1). Under climate change, forests will be more susceptible to extreme wildfires, with an almost 50 percent increase in the frequency of extreme wildfires that burn over approximately 25,000 acres, and a 77 percent increase in the average area burned statewide by the end of the century (Bedsworth et al. 2018). Within the water quality Area of Analysis, wildfires could potentially impact water quality by reducing the forest or vegetation cover around streams. Water temperature may increase due to more solar radiation reaching the stream or sediments from burn areas depositing in streams, creating shallower streams, and resulting in more rapid warming of the streams. In the short term and long term, the Proposed Project would decrease Klamath River water temperatures in the Hydroelectric Reach and Middle Klamath River from Iron Gate Dam to the confluence with the Salmon River during the late summer/fall compared with existing conditions (Potential Impact 3.2-1), which would help to offset potential increases in water temperatures in wildfire burn areas, should they occur within these reaches in the water quality Area of Analysis. This would be a benefit of the Proposed Project in combination with wildfires. The Proposed Project would have no effect on water temperatures for the Middle Klamath River downstream from the Salmon River, the Lower Klamath River, and the Klamath River Estuary in the short term or the long term, thus there would be no cumulative impact on water temperature for the Proposed Project combined with wildfires.

Wildfires could potentially impact water quality by increasing SSCs due to increased erosion in burn areas. In the short term, the increase in suspended sediment from wildfires would be expected to be small compared to the Proposed Project impacts on suspended sediment during reservoir drawdown (Potential Impacts 3.2-3 and 3.2-4) and in comparison to natural sediment conditions in the Klamath River (USBR 2012). However, a late-season (e.g., November) wildfire during dam removal year 1 or 2 that burns the landscape near or within the water quality Area of Analysis and is followed by heavy rainstorms would potentially result in a short-term cumulative increase in the SSCs. Erosion from heavy rains on a burned area from a late-season wildfire could increase SSCs during the initial drawdown of Copco No. 1 Reservoir in dam removal year 1 or during the late-fall/early winter period in dam removal year 2 and result in SSCs exceeding the significance criteria (i.e., 100 mg/L for a continuous two week period) for a longer duration than under the Proposed Project alone. However, the short-term cumulative increase in SSCs from a late-season wildfire followed by heavy rains would not be likely to increase the magnitude of SSCs outside the range modeled for the Proposed Project. Given that the Proposed Project exceeds significance criteria for SSCs, and because of the potential for an extended duration of elevated SSCs in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary from the combination of the Proposed Project and wildfires, this short-term impact is conservatively assessed as cumulatively considerable.

In the long term, SSCs under the Proposed Project are expected to resume natural background levels by the end of post-dam removal year 1 (USBR 2012) and there would be no significant impact on SSCs in the Hydroelectric Reach, Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment due to the release of sediments currently trapped behind the Lower Klamath Project dams (Potential Impact 3.2-3). While wildfires potentially would increase SSCs occasionally in the long term if eroded sediments from a burn area during heavy rain entered the Klamath River, there would be no cumulative effect on water temperature from the Proposed Project and wildfires since the SSCs would have resumed natural background levels.

Significance

Cumulatively considerable in the short term

No significant cumulative impact in the long term

Potential Cumulative Impact 3.24-5 Long-term water quality effects of the Proposed Project in combination with cannabis cultivation projects.

Cannabis cultivation related projects within the water quality Area of Analysis and the Klamath Basin were assessed to determine if there would be a cumulative effect with the Proposed Project. Cannabis cultivation projects could potentially impact multiple water quality parameters, including water temperature as flow diversions for cultivation reduce stream flows and result in more rapid warming and higher water temperatures; suspended sediment from stormwater runoff of cultivated land; nutrients from stormwater runoff containing fertilizers; chlorophyll-a and algal toxins due to nutrients in stormwater runoff promoting additional phytoplankton or periphyton growth; and inorganic and organic contaminants from pesticide application. While there are potential water quality impacts from cannabis cultivation, many of those projects are part of the environmental setting (i.e., they existed at the time of issuance of the Notice of Preparation [2016]) and numerous regulatory agencies manage the water quality impacts from cannabis cultivation. Water quality impacts from these previously existing projects are represented in the water quality environmental setting (see Section 3.2.2 *[Water Quality] Environmental Setting* for more details) even though the existing projects are only now being permitted due to the recent legalization of cannabis cultivation. Additionally, the North Coast Regional Water Quality Control Board Cannabis Cultivation Waste Discharge Regulatory Program (North Coast Regional Board 2018b), the California Department of Food and Agriculture CalCannabis Cultivation Licensing, the California Department of Pesticide Regulation, and other agencies are regulating cannabis cultivation, including water quality and waste discharge requirements. New or existing permitted cannabis cultivation projects would be required to adhere to water quality regulations and implement project-specific measures to minimize or reduce to less than significant potential impacts to water quality. Project-specific measures detailed for several existing cannabis cultivation projects include relocating cultivation away from a stream, limiting the timing of diversions from streams, replacing unpermitted wells with permitted wells, and using drip irrigation systems to minimize water use. As such, cannabis cultivation projects would be expected to have a less than significant impact on water quality in the Area of Analysis.

Depending on the reach of the Klamath River and the time scale (short-term or long-term) being analyzed, the Proposed Project would have a beneficial effect, no significant impact, or no significant impact with mitigation for the water quality parameters evaluated, including water temperature (Potential Impacts 3.2-1 and 3.2-2), suspended sediment (Potential Impacts 3.2-3 through 3.2-6), nutrients (Potential Impacts 3.2-7 and 3.2-8), chlorophyll-a and algal toxins (Potential Impact 3.2-12), and inorganic and organic contaminants (Potential Impacts 3.2-13 through 3.2-16). However, the short-term increases in suspended sediment as reservoirs sediments trapped behind the Lower Klamath Project dams are released (Potential Impact 3.2-3), would be significant and unavoidable. Since cannabis cultivation would be required to adhere to these regulations and implement project-specific measures to minimize or reduce to less than significant potential water quality impacts, the combined effect of the Proposed Project and cannabis cultivation projects not result in further impacts to water quality. Thus, there would be no significant cumulative water quality impact due to the Proposed Project.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-6 Long-term water quality effects of the Proposed Project in combination with grazing and other agricultural projects.
Grazing and other agricultural projects may increase suspended sediment within streams due to soil disturbance and increased erosion; may increase nutrients in streams due to stormwater runoff from grazing or agricultural areas containing either livestock waste (grazing) or fertilizers (agriculture); may decrease dissolved oxygen due to the biological oxygen demand from stormwater runoff containing livestock waste (grazing) or fertilizers (agriculture); and may increase chlorophyll-a and algal toxins due to nutrients in stormwater runoff promoting additional phytoplankton or periphyton growth.

Any existing grazing or agricultural impacts on the Area of Analysis are accounted for in the analysis of the existing conditions. Most of the anticipated grazing and agricultural projects would not have the potential to impact water quality conditions in the water quality Area of Analysis because they would not occur within or upstream of the water quality Area of Analysis, including within tributaries of the Klamath River in California, where sediment, nutrients, and biological oxygen demand in runoff from grazing or agricultural lands could potentially influence water quality conditions within the water quality Area of Analysis (Table 3.24-1). Reasonably foreseeable grazing or agricultural projects located downstream of the Project Boundary in California, but still near the water quality Area of Analysis, are included in Table 3.24-1.

Grazing and agricultural projects would incorporate project-specific measures to reduce potential water quality impacts, including storm water management, streambank setbacks, or exclusionary livestock fencing. Grazing (and other agricultural projects) are required to meet the requirements of the non-point source discharge policy, the prohibition against unpermitted discharges, and the North Coast Regional Water Quality Control Board's Agricultural Lands Discharge Program. These require compliance with best management practices designed to meet state water quality requirements. (North

Coast Regional Board 2018a). Grazing and agricultural projects implementing such project-specific measures would be expected to have a less than significant impact on water quality in the Area of Analysis. Assuming grazing and agricultural projects implement project-specific measures to reduce water quality impacts, the combined effect of the Proposed Project and grazing and agricultural projects would not result in further impacts to water quality and there would be no significant cumulative water quality impact due to the Proposed Project and these grazing and agricultural projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-7 Long-term water quality effects of the Proposed Project in combination with mining projects.

Mining projects within the water quality Area of Analysis and the Klamath Basin were evaluated to determine if there would be a cumulative effect with the Proposed Project. Mining projects may impact multiple water quality parameters, including increasing suspended sediment and inorganic or organic contaminants. Most of the anticipated mining projects are not within the water quality Area of Analysis or the vicinity of the mainstem Klamath River (Table 3.24-1) and they would be unlikely to impact water quality conditions within the Area of Analysis. Projects in the vicinity of the water quality Area of Analysis include the Brooks Mine, an existing mine located approximately five miles south of the Klamath River, near Humbug Creek, California. Any existing mining operations impacts on the Area of Analysis are accounted for in the analysis of the existing conditions. While there are potential water quality impacts from mining, these projects would be required to adhere to local, state, and/or federal mining regulations to protect water quality and implement project-specific measures to manage and reduce potential water quality impacts. Storm water management, waste discharge permits, and monitoring would all likely be necessary for any mining projects adjacent to water ways. As mining projects are required to implement such measures to reduce water quality impacts, the combined effect of the Proposed Project and mining would not result in further impacts to water quality. As such, there would be no significant cumulative water quality impact due the Proposed Project and mining projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-8 Long-term water quality effects of the Proposed Project in combination with stream-crossing infrastructure projects.

The potential cumulative effects of the Proposed Project and infrastructure projects with stream crossings on water quality were evaluated. Most of the anticipated infrastructure projects with stream crossings projects are not within the water quality Area of Analysis or the vicinity of the mainstem Klamath River (Table 3.24-1) and they would be unlikely to impact water quality conditions within the Area of Analysis. One infrastructure project with a proposed crossing of the Klamath River occurs outside of the Area of Analysis, but it is potentially significant enough to merit consideration for potential water quality impacts in the Klamath River that may flow into the Area of Analysis in California. In Oregon, the Jordan Cove Energy Project/Pacific Connector Gas Pipeline is proposed to cross the Klamath River near Klamath Falls. As it has been proposed, the pipeline would cross the Klamath River by drilling through the bedrock beneath the river.

The construction and operation of the pipeline potentially could impact water quality in the Klamath River, with potential impacts to suspended sediment and inorganic and organic contaminants, especially during construction. The time of construction is highly uncertain based on the project history; it would be speculative to assume that construction-related water quality impacts from the pipeline project would occur during the periods when short-term Proposed Project water quality impacts would occur. However, construction-related impacts that would potentially impact suspended sediment or inorganic and organic contaminants likely would be mitigated to less than significant by implementing BMPs. Additionally, the Project would be required to adhere to local, state, and/or federal regulations to protect water quality, including a Clean Water Act Section 401 Water Quality Certification from the Oregon Department of Environmental Quality that would minimize and mitigate potential long-term water quality impacts. Thus, there would be no significant cumulative water quality impacts due to the combined effect of the Proposed Project and the pipeline project.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-9 Short-term water quality effects of the Proposed Project in combination with KHSA Interim Measure 16 Water Diversion Project.

Under the KHSA Interim Measure 16 (IM 16), PacifiCorp would seek to eliminate three screened diversions (the Lower Shovel Creek Diversion [7.5 cfs], Upper Shovel Creek Diversion [2.5 cfs], and Negro Creek Diversion [5 cfs]) from Shovel and Negro creeks and would seek to modify its water rights to move the points of diversion from Shovel and Negro creeks to the mainstem Klamath River (Table 2.7-17). The screened diversions would be removed prior to dam removal. The intent of this measure is to increase flows in Shovel and Negro creeks and to increase the quality and amount of suitable habitat for aquatic species within these tributaries without diminishing PacifiCorp's water rights. The potential for sediments to enter the water during screen removal activities is minimal if the diversions are individual pump intakes. If the diversions are larger, concrete structures, the impacts would have a greater magnitude and a longer duration, but the impacts would still be short-term and due to construction/deconstruction activities. Impacts to water quality from suspended material would be minimized or eliminated through the implementation of BMPs for construction activities stipulated during permitting of IM 16. Additionally, IM 16 would be undertaken prior to dam removal, so any disturbed sediments would be trapped by Copco No. 1 Reservoir and not transferred downstream to the Klamath River prior to dam removal. The diversions would not be likely to affect other aspects of short-term or long-term water quality in the mainstem Klamath River since the water rights are relatively small (7.5 cfs, 2.5 cfs, and 5 cfs) compared to seasonal low flows in the mainstem upstream of Copco No. 1 Reservoir (typically greater than 800 cfs). The combined effect of the Proposed Project and IM16 would not result in further impacts to water quality. As such, there would be no significant cumulative water quality impact due the Proposed Project and IM 16.

Significance

No significant cumulative impact

3.24.3 Aquatic Resources

The geographic scope for cumulative aquatic resource effects is the same as the Area of Analysis for aquatic resources, as described in detail in Section 3.3.*1 [Aquatic Resources] Area of Analysis*. The geographic scope extends across five study reaches of the Klamath River including the Upper Klamath River and Connected Waterbodies, the Hydroelectric Reach in the Upper Klamath Basin, the Middle Klamath River from Iron Gate Dam to the confluence with the Trinity River, the Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment (Figure 3.3-1).

Existing conditions for aquatic resources in the Area of Analysis are described in Section 3.3.2 *[Aquatic Resources] Environmental Setting*. The aquatic species (Section 3.3.2.1 *Aquatic Species*); physical habitat in the waterbodies (Section 3.3.2.2 *Physical Habitat Descriptions*); and important factors affecting aquatic resources that the Proposed Project would influence (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project*), are also detailed. Section 3.3.2 *[Aquatic Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, aquatic resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of aquatic resource area effects (Section 3.3). The non-project activity types evaluated for potential cumulative impacts on aquatic resources shown below are those that would be likely to result in aquatic habitat alteration, changes in surface flows, and changes in water quality (water temperature, suspended sediment). While wildfire is a natural occurrence, under climate change more frequent and intense wildfires are reasonably foreseeable (Bedsworth et al. 2018) and thus wildfires are also evaluated for potential cumulative impacts on aquatic resources. The non-project activity types (plus wildfires) are included in Table 3.24-1.

Significance criteria for cumulative aquatic resources impacts are the same as defined in Section 3.3.3 *[Aquatic Resources] Significance Criteria*.

Potential Cumulative Impact 3.24-10 Long-term effects on aquatic resources from the Proposed Project in combination with restoration, flow enhancement, and water quality improvement projects.

As described in Section 3.3.5 *[Aquatic Resources] Potential Impacts and Mitigation*, the Proposed Project would increase habitat quantity and quality for aquatic resources. Other aquatic habitat restoration, flow enhancement, and water quality improvement projects along the Klamath River and its tributaries (creeks and rivers) are also anticipated to directly improve conditions for aquatic species (especially for juvenile salmonids rearing during winter), through the placement of off-channel habitat features, floodplain restoration, incorporation of large wood into tributaries to the Klamath River, increases in stream flow, and improved water quality (Table 3.24-1), thus having a beneficial effect. For example, the proposed relocation of water diversions from Shovel and Negro creeks to the mainstem Klamath River would increase the quality and amount of suitable habitat for aquatic species within these tributaries. Additionally, USBR's annual restoration funding of approximately $500,000 provided as part of its Klamath Irrigation Project operations benefits coho salmon through habitat improvements. Restoration funding is described in the 2013 BiOp and is focused on activities that provide benefits to SONCC coho salmon and those aspects of their designated critical habitat in the Klamath Basin that are most likely to be affected by Klamath Irrigation Project operations. Since 2013 many coho salmon fish passage and habitat restoration projects have been funded and implemented in the Mid- and Lower Klamath River. The Proposed Project, in combination with restoration, flow enhancement, and water quality improvement projects, would result in beneficial cumulative effects on aquatic resources.

Significance

Beneficial cumulative effects

Potential Cumulative Impact 3.24-11 Short-term increases in suspended sediments on aquatic resources under the Proposed Project in combination with 2017 court-ordered flushing and emergency dilution flows.

As discussed in Potential Cumulative Impact 3.24-2, the short-term combined impact of the Proposed Project and the 2017 court-ordered flow requirements (i.e., 2013 BiOp plus the court ordered flushing and emergency dilutions flows) would result in a cumulative increase in the suspended sediment concentrations during water years when reservoir drawdown flows are less than the surface and/or deep flushing flows. The 2017 court-ordered flushing flows are released from Iron Gate Dam for the purpose of disrupting the nidus downstream of Iron Gate Dam and reducing disease risk. High concentrations of suspended sediment and bedload sediment released during dam removal year 2 is anticipated to effectively scour and disrupt the periphyton intermediate host of the key fish diseases, and thus flushing flows and emergency dilution flows are highly unlikely to be required during the same period of impacts from the Proposed Project. In addition, the incremental effect of the increased suspended sediment on aquatic resources would be dwarfed by the substantial sediment volumes of sediment predicted to occur (described in detail in Appendix E). Therefore, the impacts predicted for aquatic resources under the Proposed Project (described in Section 3.3.5.9 *Aquatic Resource Impacts*) are no lesser, nor higher, when considered cumulatively with the 2017 court-ordered flushing and emergency dilution flows.

Significance

No significant cumulative impact in the short term

Potential Cumulative Impact 3.24-12 Long-term effects on aquatic resources from the Proposed Project in combination with forest and wildfire management activities.

The cumulative effect of the Proposed Project and the multiple forest and wildfire management projects within the aquatic resources Area of Analysis was evaluated. The forest and wildfire management project activities include commercial and non-commercial thinning in stands for forest health and fuel reduction, using prescribed fire, creating strategic fuel breaks, implementing fuel treatments including under-burning and pile burning, revegetating areas to accelerate the development of mature forest, enhancing meadow conditions, improving water temperature and sediment conditions in streams, modifying road conditions, and increasing recreational opportunities. The main water quality parameters related to aquatic resources (see Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project*) that would be potentially adversely impacted by these activities would be water temperature as vegetation removal allows more solar radiation to reach streams and the surrounding floodplain surfaces, and suspended sediment due to vegetation removal, prescribed burns, fuel treatments, and road construction and usage increasing erosion. The North Coast Regional Water Quality Control Board's Forest Activities Program issues waste discharge requirements and general waivers with terms and conditions to address the potential water quality problems potentially associated with a range of forest management activities on private and on USDA Forest Service lands. Forest and wildfire management projects within or near the aquatic resources Area of Analysis are included in Table 3.24-1.

The cumulative effect of the Proposed Project and forest and wildfire management activities would not have a significant impact on aquatic resources, since the cumulative magnitude of changes to water quality factors affecting aquatic habitat would not be anticipated to exceed the aquatic resource significance criteria. There would be no significant cumulative impact from drawdown of the Lower Klamath Project reservoirs and wildfire management activities, because drawdown would occur during November through March when forest and wildfire management activities (e.g., prescribed burns or commercial logging) would be limited. While some forest and wildfire management activities would potentially increase water temperature and suspended sediment in streams due to removal of vegetation cover and temporary or permanent road construction and usage for tree removal (i.e., logging), other activities would potentially improve long-term water quality and aquatic habitat conditions by revegetating areas, enhancing riparian cover along meadow streams, and decommissioning or downgrading roads to reduce suspended sediment delivery to streams. As a result, the net cumulative impact from the anticipated forest and wildfire management activities would be less than significant and there would not be a significant cumulative impact from the Proposed Project and forest and wildfire management activities.

Significance

No significant cumulative impact in the long term

Potential Cumulative Impact 3.24-13 Short-term and long-term effects on aquatic resources from the Proposed Project in combination with wildfires.

Wildfires also could potentially impact aquatic habitat through wildfire-related impacts to water temperature and increased suspended sediments (SSCs). In the short term and long term, the Proposed Project would decrease Klamath River water temperatures in the Hydroelectric Reach and Middle Klamath River from Iron Gate Dam to the confluence with the Salmon River during the late summer/fall compared with existing conditions (Potential Impact 3.2-1), which would help to offset potential increases in water temperatures in wildfire burn areas, should they occur within these reaches in the water quality Area of Analysis. This would generally be a benefit to aquatic resources. The Proposed Project would have no effect on water temperatures for the Middle Klamath River downstream from the Salmon River, the Lower Klamath River, and the Klamath River Estuary in the short term or the long term, thus there would be no cumulative impact on water temperature for the Proposed Project combined with wildfires.

As discussed in Potential Cumulative Impact 3.24-4, there would be a cumulatively considerable short-term impact of the Proposed Project on water quality due to increased SSCs during reservoir drawdown because the Proposed Project exceeds water quality significance criteria for SSCs, and because of the potential for an extended duration of elevated SSCs in the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary. However, short-term elevated SSCs during reservoir drawdown under the Proposed Project would result in no significant impact with mitigation for coho salmon critical habitat (Potential Impact 3.3-1), no significant short-term impact with mitigation for Chinook and coho salmon essential fish habitat (EFH) (Potential Impact 3.3-4), and no significant population impacts for multiple fish species within the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary (Potential Impacts 3.3-5 through 3.3-14). Further, the short-term cumulative increase in SSCs from a late-season (e.g., November) wildfire during dam removal year 1 or 2 that burns the landscape near or within the aquatic resources Area of Analysis and is followed by heavy rainstorms, would not be likely to increase the magnitude of SSCs outside the range modeled for the Proposed Project (see Potential Cumulative Impact 3.24-4) such that there would be no significant cumulative impact of the Proposed Project on aquatic resources in combination wildfires.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-14 Long-term effects on aquatic resources from the Proposed Project in combination with cannabis cultivation projects.

Cannabis-cultivation-related projects within the aquatic resources Area of Analysis and the Klamath Basin were assessed to determine if there would be a cumulative effect with the Proposed Project. Increased cannabis cultivation could potentially impact multiple water quality parameters that effect aquatic resources, including water temperature as flow diversions for cultivation reduce stream flows and result in more rapid warming and higher water temperatures; suspended sediment from stormwater runoff of cultivated land; and nutrients from stormwater runoff containing fertilizers. While there are potential water quality and thus aquatic resource impacts from cannabis cultivation, many of those projects are part of existing conditions and numerous regulatory agencies manage the impacts from cannabis cultivation. Additionally, the North Coast Regional Water Quality Control Board Cannabis Cultivation Waste Discharge Regulatory Program, the California Department of Food and Agriculture Cannabis Cultivation Licensing, the California Department of Pesticide Regulation, and other agencies are regulating cannabis cultivation, including water quality and waste discharge requirements. New or existing permitted cannabis cultivation projects would be required to adhere to water quality regulations and implement project-specific measures to reduce potential impacts to water quality (and thus aquatic resources). Project-specific measures detailed for several existing cannabis cultivation projects include relocating cultivation away from a stream, limiting the timing of diversions from streams, replacing unpermitted wells with permitted wells, and using drip irrigation systems to minimize water use: these changes are aimed at improving water quality over the existing condition. The potential impacts of new permitted cannabis cultivation projects would be addressed through the regulatory program, as well. As such, these changes in cannabis cultivation practices would have a less than significant impact on aquatic resources and the combination of the Proposed Project and these cannabis projects would not result in a significant cumulative impact to aquatic resources.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-15 Long-term effects on aquatic resources from the Proposed Project in combination with grazing projects and agriculture projects.

Grazing and agricultural projects may impact aquatic resources through an increase in suspended sediment within streams due to soil disturbance and increased erosion; an increase in nutrients in streams due to stormwater runoff from grazing areas containing livestock waste; and an decrease dissolved oxygen due to the biological oxygen demand from stormwater runoff containing livestock waste. Any existing grazing impacts on the Area of Analysis are accounted for the analysis of the existing condition. Additionally, most of the anticipated grazing and agricultural projects would not have the potential to impact water quality conditions in the aquatic resources Area of Analysis because they would not occur within or upstream of the Area of Analysis, including within tributaries of the Klamath River in California, where sediment, nutrients, and biological oxygen demand in runoff from grazing or agricultural lands could potentially influence water quality conditions within the Area of Analysis. Grazing projects located downstream of the Project Boundary in California, but still near the Area of Analysis, are included in Table 3.24-1.

Grazing projects would incorporate project-specific measures to reduce potential water quality impacts (and thus aquatic resource impacts), including storm water management, streambank setbacks, or exclusionary livestock fencing. Grazing (and other agricultural projects) are required to meet the requirements of the non-point source discharge policy, the prohibition against unpermitted discharges, and the North Coast Regional Water Quality Control Board's Agricultural Lands Discharge Program. These require compliance with best management practices designed to meet state water quality requirements. Grazing projects implementing such project-specific measures would have a less than significant impact on aquatic resources and the Proposed Project and these grazing projects would not result in a significant cumulative impact to aquatic resources.

Significance

No significant cumulative impact

3.24.4 Phytoplankton and Periphyton

The geographic scope for cumulative phytoplankton and periphyton effects is the same as the Area of Analysis for phytoplankton and periphyton, as described in detail in Section 3.4.1 *[Phytoplankton and Periphyton] Area of Analysis*. The geographic scope includes the Klamath River from the Hydroelectric Reach in the Upper Klamath Basin through the Lower Klamath River to its confluence with the Trinity River, the Klamath River Estuary, and the Pacific Ocean nearshore environment (Figure 3.4-1). The Upper Klamath River upstream of the Oregon-California state line (RM 214.1) is only considered to the extent that conditions in this reach influence phytoplankton and periphyton communities downstream in California.

Existing conditions for phytoplankton and periphyton in the Area of Analysis are described in Section 3.4.2 *[Phytoplankton and Periphyton] Environmental Setting*. Spatial and temporal trends in phytoplankton and periphyton conditions for the Klamath River from the Hydroelectric Reach through the Klamath River Estuary and the Pacific Ocean nearshore environment are detailed for the Area of Analysis. Phytoplankton, including blue-green algae, grow best in slow-moving, stable water conditions, so they compose the majority of the algal community in the reservoirs and occasionally occur in slow-moving water portions (e.g., backwater eddies and near shore shallows) of the mainstem Klamath River. Blue-green algae growth varies seasonally in the Hydroelectric Reach, reaching nuisance levels in the Copco No. 1 and Iron Gate reservoirs primarily during summer and fall months. In the Klamath River downstream of the Hydroelectric Reach, blue-green algae are less abundant due to limited slow-moving water habitat, but nuisance levels of blue-green algae occasionally occur when blue-green algae cells from the reservoirs drift downstream and habitat conditions in the mainstem river favor blue-green algae growth. Periphyton, including diatoms, green algae, fungi, and bacteria, primarily grow attached to the streambed and/or other underwater surfaces, so they grow best in the river reaches of the Klamath River. While periphyton are not abundant in the Hydroelectric Reach due to limited suitable habitat, periphyton dominate the algal community in the Middle and Lower Klamath River. Spatial and seasonal variations in periphyton correspond to changes in nutrients concentrations and flow conditions. Section 3.4.2 *[Phytoplankton and Periphyton Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, phytoplankton and periphyton resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of phytoplankton and periphyton resource area effects (Section 3.4 *Phytoplankton and Periphyton*). The non-project activity types evaluated for cumulative impacts on phytoplankton and periphyton shown below are those that would potentially alter the water temperature, hydrodynamic (water movement), and nutrient availability conditions in the Klamath River within the Area of Analysis. Changes in these variables due to the cumulative impact of the Proposed Project and other closely related projects could potentially increase the extent of optimal habitat for phytoplankton or periphyton in the Area of Analysis, contributing to additional impairment of designated beneficial uses. While wildfire is a natural occurrence, under climate change more frequent and intense wildfires are reasonably foreseeable (Bedsworth et al. 2018) and thus wildfires are also evaluated for potential cumulative impacts on phytoplankton and periphyton. The non-project activity types (plus wildfires) are included in Table 3.24-1.

Significance criteria for cumulative phytoplankton and periphyton impacts are the same as those defined in Section 3.4.3 *[Phytoplankton and Periphyton] Significance Criteria.*

Potential Cumulative Impact 3.24-16 Long-term phytoplankton and periphyton effects from the Proposed Project in combination with habitat restoration, flow enhancement, and water quality improvement projects.

Habitat restoration, flow enhancement, and water quality improvement projects along the Klamath River and its tributary creeks and rivers would alter phytoplankton and periphyton growth and habitat conditions by modifying the hydrodynamic and nutrient availability conditions in the Area of Analysis. Stream channel improvements, riparian habitat restoration, placement of off-channel habitat features, floodplain restoration, incorporation of large wood into tributaries to the Klamath River, and increases in stream flow in the Klamath River would all influence local phytoplankton and periphyton conditions where the restoration occurs, but these activities may have limited influence on phytoplankton and periphyton within the Area of Analysis if they occur outside of the Area of Analysis.

Habitat restoration, flow enhancement, and water quality improvement projects likely would have a beneficial effect on local phytoplankton and periphyton conditions by increasing turbulent mixing and reducing nutrient concentrations, but the creation of off-channel features may produce low mixing conditions and slow water habitat under some flow conditions, potentially leading to localized phytoplankton growth in backwater areas.

The Proposed Project conversion of reservoir areas to free-flowing river reaches would have a beneficial effect on phytoplankton conditions in the Klamath River from the Hydroelectric Reach to the Klamath River Estuary because it would eliminate slow-moving habitat that promotes nuisance and/or noxious blue-green algae blooms that are transported throughout these reaches of the Klamath River (Potential Impact 3.4-1). However, the conversion of reservoir areas to free-flowing river reaches would result in a significant and unavoidable impact on periphyton conditions because the newly created free-flowing river reaches would provide additional low-gradient habitat suitable for periphyton growth. The extent, duration, or biomass of nuisance periphyton may increase within these newly created free-flowing river reaches. Short-term and long-term nutrient increases from the release of sediment-associated nutrients or the lack of interception of nutrients behind the Lower Klamath Project dams due to the Proposed Project would be less than significant for phytoplankton and periphyton growth and habitat conditions, so they would have no significant impact on phytoplankton or periphyton (and Potential Impacts 3.4-1, 3.4-3, and 3.4-5).

As the Proposed Project would not have a significant adverse impact on phytoplankton related to restoration and flow enhancements and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no cumulative phytoplankton impacts due to the Proposed Project and habitat restoration, flow enhancement, and water quality improvement projects.

Although the Proposed Project would result in significant and unavoidable adverse impacts due to periphyton increases in the newly created free-flowing river reaches (see Potential Impact 3.4-4), there are no closely related anticipated activities associated with habitat restoration, flow enhancement, and water quality improvement projects that would, in combination with the Proposed Project, result in further significant and adverse periphyton impacts. Thus, there would be no cumulative periphyton impacts due to the Proposed Project and habitat restoration, flow enhancement, and water quality improvement projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-17 Short-term and long-term phytoplankton and periphyton effects from the Proposed Project in combination with 2017 court-ordered flushing and emergency dilution flows.

Formal consultation was reinitiated in 2017 on the NMFS and USFWS 2013 Joint Biological Opinion. Until formal consultation is completed and a new biological opinion (BiOp) issued, USBR is required to continue adhering to the 2013 BiOp Flow requirements while also releasing additional winter-spring surface and deep flushing flows and potentially emergency dilution flows (U.S. District Court 2017). New BiOp Flows would alter the hydrodynamic (i.e., flow) conditions in the Klamath River within the phytoplankton and periphyton Area of Analysis. The potential new BiOp flow requirements under the Proposed Project are speculative since the fish disease conditions that prompted the flushing and emergency dilution flow requirements would be reduced due to increased dispersal of spawners and carcasses, transport of bedload, and establishment of variable flows, even if infection itself is not eliminated (see Section 3.3.5.5 *Fish Disease and Parasites*). Further, if flushing and emergency dilution flow requirements were to continue under a new BiOp, it is not clear if the prior location of Iron Gate Dam would remain as the compliance point. Thus, this cumulative effects analysis analyzes only the 2017 flow requirements (i.e., 2013 BiOp Flows plus the 2017 court-ordered flushing and emergency dilution flows), which although not part of the existing conditions (2016), are considered to be a reasonably foreseeable flow condition until formal consultation is completed and a new BiOp is issued (see Potential Cumulative Impact 3.24-2 for more details).

The Proposed Project and 2017 flow requirements would decrease favorable growth conditions and optimum habitat availability for phytoplankton or periphyton since they are designed to limit periphyton establishment along the streambed, which also limits favorable habitat for the polychaete worm that hosts fish parasites (e.g., *C. shasta*) (see Section 3.3.5.5 *Fish Disease and Parasites*). Additionally, an increase in the frequency of higher flushing flows and emergency dilution flows between November and June would increase turbulent flows in the Klamath River, reducing the extent of slow-water habitat that favors phytoplankton growth. The Proposed Project would eliminate slow-water habitat in the reservoir areas and convert those areas into more turbulent free-flowing reaches that would not support extensive phytoplankton blooms, including blue-green algae blooms (Potential Impact 3.4-2). As such, the cumulative effect of the Proposed Project combined with an increase the frequency of flushing flows and emergency dilution flows would result in a beneficial effect by further reducing the availability of slow-water habitat that supports nuisance and/or noxious phytoplankton blooms.

The increase in the frequency of higher flushing flows and emergency dilution flows between November and June under the 2017 flow requirements would also increase sediment movement and streambed scour in the Klamath River, reducing conditions where periphyton could establish along the streambed when flushing flows or emergency dilution flows are occurring. As discussed in Section 3.4.5.2 *Periphyton*, the Proposed Project drawdown flows would mobilize streambed sediments and scour periphyton attached to the streambed, especially at higher flows that move larger sediments like cobbles (Potential Impact 3.4-3). Although the Proposed Project would result in an increase in periphyton and a potentially significant and unavoidable short-term and long-term increase in nuisance periphyton along the Hydroelectric Reach due to the conversion of the reservoir areas to a free-flowing river and elimination of hydropower peaking operations, the cumulative effect of increase in the frequency of higher flushing flows and emergency dilution flows would be beneficial and reduce the extent, duration, and biomass of nuisance periphyton.

Overall, the combined effect from the Proposed Project and the 2017 flow requirements would reduce the spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton blooms and the spatial extent, temporal duration, or biomass of nuisance periphyton. The combined effect from the Proposed Project and the 2017 flow requirements would potentially have a short-term and long-term beneficial effect in the Hydroelectric Reach and the Middle Klamath River by increasing streambed scour and reducing or eliminating the growth and establishment of nuisance periphyton growth during higher November through June flow conditions.

As the Proposed Project would not have a significant adverse impact on phytoplankton (Potential Impacts 3.4-1 and 3.4-2) and the flushing flows and emergency dilution flows in the 2017 flow requirements would increase turbulent flows in the Klamath River and reduce the extent of slow-water habitat that favors phytoplankton growth, there would be beneficial cumulative effects on phytoplankton due to the combined effects of the Proposed Project and the 2017 flow requirements.

Although the Proposed Project would result in significant and unavoidable adverse impacts due to periphyton increases, there are no closely related anticipated activities associated with the 2017 flow requirements that would, in combination with the Proposed Project, result in further significant and adverse periphyton impacts. Thus, there would be no significant cumulative periphyton impacts due to the Proposed Project associated with the 2017 flow requirements.

Significance

Beneficial cumulative effects for phytoplankton

No significant cumulative impact for periphyton

Potential Cumulative Impact 3.24-18 Short-term and long-term phytoplankton and periphyton effects from the Proposed Project in combination with forest and wildfire management projects.

In the phytoplankton and periphyton Area of Analysis, anticipated forest and wildfire management projects would involve thinning in stands for forest health and fuel reduction, using prescribed fire, creating strategic fuel breaks, implementing fuel treatments including under-burning and pile burning, revegetating areas to accelerate the development of mature forest, enhancing meadow conditions, improving water temperature and sediment conditions in streams, modifying road conditions, and increasing recreational opportunities. Vegetation removal or enhancement near streams would potentially affect phytoplankton and periphyton, since the activities would potentially alter the solar radiation and water temperature in the streams. Additional solar radiation from vegetation removal would potentially enable more phytoplankton or periphyton photosynthesis and growth. Higher water temperatures may potentially increase phytoplankton or periphyton growth and/or production of blue-green algae toxins, if the duration that water temperatures are within growth or toxin production optimum temperatures increases. Forest and wildfire management projects may also alter suspended sediment conditions in streams due to vegetation modifications (e.g., removal or enhancement), prescribed burns, fuel treatments, and road construction and usage increasing erosion. Reductions in suspended sediment would increase light availability in the stream, especially at the streambed, potentially increasing phytoplankton or periphyton photosynthesis and growth. While phytoplankton and periphyton are not directly addressed by the North Coast Regional Water Quality Control Board's Forest Activities Program, the program issues waste discharge requirements and general waivers with terms and conditions to address the potential water quality problems (e.g., water temperature or suspended sediment increases) potentially associated with a range of forest management activities on private and on USDA Forest Service lands (North Coast Regional Board 2018c).

Reasonably foreseeable forest and wildfire management projects within or near the water quality Area of Analysis are included in Table 3.24-1. The Proposed Project and forest and wildfire management activities would result in no significant cumulative impact on phytoplankton and periphyton because the cumulative magnitude of changes to solar radiation, water temperature, or suspended sediment would not be anticipated to alter phytoplankton and periphyton growth conditions in the Area of Analysis. Most anticipated forest and wildfire management activities are not located near the Area of Analysis, so potential overlap between the effects of the Proposed Project and forest and wildfire management activities is limited. Potential changes to solar radiation, water temperature, and/or suspended sediment from forest and wildfire management activities may alter local habitat and growth conditions for phytoplankton and periphyton, but they would be unlikely to alter habitat and growth conditions within the Area of Analysis. Additionally, Proposed Project impacts associated with drawdown (e.g., Potential Impact 3.4-1 and 3.4-3) would primarily occur during November through March when forest and wildfire management activities (e.g., prescribed burns or commercial logging) are less likely to occur. Forest and wildfire management activities would also have opposing effects on phytoplankton and periphyton growth, further limiting the cumulative effect of those near the Area of Analysis. Vegetation removal and temporary or permanent road construction and usage for tree removal (i.e., logging) would potentially increase phytoplankton and periphyton growth in the local vicinity of the project due to increases in solar radiation and water temperature or reductions in suspended sediment, but revegetating areas, enhancing riparian cover along meadow streams, and decommissioning or downgrading roads to reduce suspended sediment delivery to streams activities would potentially decrease phytoplankton and periphyton growth by reducing solar radiation and water temperature or increasing suspended sediment.

As the Proposed Project would not have a significant adverse impact on phytoplankton and periphyton related to forest and wildfire management and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative phytoplankton or periphyton impacts in the short term or long-term due to the Proposed Project associated with forest and wildfire management.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-19 Short-term and long-term phytoplankton and periphyton effects of the Proposed Project in combination with potential wildfire. Wildfires regularly occur within the Klamath Basin, with multiple large fires occurring in 2016 through 2018 (see also Table 3.24-1), and fires likely to occur in future years. Wildfires could potentially increase phytoplankton and periphyton growth by reducing the vegetation cover around streams, resulting in more solar radiation reaching the stream and warmer water temperatures. Phytoplankton and periphyton growth may also decrease due to wildfires as increases in suspended sediment from increased erosion in burn areas reduce light availability for growth. While there are potential phytoplankton and periphyton growth and habitat effects from wildfires, the magnitude of fires and their proximity to the phytoplankton and periphyton Area of Analysis would likely determine the cumulative impact of wildfires.

The Proposed Project would not have a significant short-term or long-term impact on phytoplankton (Potential Impacts 3.4-1 and 3.4-2), but it would have a long-term beneficial effect by reducing available habitat suitable for blue-green algae growth in the Hydroelectric Reach and transport of blue-green algae downstream of the Hydroelectric Reach. Wildfires may locally effect phytoplankton habitat in the phytoplankton and periphyton Area of Analysis if they occur immediately adjacent or upslope from the Klamath River, but these local effects would be unlikely to significantly alter the availability or suitability of phytoplankton habitat in the Klamath River. While a late-season (e.g., November) wildfire that burns near or within the phytoplankton and periphyton Area of Analysis followed by heavy rain would result in a potential short-term cumulative increase in the SSCs (see Potential Cumulative Impact 3.24-4), this would occur during late-fall/winter conditions when phytoplankton growth is already naturally low due to less light availability and colder temperatures and there would be minimal change in phytoplankton growth due less vegetation along the river edge or an increase in SSC and turbidity. Thus, the overall effects of wildfire on phytoplankton habitat and growth would be limited and wildfires would be unlikely to produce an increase in the extent, duration, toxicity, or concentration of nuisance and/or noxious phytoplankton blooms, including blue-green algae, in the Area of Analysis that would combine with the Proposed Project effects to result in a significant and adverse impact on phytoplankton.

There were no significant short-term or long-term impacts in the Klamath River from the Proposed Project due to changes in nutrients (Potential Impact 3.4-3 and Potential Impact 3.4-5), since the increase in nutrients either occurred during periods when periphyton growth rates were low or nutrient increases were offset by other competing processes that would limit overall periphyton growth. However, the Proposed Project would result in significant and unavoidable adverse impacts for periphyton due to increases in available low-gradient channel margin habitat in the Hydroelectric Reach from conversion of the reservoir areas to free-flowing river (Potential Impact 3.4-4). Wildfires would not significantly alter nutrient conditions in the Klamath River or the availability of periphyton habitat in the Klamath River. As such, the combined effect of the Proposed Project and wildfires would be unlikely to produce an increase in the spatial extent, temporal duration, or biomass of nuisance periphyton in the Area of Analysis that would result in a significant and adverse impact.

As the Proposed Project would not have a significant adverse impact on phytoplankton and periphyton related to wildfire and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative phytoplankton or periphyton impacts in the short term or long-term due to the Proposed Project associated with wildfires.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-20 Short-term and long-term phytoplankton and periphyton effects from the Proposed Project in combination with potential cannabis cultivation.

There are numerous anticipated cannabis cultivation projects within the Klamath Basin that could potentially affect phytoplankton and periphyton growth in the Klamath River. Flow diversions for cultivation reduce stream flows, result in more rapid warming and higher water temperatures, and increase light availability at the streambed for periphyton growth. Erosion of cultivated land potentially increases suspended sediment, reducing light availability in streams. Stormwater runoff containing fertilizer potentially increases nutrient loading in streams, promoting additional phytoplankton or periphyton growth.

While there are potential phytoplankton and periphyton impacts from cannabis cultivation, many cannabis cultivation projects are part of existing conditions and numerous regulatory agencies manage the water diversions and water quality effects of runoff from cannabis cultivation. New or existing permitted cannabis cultivation projects would be required to adhere to these regulations and implement project-specific measures to minimize or reduce to less than significant potential water quality impacts that could alter phytoplankton and periphyton conditions in streams. Additionally, most of the cannabis cultivation projects listed in Table 3.24-1 include a specified location identified in permitting documents and are not located near the phytoplankton and periphyton Area of Analysis, so potential impacts from cannabis cultivation would be unlikely to significantly overlap with the Proposed Project impacts. Short-term and long-term nutrient increases from the release of sediment-associated nutrients or the lack of interception of nutrients behind the Lower Klamath Project dams due to the Proposed Project are expected to have no significant impact on phytoplankton or periphyton (Potential Impact 3.4-3 and Potential Impacts 3.4-1 and 3.4-5). As the Proposed Project would not have a significant adverse impact on phytoplankton and periphyton related to cannabis cultivation and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative phytoplankton or periphyton impacts in the short term or long-term due to the Proposed Project associated with cannabis cultivation.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-21 Short-term and long-term phytoplankton and periphyton effects from the Proposed Project in combination with grazing and agricultural projects.

Phytoplankton and periphyton growth and habitat conditions in the Klamath River could potentially be altered by grazing and agricultural projects because they would potentially increase the solar radiation and water temperature in the streams due to reductions in riparian vegetation (grazing); decrease light availability within streams due to increased suspended sediment from soil disturbance and increased erosion (grazing and agriculture); and increase nutrients in streams due to stormwater runoff from areas containing livestock waste (grazing) or fertilizers (agriculture). However, most of the anticipated grazing and agricultural projects would not have the potential to impact phytoplankton and periphyton conditions because they would not be within the phytoplankton and periphyton Area of Analysis or the vicinity of the mainstem Klamath River (Table 3.24-1). Reasonably foreseeable grazing and agricultural projects near the phytoplankton and periphyton Area of Analysis include Dry Lake and Horse Creek Grazing Allotment, Lake Mountain & Middle Tompkins Grazing Allotment, and Cannaworx Zone Change (see also Table 3.24-1).

Additionally, future public land grazing allotment environmental assessments and approvals along with any reviews and approvals required for agricultural projects would reasonably incorporate project-specific measures to reduce potential water quality impacts, including storm water management, streambank setbacks, or exclusionary livestock fencing. Grazing and agricultural projects are required to meet the requirements of the North Coast Regional Water Quality Control Board’s Agricultural Lands Discharge Program, including a series of waivers of waste discharge requirements when applicants comply with best management practices designed to meet state water quality requirements, the State Nonpoint Source Policy, and the TMDLs in specific watersheds (North Coast Regional Board 2018a). These project-specific measures would reduce the potential effects to phytoplankton and periphyton growth and habitat conditions because the primary effects of grazing and agriculture on phytoplankton and periphyton growth are due to changes in the water quality (e.g., water temperature, suspended sediment, or nutrients). Grazing and agricultural projects implementing such project-specific measures would reduce their impact on phytoplankton and periphyton growth. As discussed under Potential Impact 3.4-1, 3.4-3, and 3.4-5, the short-term and long-term nutrient increases from the release of sediment-associated nutrients or the lack of interception of nutrients behind the Lower Klamath Project dams due to the Proposed Project are less than significant for phytoplankton and periphyton growth and habitat conditions, so they would have no significant impact on phytoplankton or periphyton. As the Proposed Project would not have a significant adverse impact on phytoplankton and periphyton related to grazing and agricultural projects and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative phytoplankton or periphyton impacts in the short term or long-term due to the Proposed Project and grazing and agricultural projects.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-22 Short-term and long-term phytoplankton and periphyton effects from the Proposed Project in combination with mining.
Most of the anticipated mining projects are not within the phytoplankton and periphyton Area of Analysis or the vicinity of the mainstem Klamath River (Table 3.24-1), so they would not impact phytoplankton and periphyton conditions within the Area of Analysis. Projects in the vicinity of the phytoplankton and periphyton Area of Analysis include the Brooks Mine, an existing mine located approximately five miles south of the Klamath River, near Humbug Creek, California. Any existing mining operations impacts on the phytoplankton and periphyton Area of Analysis are accounted for in the analysis of the existing conditions. Mining could potentially alter light availability for phytoplankton and periphyton in the Klamath River by increasing suspended sediment conditions, but since mining projects would be required to adhere to local, state, and/or federal mining regulations to protect water quality and implement project-specific measures to manage and reduce potential water quality impacts, there would be no cumulative impact. Stormwater management, waste discharge permits, and monitoring would all likely be necessary for any mining projects adjacent or draining to waterways. Mining projects implementing such project-specific measures would reduce their impacts on phytoplankton and periphyton growth. There are no significant adverse phytoplankton or periphyton impacts due to suspended sediment concentrations under the Proposed Project (Potential Impact 3.4-4 and Potential Impacts 3.4-1, 3.4-2, 3.4-3, and 3.4-5). As the Proposed Project would not have a significant adverse impact on phytoplankton and periphyton related to mining cultivation and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative phytoplankton or periphyton impacts in the short term or long-term due to the Proposed Project and mining projects.

Significance
No significant cumulative impact

3.24.5 Terrestrial Resources

The Primary Area of Analysis for terrestrial resources includes the area within the Limits of Work, a 0.25- to 1.0-mile buffer surrounding the Limits of Work, and a 0.25-mile buffer of the Klamath River from the California border to the Pacific Ocean (Figure 3.5-1).

Existing conditions for terrestrial resources are described in Section 3.5.2 *[Terrestrial Resources] Environmental Setting*. The Primary Area of Analysis for terrestrial resources includes diverse habitats, ranging from wetland surfaces just below sea level in the Klamath River Estuary (-0.16 feet elevation) to the slopes above the Upper Klamath River near the California-Oregon state line (3,428 feet elevation), and includes 19 different CWHR vegetation types. These vegetation types have the potential to support numerous special-status plant and wildlife species; species with the potential to occur in the Primary Area of Analysis for terrestrial resources are provided in Tables 3.5-4 and 3.5-5 and information about documented occurrences of special-status species within the Primary Area of Analysis for terrestrial resources are provided in Section 3.5.2 *[Terrestrial Resources] Environmental Setting*. Section 3.5.2 *[Terrestrial Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, terrestrial resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of terrestrial resource area effects (Section 3.5). Non-project activity types within the Primary Area of Analysis for terrestrial resources with the potential for significant cumulative impacts to terrestrial resources are those that may result in noise, ground disturbance, habitat alteration, and/or changes to water flows and water quality, and are included in Table 3.24-1.

Significance criteria for cumulative terrestrial resources impacts are the same as defined in Section 3.5.3 *[Terrestrial Resources] Significance Criteria*.

Potential Cumulative Impact 3.24-23 Long-term effects on terrestrial resources from the Proposed Project in combination with restoration, flow enhancement, and water quality improvement projects.

The Proposed Project includes restoration elements, as defined in the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*), that would be beneficial to willow flycatcher (Potential Impact 3.5-12), rare natural communities, wetlands, and riparian vegetation (Potential Impact 3.5-24), as well as wildlife movement corridors (Potential Impact 3.5-29). The other reasonably foreseeable restoration, flow enhancement, and water quality improvement projects within or near the Primary Area of Analysis for terrestrial resources (Table 3.24-1) would also enhance terrestrial resources in the long term by restoring native vegetation and creating beneficial wildlife habitat (e.g., western pond turtle basking habitat, foothill yellow-legged frog breeding habitat) through activities such as the placement of off-channel habitat features, floodplain restoration, and incorporation of large wood into tributaries to the Klamath River. The Proposed Project, in combination with reasonably foreseeable restoration, flow enhancement, and water quality improvement projects, would result in beneficial cumulative effects on terrestrial resources.

Significance

Beneficial cumulative effects

Potential Cumulative Impact 3.24-24 Short-term effects on terrestrial resources from the Proposed Project in combination with 2017 court-ordered flushing and emergency dilution flows.

The 2013 BiOp Flows have been analyzed under the individual resource sections for the Proposed Project. Potential Impact 3.24-1 in Section 3.24.2 *Cumulative Water Quality*

Effects provides background and context regarding agency re-consultation on the 2013 Joint Biological Opinion. For the reasons set out in Potential Impact 3.24-1, this analysis only considers the 2017 court-ordered flow requirements, which are not part of the existing conditions, and are a reasonably foreseeable flow condition; this analysis does not consider the potential new BiOp. The court-ordered flushing and emergency dilution flows are required primarily to reduce *C. Shasta* infection of Klamath River salmonids. Potential Impact 3.24-1 determines that it is unlikely that there would be exceedances of disease thresholds that would trigger emergency dilution flows In the short term, particularly in dam removal year 2; therefore, emergency dilution flows are not expected to temporally overlap with the Proposed Project. 2017 court-ordered flushing flows may overlap in space and time with the Proposed Project, thus are the focus of this analysis.

Sediment discharge, sedimentation, and impacts to channel morphology from the Proposed Project are not expected to substantially adversely impact in-channel and riparian vegetation downstream of Iron Gate Dam (Potential Impact 3.5-4). This is because vegetation growing within, or along, the river channel margins can likely withstand, or revegetate following, this scale of perturbation, which is not dissimilar to seasonal and inter-annual river system dynamics over the past century. Conversely, sediment discharge, sedimentation, and changes to channel morphology would result in potentially significant impacts to the foothill yellow-legged frog (Potential Impact 3.5-16).

In years where reservoir drawdown flows would not meet the magnitude or duration of flushing flow requirements, surface and/or deep flushing flows may be implemented to meet the 2017 court-ordered flow requirements, which would be additional to flows from the Proposed Project. Although the magnitude of flows would not be greater than assessed in Section 3.5.5 *[Terrestrial Resources] Impacts and Mitigation*, there are one to two months when flushing flows may occur outside of the Proposed Project reservoir drawdown period (November 1 to March 15) since surface flushing flows potentially would occur until April 30 and deep flushing flows potentially would occur until May 31. Given that the surface and/or deep flushing flows are within the range of flows modeled for the Proposed Project, it is unlikely that sediment discharge, sedimentation, and impacts to channel morphology, would exceed what in-channel riparian vegetation can withstand, or that vegetation would not revegetate in a few years, due to the combination of flushing flows and reservoir drawdown.

With regard to wildlife, the combination of the Proposed Project and the 2017 court-ordered surface and/or deep flushing flows would extend the period of high flows that could scour foothill yellow-legged frog eggs or displace tadpoles (Potential Impact 3.5-16); however since flows would be expected to remain below the 10-year flood event, the incremental impact of the Proposed Project to potential scour of foothill yellow-legged frog eggs would not be cumulatively considerable.

Significance

No significant cumulative impact on riparian vegetation or wildlife

Potential Cumulative Impact 3.24-25 Short-term effects on terrestrial resources from forest and wildfire management.

The Proposed Project includes ground-disturbing activities (i.e., construction) that would have significant short-term impacts on wetlands and riparian habitats before mitigation (Potential Impact 3.5-1). Additionally, the Proposed Project includes ground-disturbing activities (i.e., construction and dam removal) that would have significant and unavoidable impacts on special-status plant species and rare natural communities (Potential Impacts 3.5-7 and 2.5-8). The Proposed Project would also result in noise and habitat modifications that would have significant short-term impacts on terrestrial wildlife species before mitigation (Potential Impact 3.5-10 for amphibians and reptiles), and a significant and unavoidable impacts on some other terrestrial wildlife species (Potential Impacts 3.5-10 for other special-status wildlife species, 3.5-11, 3.5-12, 3.5-13, and 3.5-14). Other forest and wildfire management activities within the Primary Area of Analysis for terrestrial resources (Table 3.24-1) could result in improved forest health and open understory for wildlife to traverse and create habitat for wildlife that use mature forests; however, there are potential impacts on terrestrial resources from forest and wildfire management activities. For example, if a forest and wildfire management project occurred during the breeding season, adults may abandon young and/or young may be trapped and unable to escape. Most known forest and wildfire management projects are not close to the mainstem Klamath River, except the Somes Bar Integrated Fire Management Project (approximately 90 miles downstream of Humbug), and Crawford Vegetation Management Project (approximately 70 miles downstream of Humbug). Although details of implementation methods for other planned forest and wildfire management activities are currently speculative, these projects would be required to adhere to state and/or federal guidelines (e.g., CEQA, California Endangered Species Act [CESA], and California Forest Practice Rules) which ensure that sensitive habitats (e.g., wetlands), rare natural communities, and special-status plant and wildlife species are inventoried prior to project implementation and avoided, or that mitigation is applied where necessary. Given that the other known forest and wildfire management projects are expected to adhere to state and/or federal guidelines, there would be no significant cumulative ground-disturbing, noise, or habitat modification impacts from the Proposed Project in combination with forest and wildfire management projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-26 Short-term effects on terrestrial resources from the Proposed Project in combination with wildfire.

The Proposed Project includes ground-disturbing activities (i.e., construction) that would have significant short-term impacts on wetlands and riparian habitats before mitigation (Potential Impact 3.5-1). Additionally, the Proposed Project includes ground-disturbing activities (i.e., construction and dam removal) that would have significant and unavoidable impacts on special-status plant species and rare natural communities (Potential Impacts 3.5-7 and 2.5-8). The Proposed Project would result in noise and habitat modifications that would have significant short-term impacts on terrestrial wildlife species before mitigation (Potential Impact 3.5-10 for amphibians and reptiles). Additionally, the Proposed Project would result in noise and habitat modifications that would have significant and unavoidable impacts on terrestrial wildlife species (Potential Impact 3.5-10 for other special-status wildlife species, 3.5-11, 3.5-12, 3.5-13, and 3.5-14).

Wildfires regularly occur within the Klamath Basin, with multiple fires occurring in 2016 through 2018 (Table 3.24-1). Due to climate change, forests will be more susceptible to extreme wildfires, with an almost 50 percent increase in the frequency of extreme wildfires that burn over approximately 25,000 acres, and a 77 percent increase in the average area burned statewide by the end of the century (Bedsworth et al. 2018). Large fires can burn hundreds to thousands of acres; for example, in 2016 844 acres were burned in Siskiyou County. Although wildfires are a natural occurrence in California and low burning fires can improve forest health, potential impacts on special-status wildlife and plant species may occur. For example, if a wildfire occurred during the breeding season, adults may abandon young and/or young may be trapped and unable to escape. If a large fire occurs in the Primary Area of Analysis for terrestrial resources during the construction period for the Proposed Project, work would be suspended due to health and safety reasons (see Potential Cumulative Impact 3.24-34 [*Air Quality]*); therefore, temporal overlap is unlikely. If a large fire occurs in the Primary Area of Analysis for terrestrial resources immediately before or after the construction period for the Proposed Project, there could be a significant cumulative impact to terrestrial resources from the combination of the Proposed Project and wildfire, as the area affected would be increased, and the duration of time wildlife and vegetation are affected would be extended. However, the area of terrestrial resources affected by wildfire would likely be substantially greater than the confined construction, staging, and access areas affected by the Proposed Project; therefore, the incremental effect of the Proposed Project to terrestrial resources would not be cumulatively considerable in the context of wildfire.

<u>Significance</u>

Not cumulatively considerable

Potential Cumulative Impact 3.24-27 Short-term and long-term effects on terrestrial resources from the Proposed Project in combination with agriculture, including cannabis cultivation.

The Proposed Project includes ground-disturbing activities (i.e., construction) that would have significant short-term impacts on wetlands and riparian habitats before mitigation (Potential Impact 3.5-1), and ground-disturbing activities (i.e., construction and dam removal) that would have significant and unavoidable impacts on special-status plant species and rare natural communities (Potential Impacts 3.5-7 and 2.5-8). Additionally, the Proposed Project would result in noise and habitat modifications that would have significant short-term impacts on terrestrial wildlife species before mitigation (Potential Impact 3.5-10 for amphibians and reptiles), and significant and unavoidable impacts on some other terrestrial wildlife species (Potential Impact 3.5-10 for other special-status wildlife species, 3.5-11, 3.5-12, 3.5-13, and 3.5-14). Most agricultural projects, including cannabis cultivation projects, are reauthorizations of existing activities (Table 3.24-1) thus are captured by existing conditions, or are situated far from the Hydroelectric Reach where primary disturbances will take place for the Proposed Project; except for the adopted Cannaworx Zone Change near Humbug. Modifications to policies for agricultural zones to support pastured hog and poultry operations, as well as agritourism, are also underway in Siskiyou County (Table 3.24-1). Although details of implementation methods for other grazing projects are currently speculative, grazing management plans are required to adhere to state and/or federal guidelines which ensure that sensitive habitats (e.g., wetlands), rare natural communities, and special-status plant species are inventoried prior to project implementation and avoided, or that mitigation is applied where necessary. Additionally, there is a suite of relevant legislation for cannabis cultivation projects (see Potential Cumulative Impact 3.24-5 for details). Given that any closely related agricultural projects that do fall within the Primary Area of Analysis are expected to adhere to state and/or federal guidelines, any adverse ground-disturbing impact to terrestrial resources is unlikely to be cumulatively significant.

Implementation of the Proposed Project would provide long-term benefits to wildlife by increasing connectivity within the Primary Area of Analysis for terrestrial resources (Potential Impact 3.5-29). Specifically, the Proposed Project enables wildlife movement by removing the Lower Klamath Project reservoirs and dam structures, incorporating wildlife-friendly fencing, allowing for the movement of wildlife such as deer and elk, which would be placed around the reservoirs to increase the success of restoring the reservoir areas (Section 2.7.4 *Restoration Within the Reservoir Footprint*), and incorporating the use of grazing animals (sheep, goats) to control invasive species (2.7.5 *Restoration of Upland Areas Outside of the Reservoir Footprint*). Grazing projects (Table 3.24-1) within or near the Primary Area of Analysis for terrestrial resources may result in reduced habitat connectivity with the installation of any new fences, ground disturbance, and reduced water quantity and quality affecting special-status terrestrial species, such as amphibians and reptiles. Although some other grazing projects could reduce wildlife connectivity through fencing installation, because the Proposed Project would increase connectivity, there would be no cumulative wildlife connectivity impacts on terrestrial resources due to implementation of the Proposed Project and grazing projects.

Cannabis cultivation projects and grazing and agricultural projects (Table 3.24-1) within or near the Primary Area of Analysis for terrestrial resources may result in reduced water quality affecting special-status terrestrial species such as amphibians and reptiles. Please see Potential Cumulative Impacts 3.24-25 and 3.24-26 for a discussion of the potential cumulative water quality impacts of the Proposed Project in combination with cannabis cultivation projects and grazing and agricultural projects. Given that Potential Cumulative Impacts 3.24-25 and 3.24-26 determine *no significant cumulative impact*, a follow-on cumulative impact to terrestrial species from adverse water quality is not foreseeable, and there would be no significant cumulative impact to terrestrial resources from cumulatively adverse water quality conditions.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-28 Short-term effects on terrestrial resources from the combination of the Proposed Project and mining.

The Proposed Project includes ground-disturbing activities (i.e., construction) that would have significant short-term impacts on wetlands and riparian habitats before mitigation (Potential Impact 3.5-1), and ground-disturbing activities (i.e., construction and dam removal) that would have significant and unavoidable impacts on special-status plant species and rare natural communities (Potential Impacts 3.5-7 and 2.5-8). The Proposed Project would also result in noise and habitat modifications that would have significant short-term impacts on terrestrial wildlife species before mitigation (Potential Impact 3.5-10 for amphibians and reptiles), and a significant and unavoidable impacts on terrestrial wildlife species (Potential Impact 3.5-10 for other special-status wildlife species, 3.5-11, 3.5-12, 3.5-13, and 3.5-14). Mining projects within the Primary Area of Analysis for terrestrial resources (Table 3.24-1) could also result in ground disturbance. Most other mining projects are withdrawal or remediation projects, renewals of existing permits in Del Norte County, or are situated in the Salmon River sub-basin (far from the

Hydroelectric Reach), with the exception of the new Plan of Operations for the existing Brooks Mine (Table 3.24-1). The new plan of operations for the Brooks Mine is near the expected hydrological and sedimentation footprint from dam removal, which extends downstream to Humbug Creek. Although details of implementation methods for mining projects are currently speculative, these projects would be required to adhere to state and/or federal guidelines, which would ensure that sensitive habitats (e.g., wetlands), rare natural communities, and special-status plant species are inventoried prior to project implementation and avoided, or that mitigation is applied where necessary. Given that the only expected mining project within the Primary Area of Analysis for terrestrial resources is a new plan of operations there would be no significant ground-disturbing impact to terrestrial resources from the combination of the Proposed Project and other closely related mining projects.

Mining projects (Table 3.24-1) within or near the Primary Area of Analysis for terrestrial resources may result in reduced water quality affecting special-status terrestrial species such as amphibians and reptiles. The majority of mining projects are located outside of the terrestrial Primary Area of Analysis. A new (20-acre) Plan of Operations for the existing Brooks Mine (Table 3.24-1) is near the expected hydrological and sedimentation footprint from dam removal, which extends downstream to Humbug Creek. Impacts from mining projects on water quality, and terrestrial wildlife that use waterways, would be anticipated to be less than significant, since mining projects would be required to adhere to existing water quality regulations and implement project-specific measures (e.g., storm water management). Although the Proposed Project would result in significant and unavoidable adverse impacts due to short-term water quality impacts (as described in Cannabis Cultivation above), there are no closely related grazing projects that would, in combination with the Proposed Project, result in further significant and adverse impacts to water quality that would cumulatively affect terrestrial wildlife. Thus, there would be no cumulative water quality impacts on terrestrial wildlife due to the Proposed Project in combination with closely related mining projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-29 Short-term effects on terrestrial resources from the Proposed Project in combination with development and infrastructure projects.

The Proposed Project includes ground-disturbing activities (i.e., construction) that would have: significant short-term impacts on wetlands and riparian habitats before mitigation (Potential Impact 3.5-1). Additionally, the Proposed Project includes ground-disturbing activities (i.e., construction and dam removal) that would have significant and unavoidable impacts on special-status plant species and rare natural communities (Potential Impacts 3.5-7 and 2.5-8). The Proposed Project would also result in noise and habitat modifications that would have significant short-term impacts on terrestrial wildlife species before mitigation (Potential Impact 3.5-10 for amphibians and reptiles), and a significant and unavoidable impacts on terrestrial wildlife species (Potential Impact 3.5-10 for other special-status wildlife species, 3.5-11, 3.5-12, 3.5-13, and 3.5-14). Development activities (Table 3.24-1) could have overlapping adverse impacts; however, no large-scale development projects are proposed within the Primary Area of Analysis for terrestrial resources. Development projects such as the potential nanocellulose facility in Yreka, are urban and considered to be too far away from the footprint of the Proposed Project to result in a cumulative impact to terrestrial resources.

Some potential infrastructure projects that involve crossings of tributaries to the Klamath River, including the Ayres Waterline near Grider Creek, and Siskiyou Telephone Fiber Optic Cable Installation near Clear Creek and Dillon Creek, but these are not reported as needing to cross the mainstem Klamath River and are downstream of the Hydroelectric Reach. No relevant development or infrastructure projects have been identified that, in combination with the Proposed Project, would result in significant adverse cumulative impacts to terrestrial resources.

Significance

No significant cumulative impact

3.24.6 Flood Hydrology

The geographic scope for cumulative flood hydrology effects is the same as the Area of Analysis for flood hydrology, as described in in Section 3.6.1 *[Flood Hydrology] Area of Analysis.* This includes the Klamath River downstream of the Oregon-California state line, which lies in portions of three California counties (Siskiyou, Humboldt, and Del Norte) (Figure 3.6-1). Hydrologic characteristics of features in the Upper Klamath Basin in Oregon are considered as they may pertain to potential impacts to stream flows into California.

Existing conditions for flood hydrology are detailed in Section 3.6.2 *[Flood Hydrology] Environmental Setting*, which provides a description of basin hydrology including precipitation; reservoirs; major rivers and tributaries; lakes; springs and seeps providing measurable flow; historical stream flows; and flood hydrology. Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* also provides relevant information related to recent management decisions that dictate Klamath River flows downstream of Iron Gate Dam. These include the 2013 BiOp Flows and the 2017 court-ordered flushing and emergency dilution flows. Section 3.6.2 *[Flood Hydrology] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, flood hydrology resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of flood hydrology resource area effects (Section 3.6). Non-project activity types within the flood hydrology Area of Analysis with the potential for significant cumulative flood hydrology effects are included in Table 3.24-1.

Significance criteria for cumulative flood hydrology effects are the same as defined in Section 3.6.3 *Significance Criteria* for the flood hydrology resource.

Potential Cumulative Impact 3.24-30 Short-term and long-term flood hydrology effects from the Proposed Project in combination with other non-project activities.
Ongoing and reasonably foreseeable aquatic and riparian habitat restoration projects on the Klamath River have the potential for beneficial effects related to flood hydrology. Restoration projects are often designed to enhance river-floodplain connectivity in reaches with high habitat value (e.g., Mid Klamath Floodplain Assessment and Mine Tailing Remediation Plan), which provides accommodation space for flood flows and beneficial locations for depositing fine sediment.

Formal consultation of the 2013 BiOp flows was reinitiated in 2017 to improve management of *Ceratanova shasta (C. shasta)* infection among coho salmon in the Klamath River. Although specific flow details for a new BiOp resulting from re-consultation are speculative at this time, flow changes in the Klamath River due to a new BiOp (or the 2017 court-ordered flushing and emergency dilution flows [U.S. District Court 2017]) are not expected to alter flood hydrology or the FEMA 100-year floodplain in the Area of Analysis. This is because BiOp's specify minimum flow releases and do not impact peak flows during flood events.

Reasonably foreseeable large-scale development projects (see Table 3.24-1) within the flood hydrology Area of Analysis are not located within the 100-year floodplain between the Oregon-California state line and the Humbug Creek confluence, which is the reach where the Proposed Project has the potential to significantly impact the 100-year floodplain. Therefore, there would not be a significant and adverse combined impact of the Proposed Project and other large-scale development projects.

Although the Proposed Project would result in significant and unavoidable adverse impacts due to exposing structures to a substantial risk damage due to flooding (Potential Impact 3.6-3), there are no closely related projects that would, in combination with the Proposed Project, result in further significant and adverse flood hydrology impacts. Thus, there would be no significant cumulative flood hydrology impacts due to the Proposed Project and flow release and floodplain development projects. Additionally, there would be beneficial cumulative effects due to the Proposed Project and habitat restoration projects.

<u>Significance</u>

Beneficial cumulative effects for the combination of the Proposed Project and riverine restoration

No significant cumulative impact for other non-project activities

3.24.7 Groundwater

The geographic scope for cumulative groundwater effects is the same as the Area of
The geographic scope for cumulative groundwater effects is the same as the Area of
Analysis for groundwater, as described in in Section 3.7.1 *[Groundwater] Area of Analysis.* This includes the area within 2.5 miles of Copco No. 1, Copco No. 2, and Iron Gate reservoirs (Figure 3.7-1), which encompasses the area where the likelihood of impacts to groundwater wells due to implementation of the Proposed Project is greatest, as well as areas farther away from the reservoirs where regional groundwater flow data are generally available (Figure 3.7-2). The Area of Analysis lies within Siskiyou County, California and portions of Jackson and Klamath counties, Oregon. Portions of the Area of Analysis within Oregon are considered to the extent that they are likely to influence potential impacts to groundwater resources in California, rather than for potential impacts in Oregon.

Existing conditions for groundwater are detailed in Section 3.7.2 *[Groundwater] Environmental Setting*, which provides a description of regional groundwater conditions and more specific groundwater information in the Area of Analysis. This section characterizes local groundwater conditions in the Area of Analysis by examining well construction parameters in representative cross sections at Copco No. 1 and Iron Gate reservoirs. Section 3.7.2 *[Groundwater] Environmental Setting* also includes consideration of major past or ongoing projects that have impacted, or currently impact, groundwater resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of groundwater resource area effects (Section 3.7). Non-project activity types within the groundwater Area of Analysis with the potential for significant cumulative effects to groundwater are included in Table 3.24-1.

Significance criteria for cumulative groundwater effects are the same as defined in Section 3.7.3 *[Groundwater] Significance Criteria* for the groundwater resource.

Potential Cumulative Impact 3.24-31 Short-term and long-term groundwater effects from the Proposed Project in combination with other non-project activities. There are no reasonably foreseeable large-scale agricultural, residential, or commercial developments proposed within the groundwater Area of Analysis that would have the potential to use substantial amounts of groundwater and thereby lower groundwater levels.

Floodplain restoration in the Copco No. 1 and Iron Gate reservoir footprints that would occur as part of the Proposed Project's Reservoir Area Management Plan (Appendix B: *Definite Plan*) has the potential for beneficial effects related to groundwater. Floodplain restoration projects are often designed to enhance surface water-groundwater interactions that result in more water being stored as groundwater and raising aquifer levels.

As the Proposed Project would not have a significant adverse impact on groundwater and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no cumulative groundwater impacts due to the Proposed Project and agriculture, residential and commercial development, cannabis cultivation, and riverine restoration projects.

Significance

Beneficial cumulative effects for the combination of the Proposed Project and riverine restoration projects

No significant cumulative impact for other non-project activities

3.24.8 Water Supply/Water Rights

The geographic scope for cumulative water supply/water rights effects is the same as the Area of Analysis for water supply/water rights, as described in in Section 3.8.1 *[Water Supply/Water Rights] Area of Analysis.* This includes portions of the Upper, Middle, and Lower Klamath River from the Oregon-California state line downstream to the river's mouth (Figure 3.8-1). The Area of Analysis also includes California irrigators and Wildlife Refuges that receive water through USBR's Klamath Irrigation Project. The Area of Analysis does not include the Shasta, Scott, Salmon, and Trinity rivers because water supply availability and water rights compliance in these rivers are independent of mainstem Klamath water supply and water rights and the Proposed Project.

Existing conditions for water supply/water rights are detailed in Section 3.8.2 *[Water Supply/Water Rights] Environmental Setting*, which provides a description of reservoir capacities, Biological Opinion-related water storage criteria, municipal water supply for the City of Yreka, and other water right holders along the Klamath River in the Area of Analysis. Section 3.8.2 *[Water Supply/Water Rights] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, water supply/water rights.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of water supply/water rights resource area effects (Section 3.8). Non-project activity types within the water supply/water rights Area of Analysis with the potential for significant cumulative effects to water supply/water rights are included in Table 3.24-1.

Significance criteria for cumulative water supply/water rights impacts are the same as defined in Section 3.8.3 *[Water Supply/Water Rights] Significance Criteria* for the water supply/water rights resource.

Potential Cumulative Impact 3.24-32 Cumulative water supply and water rights impacts from the combination of the Proposed Project and other potential non-project activities.

Dam removal associated with the Proposed Project would have no significant impact on the amount of surface water flow available for diversion under existing water rights in the mainstem Klamath River within the Hydroelectric Reach and downstream from Iron Gate Dam (Potential Impact 3.8-1). The Proposed Project would also result in no significant impact with mitigation for releasing stored sediment that could affect water intake pumps and affecting the City of Yreka's municipal water supply (Potential Impacts 3.8-3 and 3.8-4, respectively).

The 2017 flow requirements (i.e., 2013 BiOp Flows plus the 2017 court-ordered flushing and emergency dilution flows) include winter-spring (November 1–April 30) surface flushing flows every year to scour surface riverbed sediments, deep flushing flows between February 15 and May 31 every other year to scour and disturb larger riverbed sediments, and emergency dilution flows between April 1 to June 15, if disease thresholds are exceeded (see Cumulative Potential Impact 3.24-2 for further discussion). As there is sufficient water released from the Lower Klamath Project under existing conditions and from the 2017 flow requirements to satisfy downstream water rights, and a new BiOp would be more likely to increase than decrease flows, there would be no significant cumulative impact to water supply/water rights in the hydroelectric reach or downstream of Iron Gate Dam from the combination of the Proposed Project and the re-consultation of the 2013 BiOp. In a parallel process, USBR has initiated renegotiation for a new Upper Klamath Basin agreement, which would be informed by the final flow requirements under the 2013 BiOp re-consultation regarding water rights among agricultural irrigators, Native American tribes, and environmental uses (Herald and News 2017; Herald and News 2018). However, at this time the outcome of the renegotiation for Upper Klamath Basin water rights is speculative and is not analyzed as part of the cumulative effects.

There are no reasonably foreseeable large-scale agricultural (including cannabis cultivation), development, or riverine restoration projects proposed within the water supply/water rights Area of Analysis (see Table 3.24-1) that have a stated intent to use substantial amounts of Klamath River flows and thereby preclude other existing water right holders from completely exercising their right. It is possible that future restoration and streamflow enhancement projects (e.g., Klamath Basin Restoration Program, Stream Flow Enhancement Program) will have beneficial cumulative effects related to providing more instream flows within the Area of Analysis, but specific effects are speculative at this time.

The KHSA Interim Measure 16 (*Water Diversions*) involves modification of three existing PacifiCorp water rights in the Shovel Creek watershed to move the points of diversion to the mainstem Klamath River (see Table 3.24-1). Moving the points of diversion would not affect other water rights in the Area of Analysis because these are existing, active water rights and flow from the Shovel Creek watershed, which is a tributary to the Klamath River. Thus, diverting the water from the mainstem Klamath instead of higher in the tributaries would not affect the availability of water for downstream users.

Potential sediment releases from non-project activities are assessed in Potential Cumulative Impacts 3.24-2 *[Water Quality]*, 3.24-40 and 3.24-41 *[Geology and Soils]*. No erosion- or turbidity-related impacts are found to be cumulatively considerable. Given that the Proposed Project would not have significant sedimentary impacts on water intake pumps and the City of Yreka's municipal water supply, and other projects would not result in cumulatively considerable erosion, turbidity, or sedimentation impacts, the combined impact to water intake pumps and the water supply would not be cumulatively significant.

Based on the above analysis, there are no closely related projects, including flow release, agricultural, residential, commercial, riverine restoration projects, or other non-project activities, that would, in combination with the Proposed Project, result in adverse cumulative water supply/water rights impacts.

Significance

No significant cumulative impact

3.24.9 Air Quality

The geographic scope for cumulative air quality effects is the same as the Area of Analysis for air quality (Section 3.9.1 *[Air Quality] Area of Analysis*) (Figure 3.9-1). This includes areas within and near the Limits of Work, and Siskiyou County as a whole.

Existing conditions are defined in Section 3.9.2 *[Air Quality] Environmental Setting*. A summary of annual ambient air quality data at a Yreka monitoring station is provided in Table 3.9-1, and the attainment status for air pollutants in Siskiyou County is provided in Table 3.9-2. Siskiyou County is designated as attainment or unclassified for all federal and state ambient air quality standards. Section 3.9.2 *[Air Quality] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, air quality resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of air quality resource area effects (Section 3.9). Non-project activity types within the air quality Area of Analysis with the potential for significant cumulative air quality impacts are included in Table 3.24-1.

Significance criteria for cumulative air quality impacts are the same as defined in Section 3.9.3 *[Air Quality] Significance Criteria*. As indicated in Section 3.9.5 *[Air Quality] Potential Impacts and Mitigation*, the Proposed Project would result in significant and unavoidable air quality impacts from emissions of NOx, PM_{10}, and $PM_{2.5}$ exceeding Siskiyou County Air Pollution Control District emissions thresholds (Potential Impact 3.9-2). Other potential air quality impacts from the Proposed Project, including exposure of sensitive receptors, would not be significant and adverse (Potential Impacts 3.9-1, and 3.9-3 through 3.9-5).

Potential Cumulative Impact 3.24-33: Short-term increases in criteria air pollutant emissions under the Proposed Project in combination with forest and wildfire management projects.

During the Proposed Project construction period (Table 2.7-1), there are proposed wildfire management activities, including prescribed or controlled burning, on national forest lands in Siskiyou County. These projects potentially include the Somes Bar Integrated Fire Management, Crawford Vegetation Management, and Harlan Vegetation Management and Fuels Reduction projects (Table 3.24-1). If these burning activities temporally overlap the Proposed Project construction period and produce substantial quantities of smoke near the Area of Analysis for air quality, there would be a significant cumulative impact due to elevated concentrations of NOx, PM_{10}, and $PM_{2.5}$. Given that the Proposed Project would be well below thresholds for other criteria pollutants, including CO, SO_x, and VOC, significant cumulative impacts are unlikely due to these pollutants. Reasonably foreseeable prescribed or controlled burning activities would, in combination with the Proposed Project, result in significant and adverse emissions of criteria air pollutants within the air quality Area of Analysis. Given the Proposed Project exceeds criteria thresholds for NOx, PM_{10}, and $PM_{2.5,}$ the incremental impact of the Proposed Project to the total emissions would be cumulatively considerable.

<u>Significance</u>

Cumulatively considerable

Potential Cumulative Impact 3.24-34 Short-term increases in criteria air pollutant emissions under the Proposed Project in combination with wildfires.

If wildfires were to produce substantial quantities of smoke near the proposed Limits of Work during the Proposed Project construction and restoration period, there would be an adverse air quality impact. However, if the Area of Analysis is disaster-stricken, it is likely that Proposed Project construction and restoration activities would be placed on hold to protect the health and safety of workers until the wildfire is under control. This is because while the Proposed Project includes a Fire Management Plan that is focused on prevention of fire caused by Proposed Project activities, the Fire Management Plan would also include fire watch activities and fire response methods consistent with related policies and standards in local, county, state, and federal jurisdictions (Section 2.7.8.9 *Fire Management*). The Fire Management Plan process and actions means that any wildfires in Siskiyou County large enough to have a significant impact on air quality and that would temporally overlap with scheduled air quality emissions from the Proposed Project would be unlikely to overlap with actual air quality emissions from the Proposed Project since the latter would be placed on hold; therefore, the cumulative impact would be less than significant.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-35 Short-term increases in criteria air pollutant emissions under the Proposed Project in combination with industrial development projects.
There are also two industrial projects in Yreka that have the potential to result in cumulative air quality impacts in combination with the Proposed Project. These include a Nanocellulose Facility (microscopic timber processing) and the Sousa Ready Mix Concrete Batch Plant Project (Table 3.24-1). Both of these projects would be located at least 15 miles southwest of the Limits of Work for the Proposed Project. Development of the nanocellulose facility is currently in the planning stages and it is unknown if the facility would be operational during the construction period for the Proposed Project (Table 2.7-1). An analysis of potential environmental impacts from the proposed nanocellulose facility has not been conducted, and the assessment of potential air quality impacts of nanocellulose production in general is in its infancy. For these reasons, it is currently speculative to determine if potential cumulative air quality impacts would result from operation of the proposed nanocellulose facility during the construction term for the Proposed Project.

In March 2016, a CEQA Initial Study/Mitigated Negative Declaration (IS/MND) was prepared for the Sousa Ready Mix Concrete Batch Plant Project. According to the IS/MND analysis, the batch plant project would result in less than significant air quality impacts during both construction and operation. From review of aerial photography (Google Earth™), it appears that the batch plant was constructed in 2016 and is currently operational. Due to the distance of the plant from the proposed Limits of Work, and the determination of less than significant air quality impacts from operations of the batch plant project, significant cumulative impacts would not result from operation of the batch plant during the construction period for the Proposed Project.

On this basis, the potential air quality impact of the Proposed Project, in combination with industrial development projects, would be less than significant.

Significance
No significant cumulative impact

3.24.10 Greenhouse Gas Emissions

The geographic scope for cumulative GHG effects is the same as the Area of Analysis for GHG emissions and energy effects (Section 3.10.1 *[Greenhouse Gas Emissions] Area of Analysis*) (Figure 3.10-1). This includes areas within California and Oregon where construction activities related to removal of the Lower Klamath Project dam complexes would occur and hence contribute to GHG emissions in Siskiyou County as a whole.

Existing conditions are defined in Section 3.10.2 *[Greenhouse Gas Emissions] Environmental Setting* for this resource. A summary of GHG emission sources in California is provided in Table 3.10-2. Section 3.10.2 *[Greenhouse Gas Emissions] Environmental Setting* provides information about global climate change, the California GHG emissions inventory, and statewide and regional effects of climate change.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of GHG resource area effects (Section 3.10). Non-project activity types within the Area of Analysis with the potential for significant cumulative GHG impacts are included in Table 3.24-1.

Significance criteria for cumulative GHG effects are the same as defined in Section 3.10.3 *[Greenhouse Gas Emissions] Significance Criteria*.

As indicated in Section 3.10.5 *[Greenhouse Gas Emissions] Potential Impacts and Mitigation,* the Proposed Project would not exceed the SCAQMD's GHG emissions significance threshold (Potential Impact 3.10-1), and would not conflict with AB 32, Executive Order S-3-05, SB 32, or the California Renewables Portfolio Standard (RPS) (S-14-08, SB X1-2, and SB 350) (Potential Impact 3.10-2). In particular, with respect to the California RPS, PacifiCorp would reduce its CO_2 emissions for its power generation portfolio over the next two decades and thus would not have a significant impact on GHG emissions. Overall, the Proposed Project would result in no significant GHG emissions impacts. GHG emissions, by nature, represent a cumulative impact; therefore, for CEQA purposes the relative contribution of the Proposed Project and other non-project activities to GHGs are assessed according to the aforementioned legislative guidelines. Although no other reasonably foreseeable future energy-related projects have been identified within the Area of Analysis for GHGs, should these other projects occur they would also be required to comply with AB 32, Executive Order S-3-05, SB 32, and California RPS.

Potential Cumulative Impact 3.24-36 Long-term GHG effects from the Proposed Project in combination with restoration, reforestation, and renewable energy projects.

The Proposed Project would result in no net loss of vegetation, and would not have long-term operational GHG emissions. Additionally, the replacement of hydroelectric energy following the decommissioning of the Lower Klamath Project would not result in a long-term increase in GHG emissions from non-renewable power sources, because PacifiCorp would reduce its CO_2 emissions over the next two decades (Potential Impact 3.10-2). No other closely related energy projects that are not part of existing conditions have been identified within the Area of Analysis. There are habitat enhancement projects and projects to reforest national forest lands burned in recent years by wildfires within the Area of Analysis with the potential for beneficial environmental effects related to GHG emissions (Table 3.24-1), which have the potential to increase carbon sequestration in Siskiyou County. The Proposed Project, in combination with renewable energy, restoration, and reforestation projects, would have no adverse cumulative GHG emissions effects and could have beneficial effects.

Significance

Beneficial cumulative effects

Potential Cumulative Impact 3.24-27 Short-term and long-term GHG effects from the Proposed Project in combination with forest and wildfire management projects.

Prescribed or controlled burning has the potential to generate significant adverse GHG emissions including CO_2 emissions, which have the potential to contribute to global climate change. Non-project fuel reduction activities within the Area of Analysis include the Somes Bar Integrated Fire Management, Crawford Vegetation Management, and Harlan Vegetation Management and Fuels Reduction projects. These projects may generate GHGs in the short term by undertaking prescribed or controlled burning that would overlap in space and time with short-term GHG emissions from the Proposed Project; this is conservatively assessed as a significant cumulative impact. Given that emissions from the Proposed Project would be below significance thresholds (Potential Impacts 3.10-1 and 3.10-2), and would be relatively small in the context of low burning of large acreages for wildfire management, the incremental cumulative impact of the Proposed Project would be less than cumulatively considerable. In the long term, forest management practices have the potential to reduce the occurrence of catastrophic wildfires that would produce significant quantities of GHG emissions, thus could be beneficial for reducing GHG emissions. The Proposed Project would not have long-term operational GHG emissions, and would result in no net loss of vegetation. In the long term, cumulative GHG emissions from the Proposed Project, in combination with forest and wildfire management projects, would be beneficial.

Significance

Not cumulatively considerable in the short term

Beneficial cumulative effects in the long term

Potential Cumulative Impact 3.24-38 Short-term and long-term GHG effects from the Proposed Project in combination with agriculture.

Cumulative GHG-related effects of the Proposed Project, in combination with non-project agriculture, can be considered both during the short-term construction period, and in the long term. Most agricultural projects occurring in the Klamath Watershed are reauthorizations of existing activities (Table 3.24-1), thus are existing conditions. However, zone changes are currently in-process to support additional agricultural land uses (on previously non-agricultural zoned land), including the Cannaworx Zone Change (44 ac) and Kidder Creek Orchard Camp Zone Change (170 ac), both in Siskiyou County. Modifications to policies for agricultural zones to support pastured hog and poultry operations, as well as agritourism, are also underway in Siskiyou County (Table 3.24-1). Such project could have GHG impacts, especially if they result in livestock grazing activities, which have the potential to result in the release of methane (CH_4) from animals, such as cattle, when they feed on grasses. Although GHG emissions are complex, CH_4 has a global warming potential that is 21 times greater than CO_2.

In the short term, GHG emissions during the Proposed Project construction period could overlap with the expansion of non-project agricultural activities above existing conditions within the Area of Analysis. It is speculative to assess the short-term cumulative impact without knowledge of future land uses, but we generally do not consider that the extent of reasonably foreseeable agricultural activities is substantial enough to exceed relevant GHG thresholds in combination with the Proposed Project. For example, the Cannaworx Zone Change would represent an increase of 0.0038 percent of agricultural land in Siskiyou County, and in the unlikely scenario that the entire site was used for grazing, this would represent an increase of 0.0112 percent of grazing land in Siskiyou County (above 2014 agricultural and grazing land areas shown in Table 3.15-1). The Kidder Creek Orchard Camp Zone Change is unlikely to involve any substantial increase of grazing activities, because it supports the expansion of a recreational and spiritual retreat camp. On this basis, there would be no significant short-term cumulative impact from the Proposed Project in combination with other closely related agricultural projects.

In the long term, the Proposed Project includes the transfer of PacifiCorp lands immediately surrounding the Lower Klamath Project ("Parcel B lands") from PacifiCorp to the KRRC prior to dam removal, and then to the respective states (i.e., California, Oregon), as applicable, or to a designated third-party transferee, following dam removal (Section 2.7.11 *Land Disposition and Transfer*). The Parcel B lands would thereafter be managed for public interest purposes, which could include: open space, active wetland and riverine restoration, tribal mitigation, river-based recreation, grazing, and potentially other uses. It is too speculative to determine which land uses would occur in any particular place, or over what area, on the Parcel B lands. The occurrence of agriculture on Parcel B lands, and expansion of non-project agricultural activities within the Area of Analysis, could be associated with an increase in GHG-emitting livestock grazing activities, resulting in an adverse cumulative impact. However, with limited knowledge of future land uses and complex benefits and impacts, it is speculative to qualitatively assess the long-term GHG emissions from Proposed Project agriculture and other agricultural activities within the Area of Analysis. Nevertheless, given the miniscule percentage changes of grazing lands for reasonably foreseeable agricultural projects described in the prior paragraph, it is likely that any establishment of grazing on Parcel B lands in the long term would also represent a relatively small portion of the total grazing land area in Siskiyou County. As there is unlikely to be a substantial change in grazing land area, there is no foreseeable significant cumulative impact in the long term.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-39 Long-term GHG effects from the Proposed Project in combination with industrial development projects.

Along with the wildfire management and agricultural activities, there are also two industrial projects in Yreka, CA that have the potential to result in cumulative GHG impacts in combination with the Proposed Project. These include a Nanocellulose Facility (microscopic timber processing) and the Sousa Ready Mix Concrete Batch Plant Project. Development of the Nanocellulose Facility is currently in the early planning stages and it is unknown if, or when, the facility will be constructed or become operational. An analysis of potential environmental impacts from the proposed facility has not been conducted. Depending on the process used for nanocellulose production, there is the potential for the generation of significant GHG emissions due to, among other factors, energy use and wood pulp production. Most processes used to produce nanocellulose materials are energy intensive, with the potential to result in substantial GHG emissions depending on the available energy supply (e.g., fossil-fuel vs. renewable energy sources). The production of wood pulp, which is a common starting material for nanocellulose materials, results in significant emissions of both biogenic and non-biogenic CO_2. As the production capacity of the proposed facility and the process that would be used to produce nanocellulose materials are unknown, it is currently speculative to determine if potential cumulative GHG impacts would result from operation of the proposed Nanocellulose Facility in combination with the Proposed

Project. In March 2016, a CEQA Initial Study/Mitigated Negative Declaration was prepared for the Sousa Ready Mix Concrete Batch Plant Project. According to the analysis in the CEQA document, the GHG emissions from construction and operation of the batch plant would result in less than significant impacts. From review of aerial photography, it appears that the batch plant was constructed in 2016 and is currently operational. Because the batch plant project and Proposed Project were determined to individually result in less than significant GHG impacts, significant cumulative impacts would likely not result from the Proposed Project in combination with the operation of the batch plant.

Significance
No significant cumulative impact

3.24.11 Geology, Soils, and Mineral Resources

The Area of Analysis for geology and soils includes the riverbed and reservoir banks at the sites of the Iron Gate, Copco No. 1, and Copco No. 2 dams and associated facilities, as well as the riverbed and adjacent banks along the Klamath River from the Oregon-California state line to the Pacific Ocean, including the Klamath River Estuary.

Existing conditions for geology, soils, and mineral resources are described in Section 3.11.2 *[Geology, Soils, and Mineral Resources] Environmental Setting*. The Klamath River traverses approximately 260 river miles. With a watershed area of approximately 15,722 mi^2, the Klamath River produces the second largest average annual runoff (Kruse and Scholz 2006) and sediment flux (Willis and Griggs 2003) of California's rivers. The cumulative average annual sediment delivery from the Klamath River to the ocean was estimated to be 6,237,500 tons/yr (Stillwater Sciences 2010) (Table 3.11-3). Additionally, the four Lower Klamath Project reservoirs currently store approximately 13.15 million cubic yards (yd^3) of sediment (Table 3.11-4) (USBR 2012). Section 3.11.2 *[Geology, Soils, and Mineral Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, geology, soils, and mineral resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of geology, soils, and mineral resources area effects (Section 3.11). Non-project activity types within the geology and soils Area of Analysis with the potential for significant cumulative geology and soil impacts are included in Table 3.24-1.

Significance criteria for geology and soil cumulative impacts are the same as defined in Section 3.11.3 *[Geology, Soils, and Mineral Resources] Significance Criteria*.

Potential Cumulative Impact 3.24-40 Short-term soil disturbance, erosion, and sedimentation effects from the Proposed Project in combination with other construction projects.
The Proposed Project would result in soil disturbance, erosion, and sediment deposition within the Area of Analysis for geology, soils, and mineral resources, as summarized below. The Proposed Project would not have a significant soil disturbance and erosion impact associated with heavy vehicle use, excavation, and grading, because an Erosion Control Plan would set out best management practices to be followed on-site (Potential Impact 3.11-2). The Proposed Project would also not have a significant sedimentation

impact downstream of the Lower Klamath Project reservoirs, or the sedimentation would be beneficial (Potential Impact 3.11-5). It is possible that some projects involving construction activities could overlap with the Proposed Project, including restoration and infrastructure projects, and these would have temporary, short-term soil disturbance, erosion, and sedimentation impacts (Table 3.24-1). Potential future overlapping riverine restoration projects include projects under the Klamath Basin Restoration Program and Gravel Enhancement below Iron Gate Dam for Salmon. Some potential infrastructure projects that involve crossings of tributaries to the Klamath River, including the Ayres Waterline near Grider Creek, and Siskiyou Telephone Fiber Optic Cable Installation near Clear Creek and Dillon Creek, but these are not reported as needed to cross the mainstem Klamath River and are downstream of the Hydroelectric Reach. No potential large-scale development projects identified in Table 3.24-1 are near the mainstem Klamath River. Section 402 of the Clean Water Act requires a *General Stormwater National Pollution Discharge Elimination System Permit for Construction Activities* across Oregon and California, and an *Erosion Control Plan* is required together with this Permit. Because infrastructure and development projects near the mainstem Klamath are not expected to overlap with the Proposed Project, and other construction-related disturbances including construction for riverine restoration, would be subject to the same rigorous erosion planning and prevention as the Proposed Project, there would not be a significant cumulative erosion impact from construction activities.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-41 Short-term soil disturbance, erosion, and sedimentation effects from the Proposed Project in combination with mining, forest and wildfire management, and agriculture.

Non-construction sediment-generating activities, such as wildfire, forest and wildfire management, mining and agriculture, would be subject to separate planning standards and requirements than for construction activities assessed in Potential Cumulative Impact 3.24-42 above. Wildfires are a naturally recurring event in the Klamath Basin, and have the potential to result in substantial erosion and sediment delivery if rainfall events occur before vegetation reestablishes. Increased sediment delivery would be most likely if a wildfire occurred late in the fire season (fall), and a combination of the Proposed Project and rain storms occurred shortly following the fire. As discussed in Potential Cumulative Impact 3.24-4, this could increase suspended sediment and sedimentation additional to the Proposed Project, and the water quality impact could be significant. The combination of geology and soils impacts under the Proposed Project and wildfires would also be significant, if temporal and spatial overlap occurs. However, given that geology and soil impacts, including soil disturbance, erosion, and sedimentation impacts, associated with the Proposed Project in isolation would not be significant (see Potential Impacts 3.11-2, 3.11-3, 3.11-5, 3.11-6), and these impact would likely be small compared with flooding on large areas of bare ground exposed by wildfire, the incremental impact of the Proposed Project would not be cumulatively considerable.

Most known forest and wildfire management projects are not close to the mainstem Klamath River, except the Somes Bar Integrated Fire Management Project (approximately 90 miles downstream of Humbug), and Crawford Vegetation Management Project (approximately 70 miles downstream of Humbug). Most mining projects described in the assessment of existing conditions for the Proposed Project are withdrawal or remediation projects, or are situated in tributaries far from the Hydroelectric Reach, apart from the new Plan of Operations for the existing Brooks Mine. The new plan of operations for the Brooks Mine (Table 3.24-1) is near the expected hydrologic and sedimentation footprint from Lower Klamath Project dam removal, which extends through the Hydrologic Reach and the Middle Klamath River from Iron Gate Dam to Humbug Creek. Most agricultural projects, including cannabis cultivation projects, are also captured by existing conditions, or are situated far from the Hydroelectric Reach, except for the adopted Cannaworx Zone Change near Humbug. The Cannaworx Zone Change would convert Open Space to Non-Prime Agricultural zoned land, thus supporting agricultural activities on previously agriculture-free land. Based on the above information, the soil disturbance, erosion, and sedimentation impact of the Proposed Project, in combination with forest and wildfire management, mining-related activities, and agricultural activities, would not be cumulatively significant.

Significance

Not cumulatively considerable for wildfire

No significant cumulative impact for forest and wildfire management, mining-related activities, and agricultural activities

Potential Cumulative Impact 3.24-42 Short-term hillslope instability, effects to earthen dam embankments, and/or bank erosion from the Proposed Project in combination with other potential non-project activities.

Slope stability analyses conducted for the Proposed Project indicate that segments of the Copco No. 1 Reservoir rim have a potential for slope failure that could impact existing roads and/or private property. These areas include approximately 3,700 linear feet of slopes along Copco Road and approximately 2,800 linear feet of slope adjacent to private property (Appendix B: *Definite Plan*). Up to eight parcels in these areas have existing habitable structures that could potentially be impacted. The impact of the Proposed Project on hillslope instability in reservoir rim areas would be significant. Implementation of Mitigation Measure GEO-1 would reduce the cumulative impact to less than significant. No other projects have been identified that would cause hillslope instability along the rim of Copco No. 1 Reservoir (or the rims of Iron Gate or Copco No. 2 reservoirs) (Table 3.24-1); therefore, there would be no cumulative impact.

Analyses of embankment stability during drawdown at the earthen dams (i.e., Iron Gate Dam and J.C. Boyle Dam) indicate that the proposed reservoir drawdown rates would not result in substantial embankment instability (Appendix B: *Definite Plan*). Small, shallow slumping along the upstream embankment slopes due to the potential strength loss of surficial materials during drawdown would not threaten the structural integrity of the embankments or deliver a substantial amount of sediment. No other projects have been identified that would cause embankment instability at Iron Gate Dam and J.C. Boyle Dam (Table 3.24-1); therefore, there would be no cumulative impact related to embankment stability.

Drawdown flow rates for the Proposed Project are similar to existing and historical flow rates, and would be adjusted according to the water year type, thus substantial bank erosion is not expected (Potential Impact 3.11-4). As discussed in Potential Impact 3.24-2 *[Water Quality]*, 2017 flow requirements (i.e., 2013 BiOp Flows plus the court-ordered flushing and emergency dilution flows) are within the range of flows modeled under the Proposed Project; therefore, there would not be any cumulative impact related to bank erosion.

Significance
Not cumulatively considerable with mitigation for short-term instability in reservoir rim areas

No significant cumulative impact for instability of earthen embankments or bank erosion downstream of reservoirs

Potential Cumulative Impact 3.24-43 Short-term seismic activity effects from the Proposed Project in combination with other potential non-project activities.
The nearest active fault is approximately five miles from the dams proposed for removal. These faults are reported not to have moved within the past 1.5 million years and, therefore, are considered inactive (Personius et al. 2003). Drawdown of reservoirs of this size is not expected to induce seismicity. Reservoir draining is also not expected to cause volcanic activity due to the distance from volcanic hazards (e.g., Mount Shasta). No other closely related projects have been identified that are likely to induce seismic or volcanic activity. Based on the above information, the short-term seismic activity effects from the Proposed Project, in combination with other potential non-project activities, would not be cumulatively significant.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-44 Long-term mineral resources effects from the Proposed Project in combination with mining activities.
Diatomite deposits near the southern downstream shore of Copco No. 1 Reservoir are currently inaccessible for extraction purposes due to their location in the reservoir and existing erosion. Under the Proposed Project, land ownership within the reservoir areas would be transferred to the KRRC and then to the State of California, or to a designated third-party transferee in the case of Copco No. 1 Reservoir (Section 2.7.11 *Land Disposition and Transfer*). The lands would thereafter be managed for public interest purposes, which could include open space, active wetland and riverine restoration, river-based recreation, grazing, and potentially others. It is likely that the accessibility of diatomite deposits will be a continuation of the existing condition, and effects from the Proposed Project, in combination with other potential mining activities (Table 3.24-1), would not be cumulatively significant.

Significance
No significant cumulative impact

3.24.12 Historical Resources and Tribal Cultural Resources

The geographic scope for cumulative historical and tribal cultural resources effects is the same as the Area of Analysis for historical and tribal cultural resources, as described in in Section 3.12.1 *[Historical and Tribal Cultural Resources] Area of Analysis.* This includes the combined area of analysis (Figure 3.12-1) and its four subareas[176] (Figures 3.12-2 through 3.12-5). The four subareas allow for individual impact analyses specific to geographic location (e.g., reservoir footprint, riverside location) and Proposed Project activity timing (e.g., pre-dam removal, reservoir drawdown, restoration activities). While the subareas overlap, this has no bearing on the analysis of any historical or tribal cultural impact, since the subareas are considered independently by impact.

Existing conditions for historical and tribal cultural resources are detailed in Section 3.12.2 *[Historical and Tribal Cultural Resources] Environmental Setting*. Archaeological investigations have confirmed nearly 10,000 years of human presence in the Mid and Upper Klamath Basins. The Klamath River flows through several culture regions in California's Northwest Coast, the Great Basin, and portions of the Columbia Plateau. These unique cultural regions have been occupied by Native American Tribes recognized now as part of the Klamath Tribes, Quartz Valley Indian Reservation, Shasta Nation, Shasta Indian Nation, Karuk, the Hoopa Valley Tribe[177], Resighini Rancheria, and the Yurok Tribe. The discovery of gold in 1848 was the catalyst that caused a dramatic alteration of both Native American and Euro American cultural patterns in California. Section 3.12.2 *[Historical and Tribal Cultural Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, historical and tribal cultural resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of historical and tribal cultural resources effects (Section 3.12). Non-project activity types within the historical and tribal cultural resources Area of Analysis with the potential for significant cumulative effects to historical and/or tribal cultural resources are included in Table 3.24-1.

Significance criteria for cumulative historical and tribal cultural resources are the same as defined in Section 3.12.3 *[Historical and Tribal Cultural Resources] Significance Criteria* for the resource.

Potential Cumulative Impact 3.24-45 Long-term effects on the Klamath River fishery tribal cultural resource of the Proposed Project in combination with restoration, flow enhancement, and water quality improvement projects.
The Proposed Project would benefit the cultural riverscape and ecosystem health, including tribal fisheries resources, in the long term by dam removal and elimination of hatchery production (Potential Impact 3.12-9). The Proposed Project would also benefit the ability of tribes to use the Middle and Lower Klamath River for ceremonial and other purposes because of reductions in blue-green algae concentrations (Potential Impact 3.12-10). Other restoration, flow enhancement, and water quality improvement projects along the Klamath River and its tributaries (creeks and rivers) are anticipated to improve

[176] *Subarea 1* – Proposed Project Limits of Work inclusive of known cultural sites that lie partially within and partially outside the Limits of Work; *Subarea 2* − Post-dam removal altered 100-year floodplain along the 18-river mile stretch of the Middle Klamath River downstream of Iron Gate Dam (RM 193.1) to the confluence with Humbug Creek (RM 174); *Subarea 3* – 0.5-mile buffer on either side of the Hydroelectric Reach, Middle Klamath River, and Lower Klamath River encompassing the existing conditions and post-dam removal 100-year floodplain; *Subarea 4* – Parcel B lands.
[177] The term Hupa describes the Hupa People. The term Hoopa is used to reference the Hoopa Valley place or the tribal government.

the Klamath River fishery tribal cultural resource by enhancing water quality (e.g., water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-a, and algal toxins) and habitat through riparian habitat restoration, placement of off-channel habitat features, floodplain restoration, incorporation of large wood into tributaries to the Klamath River, and increases in stream flow. Reasonably foreseeable restoration projects that would occur within the post-dam removal altered 100-year floodplain between Iron Gate Dam and Humbug Creek, corresponding to *Subarea 2* (Figure 3.12-3) of the historical and tribal cultural resources Area of Analysis, or the existing conditions and post-dam removal 100-year floodplain of the Klamath River, corresponding to *Subarea 3* (Figure 3.12-4) of the historical and tribal cultural resources Area of Analysis, are included in Table 3.24-1). Note that this potential effect is not relevant to other historical and tribal cultural resources Area of Analysis subareas (i.e., *Subarea 1* and *Subarea 4*).

Restoration, flow enhancement, and water quality improvement projects would increase the amount of cold water flowing in the river, improving water temperature conditions for salmonids, while the Proposed Project would improve water temperature conditions by returning more natural seasonal and daily variations. Increases in river flows from restoration, flow enhancement, and water quality improvement projects would also be beneficial for water quality by diluting chlorophyll-*a* and algal toxins concentrations. The Proposed Project also would decrease high seasonal chlorophyll-*a* concentrations and periodically high algal toxin concentrations by eliminating reservoir environment that currently supports growth conditions for toxin-producing nuisance blue-green algal species such as *Microcystis aeruginosa.* Overall, the Proposed Project, in combination with restoration, flow enhancement, and water quality improvement projects, would result in beneficial cumulative effects on the Klamath River fishery tribal cultural resource within *Subarea 2* and *Subarea 3* of the historical and tribal cultural resources Area of Analysis.

Significance

Beneficial cumulative effects in *Subarea 2* and *Subarea 3* of the historical and tribal cultural resources Area of Analysis

Potential Cumulative Impact 3.24-46 Short-term historical and tribal cultural resources effects of the Proposed Project in combination with 2017 court-ordered flushing and emergency dilution flows.

The 2013 BiOp Flows have been analyzed under the individual resource sections for the Proposed Project. Potential Impact 3.24-2 in Section 3.24.2 *Cumulative Water Quality Effects* provides background and context regarding agency re-consultation on the 2013 BiOp. For the reasons set out in Potential Impact 3.24-2, this analysis only considers the 2017 court-ordered flow requirements, which were imposed after issuance of the Notice of Preparation (i.e., are not part of the existing conditions), and are a reasonably foreseeable flow condition; this analysis does not consider the potential new BiOp.

The existing 100-yr floodplain in the Middle Klamath River downstream of Iron Gate Dam between RM 190 and 171, defined as *Subarea 2*, would increase slightly under the Proposed Project, and associated flooding and erosion may have a significant and unavoidable impact on historical and tribal cultural resources along this reach of the Klamath River, (Potential Impacts 3.12-3 and 3.12-14). In other reaches of the Klamath River, the floodplain is not expected to change (Potential Impacts 3.12-3 and 3.12-14). There are no closely related development projects that would, in combination with the

Proposed Project, have a significant and adverse impact on flooding in *Subarea 2* (Table 3.24-1), where the floodplain is expected to increase under the Proposed Project. During the period when the Proposed Project would occur, the 2017 flow requirements (i.e., 2013 BiOp Flows plus the 2017 court-ordered flushing and emergency dilution flows) would be in effect (see Cumulative Impact 3.24-1 for additional detail). However, these flow requirements are not sufficiently high as to increase flooding risk, thus there would be no cumulative flooding and/or erosion impacts to historical and tribal cultural resources located within the 100-year floodplain.

As mentioned in Impact 3.24-45 above, the Proposed Project would benefit the cultural riverscape and ecosystem health, including tribal fisheries resources, by dam removal and elimination of hatchery production (Potential Impact 3.12-9). The 2017 flow requirements would improve Klamath River fishery tribal cultural resource by reducing the incidence of fish disease (see Section 3.3.5.5 *Fish Disease and Parasites*), and in combination with the removal of upstream migration barriers (i.e., the Lower Klamath Project dams) and improvements to the quality of riverine habitat in the Middle Klamath River and the Hydroelectric Reach (see Section 3.3.5.8 *Aquatic Habitat*), there would be a cumulative beneficial effect on the fishery tribal cultural resource.

Significance

No significant cumulative impact related to short-term flooding and/or erosion of tribal cultural resources located within the 100-year floodplain

Beneficial cumulative effects on fishery tribal cultural resource in the short term

Potential Cumulative Impact 3.24-47 Short-term and/or long-term historical and tribal cultural resources effects from the Proposed Project in combination with development projects.

Tribal Cultural Resources

Significant and unavoidable short-term ground-disturbing construction-related impacts on archaeological and non-archaeological tribal cultural resources (TCRs) would occur with mitigation for the 4 to 8-year period of dam removal and restoration activities under the Proposed Project (Potential Impacts 3.12-1, 3.12-4, 3.12-5). The ground-disturbing activities would occur within *Subarea 1* of the historical and tribal cultural resources Area of Analysis (Figure 3.12-2). Additionally, the Proposed Project would result in potential significant shifting and exposure of existing tribal cultural resources within the reservoir footprints and Klamath River (Potential Impacts 3.12-2, 3.12-3, and 3.12-7) during and following reservoir drawdown. Following reservoir drawdown, the Proposed Project would include floodplain restoration activities in the reservoir footprints and upland areas of *Subarea 1* (Appendix B: *Definite Plan – Appendix H*). There are no reasonably foreseeable large-scale development projects (see Table 3.24-1) within *Subarea 1* that that would, in combination with the Proposed Project, result in significant and adverse impacts to archaeological and non-archaeological TCRs.

Following dam removal, transfer of Parcel B lands would occur under the Proposed Project, where Parcel B lands correspond to *Subarea 4* of the historical and tribal cultural resources Area of Analysis (Figure 3.12-5). This would result in public interest land management on these lands, which could include open space, active wetland and riverine restoration, tribal mitigation, river-based recreation, grazing, and potentially other uses. While it is too speculative to determine which land uses would occur in any particular place within the Parcel B lands, there are no reasonably foreseeable large-scale development projects currently identified within the Parcel B lands (Table 3.24-1) and it is highly unlikely that public interest land management would include large-scale development projects.

Overall, there would be no cumulative impacts to tribal cultural resources in *Subarea 1* and *Subarea 4* due to the combination of the Proposed Project and development projects. Note that this potential effect is not relevant to other historical and tribal cultural resources Area of Analysis subareas (i.e., *Subarea 2* and *Subarea 3*).

Historical Built Environment
The Proposed Project would result in significant adverse impacts to Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and the Klamath River Hydroelectric Project District (Potential Impact 3.12-11) because these historic period complexes would be removed. The Klamath River Hydroelectric Project District is located within *Subarea 1* of the historical and tribal cultural resources Area of Analysis (Figure 3.12-2). There are no reasonably foreseeable large-scale development projects (see Table 3.24-1) within *Subarea 1* that that would, in combination with the Proposed Project, result in a combined significant impact to the historical built environment.

Significant and unavoidable short-term ground-disturbing construction-related impacts on historic-period archaeological resources would occur with mitigation for the 4 to 8-year period of dam removal and restoration activities under the Proposed Project (Potential Impacts 3.12-12, 3.12-15, 3.12-16). The ground-disturbing activities would occur within *Subarea 1* of the historical and tribal cultural resources Area of Analysis (Figure 3.12-2). There are no reasonably foreseeable large-scale development projects (see Table 3.24-1) within *Subarea 1* that that would, in combination with the Proposed Project, result in significant and adverse impacts to historic-period archaeological resources.

Significance
No significant cumulative impact in *Subarea 1* and *Subarea 4* of the historical and tribal cultural resources Area of Analysis

3.24.13 Paleontologic Resources

The Area of Analysis for paleontologic resources is the region within and adjacent to the Klamath River 100-year floodplain, from the Oregon-California state line to the Klamath River's mouth near Requa, California (Figure 3.13-1). This includes the area within 1,000 feet of FEMA Flood Zones A and AE, or downstream of Iron Gate Dam within 1,000 feet of the National Hydrography Dataset Klamath River centerline, and upstream of Iron Gate Dam within five miles of the Klamath River centerline.

Existing conditions for paleontologic resources are as described in Section 3.14.2 *[Paleontologic Resources] Environmental Setting*. The majority of bedrock deposits within the Area of Analysis for paleontologic resources are not fossil-bearing units. Two mapped geologic units that contain paleontologic resources are present within the Area of Analysis: (1) the unnamed diatomite deposit at Copco No. 1 Reservoir; and (2) the Hornbrook Formation. The diatomite deposit is determined to be of Low Paleontologic Potential. The fossils in the Hornbrook Formation are documented to include megafossils and microfossils, but it is not known if the fossil abundance varies spatially within this geologic unit. The Klamath River cuts across the Hornbrook Formation in the region of Hornbrook, California, along approximately three river miles (Figure 3.13-2). Sub-units within the Hornbrook formation are described in Section 3.14.2 *[Paleontologic Resources] Environmental Setting.* Section 3.14.2 also includes consideration of major past or ongoing projects that have impacted, or currently impact, paleontologic resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of paleontologic resource area effects (Section 3.13). Non-project activity types within the paleontologic Area of Analysis with the potential for significant cumulative paleontologic impacts are included in Table 3.24-1.

Significance criteria for cumulative geology and soils impacts are the same as defined in Section 3.13.3 *[Paleontologic Resources] Significance Criteria*.

Potential Cumulative Impact 3.24-48 Long-term paleontologic resources effects from the Proposed Project in combination with other non-project activities.
The Hornbrook Formation is classified as Low Paleontological Potential in Potential Impact 3.13-1, and river discharges during the Proposed Project drawdown would have a low likelihood of downcutting or erosion of the Hornbrook Formation. Thus, there would be no significant impact of the Proposed Project on paleontologic resources. As there are no closely related projects that would, in combination with the Proposed Project, result in cumulative flood hydrology impacts (see Section 3.24.6 *Cumulative Flood Hydrology Effects*) there would be no cumulative downcutting and erosion impacts related to altered flood flows within the Klamath River. No other mining, infrastructure, or restoration projects that would involve excavation into the Hornbrook Formation have been identified (Table 3.24-1). As the Proposed Project would have no significant impact on paleontologic resources, and there are no closely related projects that would have a significant and adverse impact on paleontologic resources, there would be no cumulative impact from the Proposed Project in combination with other projects identified above.

Significance
No significant cumulative impact

3.24.14 Land Use and Planning

The Area of Analysis for land use and planning is defined as the Project Boundary, including the Limits of Work and Parcel B lands (Figure 2.2-5).

Existing conditions for land use and planning are as described in Section 3.14.2 *[Land Use and Planning] Environmental Setting*. PacifiCorp owns the majority of the land within the Project Boundary (Figure 2.2-5), BLM manages 59.3 acres within the Proposed Project area, and most of the land surrounding Copco No. 1 Reservoir is privately owned. The majority of the Area of Analysis for land use and planning is categorized as Open Space – Natural Resources, which includes activities such as timber production, grazing land, and developed and dispersed recreational uses. Public lands are managed by BLM, USDA Forest Service, and other agencies. In the Area of Analysis for this resource, there are residential developments along portions of the Copco No. 1 Reservoir. There are commercial and industrial developments in some rural areas downstream from Iron Gate Dam. Copco No. 1 Dam, Copco No. 2 Dam, Iron Gate Dam, and Fall Creek facilities are described in Section 3.14.2 *[Land Use and Planning] Environmental Setting*. Downstream from Iron Gate Dam are several rural developments located along the Klamath River shoreline. Section 3.14.2 *[Land Use and Planning] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, land use resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of land use and planning resource area effects (Section 3.14). Non-project activity types within the land use and planning Area of Analysis with the potential for significant cumulative land use and planning impacts are included in Table 3.24-1.

Significance criteria for cumulative aquatic resources impacts are the same as defined in Section 3.14.3 *[Land Use and Planning] Significance Criteria*.

Potential Cumulative Impact 3.24-49 Short-term or long-term physical division of communities from the Proposed Project in combination with other potential non-project activities.

The Proposed Project would not physically divide an established community by interrupting road access for supplies and services (Potential Impact 3.14-1). Although installation of livestock exclusion fencing is included in the Proposed Project, fencing would only be placed where grazing land abuts planned reservoir restoration areas and would be installed to replace the existing function of the Lower Klamath Project reservoirs as natural barriers (Potential Impact 3.14-1). No other projects have been identified within the Area of Analysis that could create an adverse physical division that interrupts supplies and services. Although there are agricultural projects identified in Table 3.24-1, none of them are within the Area of Analysis for land use and planning, and most are situated farther downstream. Some restoration projects are potentially within the Area of Analysis for land use and planning, including: the Klamath Basin Restoration Program projects and the Mid Klamath Coho Rearing Habitat Enhancement Project; however, these restoration projects do not specify that they would include riparian fencing. Forest and wildfire management projects that create fuel breaks, and road repair and construction projects, could both have beneficial cumulative effects by creating new roads. As the Proposed Project would not have a significant adverse impact on the physical division of communities, and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no cumulative physical division impacts due to the Proposed Project and other closely related projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-50 Short-term or long-term land use resources effects from the Proposed Project in combination with other non-project activities.

The Proposed Project does not conflict with any land use plan, policy, or regulation, nor any Habitat Conservation Plan (HCP) or Natural Community Conservation Plan (NCCP) (Potential Impact 3.14-2). Other closely related, reasonably foreseeable projects would be subject to their own planning processes to assess conflicts with adopted plans, policies, and regulations. There is no identified potential for a significant cumulative impact due to conflict with plans, policies, regulations, HCPs, or NCCPs. As the

Proposed Project would not have a significant adverse impact on land use, and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no cumulative land use impacts due to the Proposed Project and other closely related projects.

Significance

No significant cumulative impact

3.24.15 Agriculture and Forestry

For agricultural and forestry resources, the Area of Analysis includes all lands within the Project Boundary (Figure 2.2-5), plus a half-mile buffer around Copco No. 1 Reservoir (Figure 3.15-1).

Existing conditions for agriculture and forestry resources are as described in Section 3.15.2 *[Agriculture and Forestry Resources] Environmental Setting*. Most of the land in the Area of Analysis is classified by the DOC as Grazing Land, with a small area of Unique Farmland located approximately two miles south of Copco No. 1 Reservoir (Figure 3.15-1). Parcels zoned by Siskiyou County for Agriculture-Grazing are located within the Area of Analysis to the north and south of Copco No. 1 Reservoir (Figure 3.14-1). There are a number of parcels located immediately upstream of Copco No. 1 Reservoir that are used primarily for grazing and hay production. The DOC (2016c) identified these lands as Prime Farmland or Farmland of Statewide Importance (Figure 3.15-1). No Williamson Act parcels nor lands zoned Forest Resources under the Siskiyou County General Plan occur within the Area of Analysis. Section 3.15.2 *[Agriculture and Forestry Resources] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, agriculture and forestry resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of agriculture and forestry resource area effects (Section 3.15). Non-project activity types within the agriculture and forestry Area of Analysis with the potential for significant cumulative impacts are included in Table 3.24-1.

Significance criteria for cumulative agricultural and forestry impacts are the same as defined in Section 3.15.3 *[Agriculture and Forestry] Significance Criteria*.

Potential Cumulative Impact 3.24-51 Short-term and long-term effects to agricultural resources from the combination of the Proposed Project and agricultural and rezoning projects.

The Proposed Project includes the transfer of PacifiCorp lands immediately surrounding the Lower Klamath Project ("Parcel B lands") from PacifiCorp to the KRRC prior to dam removal, and then to the respective states (i.e., California, Oregon), as applicable, or to a designated third-party transferee, following dam removal (Section 2.7.11 *Land Disposition and Transfer*). The Parcel B lands would thereafter be managed for public interest purposes, which could include: open space, active wetland and riverine restoration, tribal mitigation, river-based recreation, grazing, and potentially other uses. It is speculative to determine which land uses would occur in any particular place, or over what area, on the Parcel B lands.

Most agricultural projects occurring in the Klamath Watershed are reauthorizations of existing activities (Table 3.24-1), thus are captured by the Proposed Project existing conditions. However, zone changes are currently in-process to support additional agricultural land uses (on previously non-agricultural zoned land), including the Cannaworx Zone Change and Kidder Creek Orchard Camp Zone Change, both in Siskiyou County. Modifications to policies for agricultural zones to support pastured hog and poultry operations, as well as agritourism, are also underway in Siskiyou County (Table 3.24-1). The Kidder Creek Orchard Camp Zone Change is situated outside of the Area of Analysis. The adopted Cannaworx Zone Change is within the Area of Analysis near Humbug; it will convert Open Space to Non-Prime Agricultural zoned land, thus supporting agricultural activities on previously agriculture-free land. This would have a beneficial effect on the agricultural resource. As the Proposed Project would not have a significant adverse impact on agricultural resources, and there is only one closely related (beneficial) non-project action, there would be no significant cumulative agricultural impacts due to the Proposed Project.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-52 Short-term and long-term effects to forestry resources from the combination of the Proposed Project and forest and wildfire management.
The Proposed Project would have no significant impact on forest lands (Potential Impacts 3.15-2, 3.15-3, and 3.15-4 *[Agriculture and Forestry Resources]*. Non-project activities relating to forest health and fuels management (Table 3.24-1) are proposed in the Klamath Basin, which would result in benefits to forestry resources by reducing the potential for catastrophic stand-replacing wildfire and faster late-successional timber development. However, these projects are not proposed within the agriculture and forestry Area of Analysis. As the Proposed Project would not have a significant adverse impact on forestry resources, and there are no closely related forest or wildfire management projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative forestry resource impacts.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-53 Short-term and long-term effects to forestry resources from the combination of the Proposed Project wildfire.
As mentioned above, the Proposed Project would have no significant impact on forest lands (Potential Impacts 3.15-2, 3.15-3, and 3.15-4 *[Agriculture and Forestry Resources]*. Wildfires regularly occur within the Klamath Basin, with multiple fires occurring in 2016 through 2018 (Table 3.24-1). Under climate change, forests will be more susceptible to extreme wildfires, with an almost 50 percent increase in the frequency of extreme wildfires that burn over approximately 25,000 acres, and a 77 percent increase in the average area burned statewide by the end of the century (Bedsworth et al. 2018). Large fires can burn hundreds to thousands of acres; for example, in 2016, 844 acres were burned in Siskiyou County. That said, wildfires are a natural occurrence in California and low-burning fires can improve forest health. Given that the Proposed Project would not have significant impacts on forest lands, there would be no significant cumulative impact to forests when the Proposed Project is

considered together with substantial changes that would result if a wildfire were to occur in the Area of Analysis.

Significance
No significant cumulative impact

3.24.16 Population and Housing

The Area of Analysis for population and housing extends beyond the Project Boundary (Figure 2.2-5) to encompass the following urban and rural communities in California: the community of Hornbrook, the City of Yreka, and the residential rural areas near Copco No.1, Copco No. 2, and Iron Gate reservoirs. Existing conditions for population and housing are described in Section 3.16.2 *[Population and Housing] Environmental Setting*. Within the population and housing Area of Analysis, there are approximately 12 residences proposed for demolition that are currently owned by PacifiCorp and are for use by workers maintaining the dams or other PacifiCorp properties. Section 3.16.2 *[Population and Housing] Environmental Setting* presents Siskiyou County census data, along with data for Yreka and Hornbrook, and considers major past or ongoing projects that have impacted, or currently impact, population and housing resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of population and housing resource area effects (Section 3.16). Non-project activity types within the population and housing Area of Analysis with the potential for significant cumulative population and housing impacts are included in Table 3.24-1.

The nature of the above-listed projects is that they could increase population growth and create housing demand, especially during construction periods when additional workers would be present.

Significance criteria for cumulative aquatic resources impacts are the same as defined in Section 3.16.3 *[Population and Housing] Significance Criteria*.

Potential Cumulative Impact 3.24-54 Short-term and long-term population and housing effects from the Proposed Project in combination with residential and industrial development projects.
The potential effects of the Proposed Project on unplanned population growth would be limited to the temporary influx of workers required for dam removal construction activities and would have no significant impact (Potential Impact 3.16-1). Similarly, the potential effects of the Proposed Project on the displacement of people or housing is limited to the need for an additional temporary worker population during construction activities, and their potential housing needs, and there would be no significant impact (Potential Impact 3.16-2). No large-scale residential development projects have been identified within the vicinity of the Proposed Project. It is possible that other construction projects would attract workers to the area at a similar time, such as the Sousa Ready Mix Concrete Batch Plant Project in Yreka, development of Siskiyou County jail in Yreka, a nanocellulose facility development in Yreka, as well as restoration projects, road repair and construction, mining, and telecommunications projects (Table 3.24-1). The combined impact of the Proposed Project and these other reasonably foreseeable future projects that could attract workers to the area would be a less than significant impact with respect to unplanned population growth or the need for replacement housing at the

County-wide level due to the large (>4,000) number of vacant units available for use (Potential Impact 3.16-1). Within the City of Yreka, the cumulative impact on unplanned population growth or the need for replacement housing has potential to be significant and adverse if other development projects occur concurrently with the Proposed Project and a substantial number of workers from outside of Yreka converge on the city. However, given that the temporary population increase due to the Proposed Project would be small (0.4 percent) (Potential Impact 3.16-2), and most workers for the Proposed Project are anticipated to be sourced from Yreka and smaller nearby communities, the Proposed Project's use of vacant units would be minimal, and the incremental impact on population and housing would not be cumulatively considerable.

Significance

No significant cumulative impact at the County-wide level

Not cumulatively considerable for the City of Yreka

3.24.17 Public Services

The Area of Analysis for public services includes the immediate vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams, including their associated reservoirs, and areas identified as construction/demolition and staging areas. The Area of Analysis for public services also includes communities in the immediate vicinity of the Proposed Project, lands managed for public use by the USDA Forest Service and the BLM, and routes utilized for providing public services. Recreation, roads, fire hazards, and energy production are discussed in this section only in terms of their relationship to analysis of public services.

Existing conditions for public services are described in Section 3.17.2 *[Public Services] Environmental Setting,* which describes fire protection, police, medical services, schools, parks, and other public facilities within the Area of Analysis. Fire protection in the Area of Analysis is provided via cooperative fire protection agreement with CALFIRE. Police services are provided by The Siskiyou County Sheriff's Department and the California Highway Patrol. There are no medical services provided directly within the Area of Analysis. The nearest medical facilities are located in Klamath Falls, OR, Ashland, OR, Dorris, CA, and Yreka, CA. Dispatch services for emergencies are provided by the Yreka Communications Center. Bogus Elementary School is the closest school to the public services Area of Analysis. It is located 5.3 miles from Copco No. 1 Reservoir. As described in Section 3.20 *Recreation,* the Area of Analysis contains a number of recreational facilities, including the reservoirs associated with the Lower Klamath Project. Section 3.17.2 *[Public Services Effects] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, public services.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of public services resource area effects (Section 3.17). Non-project activity types within the Area of Analysis with the potential for significant cumulative effects were considered in relation to the potential project impact types evaluated in Section 3.17.5 *[Public Services] Potential Impacts and Mitigation*, including:

- Construction and demolition activities that could increase response times or increase the need for police and medical services;
- Increased risk of wildfires and the need for firefighting measures or resources;
- Changes in long-term water source availability for wildfire fighting; and
- Potential effects to parks and other public facilities.

Potential Cumulative Impact 3.24-55 Short-term and long-term public services effects from the Proposed Project in combination with non-project activities. The Proposed Project could result in a significant short-term impact if it resulted in substantial increased emergency response times within the Area of Analysis. Other projects and activities that could potentially impact emergency response times include multiple thinning and forest fuel reduction projects in the Happy Camp, Oak Knoll, Salmon River, Scott River, and Goosenest Ranger Districts of the Klamath National Forest, the Brooks Mine, fiber optic cable installation along Highway 96, PacifiCorp powerline replacement in the Happy Camp Ranger District, Guys Gulch Road Realignment, Wooley Creek Bridge Rehabilitation, KHSA (IM)-16 Water Diversion Projects, and construction of the Yreka Nanocellulose Facility, Siskiyou County Jail, Rain Rock Casino, Sousa Ready Mix Concrete Batch Plant, and the Fruit Growers Supply Company Sawmill (Table 3.24-1). These projects are unlikely to overlap in space and time with the Proposed Project's potential impacts to public services response times or emergency service routes, with the exception of KHSA (IM)-16 Water Diversion Projects and the Yreka Nanocellulose Facility, Siskiyou County Jail, Rain Rock Casino, Sousa Ready Mix Concrete Batch Plant, and Fruit Growers Supply Company Sawmill projects. If these projects occur at the same time as the Proposed Project, they could add to the increased emergency response times from the Proposed Project described as Potential Impact 3.17-1. Although the Emergency Response Plan, Fire Management Plan, Traffic Management Plan (TMP), and Hazardous Materials Management Plan to be prepared per Mitigation Measures HZ-1 and Recommended Measure TR-1 would take into account any other construction projects occurring at the same time that could potentially slow emergency services access in the affected area, the State Water Board cannot ensure the TMP's and Emergency Response Plan's implementation. As with Potential Cumulative Impact 3.24-65, the combination of the Proposed Project, measures HZ-1 and TR-1, and one or more other construction projects within the Area of Analysis would be unlikely to result in significant impacts to traffic and transportation. However, because the State Water Board has determined that short-term construction-related impacts of the Proposed Project would be significant and unavoidable with respect to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation, unless and until KRRC reaches enforceable 'good citizen' agreements through the FERC process, it has determined the incremental contribution of the Proposed Project in this Draft EIR to be cumulatively considerable.

The Proposed Project could result in effects to public services via environmental incidents and accidents that could add additional burden to fire protection, police, medical services, schools, parks, and other public facilities (Potential Impact 3.17-1). The Campora Propane project in Yreka and Pacific Connector Gas Pipeline in Oregon (Table 3.24-1) are in development and may present such risks, but are a substantial distance from the Proposed Project, such that they are not expected to cause significant impacts in the Area of Analysis in the unlikely event that an environmental incident or accident occurred. Additionally, the Pacific Connector Gas Pipeline would be not be transporting gas in liquified form. Therefore, the cumulative impact would not be significant.

The Proposed Project could expose people or structures to a risk of loss, injury, or death involving wildland fires by reducing reservoir storage (Potential Impact 3.17-2, and Potential Cumulative Impact 3.21-8). 2017 court-ordered flushing and emergency dilution flows could change flows from upstream of the Proposed Project and affect the volume of water available for firefighting in the Area of Analysis, and the timing of the 2017 flows is likely to have a beneficial effect during wildfire season. Although changes to flow management may occur in the future, no other projects identified in Table 3.24-1 would reduce reservoir water storage. USDA Forest Service wildfire fuel reduction projects on National Forest land such as the Six Shooter Project are intended to reduce the risk of catastrophic fire. Therefore, the cumulative impact is not significant.

No project or non-project activity types within the area of analysis that could potentially effect school services and facilities (Potential Impact 3.17-3) overlap in type, location, or time with anticipated Proposed Project impacts; therefore, there would be no cumulative impact to public services related to school services and facilities.

Significance

Cumulatively considerable in the short term

No significant cumulative impact in the long term

3.24.18 Utilities and Service Systems

The Area of Analysis for utilities and service systems consists of lands within the Project Boundary (Figure 2.2-4), plus consideration of disposal capacities for accommodating solid wastes at the Yreka Transfer facility near Hornbrook, CA, the Class 1 Landfill near Anderson, CA, and the Dry Creek landfill site in White City, OR. These areas could potentially experience utility and service effects from the Proposed Project. Potential cumulative impacts to wastewater and stormwater would be limited to lands within he Project Boundary. Potential cumulative impacts of short-term waste export are also addressed in Section 3.24.21 *[Cumulative Effects] Hazards and Hazardous Materials* and Section 3.24.22 *[Cumulative Effects] Transportation and Traffic.* Potential cumulative impacts to water supply are addressed in Section 3.24.8 *Cumulative Effects [Water Supply/Water Rights].*

Existing conditions for wastewater, stormwater, and solid waste systems are described in Section 3.18.2 *[Utilities and Service Systems] Environmental Setting*.
The City of Yreka's wastewater treatment plant treats domestic and industrial sewage generated within the city's boundaries (City of Yreka 2017). Communities in unincorporated Siskiyou County either operate community wastewater treatment systems, on-site septic systems, or use an adjacent city's wastewater treatment facilities (USBR 2012). Recreational facilities located along the shoreline of Project reservoirs have vault toilets. No municipal stormwater systems are located within the Area of Analysis for utilities and service systems. Stormwater captured by impervious surfaces at existing Project facilities and within Hornbrook and Copco Village is conveyed by and to natural drainages (FERC 2004).

The Area of Analysis is not served by any water district. Water supplies are provided to rural residences near the Lower Klamath Project facilities by private wells (USBR 2012). The Proposed Project site is within the jurisdictional boundaries of the Siskiyou County Integrated Solid Waste Management Regional Agency, which operates five solid waste recycling and transfer sites (CalRecycle 2017a, Siskiyou County 2017b). Section 3.18.2 *[Utilities and Service Systems] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, utilities and service systems.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of utilities and service systems resource area effects (Section 3.18). The following project types were considered:

- Large-scale construction projects;
- Large-scale demolition projects;
- Industrial development projects;
- Community development projects; and
- Large-scale residential subdivisions.

Potential Cumulative Impact 3.24-56 Short-term and long-term utilities and service system effects from the Proposed Project in combination with non-project activities.

The Proposed Project proposes to dispose of solid waste at the County transfer station located at the former landfill site on Oberlin Road, two miles southeast of Yreka, California, which is the nearest transfer station that could be used for recycling and waste disposal/transfer during dam demolition. The transfer station is permitted to accept general residential, commercial, and industrial refuse for disposal. The Yreka Transfer Facility has a capacity of 100 tons per day. Currently, solid waste is transferred to the Dry Creek Landfill near White City Oregon. In 2018, this landfill had a total capacity of 76,800,000 tons with a life projected at over 100 years (Dry Creek Landfill, 2018).

Hazardous materials must be disposed at certified Class I landfill facilities, which are lined to prevent the contamination of underlying soils and groundwater. The Anderson Landfill in Anderson, California, is located 122 miles south of Hornbrook, California, and is permitted to accept hazardous waste. The Anderson Landfill had an estimated remaining capacity of 11,914,025 cubic yards (72 percent of capacity remaining) in 2008, with an anticipated closure date of 2055 (CalRecycle 2017a). Estimated quantities of solid waste from the Proposed Project are described in Section 2.7.1 *Dam and Powerhouse Deconstruction*, as well as in the Definite Plan (Appendix B: *Definite Plan – Tables 5.3-3, 5.4-3* and *5.5-3*). Solid waste volumes from the Proposed Project would be within the limitations noted above (Potential Impacts 3.18-3 and 3.18-4). The expansion of the Kidder Creek Orchard Camp, the opening of the Siskiyou County Jail, Trinity County Jail, and Rain Rock Casino, and the potential demolition of the Ringe Pool Facility (Table 3.24-1) have the potential to increase solid waste contributions to regional landfills. The landfills described above are expected to have the capacity to accept solid waste from these projects as well as from the Proposed Project.

The Proposed Project would not have significant impacts associated with the construction of new wastewater and/or stormwater treatment facilities, or expansion of existing facilities (Potential Impacts 3.18-1 and 3.18-2). Large non-project construction activities would be required to obtain coverage individually under the Statewide Construction General Permit (CGP), requiring applicants to address erosion and sediment control, stormwater, spill prevention and containment, and site cleanup. No non-project activity types within the Area of Analysis that could potentially effect wastewater or stormwater would overlap in type, location, or time with anticipated impacts due to the Proposed Project; therefore, there would be no significant cumulative impact associated with wastewater or stormwater services.

As the Proposed Project would not have a significant adverse impact on utilities and service systems, and there are no closely related projects that would, in combination with the Proposed Project, have a significant and adverse impact, there would be no significant cumulative utilities and service systems impacts.

Significance

No significant cumulative impact

3.24.19 Aesthetics

The Area of Analysis for aesthetics is the Klamath River from the Oregon-California state line to the Klamath River Estuary. The Primary Area of Analysis for aesthetics is within the viewshed of the Lower Klamath Project reservoirs, which includes the proposed Limits of Work in California (i.e., Copco No. 1, Copco No. 2, and Iron Gate dams, reservoirs, and associated facilities, and the areas identified as construction/demolition areas and staging areas), plus a buffer to the ridgeline of surrounding the reservoirs (Figure 3.19-1).

Existing conditions for aesthetics are defined in Section 3.19.2 *[Aesthetics] Environmental Setting*. The Area of Analysis for aesthetic resources contains BLM VRM Class III visual resources, for which the objective is to retain the existing character of the landscape, with only moderate change from a project such as the Proposed Project. The variety of color, vegetation, landforms, adjacent scenery, scarcity, cultural modifications, and the presence of water within the Area of Analysis leads to a BLM Class A (distinctive inherent scenic attractiveness) classification for scenic quality. The Area of Analysis also has a High BLM visual sensitivity classification, meaning the public seeks a high level of visual quality in the landscape, and a foreground-middleground distance zone classification. Additionally, Klamath River components are part of the National (and state) Wild and Scenic Rivers (WSR) System, because of their free-flowing condition and “outstandingly remarkable” values. The “State of Jefferson” National Forest Scenic Byway, and “Bigfoot” National Forest Scenic Byway are also situated within the Area of Analysis. Section 3.19.2 *[Aesthetics] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, aesthetics resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of utilities and service systems resource area effects (Section 3.18).

This cumulative impact analysis focuses on the impact of the Proposed Project and other projects that are not already considered in the analysis of aesthetics resource area effects (Section 3.19) due to actions and elements included in the Proposed Project (Section 2). Non-project activity types within the aesthetics Area of Analysis with the potential for significant cumulative land use and planning impacts include (Table 3.24-1):

- Large-scale construction projects;
- 2017 court-ordered flushing and emergency dilution flows, or other hydrological impacts that change flow characteristics, open water conditions, channel morphology, or turbidity;
- Water discharges that visually affect water quality;
- Riverine restoration projects;
- Changes or removal of historic structures;
- Near-channel infrastructure projects (i.e., bridges, culverts); and
- Large-scale infrastructure projects.

Significance criteria for cumulative aquatic resources impacts are the same as defined in Section 3.19.3 *[Aesthetics] Significance Criteria*.

Potential Cumulative Impact 3.24-57 Short-term and long-term scenic vista effects from the loss of open water from the Proposed Project in combination with other non-project activities.

The Proposed Project would have no significant impact from the loss of open water vistas, because open water and lake vistas would be altered in favor of more natural river, canyon, and valley vistas, there are numerous open-water lakes in the region, and visual quality for the public would not be substantially degraded (Potential Impact 3.19-1). No other projects that would result in loss of open water have been identified (Table 3.24-1), thus there would be no significant cumulative impacts to scenic vistas due to the Proposed Project and other closely related projects.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-58 Short-term and long-term scenic resources effects from the Proposed Project in combination with restoration, flow enhancement, and water quality improvement projects, and other non-project activities.

The Proposed Project could affect flow characteristics within sections of Klamath River classified as WSR. Potential changes to flow characteristics include the timing, duration, and magnitude of flows, which can affect channel morphology; however, the Proposed Project would have flow characteristics that are visually similar to existing conditions and visual impacts related to changes of river channel morphology would not be significant (Potential Impact 3.19-2). Other projects (Table 3.24-1) have the potential to alter river channel morphology and result in a cumulative impact. Potential Impact 3.24-1 in Section 3.24.2 *Cumulative Water Quality Effects* provides background and context regarding agency re-consultation on the 2013 BiOp, and Potential Impact 3.24-24 provides a summation of the approach taken in this document. As for Potential Impact 3.24-24, the 2017 court-ordered flushing flows are the focus of this analysis. Surface and deep flushing flows would reflect a more natural regime, thus could have either no impact or beneficial effects to river channel morphology in combination with the Proposed Project.

The Proposed Project would result in significant and unavoidable short-term changes in water quality due to elevated suspended sediment concentrations during reservoir drawdown (Potential Impact 3.2-3); however, the visual quality (water clarity) impact from this would not be a significant impact as the contrast is expected to be weak to moderate (i.e., not a visually noticeable change from existing conditions for most of the drawdown period) and spatially limited (decreasing downstream) (Potential Impact 3.19-3). While there may be an increase in the duration of elevated suspended sediment concentrations in water years when the Proposed Project reservoir drawdown flows do not meet the surface and/or deep flushing flow requirements and the 2017 court-ordered flushing flows are still required to occur until either April 30 (surface flushing flows) or May 31 (deep flushing flows) (see Potential Cumulative Impact 3.25-1 for more details); reduced clarity conditions would be of short duration (i.e., 24 to 72 hours) and spatially limited. Overall, there would not be a short-term cumulative visual quality impact due to the Proposed Project and the 2017 court-ordered flushing flows.

In the long term, the beneficial reductions of seasonal nuisance algae blooms would have no impact on aesthetics (Potential Impact 3.18-3). The 2017 court-ordered flushing flows would improve management of *C. Shasta,* which could have adverse visual water quality outcomes if left uncontrolled. Similarly, other restoration projects occurring within the Klamath Watershed, such as the Long-Term Plan to Protect Adult Salmon in the Lower Klamath River, would reduce nutrients and thus the prevalence of seasonal algae blooms (Table 3.24-1). The Proposed Project, in combination with riverine restoration projects, would have beneficial effects on visual water quality.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-59 Short-term and long-term visual character and quality effects from the Proposed Project in combination with other ground disturbing and construction activities.

The Proposed Project would potentially impact the visual character and quality of the site and its surroundings. Substantial areas of bare sediment and rock would be exposed in previously inundated areas after reservoir drawdown and dam removal, and would remain exposed until vegetation establishes, which would result in a significant impact in the short term (Potential Impact 3.19-4). Existing wetland vegetation on the reservoir shorelines may also die. Other closely related activities that could cause a similar change in visual character within the Lower Klamath Project reservoir footprints include mining and near-channel infrastructure. However, no reasonably foreseeable projects involving such activities within the reservoir footprints have been identified (Table 3.24-1); therefore, there would be no cumulative impact.

Replacement of the Yreka water supply pipeline, bridges, culverts, roads, and recreational facilities would result in minor visual changes compared to existing conditions, which would not constitute a significant short-term or long-term impact (Potential Impacts 3.19-5 and 3.19-6). Although there are other projects of this nature within the Klamath Basin, none of them are within the aesthetics Area of Analysis; therefore, the combination of the Proposed Project and other construction-related projects would not result in a significant cumulative visual impact.

The Proposed Project involves the removal of historic structures (Copco No. 1 Hydroelectric Powerhouse and Dam; Copco No. 2 Hydroelectric Powerhouse; and Copco No. 2 Wooden Stave Penstock) (Potential Impact 3.19-5). Separate from the Proposed Project, no other historic structures have recently been removed, or are known to be planned for removal, in the aesthetics Area of Analysis (Table 3.24-1). Thus, there would be no significant cumulative scenic historic resource impact resulting from the Proposed Project and other closely related projects.

Additionally, there would be potential short-term impacts to visual character and quality due to Proposed Project construction activities, including the presence of vehicles and equipment, temporary structures, temporary access roads, equipment storage, stockpiles, and demolition. The Proposed Project would have temporary weak to strong visual contrasts associated with construction activities and would generate dust, but most nearby recreational facilities with views of the construction site would be closed for the duration of the construction period, thus the impact would not be significant (Potential Impact 3.19-6). Although it is possible that there would be small-scale construction activities within the Area of Analysis at the same time as the Proposed Project, no overlapping large-scale construction projects are anticipated that would, in combination with the Proposed Project, result in reasonably foreseeable significant and adverse aesthetics impacts. Thus, there would be no cumulative aesthetics impacts due to the construction activities associated with the Proposed Project.

Significance

No significant cumulative impact

Potential Cumulative Impact 3.24-60 Short-term light and glare effects from the Proposed Project in combination with other construction projects.

Temporary lighting would be erected for nighttime construction activities under the Proposed Project, and security lighting may be required during deconstruction (Potential Impact 3.19-7). Although the Proposed Project would result in significant and unavoidable adverse impacts due to construction-related lighting, there are no closely related, spatially and temporally overlapping projects that would, in combination with the Proposed Project, result in further significant and adverse light or glare impacts (Table 3.24-1). Thus, there would be no significant cumulative aesthetics impacts due to short-term lighting and glare under the Proposed Project.

Significance

No significant cumulative impact

3.24.20 Recreation

The Area of Analysis for recreation includes recreation areas and associated access along the Klamath River corridor from the California-Oregon border to the Klamath River Estuary (Figure 3.20-1).

Existing conditions for recreation are defined in Section 3.20.2 *[Recreation] Environmental Setting*. Within the Klamath Basin, there are four national forests (Klamath, Fremont – Winema, Six Rivers, and Modoc), one joint national and state park (Redwood), one national park (Crater Lake), two national monuments (Lava Beds and Cascade – Siskiyou), and five National Wildlife Refuges (NWRs) (Klamath Marsh, Tule

Lake, Clear Lake, Upper Klamath, and Lower Klamath). These areas provide sightseeing, camping, hiking, fishing, wildlife viewing, and other recreational opportunities. Within the Klamath Basin, the Klamath, Scott, Salmon, Sprague, Sycan, Smith, and Trinity rivers, and Wooley Creek have segments classified as having Wild and Scenic values under the WSRA. Additionally, there are extensive public and private recreational opportunities along the Klamath River and within several lakes/reservoirs. Developed recreational facilities, including: Agency Lake, Upper Klamath Lake, the Link River Trail, and the Keno Impoundment/Lake Ewauna, and activity specific recreational resources, are described in Section 3.30.2 *[Recreation] Environmental Setting*. Section 3.20.2 also includes consideration of major past or ongoing projects that have impacted, or currently impact, recreation resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of recreation resource area effects (Section 3.20). Non-project activity types within the recreation Area of Analysis with the potential for significant cumulative recreational impacts include (see also Table 3.24-1):

- Development projects, especially large-scale construction;
- Restoration, flow enhancement, and water quality improvement projects ; and
- Water flow changes and whitewater boating.

Significance criteria for cumulative aquatic resources impacts are the same as defined in Section 3.20.3 *[Recreation] Significance Criteria*.

Potential Cumulative Impact 3.24-61 Short-term and long-term recreation effects from the Proposed Project in combination with development projects.
Proposed Project short-term construction-related impacts on existing recreational opportunities would not be significant (Potential Impact 3.20-1) for the following reasons: a number of reservoirs, lakes, and rivers are present within and adjacent to the Klamath Basin that provide similar recreational opportunities as areas where access would be restricted during Proposed Project construction; several existing recreational sites are located away from where dust and noise would be generated during Proposed Project construction; turbidity impacts would be short-term and primarily during the winter when recreational use for non-contact (e.g., boating) and contact recreation (e.g., swimming and fishing) is relatively low; and water quality and clarity would improve with distance downstream of Iron Gate Dam, as sediments are flushed downstream and into the Pacific Ocean. Although there is potential for other large-scale construction projects in the Klamath Basin to temporally overlap with the Proposed Project, such as the Sousa Ready Mix Concrete Plant and the potential nanocellulose facility, these projects would be located in Yreka (Table 3.24-1). Such projects in Yreka are not close enough to the Proposed Project reservoir footprints and/or the Middle Klamath River immediately downstream of Iron Gate Dam (where turbidity impacts would be greatest) to result in a significant cumulative impact. There may be some overlapping, small-scale construction projects in more proximal locations (Table 3.24-1), but there are no other reasonably foreseeable construction projects that would contribute to a short-term adverse cumulative impact on recreation in the area where the Copco No. 1, Copco No. 2, and Iron Gate dams are proposed for removal (Table 3.24-1). Thus, the Proposed Project, in combination with other construction projects, would not have a significant adverse cumulative impact on recreational opportunities in the Area of Analysis.

The Proposed Project would not have significant long-term impacts on reservoir-based recreation activities (Potential Impact 3.20-2), or substantial or accelerated physical deterioration of other regional facilities (Potential Impact 3.20-3). Under the Proposed Project, Fourmile Lake, Agency Lake, Applegate Reservoir, and Medicine Lake would all continue to provide region-wide open-water activities, some reservoir facilities would remain, and would be upgraded or enhanced where possible, and most existing river access would be retained and upgraded. Steelhead, trout, and salmon fisheries in the Klamath River would be enhanced. Any loss of warm water fishing opportunities is not over a large area and there are other warm water fishing opportunities elsewhere in California and Oregon. No other reasonably foreseeable development projects have been identified in the Area of Analysis for recreation that would remove reservoirs, adversely impact recreational opportunities in other lakes and reservoirs, or reduce warm water fishing opportunities. In the absence of spatially and temporally overlapping development projects, there would be no significant cumulative impacts to reservoir-based recreation or physical deterioration of regional facilities.

Significance
No significant cumulative impact

Potential Cumulative Impact 3.24-62 Short-term and long-term recreation effects from the Proposed Project in combination with other restoration, flow enhancement, and water quality improvement projects.
The Proposed Project would improve scenery, recreation, fisheries, and wildlife values (which are values specified in the Wild and Scenic River Act Section 7(a)) on the California Klamath Wild and Scenic River segments (both designated and eligible for listing) (Potential Impact 3.20-7). Other aquatic habitat restoration, flow enhancement, and water quality improvement projects along the Klamath River and its tributaries (see Table 3.24-1) would include placement of off-channel habitat features, floodplain restoration, incorporation of large wood into tributaries to the Klamath River, increases in stream flow, and reduction in water quality pollutants. These types of projects would have a beneficial cumulative effect on recreation associated with wild and scenic values in the long term.

The Proposed Project would be beneficial with respect to the river-based recreational fishing because it would: restore volitional fish passage, improve long-term water quality, likely increase recreational fish species, and implement the Recreation Facilities Plan for the Hydroelectric Reach (Potential Impact 3.20-6). There would be no significant impact to, or loss of, other river-based recreation, for the Middle Klamath River between Iron Gate Dam and Humbug Creek under the Proposed Project, because there is only one structure that is expected to be within the post-dam removal 100-year floodplain that is not in the floodplain under existing conditions (Potential Impact 3.20-6). Other restoration projects (Table 3.24-1) would also improve fisheries by restoring habitat; therefore, the Proposed Project in combination with other restoration projects would be beneficial for recreational fishing.

Significance
Beneficial cumulative effects

Potential Cumulative Impact 3.24-63 Short-term and long-term whitewater boating effects from the combination of the Proposed Project and water flow changes.

The Proposed Project would result in a significant adverse impact due to reduction of whitewater boating opportunities in the Hell's Corner river reach (in the upper portion of the Hydroelectric Reach) (Potential Impact 3.20-5). However, with the Proposed Project there would also be an increase in whitewater boating opportunities in the Copco No. 2 Bypass Reach, and there could be improvements in the quality and quantity of whitewater boating opportunities in areas currently inundated by reservoirs. There are no closely related projects (Table 3.24-1) that would, in combination with the Proposed Project, result in further significant and adverse whitewater boating impacts in the Hell's Corner river reach or other reaches of the Klamath River or its tributaries. The 2017 court-ordered flushing flows (interim flows until re-consultation of the 2013 BiOp is completed, see also Potential Cumulative Impact 3.24-1) would increase water flows during relatively short (i.e., 24 to 72 hours) controlled periods (see Potential Cumulative Impact 3.24-1), which could provide periodic benefits to whitewater boaters. No projects have been identified that would substantially reduce flows and result in a significant cumulative impact on whitewater boating opportunities in combination with the Proposed Project (Table 3.24-1).

Significance
No significant cumulative impact

3.24.21 Hazards and Hazardous Materials

The Area of Analysis for hazards and hazardous materials includes the area in the immediate vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams and reservoirs, and areas identified as construction/demolition and staging areas. The Area of Analysis for hazards and hazardous materials also includes routes proposed to be utilized for the transportation of construction debris and equipment.

Existing conditions for hazards and hazardous materials are described in Section 3.21.2 *[Hazards and Hazardous Substances] Environmental Setting*, which describes transport/releases of hazardous materials, school proximity, contaminants/contaminated sites, nearby airports, emergency response, and wildfires. Section 3.21.2 *[Hazards and Hazardous Substances] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, environmental resources. This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of hazards and hazardous substances resource area effects (Section 3.21). Non-project activity types within the hazards and hazardous materials Area of Analysis with the potential for significant cumulative impacts include (see also Table 3.24-1):

- Construction or demolition projects involving the transport, use, disposal of emissions, or accidental release of hazardous materials;
- Land use or land management changes involving the transport, use, disposal of emissions, or accidental release of hazardous materials;
- Projects or plans that could impair implementation emergency response or emergency evacuation plans;
- 2017 court-ordered flushing and emergency dilution flows;
- Wildfires; and
- Forest and wildfire management.

Potential Cumulative Impact 3.24-64 Short-term and long-term hazards and hazardous materials effects from the Proposed Project in combination with non-project activities.

No non-project activity types within the hazards and hazardous materials Area of Analysis that could be located on a hazardous materials site, projects that could result in a safety hazard within two miles of airports, or that could impair implementation emergency response or emergency evacuation plans (Potential Impacts 3.21-5, 3.21-6, and 3.21-7), would have the potential for significant incremental short- or long-term cumulative impacts related to hazards and hazardous substances because none of these activities would overlap in type, location, or time with anticipated impacts under the Proposed Project.

The Proposed Project could result in substantial exposure for the public or environment to hazards or hazardous materials due to routine transport, use, or disposal of hazardous materials, potential accidental release of hazardous materials, or be located on a hazardous site (Potential Impacts 3.21-1, 3.21-2, and 3.21-3), and would require implementation of Mitigation Measure HZ-1 to reduce potential impacts to less than significant. Although the Campora Propane and Pacific Connector Gas Pipeline projects are in development and may present similar risks, both projects are too distant from the Lower Klamath Project dam complexes in California to cause significant impacts in the Area of Analysis. Thus, there would be no cumulative impact.

The Proposed Project would result in a significant and unavoidable long-term impact due to reduction in reservoir storage for fighting wildland fires (Potential Impact 3.21-8) because the State Water Board cannot ensure the implementation of Recommended Measure PS-1, which would require a Fire Management Plan after reaching agreement with CALFIRE on a long-term water source replacement for helicopter and ground crews (including construction and utilization of proposed dry hydrants, dip ponds or other alternatives). While the effects of new BiOp flow requirements for the Klamath Irrigation Project are speculative, the 2017 flow requirements (i.e., 2013 BiOp Flows plus the 2017 court-ordered flushing and emergency dilution flows) periodically increase the volume of water entering the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam by requiring 24-hr to 72-hr periods of higher flows into May and June. While this short period of inflow and limited periodicity is not sufficient to be beneficial with respect to fighting wildland fires, the 2017 flow requirements would not reduce the volume of water available for firefighting during the spring and early summer months (see also Potential Cumulative Impact 3.24-1) and there would be no cumulative impact to water supply. Although changes to flow management in the Hydroelectric Reach and the Middle Klamath River may occur in the future, no other reasonably foreseeable projects identified in Table 3.24-1 would reduce flows or water storage in the Hydroelectric Reach. Further, wildfire fuel reduction projects, including the USDA Forest Service projects on National Forest lands (e.g., Six Shooter Project) and firefighting are intended to reduce the risk of catastrophic fire. Therefore, the cumulative effects of the Proposed Project, when combined with the USDA Forest Service or any other wildfire fuel reduction projects, would not be significant in regard to wildfire ignition risk. As discussed above (Potential Cumulative Impact 3.24-25), wildfire itself is a potential hazard, and may occur in Area of Analysis in the future. If a large fire occurs in the Area of Analysis during the construction period for the Proposed Project, work would be suspended due to health and safety reasons (see Potential Cumulative Impact 3.24-34 [Air Quality]); therefore, temporal overlap is unlikely.

Significance
No significant cumulative impact for hazardous materials

Cumulatively considerable for firefighting water access

3.24.22 Transportation and Traffic

The Area of Analysis for cumulative transportation and traffic effects encompasses roadways in Siskiyou and Shasta Counties that would be used by construction vehicles and workers and could potentially be affected by the Proposed Project. Table 3.22-1 lists the regional and local roads that access each California site of the Proposed Project (Copco No. 1, Copco No. 2, and Iron Gate dams). These roads include Copco Road, Ager-Beswick Road, Lakeview Road, and California segments of I-5. Equipment hauling and waste disposal for J.C. Boyle Dam would occur only in Oregon (Appendix B: *Definite Plan*).

Existing conditions for transportation resources are described in Section 3.22.2 [*Transportation*] *Environmental Setting*. Roadways in Siskiyou County are generally rural. Most of the private property in the area is undeveloped and/or used as grazing land for cattle, with the exception of several small communities in the vicinity of Copco No. 1 and Iron Gate reservoirs. With the exception of Interstate 5, roads in the Area of Analysis are one- or two-lane collector or local rural roads. Level of Service (LOS) conditions on Interstate 5 are currently at LOS A, which indicates free flow of traffic. The major access roadways in the Area of Analysis that are likely to be affected by Proposed Project-related traffic are also currently at LOS A (Greendot 2016). Surveys conducted in 2017 identified several roadways, bridges and culverts that are not structurally competent to withstand construction-related traffic. Section 3.22.2 *[Transportation and Traffic Effects] Environmental Setting* includes consideration of major past or ongoing projects that have impacted, or currently impact, transportation and traffic resources.

This cumulative impact analysis focuses on the potential impacts of the Proposed Project combined with other closely related projects that are not already considered in the analysis of transportation and traffic resource area effects (Section 3.22). Non-project activity types within the Area of Analysis with the potential for significant cumulative effects when combined with the Proposed Project were considered in relation to the potential impact types evaluated in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation*. These include activities that could create potential impacts to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation by either temporarily increasing traffic volume or impeding traffic flow. The non-project activity types (plus wildfires) include the following (see also Table 3.24-1):

- Forest and wildfire management;
- Construction projects;
- Restoration projects; and
- Road repair.

Potential Cumulative Impact 3.24-65 Short-term and long-term traffic and transportation effects from the Proposed Project in combination with non-project activities.

As described in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation*, the Proposed Project would result in significant and unavoidable short-term impacts to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation, unless and until KRRC reaches enforceable 'good citizen' agreements that are finalized and implemented through the FERC process and that include proposed items for the final TMP and Emergency Response Plan (Appendix B: *Definite Plan − Appendices O1 through O4*), as well as the additional components included in Recommended Measure TR-1 (Potential Impacts 3.22-1 through 3.22-5).

The Proposed Project is not located within two miles of an airport nor would it result in a change in air traffic patterns that would result in a substantial safety risks (Potential Impact 3.22-6). Therefore, there would be no cumulative impacts related to air traffic due to the Proposed Project in combination with non-project activities within the traffic and transportation Area of Analysis.

It is possible that some riverine restoration projects, such as projects under the Klamath Basin Restoration Program, forest and wildfire management projects, and road repair projects, could overlap temporally, but they are unlikely to occur close enough to Proposed Project construction areas to contribute to a cumulative impact. The closest known forest and wildfire management projects are not within the Area of Analysis for transportation and traffic (i.e., Somes Bar Integrated Fire Management Project; approximately 90 miles downstream of Humbug, and Crawford Vegetation Management Project; approximately 70 miles downstream of Humbug) and so would not overlap spatially with the Proposed Project. The Proposed Project includes road, bridge, and improvement projects associated with the primary access roads (Copco Road, Ager-Beswick Road, Lakeview Road), so other road repair projects occurring at the same time as the Proposed Project would necessarily be located elsewhere.

Other potential construction projects identified in Table 3.24-1 (e.g., Sousa Ready Mix Concrete Batch Plant Project, Siskiyou County jail development, and a potential nanocellulose facility development) are all located in Yreka, and as such, would not be likely to require use of the primary access roads associated with the Proposed Project (Copco Road, Ager-Beswick Road, Lakeview Road) for which short-term impacts to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation could occur. California segments of Interstate 5, which would be used by workers and for hauling equipment and supplies to and from the Proposed Project, could be used by one or more of the potential other construction projects for the same reasons and during the same time period, although the smaller scale of the other projects would be unlikely to result in a high number of vehicle trips relative to the Proposed Project. Since Interstate 5 has sufficient capacity for added traffic (391 ADT) associated with the Proposed Project to keep the LOS level at LOS A (see Potential Impact 3.22-1), the combination of the Proposed Project and one or more other construction projects within the Area of Analysis would be unlikely to result in significant impacts to traffic and transportation. However, because the State Water Board has determined that short-term construction-related impacts of the Proposed Project would be significant and unavoidable with respect to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation, unless and until KRRC reaches enforceable 'good citizen' agreements through the FERC process (as described above), it has determined the incremental contribution of the Proposed Project in this Draft EIR to be cumulatively considerable.

Significance
Cumulatively considerable

3.24.23 Noise

The Area of Analysis for noise and vibration consists of areas in the general vicinity of Copco No. 1, Copco No. 2, and Iron Gate reservoirs, and project haul routes in Siskiyou County where there is potential for impacts to sensitive receptors (i.e., residences) from deconstruction, waste transportation, and worker commutes.

Existing conditions for noise are described in Section 3.23.2 *[Noise] Environmental Setting*. Noise-sensitive receptor locations (e.g., rural residences, residences, certain parks) were identified within the Area of Analysis for noise and vibration, based on a review of current topographic, aerial, and land use maps. Existing ambient noise levels were identified for both daytime and nighttime. At each dam work site, the estimated existing daytime and nighttime outdoor L_{eq} (equivalent sound level) at nearby sensitive receptors are 40 and 30 dBA (A-weighted decibels, representing the perception of loudness), respectively (USEPA 1974) (Table 3.23-1; and section 3.23.2.1 for definitions of relevant terms). Existing roadway traffic noise along the proposed haul routes associated with each dam is shown in Table 3.23-2.

The nature of noise impacts is that they are inherently in the present. For there to be a cumulative impact from two or more projects together exceeding acceptable noise volumes, there would need to be temporal overlap with the Proposed Project. Projects that do not have temporal overlap, but occur immediately before or after the Proposed Project, could have a cumulative impact by increasing the duration of elevated noise volumes. Therefore, this analysis considers projects that may overlap in space and time with the Proposed Project, or that may overlap in space and occur immediately before or after the Proposed Project.

This cumulative impact analysis focuses on the potential impacts of the Proposed that are not already considered in the analysis of noise resource area effects (Section 3.23). Other project activity types within the noise Area of Analysis with the potential for significant cumulative noise and vibration impacts include (see also Table 3.24-1):

- Large-scale development;
- Construction for riverine restoration projects;
- Fire management activities, including thinning;
- Mining;
- Use of agricultural vehicles and equipment; and
- Recreational activities involving motors or large crowds.

Significance criteria for noise and vibration impacts are the same as defined in Section 3.23.3 *[Noise] Significance Criteria*.

Potential Cumulative Impact 3.24-66 Short-term noise effects from the Proposed Project in combination with other non-project activities.
The Proposed Project would result in noise and vibration that will affect sensitive receptors and exceed Siskiyou County General Plan standards. Significant and unavoidable adverse environmental impacts would result from: construction equipment

exceeding maximum allowable noise levels (Potential Impact 3.23-1); noise disturbance to residents from construction-generated noise at Copco No. 1 and Iron Gate dams (Potential Impacts 3.23-2 and 3.23-4), reservoir restoration at Copco No.1 and Iron Gate dams (Potential Impact 3.23-5); and vibration disturbance from blasting activities at Copco No. 1, Copco No. 2, and Iron Gate dams (Potential Impact 3.23-6). Other noise and vibration generation from the Proposed Project would not have a significant adverse impact (Section 3.23-5 *[Noise] Potential Impacts and Mitigation*). Upon review of other projects that are anticipated to result in a noise or vibration disturbance (Table 3.24-1), most of these do not overlap in space and time with the Proposed Project. It is possible that some riverine restoration projects, such as projects under the Klamath Basin Restoration Program, and fire management projects, could overlap temporally, but they are unlikely to occur close enough to Proposed Project construction and blasting areas to contribute to a cumulative impact. Ongoing mining, agricultural, and recreational activities could also overlap temporally, but no new projects or activities of this nature have been identified within the vicinity of Copco No. 1, Copco No. 2, and Iron Gate dams; therefore, noise generation from these activities would be part of the existing conditions. Additionally, recreational access to the Lower Klamath Project reservoirs would be limited during blasting and heavy construction periods such that ongoing recreational activities that generate noise would be unlikely to occur within the noise and vibration Area of Analysis. Potential future large-scale development projects identified in Table 3.24-1 (e.g., Sousa Ready Mix Concrete Batch Plant Project, Siskiyou County jail development, and a potential nanocellulose facility development, all in Yreka) are not close enough to the Proposed Project's expected area of noise and vibration generation to result in a significant and adverse combined impact. No other closely related projects that would result in a significant and adverse combined noise impact along Proposed Project haul routes have been identified.

Although the Proposed Project would result in significant and unavoidable adverse impacts due to construction- and restoration-related noise, there are no closely related projects that would, in combination with the Proposed Project, result in further significant and adverse noise and/or vibration impacts. Thus, there would be no significant cumulative noise or vibration impacts due to the Proposed Project and other closely related projects.

Significance

No significant cumulative impact

4 ALTERNATIVES

4.1 Alternatives Selection/Overview

Section 15126.6 of the CEQA Guidelines requires that an EIR describe and evaluate a reasonable range of alternatives to the project, or to the location of the project, which could attain most of the basic project objectives but would avoid or substantially lessen any of the significant environmental effects of the project. The “rule of reason” governing the range of alternatives specifies that an EIR should discuss sufficient alternatives to allow a reasoned choice by the decision makers, but it does not require consideration of all possible alternatives to a project. Alternatives must be “feasible”, meaning that they can be successfully implemented to accomplish the project’s overall purpose and objectives in a reasonable amount of time, taking into account considerations including cost, existing technology, social factors, legal factors, and environmental issues. (CEQA Guidelines, section 15364.) Therefore, “an EIR need not consider an alternative whose effect cannot be reasonably ascertained and whose implementation is remote and speculative.” (CEQA Guidelines, section 15126.6, subdivision (f)(3).) The EIR should include sufficient information about each alternative to allow meaningful evaluation, analysis and comparison.

The underlying project purpose is the timely improvement of water quality related to the Lower Klamath Project within and downstream of the current Hydroelectric Reach and the restoration of anadromous access upstream of Iron Gate Dam (the current barrier to anadromy). In furtherance of this underlying purpose, the State Water Board has identified the following project objectives (see also Section 1 *Introduction*):

In a timely manner:

1. Improve the long-term water quality conditions associated with the Lower Klamath Project in the California reaches of the Klamath River, including water quality impairments due to Microcystis aeruginosa and associated toxins, water temperature, and levels of biostimulatory nutrients.
2. Advance the long-term restoration of the natural fish populations in the Klamath Basin, with particular emphasis on restoring the salmonid fisheries used for subsistence, commerce, tribal cultural purposes, and recreation.
3. Restore volitional anadromous fish passage in the Klamath Basin to viable habitat currently made inaccessible by the Lower Klamath Project dams.
4. Ameliorate conditions underlying high disease rates among Klamath River salmonids.

4.1.1 Alternatives Selection

In determining a reasonable range of alternatives for the EIR, the State Water Board considered a wide range of potential alternatives. These included prior environmental analyses’ alternatives—both accepted and rejected. The potential alternatives also included alternatives and adjustments to previously-analyzed alternatives raised by agencies, the applicant and the general public since release of the Notice of Preparation, as well as alternatives that arose by incorporating new information generated since completion of prior environmental analyses.

The 2007 FERC EIS analyzed five action alternatives: (1) PacifiCorp's Proposal at that time for continued operation; (2) FERC Staff Alternative for continued operation; (3) FERC Staff Alternative with Mandatory Conditions imposed through the licensing process by other federal agencies; (4) Retirement of Copco No. 1 and Iron Gate Developments; and (5) Retirement of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate Developments. The 2007 FERC EIS considered, but decided not to move forward with, analysis of federal take-over of the dams and cessation of power generation at the facilities, but not requiring removal of the dam facilities themselves.

The 2012 KHSA EIS/EIR analyzed four action alternatives: (1) Dam Removal of Four Dams; (2) Partial Removal of Four Dams; (3) Fish Passage at Four Dams; and (4) Removal of Copco 1 and Iron Gate with Fish Passage at Copco 2 and J.C. Boyle. These were selected from the 17 action alternatives and the No Action/No Project Alternative in the initial alternatives screening process. The 13 rejected action alternatives were: (a) Three Dam Removal; (b) Sequenced Removal of Four Dams; (c) Full Facilities Removal of Four Dams without KBRA; (d) Trap and Haul; (e) Bogus Creek Bypass; (f) Bogus Creek Bypass – Alternative Tunnel Route; (g) Notching Four Dams; (h) Federal Takeover of Project; (i) Full Removal of Five Dams; (j) Full Removal of Six Dams; (k) Dredge Upper Klamath Lake; (l) Predator Control; and (m) Partition Upper Klamath Lake.

The State Water Board revisited the aforementioned listed alternatives, as well as three additional potential alternatives raised in Lower Klamath Project scoping (see also Appendix A). First, Siskiyou County and others proposed examining a fish passage alternative that looks at a combination of trap and haul, fish cannons (a new technology since 2012), and other mechanisms for fish passage without dam removal. The Siskiyou County proposal combines elements of other Lower Klamath Project scoping comments regarding methods of fish passage with dams in place. Second, Siskiyou County and Siskiyou Water Users Association scoping comments also suggested developing an alternative of additional water storage in the Scott and Quartz valleys to augment late summer and fall instream flows. Third, Siskiyou County and Siskiyou County Water Users Association scoping comments also suggested transferring 60,000 acre-feet of water from Iron Gate Reservoir (or J.C. Boyle Reservoir or Keno Reservoir) to the Shasta River sub-watershed as irrigation supply to allow Lake Shastina discharges to go directly into the Shasta River rather than being used as irrigation supply first.

From this initial pool of 24 alternatives, the State Water Board selected five feasible action alternatives that would reduce one or more potentially significant impacts of the Proposed Project and would meet the underlying purpose of the Proposed Project and most of the Proposed Project objectives. Consistent with CEQA Guidelines section 15126.6(e)(2), the State Water Board also included the No Project Alternative in the set of alternatives considered in this EIR. The six alternatives to the Proposed Project that were carried forward for more detailed analysis are introduced briefly in Section 4.1.1.1 and revisited in Sections 4.2 to 4.6 in comparison to existing conditions and the Proposed Project (CEQA Guidelines section 15126.6(d)). Alternatives that were eliminated from consideration because they would not meet the underlying purpose of the Proposed Project or most of the Proposed Project objectives, were substantially similar to other alternatives, would not avoid or substantially lessen significant environmental effects of the Proposed Project, or were otherwise infeasible, are discussed in Sections 4.1.1.2 through 4.1.1.5.

4.1.1.1 Alternatives Carried Forward for More Detailed Analysis

No Project Alternative

CEQA Guidelines section 15126.6(e)(2) states that the No Project analysis shall discuss the existing conditions at the time the Notice of Preparation is published, or if no Notice of Preparation is published, at the time environmental analysis is commenced, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services. In this instance, the No Project Alternative would be no change from the current management conditions, other than as noted below, with the dams remaining in place. There is significant uncertainty about the long-term results if the KRRC's Proposed Project does not proceed. It is recognized that future consultations with the NMFS and the USFWS on the USBR's operation of the Klamath Irrigation Project, adaptive management of existing projects, and planned restoration activities can significantly alter conditions in the Klamath Basin, but the extent that these and other future basin activities would modify conditions is speculative. In light of this uncertainty, the No Project Alternative analysis focuses on the reasonably foreseeable period of 1–5 years), as described in Section 4.2.1.1 *[No Project Alternative] Alternative Description*.

Partial Removal Alternative

This alternative involves removal of Lower Klamath Project facilities at all four dam complexes to the extent sufficient to allow a free-flowing river. This alternative would therefore meet the underlying purpose and all the objectives of the Proposed Project. However, it would leave in place certain facilities described in Section 4.3.1.1 *Alternative Description*, thereby reducing the construction footprint and potentially the impact to historic resources from implementation of the Proposed Project. The KRRC has requested analysis of this scenario, indicating its feasibility, despite a lack of clarity regarding responsibility for long-term maintenance of remaining facilities.

Continued Operations with Fish Passage Alternative

This alternative examines the impacts of leaving the existing J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dam complexes in place and relicensing the dams before FERC for continued operations, but incorporating alterations to allow for anadromous fish passage. The Continued Operations of the Lower Klamath Project with Fish Passage Alternative is based on the 2007 FERC Staff Alternative with Mandatory Conditions (see Section 4.4 *Continued Operations with Fish Passage Alternative* for more details) and the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative*, but it has been updated based on the most recent requirements that would apply to fish passage at the dams. The alternative includes:

- Volitional, year-round upstream and downstream fish passage at J.C. Boyle, Copco No.1, Copco No. 2, and Iron Gate dams, consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007), and upheld in a trial-type administrative hearing;
- Changes to J.C. Boyle operations to increase minimum flows, limit peaking flows (and recreation flows) to once per week;
- Changes to Copco No. 2 operations to increase minimum flows;
- Flows specified in the NMFS and USFWS 2013 BiOp for the USBR Klamath Irrigation Project (see also 3.1.6.1 *Klamath River Flows under the Klamath Irrigation Project's 2013 BiOp*);

- Court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam which became required after February 2017 (U.S. District Court 2017) (see also Section 4.2.1.3 *Summary of Available Hydrology Information for the No Project Alternative*); and
- Design and implementation of a Reservoir Management Plan.

Prior analyses of similar alternatives indicate a failure to meet the Proposed Project's underlying purpose of addressing project-related water quality impairments and its related objectives (FERC 2007, USBR and CDFG 2012). However, this alternative does further the underlying purpose of providing fish passage upstream of Iron Gate Dam and related objectives by providing volitional adult fish passage. A number of entities requested analysis of dams-in scenarios during Lower Klamath Project scoping: this scenario, with federal mandatory fish passage conditions and FERC-required modifications to operations to address some water quality impacts, fulfills that request and also describes a likely potential long-term condition should dam removal not occur. The Continued Operations with Fish Passage Alternative would reduce the potential impacts of the proposed project related to dam removal and restoration of a riverine environment and elimination of hydropower, and it would likely also reduce construction impacts.

Prior environmental analyses and/or Lower Klamath Project scoping have also raised trap and haul and fish cannons as methods that could allow fish passage with dams remaining in place (FERC 2007, State Water Board 2017). These methods are likely infeasible. Federal mandatory conditions specify volitional fish passage[178], and neither of these proposals have a project proponent. There are few specifics regarding where such facilities would be located and whether the use of the passage method is physically possible at various facilities. Fish cannons (e.g., Whooshh Innovations) present several implementation challenges for the Lower Klamath Project. Even if it is assumed that passage at J.C. Boyle Dam would be provided by a separate facility, the distance separating Iron Gate Dam and Copco 1 Dam (6 miles), along with the height of Iron Gate Dam (173 feet) are prohibitive to current fish cannon technology. To date, the longest distance and height of successful transport using fish cannon technology was 1,700 feet in length and 165 feet in height in a temporary demonstration implementation at Cle Elum Dam in Washington. If fish cannons were to be used at one or more Lower Klamath Project dams, it would most likely have to be in combination with other fish passage facilities at the remaining Lower Klamath Project dams; resulting in similar habitat access and migration mortality as for volitional fishways. In addition, a range of sizes of fish would need to be transported around the dams using the fish cannon technology, to account for fish ranging from relatively small Pacific lamprey or steelhead, to adult Chinook salmon. To date, a passive sorting system has not been developed for fish cannons. Passage of multiple sizes of fish would require multiple sizes of transport tubes, as well as an active sorting system, which has yet to be developed. Furthermore, NMFS considers fish cannons an experimental device. As fish cannons are not identified as a type of conventional fish passage facility by NMFS (2011), their use at the Lower Klamath Project dams would be experimental in nature and, consistent with Section 16.5 of NMFS (2011), would require design and development of conventional fish passage facility at each dam where experimental fish cannons would be used. To date, no implementation of fish cannon technology has successfully demonstrated safe,

[178] Fish passage made continuously available without trap and transport (NMFS 2011).

timely, or effective passage for listed anadromous species, and NMFS has not approved a design. Therefore, there is no evaluation or monitoring data of fish cannons from which to estimate potential mortality or injury to migrating fish if this technology were to be implemented at the Lower Klamath Project under the Continued Operations with Fish Passage Alternative. Thus, fish cannons are considered to be infeasible as a method for fish passage for the Lower Klamath Project in this and other alternatives involving fish passage. However, in light of strong public interest in analysis of alternative fish passage methods, and in light of the similarities among fish passage scenarios, this EIR provides information regarding where the impacts and mitigations for trap and haul would differ from those for fish ladders for the Continued Operations with Fish Passage Alternative, as well as other alternatives involving fish passage.

Two Dam Removal Alternative

In this alternative, the Copco No. 1 and Iron Gate dam complexes in California would be fully removed, while the J.C. Boyle dam complex in Oregon and Copco No. 2 dam complex in California would remain in place (see Section 4.5 *Two Dam Removal Alternative* for more details). This alternative assumes that the J.C. Boyle and Copco No. 2 dam complexes would be relicensed by FERC for continued operations under federal mandatory conditions, with changes to J.C. Boyle operations to increase minimum flows, eliminate peaking and/or recreational flows, and allow for a seasonal high flow event in late winter/spring, as well as fishway prescriptions to allow for volitional year-round upstream and downstream fish passage. Leaving the two dams in place would reduce the amount and duration of sediment release, reduce construction and waste disposal, and retain some level of hydropower production, thus reducing the associated potentially significant impacts. The extent of the reduction in impacts would be slightly greater for this two dam removal alternative compared to the three dam removal alternative described above. This alternative would further all the underlying purposes and project objectives, but not to the same extent as the Proposed Project. Objective 3 would not be met as completely under this alternative since anadromy would continue to be inhibited to some extent by the J.C. Boyle Dam and Reservoir, and to a lesser degree by the Copco No. 2 Dam and Reservoir. This could, in turn, affect the extent to which the alternative achieves Objective 2. This alternative was analyzed because it eliminates the reservoirs with the largest contributions to water quality impairment and with the tallest dams for fish ladder construction, while allowing for continued power generation.

Three Dam Removal Alternative

This alternative considers the potential impacts of removing the three California Lower Klamath Project dams, with J.C. Boyle operating under Mandatory Conditions, except that peaking flows would be completely eliminated (see Section 4.6 *Three Dam Removal Alternative* for more details). This alternative assumes that the J.C. Boyle facility would be relicensed by FERC for continued operations under federal mandatory conditions, with changes to J.C. Boyle operations to increase minimum flows, eliminate peaking and/or recreational flows, and allow for a seasonal high flow event in late winter/spring, as well as fishway prescriptions to allow for volitional year-round upstream and downstream fish passage. Retaining one dam would potentially reduce the amount and duration of sediment release, reduce construction and waste disposal and to retain some level of hydropower production, thus reducing associated significant impacts. The alternative would further all the underlying purposes and project objectives, but not to the same extent as the Proposed Project. It would not meet Objective 3 as completely because J.C. Boyle Dam and Reservoir would continue to inhibit anadromy to some extent. This could, in turn, affect the extent to which the project achieves Objective 2. Evaluation of this scenario was undertaken in light of the separate authority of the states of Oregon and California to issue water quality certification for the Proposed Project. Oregon issued water quality certification for the Proposed Project in September 2018, making this alternative unlikely. However, in light of the significant progress made in evaluating the scenario, and the analysis regarding the extent to which it meets project alternatives and avoids potential impacts, the State Water Board has determined to include the alternative in order to provide decisionmakers and the public with the information developed.

No Hatchery Alternative

This alternative is the Proposed Project, except with no hatchery operation during or after dam removal (see Section 4.7 *No Hatchery Alternative* for more details). The alternative would further the underlying purpose and most of the project objectives, although it is not clear at a screening level the extent to which the alternative would meet Objective 2. The alternative would reduce construction-related impacts of reopening Fall Creek Hatchery and making modifications at Iron Gate Hatchery. The alternative emerged from scoping concerns regarding the water source for the Iron Gate Hatchery, and in light of uncertainty regarding whether the Fall Creek Hatchery could be timely reopened.

4.1.1.2 Elimination of Potential Alternatives for Failure to Meet Underlying Project Purpose

A number of the potential alternatives fail to meet the basic underlying purpose of the Proposed Project because they (1) fail to address project-related water quality impairments within and downstream of the Lower Klamath Project; and/or (2) fail to expand anadromous fish habitat upstream of Iron Gate Dam. Potential alternatives eliminated based upon this criterion are described below.

2007 FERC PacifiCorp's Proposal (for Continued Operation of the Klamath Hydroelectric Project)

This alternative in the 2007 FERC EIS proposes removing Keno and Link River facilities from the Klamath Hydroelectric License, and continuing operation of other facilities with implementation of a Reservoir Management Plan, improvement of existing fish passage facilities at J.C. Boyle Dam, and other operational changes. The 2007 FERC EIS found that PacifiCorp's Proposal failed to address the project's water quality impairments within and downstream of the hydroelectric reach (FERC 2007). Additional studies since 2007 have indicated that proposed reservoir management techniques can improve some of the project impacts to water quality (e.g., transport of nuisance and/or noxious blue-green algae downstream of Iron Gate Dam), but the various techniques have not been shown to sufficiently improve project impacts to water quality (e.g., dissolved oxygen) to meet all the water quality requirements (Carlson and Foster 2008, 2009; Deas et al. 2009; Horne et al. 2009; PacifiCorp 2008, 2011, 2013a, 2013b, 2014, 2015, 2017, 2018; Deas et al. 2012; CH2M HILL 2013, 2015; Austin et al. 2016). Because the proposal does not include fish passage, it also fails to extend anadromous fish habitat upstream of Iron Gate Dam. In addition to failing to meet either underlying project purpose, PacifiCorp is not currently pursuing this alternative, having asked for and received a stay in FERC proceedings to allow consideration of the KRRC's Proposed Project. The alternative also does not appear to be legally feasible, even if FERC were to lift the stay in the relicensing proceeding, as it does not include federal mandatory relicensing conditions.

2007 FERC Staff Alternative

This potential alternative, analyzed in FERC's 2007 EIS, modifies PacifiCorp's Proposal detailed in FERC (2007) to include fish disease studies, turbine venting, limited trap and haul with associated studies, and other improvements to Klamath Hydroelectric Project operations that would reduce ongoing impacts. The FERC 2007 EIS found that the alternative failed to meet water quality standards within and downstream of the Hydroelectric Reach (FERC 2007). Thus, this alternative would not achieve the project's underlying purpose of addressing project-related water quality impairments. The alternative also does not appear to be legally feasible, even if FERC were to lift the stay in the relicensing proceeding, as it does not include federal mandatory relicensing conditions.

Bogus Creek Bypass

This proposed alternative envisions a fish bypass reach from below Iron Gate to above Copco 1 Dam, using primarily the natural waterways of Bogus Creek, Cold Creek, and Little Deer Creek, with a constructed canal that would connect to Copco No. 1 Reservoir. The alternative proposes upstream fish passage via Bogus Creek, upstream into Cold Creek, through a constructed canal from Cold Creek to Deer Creek on the other side of a ridgeline, and moving downstream from Deer Creek into Copco No. 1 Reservoir. It assumes downstream fish passage for outmigrating juveniles is possible from Copco No. 1 Reservoir to the Klamath River below Iron Gate in the reverse direction, but it does not provide any examples of similar projects where this occurs to demonstrate its feasibility. This alternative fails to meet the underlying purpose of addressing project-related water quality impairments. Additionally, it would be extremely unlikely to meet the underlying objective of extending anadromous fish habitat above Iron Gate Dam since key elements of the alternative do not comport with known behavioral traits of adult salmonids preventing their usage of the bypass; the steep gradient and low flow in streams involved in the bypass would restrict migration; and it does not address the needs of outmigrating juvenile salmonids (CDFG 2009; White 2011). The migratory behavior of adult salmon to swim upstream to spawn would lead to spawning in the highest reaches of the bypass route rather than migration through the tunnel and spawning upstream of Copco No. 1 Reservoir (White 2011). The alternative also is not viable because the amount of water required to provide passage for salmonids through the bypass exceeds the amount of water currently available in Cold Creek or Deer Creek and no alternative source has been currently identified. Additionally, the alternative does not meet screening-level indications of feasibility, as there is no funding, no project proponent with the authority to implement it, and no indication that the project could be implemented in a timely manner.

Bogus Creek Bypass with Alternative Tunnel Route

This proposed alternative is a modification of the Bogus Creek Bypass above, that would use Bogus Creek and a five-mile tunnel to Copco No. 1 Reservoir. In this alternative, upstream fish passage would occur with fish in the Klamath River entering Bogus Creek, swimming from Bogus Creek into a constructed 4.75-mile tunnel, and moving downstream through the tunnel into Copco No. 1 Reservoir. Downstream fish passage from Copco No. 1 Reservoir to the Klamath River downstream of Iron Gate would occur in the reverse direction. The alternative addresses some of the constraints of the Bogus Creek Bypass alternative related to the underlying purpose of fish passage above Iron

Gate Dam, in that it avoids the concern about requiring adult salmonids to swim downstream during their upstream migration. Additionally, it addresses flow constraints in Cold Creek. However, a review of the alternative concluded that the tunnel alternative would be a very high risk option that may not provide effective fish passage because substantial data on the migratory behavior of adult salmon show the tunnel would eliminate many of the natural stimuli for fish migration and salmon have a general, although not absolute, avoidance of movement through culverts and short tunnels. Predicting fish movement through the 4.75-mile tunnel proposed in this alternative would be risky and there would be little flexibility in the alternative if fish avoided using the tunnel for migration (Mefford 2011). Additionally, because the tunnel would not maintain the ecological function of the stream to promote fish passage and it would not adhere to NMFS conventional fish passage design guidelines (NMFS 2011), its use would be experimental in nature and, consistent with Section 16.5 of NMFS (2011), would require design and development of a conventional fish passage facility at any location where it would be used. Further, the alternative does not include provisions for collecting and bypassing outmigrating juvenile fish. As proposed, it is expected only a small portion of juvenile fish would follow the low flows into the tunnel rather than the high flows downstream through the reservoir, so fish passage effectively would not be achieved (Mefford 2011; White 2011). The project's underlying purpose of addressing project-related water quality impairments would also not be achieved, with the tunnel providing no ecological benefit to the river and potentially further degrading the ecology of the river within this reach by diverting water from the river for the tunnel (Mefford 2011). Additionally, the alternative does not meet screening-level indications of feasibility, as there is no funding, no project proponent with the authority to implement it, and no indication that the project could be implemented in a timely manner.

Federal Takeover

This alternative entails a federal agency assuming control over the dams. That entity would then determine the fate of the facilities. Because this alternative does not involve particular operational or structural changes, it does not further the underlying project purposes of addressing project-related water quality impairments or expanding anadromous fish habitat. There is also no indication that this alternative is feasible, as no federal agency has indicated an interest in federal takeover. Further, because the alternative is a change in ownership, rather than in outcome, it fails to reduce the potentially significant impacts of the Proposed Project in a manner different from the evaluated alternatives. This EIR evaluates a reasonable range of alternatives that could be the outcome of the proposed process by the KRRC, or of ownership and management by a different entity.

Cessation of Power Production with Dams in Place

This alternative would end power production at the facilities, but not remove or modify them. Ceasing power production would not meet the underlying project purposes of addressing water quality impairments or expanding anadromous fish habitat beyond Iron Gate Dam. Additionally, this alternative does not meet screening-level indications of feasibility. Maintenance of the facilities would be costly, and eliminating power production would remove the facilities' primary earnings potential. No entity has stepped forward to operate the dams as non-power facilities.

Dredge Upper Klamath Lake

This alternative involves removing sediments from Upper Klamath Lake in Oregon, in order to reduce nutrients and to increase storage capacity of the lake. This action would not address the underlying project purpose of expanding anadromous fish habitat. The extent of required dredging to affect the phosphorus balance in Upper Klamath Lake is unclear, and the process would not remove nitrogen from the system. Thus, it is not clear the extent to which it would achieve a nutrient reduction sufficient to improve water quality in the hydroelectric reach. The alternative does not address facility-related water quality impairments that do not depend on phosphorus input in Upper Klamath Lake, such as the seasonal shift in water temperature, hydromorphology impacts, sediment starvation of the reach downstream of Iron Gate Dam, nuisance and/or noxious blue-green algae blooms within the reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. Thus, it fails in large part to achieve the project's underlying purpose of addressing project-related water quality impacts. Additionally, the project does not meet screening level indications of feasibility because expansive dredging is high-cost, creates a large amount of dredged material for disposal (Stillwater Sciences et al. 2013), and there is no identified proponent to take on this activity. The location of the action outside of California creates additional barriers to feasibility from a CEQA perspective.

Predator Control

This alternative proposes controlling sea lion, seal, and cormorant populations on the coast, in order to reduce predation of adult and juvenile salmonids. It has been suggested that predation of anadromous salmonids by these marine species is having a major effect on the salmonid population as they return to the Klamath River to spawn. A number of seal and sea lion haul outs and sea bird colonies exist in the vicinity of the mouth of the Klamath River, but no studies have been conducted to determine the impact of these predators on Klamath River populations. Observations of sea lion and seal predation on salmonids in the Columbia or Willamette rivers have estimated approximately 0.3 to 5.5 percent of the adult return is consumed by sea lions or seals (NOAA 2006), with 2014 to 2017 data from the Willamette River showing the average percent of potential escapement eaten be sea lions ranging from 6 to 9 percent of Chinook and 3 to 25 percent of steelhead (ODFW 2017). Analysis of Chinook salmon consumption from California to Alaska shows an increasing trend in salmonid predation by sea lions and seals from 1975 to 2015 as their populations increase (Chasco et al. 2017). The impact of avian predators, such as gulls, cormorants, and certain species of ducks, on out-migrating smolts in the Columbia River at reservoirs concluded that avian predators in the reservoirs accounted for the mortality of less than one percent of the juvenile salmonid population (Wiese et al. 2008). Similar percent reductions in the salmonid populations in the Klamath River may occur. This alternative would not meet the underlying purposes of expanding anadromous fish habitat beyond Iron Gate Dam. Additionally, it would not address downstream project-influenced water quality conditions, including the seasonal shift in water temperature, hydromorphology impacts, sediment starvation of the reach downstream of Iron Gate Dam, nuisance and/or noxious blue-green algae blooms within the reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. Additionally, the alternative does not meet screening-level indications of feasibility, as there is no funding, no project proponent with the authority to implement it, and no indication that the project could be implemented in a timely manner.

Partition Upper Klamath Lake

This alternative would create an "inner lake" in Upper Klamath Lake, which would reduce residence time in the lake, and potentially improve water quality (Herald and News 2010). This action would not meet the underlying purpose of expanding anadromous fish habitat beyond Iron Gate Dam. Additionally, it would not address downstream project-influenced water quality conditions, including the seasonal shift in water temperature, hydromorphology impacts, sediment starvation of the reach downstream of Iron Gate Dam, nuisance and/or noxious blue-green algae blooms within the reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. There is no indication that there is available funding for this project, or that there is an entity capable of and interested in performing it, so it does not meet initial screening indicators for feasibility. Additionally, it is outside of California, further casting doubt on the alternative's feasibility for CEQA purposes.

Water Storage Development in the Scott and Quartz Valleys

This alternative would involve constructing additional storage facilities in the Scott and/or Quartz Valley and releasing stored water into the Scott River to improve conditions in the Scott and Klamath rivers. In a previous study, two potential reservoir sites with a 20,000 acre-feet capacity per reservoir were identified in the East Fork Scott River sub-watershed (DWR 1991), with releases from these reservoirs potentially improving water quality downstream in the Scott River and eventually the Klamath River. However, the alternative does not meet the underlying project purpose of extending anadromous fish habitat above Iron Gate Dam. Additionally, there has been no quantification of the amount of water needed to sufficiently improve water quality in the Klamath River. A previous study of environmental water releases in the Scott River highlighted that current water temperatures in portions of the Scott River are too warm for anadromous fish, and there is significant uncertainty about whether environmental water releases would adequately improve water temperature (DWR 1991). The alternative also would not address water quality impacts upstream of the Scott River (e.g., the Hydroelectric Reach of the Klamath River) or other impacts of the dam, including the seasonal shift in water temperature, hydromorphology impacts, sediment starvation of the reach downstream of Iron Gate Dam, nuisance and/or noxious blue-green algae blooms within the reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. The alternative does not meet screening levels of feasibility: there is no project proponent with the authority to implement it, no analysis of water quantity needed to sufficiently improve the mainstem Klamath River water quality, and no indication that the two identified reservoir sites would have sufficient storage to meet the water quantity needed.

Transfer Water from Klamath River to Shasta River

This alternative would involve constructing a canal to transfer 60,000 acre-feet of water from Iron Gate Reservoir (or J.C. Boyle Reservoir or Keno Reservoir) to the Shasta River sub-watershed as irrigation supply to allow Lake Shastina discharges to go directly into the Shasta River rather than being used as irrigation supply first. This alternative does not meet the underlying project purpose of extending anadromous fish habitat above Iron Gate Dam. While releasing water from Lake Shastina directly into the Shasta River may improve water quality in the reaches downstream of the releases, there has been no quantification of the impact of flow releases from Lake Shastina on water quality in the Klamath River or whether sufficient water is available to be released from Lake

Shastina to sufficiently improve water quality in the Klamath River. Additionally, this alternative does not have the potential to address water quality impacts upstream of the Shasta River (e.g., the Hydroelectric Reach of the Klamath River) or other impacts of the dam, including the seasonal shift in water temperature, hydromorphology impacts, sediment starvation of the reach downstream of Iron Gate Dam, nuisance and/or noxious blue-green algae blooms within the reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. The alternative does not meet screening levels of feasibility: there is no project proponent with authority to implement it, no analysis the impact of flow releases from Lake Shastina on improving Klamath River water quality, and no analysis of water quantity and availability needed to sufficiently improve the mainstem Klamath River water quality.

4.1.1.3 Removal or Consolidation of Substantially Similar Alternatives

CEQA requires an EIR to examine a reasonable range of alternatives to foster informed decision-making, rather than to evaluate all possible alternatives or permutations thereof (CEQA Guidelines section 15126.6, subd. (a).) Therefore, when identified alternatives provided only minor variations of the same primary elements, the State Water Board either eliminated the closely-linked alternatives from consideration or analyzed an alternative that combines various aspects of the slightly different potential alternatives.

Alternatives Similar to Removal of Four Dams

The Proposed Project is substantially similar to the 2007 FERC Four-Dam Removal alternative; the rejected KHSA EIS/EIR Dam Removal of Four Dams Without KBRA alternative; and the KHSA EIS/EIR Project Full Facilities Removal of Four Dams. Because all of these alternatives analyze the major impacts of removing four major dam facilities, the State Water Board has moved forward only the analysis of the Proposed Project, rather than analyzing all four variations. The Proposed Project, as it is currently being proposed, has funding and has the backing of a range of stakeholders under the Klamath Hydroelectric Settlement Agreement. Additionally, it incorporates additional studies and information on feasible methods of dam removal vis-à-vis the other potential alternatives. The Proposed Project is therefore more feasible than the other similar four-dam removal scenarios.

The alternatives of Notching Four Dams, and Partial Removal of Four Dams have a significant overlap: both reduce the extent of facilities removal as compared to the Proposed Project. Therefore, the potential alternatives will likely both reduce construction-related impacts vis-à-vis the Proposed Project. Both alternatives would also require some sort of monitoring or other actions regarding the remaining project facilities. Here, the KRRC has proposed Partial Removal as an alternative, indicating potential feasibility of the alternative, but it has not proposed evaluation of notching. A notching alternative would be highly dependent on successful dam demolition and notching during winter months, with the following identified constructability and schedule risks: safety of construction workers operating on narrow, steep access roads during winter months with wet and icy conditions; weather delays that are likely to be worse in the wettest years when reservoir drawdown would rely on notching more than in dry years; and incomplete reservoir drawdown during wet years if notching is not complete. Additionally, Iron Gate Dam is an earthen dam that cannot be notched. Therefore, the State Water Board has elected to review Partial Removal of Four Dams as the more feasible and reasonable alternative between the two reduced-construction proposals.

Alternatives Similar to Retaining All Facilities

A number of alternatives contemplate retaining existing facilities and continuing power generation, but undertaking facility modifications to allow for passage of anadromous fish. All of these alternatives would reduce the Proposed Project's potentially significant impacts to a range of resources affected by removal of the facilities, including impacts from changes to hydrology, sediment release, elimination of reservoirs, and removal of facilities of potentially historic significance. Additionally, maintaining the dams has the potential to reduce the intensity of construction-related impacts, as construction of fish passage facilities requires less activity than dam deconstruction. The proposals also contain a significant weakness in meeting the habitat expansion purpose in that the technologies are better suited to accommodating upstream migration of spawning salmonids than they are to downstream migration of juveniles. They also have similar weaknesses in meeting the water quality and fisheries improvement purposes and objectives because they maintain the reservoirs, with associated water quality problems.

The EIR evaluates the most well-developed dams-in alternative which comports with federal mandatory conditions and includes FERC staff's proposed corresponding operational and physical modifications to the existing project. There are also proposals to use different technologies than those described in federal mandatory conditions in the Klamath Hydroelectric Project's relicensing process. For example, the 2007 FERC Staff Alternative included a testing protocol for determining whether trap and haul between various locations would be able to successfully expand anadromous fish habitat (FERC 2007). Scoping comments in this process have recommended evaluation of trap and haul, but they have also recommended evaluation of a new technology that has emerged in recent years—the use of fish cannons to lift fish over dams. However, trap and haul and other alternative technologies would not meet federal mandatory conditions and fish cannons are considered experimental (Section 16.5 of NMFS [2011]), so NMFS guidelines for experimental technologies would be needed, including construction of a conventional back-up fish passage design (see also Section 4.1.1.1 *Alternatives Carried Forward for More Detailed Analysis – Continued Operations with Fish Passage*). Additionally, no concrete plans or proponents for undertaking fish passage through trap and haul or other alternate measures exist. In light of the above, these proposals are likely infeasible. However, in light of the public's high degree of interest in fish passage alternatives, the EIR notes where the environmental impacts of trap and haul would differ from the fishways required under federal mandatory conditions.

Alternatives Similar to Removal of Fewer Facilities

Both the 2007 FERC EIS and the 2012 KHSA EIS/EIR analyzed an alternative of removing Iron Gate and Copco No. 1 dams, while leaving Copco No. 2 and J.C. Boyle dams in place with fish passage. The 2012 KHSA EIS/EIR also rejected the potential alternative of Three Dam Removal, removing all three California facilities and leaving J.C. Boyle Dam in place. Removing fewer facilities would allow for hydropower production, reduce the amount of construction and disposal of waste, and reduce the amount and duration of sediment releases, with potential reductions to the associated Project impacts. These alternatives would further both the water quality and fish habitat underlying project purposes, and would further all project objectives, but not to the same extent as the Proposed Project. Water quality under these alternatives would likely show improvement in the Hydroelectric Reach and downstream of Iron Gate Dam, with the elimination of the seasonal shift in water temperature, reduction in the hydromorphology impacts, decreased sediment starvation of the reach downstream of Iron Gate Dam, elimination of nuisance and/or noxious blue-green algae blooms within the Iron Gate and Copco No. 1 reservoirs and potential transport of blue-green algae from the reservoirs into the Klamath River downstream of the reservoirs, and the contribution of these impacts to fish disease. However, the remaining dam(s) and reservoir(s) in these potential alternatives may limit the improvements and achievement of Objective 1 due to power production operations altering flow and potentially water temperature and the reservoir(s) retaining some sediment. The remaining dam(s) and reservoir(s) in these potential alternatives also would continue to inhibit adult and juvenile migration to some extent, limiting achievement of Objective 3. This, in turn, has the potential to affect the ability to meet Objective 2.

Copco No. 2 is a relatively small facility, with a dam only 33 feet high and a reservoir approximately 0.25-mile long with a storage capacity of 73 acre-feet (FERC 2007). Therefore, keeping the facility in place and building fish passage would not significantly reduce the sediment releases and associated water quality impacts from those releases or the construction and disposal impacts compared to the Proposed Project. Hydropower production is possible at this facility absent the presence of Iron Gate Dam to moderate peaking downstream, although production would be considerably less than under existing conditions. No party is proposing operation of J.C. Boyle Dam or Copco No. 2 Dam independent of any other Lower Klamath Project facilities.

In light the above, this EIR reviews the Three Dam Removal and Two Dam Removal scenarios as alternatives that analyze removal of fewer facilities than proposed.

4.1.1.4 Elimination of Potential Alternatives that Would Not Avoid or Substantially Lessen Significant Environmental Effects of the Proposed Project

Alternatives for Removing Additional Facilities

Scoping comments in this process have suggested analysis of alternatives that would remove not only the Lower Klamath Project facilities, but also additional facilities in Oregon—Keno and Link River Dams. The 2012 KHSA EIS/EIR and the 2007 FERC EIS noted, but they did not analyze these alternatives. Proponents of these alternatives emphasize the potential habitat expansion benefits of these alternatives. However, the proposed Five and Six Dam Removal alternatives would not reduce the potential significant impacts of removing the four lower facilities under the Proposed Project. Additionally, these upstream facilities are not part of the Lower Klamath Project. Keno and Link River Dams are components of the Klamath Irrigation Project as well as being part of the Klamath Hydroelectric Project, and the facilities provide water for consumptive use in Southern Oregon and Northern California. PacifiCorp has proposed removing the facilities from hydroelectric production, but neither USBR, nor the water users that rely on these facilities have put forth a proposal to remove them. Comments have identified no funding mechanism, water replacement, or concrete proposal for removal. Thus, in addition to not reducing the potential impacts of the Proposed Project, these alternatives are not feasible.

Sequenced Removal of Four Dams

Sequenced Removal of Four Dams contemplates an alternate method of dam removal than that in the Proposed Project. Rather than removing all four facilities in an overlapping timeframe in a single season, sequenced removal would remove facilities one at a time. This would reduce the concentration of sediment released, as sediments would be released over an extended period of time. Additionally, depending on the amount of time between removals, it could allow for evaluation of model assumptions and restoration methods. Analysis of sequenced removal indicates that the reduced concentration of sediment from removing a single facility at once would not significantly reduce mortality during removal. The Proposed Project's timing is proposed to minimize the duration of sediment release, and to have the high concentrations of sediment occur at a time that interferes least with the life stages of the different fish populations in the Klamath system. Sequenced removal over three to five years likely would result in drawdown and repeated refills of reservoirs, based on modeling of more rapid drawdown during individual water year types for the Proposed Project showing some refill occurring under all water year types except Dry (Appendix B: *Definite Plan*). Sequenced removal would result in elevated suspended sediment concentrations over a longer time than the Proposed Project impacting additional life stages of fish, additional year-classes of fish, or both (Stillwater Sciences 2011). Elevated suspended sediments would be sufficiently high that the adverse impacts to water quality and fish would still occur during the sequenced removal even though the maximum suspended sediment concentration likely would be reduced compared to the Proposed Project. As such, sequenced removal would extend, rather than reduce, the impacts to fish species. Because of the increased duration of impact over more life stages and/or additional year-classes, it is unclear whether sequenced removal would fulfill Objective 2 of advancing the long-term restoration of the natural fish populations in the Klamath Basin. Additionally, sequenced removal would extend the time before other objectives would occur, so they would not be achieved in as timely a manner as under the Proposed Project.

4.1.1.5 Alternatives With Other Feasibility Concerns

The 2012 KHSA EIS/EIR included implementation of the Klamath Basin Restoration Agreement (KBRA) as a coordinated action for alternatives that implemented the KHSA. The KBRA has expired, and stakeholders have not reached a similar agreement. While negotiations regarding such an agreement are ongoing, it is speculative at this point to assume whether agreement will be reached, when, and what such an agreement would look like. Therefore, the EIS does not analyze any KBRA-implementation alternatives.

4.2 No Project Alternative

4.2.1 Introduction

4.2.1.1 Alternative Description

The No Project Alternative describes the environment should the Klamath River Renewal Corporation's (KRRC's) Proposed Project to decommission the Lower Klamath Project not proceed. California Environmental Quality Act (CEQA) Guidelines Section 15126.6(e)(2) states that "The 'no project' analysis shall discuss the existing conditions at the time the notice of preparation is published, or if no notice of preparation is published, at the time environmental analysis is commenced, as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services." Specifically, where a CEQA document concerns revisions to an ongoing operation, "the 'no project' alternative will be the continuation of the existing … operation into the future."

In this instance, in the short term, the No Project Alternative would be no change from the current management conditions, other than as noted below with regard to 2017 flow requirements and cessation of certain KHSA measures related to water quality and habitat. The Lower Klamath Project facilities would remain in place and operate under annual FERC licenses. This short-term scenario is anticipated for the duration of the FERC proceeding for relicensing of the hydroelectric facilities, estimated at one to five years, depending on the time necessary to obtain water quality certification from California and Oregon, on the time to obtain Clean Water Act section 404 permits from the Army Corps of Engineers for construction work, and on whether Federal Energy Regulatory Commission (FERC) and the Army Corps of Engineers relies on existing environmental reviews. It also includes time to conduct planning and monitoring required prior to facilities modification and/or removal.

The outcome of such a proceeding has not yet been determined, although there are bounds to the uncertainty. It is clear that the continued operation of the Lower Klamath Project as permitted under annual licenses is infeasible, as federal agencies have imposed fish passage requirements, ramping requirements, and other significant changes to the Lower Klamath Project dam complexes and operations in the context of the PacifiCorp Klamath Hydroelectric Project relicensing (FERC Project No. 2082). These requirements were challenged and upheld under a trial-type administrative hearing (Section 241 of the Energy Policy Act of 2005). Additionally, any relicensing procedure would have to comply with conditions to meet water quality standards in California and in Oregon, and it is not clear that this would be possible with all (or perhaps any) of the Lower Klamath Project dams and reservoirs in place.

Projecting one specific No Project scenario for the long term would be speculative, in light of the above, and would be contrary to the CEQA Guidelines' mandate to disclose and assess the environmental impacts that would "reasonably be expected to occur in the foreseeable future." The potential future for the existing hydroelectric facilities could include the transfer, decommissioning, or relicensing with modifications of all or some of the dams and associated facilities. However, this Environmental Impact Report (EIR) addresses the environmental effects of a range of potential long-term operation and decommissioning scenarios that could occur: all of the dams remain in place with fish passage (Section 4.4 *Continued Operations with Fish Passage Alternative*); removal of all (or substantially all) of the facilities (Proposed Project, Sections 2 and 3, Section 4.3 *Partial Removal Alternative*, Section 4.7 *No Hatchery Alternative*) or some of the dams, with fish passage on the remaining facilities (Section 4.5 *Two Dam Removal Alternative* and 4.6 *Three Dam Removal Alternative*). Therefore, while the long-term effects of the No Project Alternative cannot reasonably be ascertained with specificity, the range of potential long-term effects are found in the Proposed Project and the other alternatives.

In light of this uncertainty, the No Project Alternative analysis focuses on the reasonably foreseeable period of 0−5 years, as described below. Citations to the Proposed Project and other alternatives are provided for ease of reference in examining the effects of not implementing the Proposed Project in the long term.

Foreseeable Short-term Operations

For the next zero to five years, the Lower Klamath Project (i.e., J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities) and the remaining Klamath Hydroelectric Project facilities (East and West Side Powerhouses, Keno Dam, Fall Creek dam complexes—see also Section 2.6.2 *Relationship with Klamath Hydroelectric Project*) would continue to operate under annual licenses issued by FERC while the disposition of all the Lower Klamath Project facilities would be determined through the FERC relicensing process. This would include the potential of reaching another settlement agreement under that process. This timeframe also includes time for completion of any necessary planning or studies to undertake facilities modifications. The current annual license issued for Lower Klamath Project facilities under PacifiCorp's annual FERC licenses for Project No. 2082 has no requirements for additional fish passage or implementation of the prescriptions that are currently before FERC in the relicensing process. In the No Project Alternative analysis, the existing environmental conditions associated with the Lower Klamath Project and its operations would continue except as modified by:

- Court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam, which became required after February 2017 (U.S. District Court 2017)

Please see Section 4.2.1.1 *[Alternative Description] Summary of Available Hydrology Information for the No Project Alternative* for a discussion of the effect of this addition on the analysis of the No Project Alternative).

- The cessation of certain interim measures (IMs) from the KHSA, as discussed in Section 4.2.1.1 *[Alternative Description] KHSA Interim Measures*. Some of these measures would continue to form part of the existing conditions, while others would cease.

There are various efforts underway in the Klamath Basin to improve water quality, as discussed in Section 3.24 *Cumulative Effects*. However the effects of these efforts, including efforts aimed at meeting Klamath River TMDLs are not analyzed for the reasonably foreseeable period under the No Project Alternative because the basin response to the restoration measures to meet the total maximum daily loads (TMDLs) during the short-term is too speculative.

Long-term water quality improvements that bring water quality in the Klamath Basin closer to the load allocations established in the TMDLs are foreseeable through a variety of implementation measures. However, TMDLs are not self-implementing, and the extent of reasonably foreseeable financial resources are insufficient to implement the extensive efforts necessary to meet TMDL goals. While the TMDLs are expected to result in improvements to water quality conditions over time, the pace of attaining improvements and the specific implementation measures are not fully known. Additionally, the Klamath River TMDL includes load allocations for Copco No. 1 and Iron Gate reservoirs. As discussed in Section 3.2 *Water Quality*, removing the dams under the Proposed Project would rapidly and substantially move the Hydroelectric Reach and the Klamath River downstream of Iron Gate Dam towards achieving compliance. However, it is not clear the extent to which the allocations can be met absent dam removal, and within what timeframe. Water quality improvement measures in Oregon and California due to the Klamath TMDLs would result in long-term changes in water quality, so they are analyzed as part of the Proposed Project and other alternatives.

Summary of Available Hydrology Information for the No Project Alternative

Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* describes information regarding the EIR's analysis of the 2013 Biological Opinion (BiOp) flow requirements.

In addition to the 2013 BiOp Flows, and until the reinitiated formal consultation is complete, the USBR is also required to manage *Ceratanova Shasta (C. Shasta)* infection among coho salmon in the Klamath River with additional winter-spring surface flushing flows and deep flushing flows, as well as emergency dilution flows. Flushing flows are designed to dislodge and flush out polychaete worms that host *C. Shasta* in the Klamath River. Emergency dilution flows were developed to reduce *C. Shasta* infections in coho salmon if certain disease thresholds in the Klamath River are exceeded. The details of the flushing flow and emergency dilution flow requirements are outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and US District Court Filing 111 (U.S. District Court 2017). The flushing flow and emergency dilution flow requirements include:

- Releasing surface flushing flows every year from Iron Gate Dam of at least 6,030 cfs for a 72-hour period during the winter period (November 1–April 30) sufficient to move surface sediments.
- Releasing deep flushing flows at least every other year (beginning in 2017) with the Klamath River flow measured at Iron Gate Dam averaging at least 11,250 cubic feet per second (cfs) over a single 24-hour period between February 15 and May 31, unless USBR determines that such flows are limited and/or precluded by inherent hydrologic, infrastructure, and/or public safety constraints.
- Releasing emergency dilution flows of downstream of Iron Gate Dam between April 1 to June 15 or when 80% of juvenile Chinook Salmon outmigration has occurred if either: (1) spore concentrations exceed five spores (non-specified genotype) per liter for the preceding sample based on quantitative polymerase chain reaction (qPCR) from water filtration samples at any sampling station, or (2) the prevalence of inflection (POI) of all captured juvenile Chinook salmon (both wild and hatchery) exceeds 20 percent in aggregate for the preceding week at the Kinsman Rotary Screw Trap. Emergency dilution flows are 3,000 cfs measured at Iron Gate Dam until spore or POI at Kinsman Trap decreases if flows at Iron Gate Dam are below 3,000 cfs when disease thresholds are met or exceeded. Emergency flows at Iron Gate Dam are maintained at 3,000 cfs or increased from 3,000 cfs to 4,000 cfs if disease levels remain above disease thresholds after flows

at Iron Gate Dam have been 3,000 cfs for at least seven days. The volume of emergency dilution releases is capped at 50,000 acre-feet (AF).

The requirements of the flushing and emergency dilution releases are in addition to the 2013 BiOp flow requirements, which must still be met by USBR. Water released during flushing and emergency dilution flows are not part of the Environmental Water Account detailed in the 2013 BiOp. The exact timing of the releases of flushing flows is left to the discretion of USBR, provided they occur within the specified timeframes for the releases. Provisions for adaptive management of the flushing and emergency dilution flows exist, provided consensus for an amended flow plan is reached among the applicable agencies and submitted to the U.S. District Court for the Northern District of California San Francisco Division.

The additional surface and deep flushing flows, along with the emergency dilution flows to manage *C. Shasta,* are within the range of historical Klamath River flows evaluated in the 2013 BiOp studies. For example, while infrequent (i.e., less than 1 percent of the time at Iron Gate Dam), daily average flows in the Klamath River exceed the deep flushing flow requirement of 11,250 cfs during some storm events in the period of analysis. Additionally, the duration of a deep flushing flow event is short (i.e., 24 hours plus the time to ramp down the flushing flow) and is designed to occur every other year (beginning in 2017), such that the overall period that deep flushing flows influence Klamath River hydrology is limited.

In summary, river flow-related environmental impacts under the EIR No Project Alternative are evaluated by synthesizing the existing 2013 BiOp hydrology including the winter-spring surface and deep flushing flows as well as emergency dilution flow requirements, the No Project Alternative hydrology analysis presented in the 2012 KHSA EIS/EIR (which is modeled using 2010 BiOp Flows), and the technical studies that supported the 2012 KHSA EIS/EIR. Additional analysis is undertaken when necessary to evaluate how the flushing and dilution flows impact conditions in the Klamath Basin.

KHSA Interim Measures

The KHSA includes a series of “interim measures” (IMs) (KHSA Section 1.2.4) that have been implemented by PacifiCorp since 2010 to assess and address environmental conditions and improve fisheries prior to dam removal. The KHSA defines the interim period as the period between the date that the KHSA was originally executed (February 18, 2010 (i.e., the Effective Date) and PacifiCorp’s physical removal from a facility of any equipment and personal property that PacifiCorp determines has salvage value, and physical disconnection of the facility from PacifiCorp’s transmission grid (i.e., Decommissioning). However, some of the IMs were either one-time measures that were already completed, or have been integrated into PacifiCorp’s annual licenses as part of an Interim Conservation Plan (ICP). Additionally, it is assumed that flow and peaking operations associated with J.C. Boyle as specified in IMs 13 and 14 would continue. The ICP measures, therefore, form part of the existing conditions under the No Project Alternative. Assumptions regarding ICP and Non-ICP IMs are presented in Table 2.7-19.

Table 4.2-1. KHSA Interim Measures Relevant to California Under the No Project Alternative Compared with Existing Conditions and the Proposed Project.

Interim Measure	Interim Conservation Plan (ICP)[1]	Description	Existing Conditions	No Project Alternative	Proposed Project
IM1 – Interim Measures Implementation Committee (IMIC)	ICP	The IMIC is comprised of representatives from PacifiCorp, other parties to the KHSA (as amended on November 30, 2016), and non-signatory representatives from the State Water Board and Regional Water Board (see KHSA Appendix B, Section 3.2). The purpose of the IMIC is to advise on implementation of the Non-Interim Conservation Plan Interim Measures set forth in Appendix D of the Amended KHSA.	Ongoing	Would continue	Would continue separate from the Proposed Project[2]
IM2 – California Klamath Restoration Fund/Coho Enhancement	ICP	PacifiCorp would fund actions to enhance survival and recovery of coho salmon, including habitat restoration and acquisition.	Ongoing	Would continue	Would not continue
IM3 – Iron Gate Turbine Venting	ICP	PacifiCorp shall implement turbine venting on an ongoing basis beginning in 2009 to improve dissolved oxygen concentrations downstream of Iron Gate Dam.	Construction complete, implementation ongoing	Would continue	Would not continue
IM4 – Hatchery and Genetics Management Plan (See also IM19 and IM20)	ICP	PacifiCorp would fund the development and implementation of a Hatchery and Genetics Management Plan for the Iron Gate Hatchery.	Plan development is complete, implementation ongoing	Implementation would continue	Implementation would continue for eight years after removal of Iron Gate Dam as part of the Proposed Project, see also IM19 and IM20

Interim Measure	Interim Conservation Plan (ICP)[1]	Description	Existing Conditions	No Project Alternative	Proposed Project
IM5 – Iron Gate Flow Variability	ICP	PacifiCorp and USBR would annually evaluate the feasibility of enhancing fall and early winter flow variability to benefit salmonids downstream from Iron Gate Dam. In the event that fall and early winter flow variability can feasibly be accomplished, PacifiCorp would develop and implement flow variability plans. This IM would not adversely affect the volume of water available for Reclamation's Klamath Project or wildlife refuges.	Complete	Would continue	Would not continue
IM6 – Fish Disease Relationship and Control Studies	ICP	PacifiCorp has established a fund to study fish disease relationships downstream from Iron Gate Dam. PacifiCorp would consult with the Klamath River Fish Health Workgroup regarding selection, prioritization, and implementation of such studies.	Ongoing	Would continue	Would not continue
IM7 – J.C. Boyle Gravel Placement and/or Habitat Enhancement	Non-ICP	PacifiCorp would provide funding for the planning, permitting, and implementation of gravel placement or habitat enhancement projects, including related monitoring, in the Klamath River upstream of Copco No. 1 Reservoir.	Ongoing	Would not continue	Would not continue
IM8 – J.C. Boyle Bypass Barrier Removal	Non-ICP	PacifiCorp would remove the sidecast rock barrier approximately 3 miles upstream of the J.C. Boyle Powerhouse in the Bypass Reach, to improve upstream fish passage.	Complete	Completed, part of existing conditions	Completed, part of existing conditions

Interim Measure	Interim Conservation Plan (ICP)[1]	Description	Existing Conditions	No Project Alternative	Proposed Project
IM9 – J.C. Boyle Powerhouse Gage	Non-ICP	Upon the Effective Date, PacifiCorp shall provide the U.S. Geological Survey with continued funding for the operation of the existing gage below the J.C. Boyle Powerhouse.	Ongoing	Would not continue	Would not continue
IM10 – Water Quality Conference	Non-ICP	PacifiCorp shall provide one-time funding of $100,000 to convene a basin-wide technical conference on water quality within one year from the Effective Date of the KHSA.	Complete	Completed, part of existing conditions	Completed, part of existing conditions
IM11 – Interim Water Quality Improvements	Non-ICP	PacifiCorp shall spend up to $250,000 per year to be used for studies or pilot projects developed in consultation with the Implementation Committee to improve interim water quality in the Klamath River.	Studies and pilot projects ongoing	Would not continue	Studies and pilot projects would not continue. Water Quality Improvement Project would begin[2]
IM12 – J.C. Boyle Bypass Reach and Spencer Creek Gaging	Non-ICP	PacifiCorp shall install and operate stream gages at the J.C. Boyle Bypass Reach and at Spencer Creek.	Complete	Would not continue	Would not continue
IM13 – Flow Releases and Ramp Rates	Non-ICP	PacifiCorp would maintain current operations including instream flow releases of 100 cfs from J.C. Boyle Dam to the J.C. Boyle Bypass Reach and a 9-inch per hour ramp rate below the J.C. Boyle Powerhouse prior to transfer of the J.C. Boyle facility.	Ongoing	Would continue as part of existing operations	Would not continue
IM14 – 3,000 cfs Power Generation	Non-ICP	Upon approval by Oregon Water Resources Department, PacifiCorp would continue maximum diversions of 3,000 cfs at J.C. Boyle Dam for power generation.	Ongoing	Would continue as part of existing operations	Would not continue

Interim Measure	Interim Conservation Plan (ICP)[1]	Description	Existing Conditions	No Project Alternative	Proposed Project
IM15 – Water Quality Monitoring	Non-ICP	PacifiCorp shall fund long-term baseline water quality monitoring to support dam removal, nutrient removal, and permitting studies, and also will fund blue-green algae and blue-green algae toxin monitoring as necessary to protect public health. Funding of $500,000 shall be provided per year. The funding shall be made available beginning April 1, 2010 and annually on April 1.	Ongoing	Would not continue	Would not continue
IM16 – Water Diversions	Non-ICP	PacifiCorp shall seek to eliminate three screened diversions from Shovel (2) and Negro (1) Creeks and shall seek to modify its water rights as listed above to move the points of diversion from Shovel and Negro Creek to the mainstem Klamath River.	Not yet occurred	Would not occur	PacifiCorp would undertake separate from the Proposed Project —see Section 3.24 *Cumulative Effects*
IM17 – Fall Creek Flow Releases	Non-ICP	PacifiCorp would continue to provide a continuous flow release to the Fall Creek Bypass Reach targeted at 5 cfs.	Ongoing	Would continue as part of existing operations	Would continue as part of existing operations
IM18 – Hatchery Funding	Non-ICP	PacifiCorp shall fund 100 percent of Iron Gate Hatchery operations and maintenance necessary to fulfill annual mitigation objectives developed by the California Department of Fish and Wildlife in consultation with the National Marine Fisheries Service (NMFS) and consistent with existing FERC license requirements.	Ongoing	Percent of funding may not continue but hatchery would continue operations	Would not continue, see IM19 and IM20

Interim Measure	Interim Conservation Plan (ICP)[1]	Description	Existing Conditions	No Project Alternative	Proposed Project
IM19 – Hatchery Production Continuity	Non-ICP	PacifiCorp will begin a study to evaluate hatchery production options that do not rely on the current Iron Gate Hatchery water supply. Based on the study results, and within six months following the DRE's acceptance of the FERC surrender order, PacifiCorp will propose a post-Iron Gate Dam Mitigation Hatchery Plan (Plan) to provide continued hatchery production for eight years after the removal of Iron Gate Dam.	Ongoing	Would not continue	Would be complete
IM20 – Hatchery Funding After Removal of Iron Gate Dam	Non-ICP	After removal of Iron Gate Dam and for a period of eight years, PacifiCorp shall fund 100 percent of hatchery operations and maintenance costs necessary to fulfill annual mitigation objectives developed by CDFW in consultation with NMFS.	Not yet occurred	Would not occur	Would occur

[1] The Interim Conservation Plan refers to the plan developed by PacifiCorp through technical discussions with NMFS and USFWS regarding voluntary interim measures for the enhancement of coho salmon and suckers listed under the ESA, filed with FERC on November 25, 2008, or such plan as subsequently modified.

[2] Per the KHSA Appendix D, Non-Interim Conservation Plan Interim Measures, following the DRE's (Dam Removal Entity or KRRC) acceptance of the license surrender order, PacifiCorp shall provide funding of up to $5.4 million for implementation of projects approved by the Oregon Department of Environmental Quality (ODEQ) and the California State and Regional Water Quality Control Boards, and an additional amount of up to $560,000 per year to cover project operation and maintenance expenses related to those projects, these amounts subject to adjustment for inflation as set forth in Section 6.1.5 of the KHSA. PacifiCorp would provide funding for these nutrient reduction projects separate from the Proposed Project (see Section 3.24 *Cumulative Effects*).

4.2.1.2 Alternative Analysis Approach

As for the Proposed Project, the potential impacts of the No Project Alternative are analyzed in comparison to existing conditions. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the No Project Alternative are the same as those described for the Proposed Project (see Section 3.1 *Environmental Setting Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Impacts, and Mitigation Measures*). The time frame of analysis for the No Project Alternative differs from that of the Proposed Project, as described above.

4.2.2 Water Quality

As described for the Proposed Project Water Quality *Impact Analysis Approach* (Section 3.2.4), the approach to analyzing potential water quality impacts associated with the No Project Alternative involves quantitative numeric models, where possible and appropriate, and qualitative analyses otherwise. However, the time frame of the No Project Alternative is different from that of the Proposed Project. As described in Section 4.2.1.1 *Alternative Description – Foreseeable Short-term Operations*, the No Project Alternative considers reasonably foreseeable conditions over the period of 0−5 years.

Water Temperature

For the No Project Alternative, there would be no short-term sediment release due to removal of the Lower Klamath Project. As such, there would be no potential for changes in water temperature from existing conditions in the Klamath River Estuary due to sediment-related morphological changes in the estuary since sediment releases from dam removal would not occur (Potential Impact 3.2-2).

Water temperature existing conditions would not be altered by changes to the IMs implemented by PacifiCorp under the No Project Alternative (Table 2.7-19). IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue implemented by PacifiCorp under the No Project Alternative, while IMs not incorporated into the ICP (non-ICP) would either cease or continue as listed in Table 2.7-19. The non-ICP IMs primarily relate to monitoring, funding, and hatcheries, so there would be no effect on water temperature from ending those IMs.

As described under the Proposed Project (Potential Impact 3.2-1), climate change would be anticipated to only significantly influence water temperature existing conditions in the long term (5+ years), so climate change is not discussed further for water temperature under the No Project Alternative. As noted in Section 4.2.1.1 *Alternative Description – Foreseeable Short-term Operations*, long-term outcomes are considered in the Proposed Project and other alternatives, thus long-term water temperature impacts are described in: Section 3.2.5.1 [*Water Quality*] *Water Temperature;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to water temperature in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-1 Seasonal alterations in water temperature due to continued impoundment of water in the reservoirs.

In general, the No Project Alternative would not affect the current ongoing changes to water temperature caused by the reservoirs and by dam operations, as described in Section 3.2.2.2 *Water Temperatur*e. The existing temperature conditions in the Lower Klamath Project reservoirs would continue under the No Project Alternative, including larger diel (i.e., 24-hour period) variations in summer water temperature due to hydropower peaking operations, seasonal reservoir stratification, and seasonal shifts in water temperature downstream of the reservoirs, as described under existing conditions in Section 3.2.2.2 *Water Temperature*.

Hydroelectric Reach

In the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir, daily hydropower peaking operations would continue to cause artificially high daily maximum water temperatures and daily variability in water temperatures that occur under existing conditions. In the remainder of the Hydroelectric Reach (i.e., Copco No. 1 and Iron Gate reservoirs) water temperatures would be the same as those described under the existing condition (see Section 3.2.2.2 *Water Temperature*), where spring, summer, and fall water temperatures would continue to be influenced by the thermal mass of Copco No. 1 and Iron Gate reservoirs, and the seasonal stratification patterns of the two reservoirs. It is unclear what, if any, steps could reduce the impact of the reservoirs on the thermal regime within the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam and comply with the Thermal Plan's ban on elevated temperature discharges into COLD interstate waters (Table 3.2-4). Improvements from existing conditions under the Proposed Project described in Potential Impact 3.2-1 would not occur under the No Project Alternative.

Middle and Lower Klamath River and Klamath River Estuary

The continued impoundment of water in Copco No. 1 and Iron Gate reservoirs under the No Project Alternative would maintain existing adverse late summer/fall water temperatures in the Hydroelectric Reach downstream of Copco No. 1 Reservoir and in the Middle Klamath River downstream of Iron Gate Dam (see Section 3.2.2.2 *Water Temperature*). Temperature effects of the dams do not extend downstream of the Salmon River confluence (see Section 3.2.2.2 *Water Temperature*). Implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would not significantly alter the existing conditions for water temperature downstream of Iron Gate Dam in the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment, but the additional flushing and emergency dilution releases would potentially result in a temporarily more prominent seasonal shift in water temperature downstream of Iron Gate Dam during the releases. Water temperature existing conditions downstream of Copco No. 1 and Iron Gate dams are generally warmer than expected under natural conditions during late-summer and fall and cooler than expected under natural conditions during spring and early summer (see Section 3.2.2.2 *Water Temperature*). These existing conditions could be accentuated by the additional flushing and emergency dilution releases since these flows would potentially occur from November 1 to June 15 (see Section 4.2.1.1 *Alternative Description – Summary of Available Hydrology Information for the No Project Alternative*). However, these conditions would be accentuated only if releases occurred outside of winter and only for a brief time with surface flushing flows occurring for only 72-hours once every year, deep flushing flows occurring for only 24 hours once every other year, and emergency dilutions only occurring in some years if specific disease conditions are met in the Klamath River. As such, the temporary accentuation of the existing fall or spring shifts in water temperature in the Middle Klamath River downstream of Iron Gate Dam during flushing and emergency dilution releases would result in a less than significant change to existing water temperature conditions. Therefore, there would be no change in water temperature existing conditions in the Middle and Lower Klamath River reaches downstream from the confluence with the Salmon River, including the Klamath River Estuary and the Pacific Ocean nearshore environment under the No Project Alternative.

Overall, there would be no change from existing, adverse conditions for water temperature in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the Pacific Ocean nearshore environment in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative and the existing, adverse conditions for water temperature would continue to cause an exceedance of water quality standards as set forth in the Thermal Plan. Thus, there would be no significant impact to water temperature under the No Project Alternative.

Significance
No significant impact

Suspended Sediments
The No Project Alternative would not release the reservoir sediment stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams. Thus, there would be no short-term increase in suspended sediment concentrations (SSCs) during drawdown (Potential Impact 3.2-3) and there would be no significant impact.

IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue to be implemented by PacifiCorp under the No Project Alternative, while IMs not incorporated into the ICP (non-ICP) would either cease or continue as listed in Table **2.7-19**4.2-1. The non-ICP IMs primarily relate to monitoring, funding, and hatcheries, so there would be no change from existing conditions for suspended sediments from ending those IMs. J.C. Boyle gravel placement and/or habitat enhancement (IM7) (Table 4.2-1), including gravel augmentation downstream of Iron Gate Dam (PacifiCorp 2014a), would not continue under the No Project Alternative. Thus, any incidental sediment release occurring under the existing condition as a result of this activity would cease. Because of construction management practices employed, this currently does not cause a meaningful degree of sedimentation in the river, and so ceasing this practice would be unlikely to affect suspended sediments relative to existing conditions.

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description – Foreseeable Short-term Operations*, the long-term outcomes, including climate change and changes in algal-derived (organic) suspended material due to nutrient reduction measures in Oregon and California, are considered for the Proposed Project and other alternatives, thus the long-term suspended sediment impacts are described in: Section 3.2.5.2 [*Water Quality*] *Suspended Sediments;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to suspended sediments in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under new impact headings, below.

Potential Impact 4.2.2-2 Seasonal increases in algal-derived (organic) suspended material due to continued impoundment of water in the reservoirs.

The No Project Alternative would result in no change from existing conditions with respect to interception, decomposition, retention, and/or dilution[179] of algal-derived (organic) suspended material originating from Upper Klamath Lake (in Oregon) within J.C. Boyle Reservoir and the Hydroelectric Reach to Copco No. 1 Reservoir (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). With its shallow depth and short residence time, J.C. Boyle Reservoir does not provide suitable habitat for seasonal phytoplankton (including blue-green algae) blooms (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). The No Project Alternative would continue to result in the same adverse seasonal increases in algal-derived (organic) suspended material in Copco No. 1 and Iron Gate reservoirs as existing conditions, with subsequent release of suspended material to the Middle and Lower Klamath River, and eventually the Klamath River Estuary (Section 3.2.2.3 *Suspended Sediments*), and there would be no significant impact.

Nutrient reduction measures in Oregon and California due to the Klamath TMDLs only would result in long-term changes in algal-derived (organic) suspended material, so they are considered as part of the Proposed Project and other alternatives.

<u>Significance</u>

No significant impact

Potential Impact 4.2.2-3 Increases in suspended material due to implementation of 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam.

Implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would mobilize more sand, silt, and clay sized sediment downstream of Iron Gate Dam than under the existing conditions when the releases occur since the flushing releases are designed to mobilize such sediments. There would be an increase in suspended sediment concentrations (SSCs) under flushing flows compared to existing conditions, but the increase in SSCs downstream of Iron Gate Dam would have a limited duration much less the two-weeks that would result in a significant impact. Flushing flows would only occur for 72-hours (surface flushing) or 24-hours (deep flushing), so increases in SSCs due to flushing flows are unlikely to increase SSCs above 100 milligrams per liter (mg/L) for an entire two-week period (i.e., the suspended sediment threshold of significance; see Section 3.2.3.1 *Thresholds of Significance – Suspended Sediments*). While emergency dilution releases would potentially occur for a longer period, emergency dilution flows (3,000 to 4,000 cfs) are unlikely to increase SSCs since they are below the thresholds recognized to cause transport of suspended sediment in the Klamath River downstream of Iron Gate Dam (see USBR 2012). Thus, increases in SSCs due to implementation of the flushing and emergency dilution releases would have a less than significant impact on suspended sediment concentrations under the No Project Alternative.

[179] Dilution from coldwater springs downstream of J.C. Boyle Dam.

Significance
No significant impact

Nutrients
The No Project Alternative would not release the reservoir sediment or sediment-associated nutrients stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams (Potential Impact 3.2-7).

There would be no change from existing conditions for nutrients in the Klamath River under the No Project Alternative due to changes in IMs implemented since IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue under the No Project Alternative and IMs ending primarily relate to monitoring, funding, and hatcheries that would not alter nutrient compared to existing conditions. There would be no change from existing conditions for nutrients under the No Project Alternative due to ceasing J.C. Boyle gravel placement and/or habitat enhancement (IM7) (Table 4.2-1), including gravel augmentation downstream of Iron Gate Dam (PacifiCorp 2014), since gravel augmentation does not alter nutrients in the Klamath River under existing conditions.

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description – Foreseeable Short-term Operations*, the long-term outcomes, including gradual increases in nutrients and organic matter in reservoir sediments (i.e., reservoir aging [USGS 2018]) that would potentially alter nutrients in the reservoirs and the Klamath River and decreases in nutrients from implementing nutrient reduction measures in Oregon and California as part of the Klamath TMDLs, are considered in the Proposed Project and other alternatives, thus long-term nutrient impacts are described in: Section 3.2.5.3 [*Water Quality*] *Nutrients;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to nutrients in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-4 Annual interception and retention of nutrients and seasonal release of nutrients due to continued impoundment of waters in the reservoirs.

Hydroelectric Reach
Nutrients in the Hydroelectric Reach would be the same as existing conditions (Section 3.2.2.4 *Nutrients*) in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative since this alternative would not remove the existing dams. The No Project Alternative would continue to result in the same small annual decreases in total phosphorus (TP) and total nitrogen (TN) through the Hydroelectric Reach as occurs under existing conditions, due to settling of particulate matter and retention of associated nutrients originating from upstream reaches, including Upper Klamath Lake (in Oregon), in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs, and dilution by the coldwater springs located downstream of J.C. Boyle Reservoir (Section 3.2.2.4 *Nutrients*). Seasonal increases in TP, and to a lesser degree TN, in the Hydroelectric Reach would continue to occur under this alternative due to the release (export) of dissolved forms of phosphorus (ortho-phosphorus) and nitrogen (ammonium) from Copco No. 1 and Iron Gate reservoir sediments during summer and fall, when reservoir bottom waters are anoxic (i.e., through the process of internal nutrient loading, see Figure 3.2-2).

Middle and Lower Klamath River and Klamath River Estuary

Nutrients transport from the Hydroelectric Reach into the Klamath River downstream of Iron Gate Dam would be the same as existing conditions (Section 3.2.2.4 *Nutrients*) in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative since this alternative would not remove the existing dams. Dissolved forms of nutrients can be transported on a seasonal basis from Copco No. 1 and Iron Gate reservoirs downstream to the Middle Klamath River where they can stimulate excessive growth of periphyton (aquatic freshwater organisms attached to river bottom surfaces) (see also Section 3.4.2.2 *Periphyton*). In the downstream direction, nutrient effects of the Lower Klamath Project reservoirs diminish due to both tributary dilution and nutrient retention (see Section 3.2.2.4 *Nutrients*).

There would be no change from existing conditions for nutrients due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam under the No Project Alternative since suspended sediments transported by these releases would be primarily mineral (inorganic) sediments occurring in the Klamath River under existing conditions.

Significance

No significant impact

Dissolved Oxygen

The No Project Alternative would not release sediments stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams. Thus, there would be no short-term depletion of oxygen from the river due to resuspension of unoxidized organic matter during drawdown (Potential Impact 3.2-9) and there would be no significant impact.

There would be no change from existing conditions for dissolved oxygen in the Klamath River under the No Project Alternative due to changes in IMs implemented since IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue under the No Project Alternative and IMs ending primarily relate to monitoring, funding, and hatcheries that would not alter dissolved oxygen concentrations compared to existing conditions.

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description– Foreseeable Short-term Operations*, the long-term outcomes, including climate change and variations in dissolved oxygen from implementing nutrient reduction measures in Oregon and California as part of the Klamath TMDLs, are considered in the Proposed Project and other alternatives, thus long-term dissolved oxygen impacts are described in: Section 3.2.5.4 [*Water Quality*] *Dissolved Oxygen;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to dissolved oxygen in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-5 Seasonal low dissolved oxygen concentrations due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

The No Project Alternative in the Klamath River would result in no change from existing, adverse conditions in the reasonably foreseeable short-term (0−5 years) with respect to large summertime variations in dissolved oxygen in the Hydroelectric Reach and dissolved oxygen concentrations in the Middle Klamath River immediately downstream of Iron Gate Reservoir that fall below the Basin Plan minimum dissolved oxygen criteria (Section 3.2.2.5 *Dissolved Oxygen*). In J.C. Boyle Reservoir, summertime variations in dissolved oxygen, especially at depth, would continue to occur and potentially release water with low dissolved oxygen concentrations to the Klamath River immediately downstream of J.C. Boyle Dam during summer/late fall when dissolved oxygen concentrations would potentially be below 5 mg/L (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.1*). The influence of J.C. Boyle Dam on dissolved oxygen concentration in the Klamath River decreases in the downstream direction as turbulent mixing and water velocities in the free-flowing river reach provides sufficient aeration under existing conditions (Appendix C – *Section C.4.1*). Due to seasonal stratification in Copco No. 1 and Iron Gate reservoirs that would occur under the No Project Alternative similar to existing conditions, adverse seasonal anoxia (0 mg/L dissolved oxygen) in reservoir bottom waters could continue to occur under this alternative, with seasonal stratification and associated anoxia typically beginning by May and lasting through October to early November (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.1*). Daily dissolved oxygen concentration variations within the Lower Klamath Project reservoirs due to phytoplankton growth in the reservoir would continue, so there would be no change for existing conditions and no significant impact on dissolved oxygen in the Hydroelectric Reach for the reasonably foreseeable short-term (0−5 years) under the No Project Alternative.

Middle and Lower Klamath River and Klamath River Estuary

Immediately downstream of Iron Gate Dam, this alternative would continue to result in low dissolved oxygen in waters released from Iron Gate Reservoir during summer/late fall months, where concentrations regularly fall below 8.0 mg/L and the current Basin Plan minimum dissolved oxygen criteria based on percent saturation[180] (see also Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*). Further downstream, the effects of the Lower Klamath Project on dissolved oxygen diminish due to natural stream re-aeration, such that effects are not generally discernable by Seiad Valley (River Mile [RM] 132.7) (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*).

Dissolved oxygen concentrations due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would be similar to existing conditions, but dissolved oxygen would likely increase immediately downstream of Iron Gate Dam in the Middle Klamath River during releases due to increased turbulent mixing and aeration under the higher flushing flows. However, these conditions would be present for only a brief time between November 1 to May 31 since surface flushing flows occur for only 72-hours once every year and deep flushing flows occur for only 24-

[180] Minimum dissolved oxygen criteria of 85 percent saturation for the period April 1 through September 30, and below the minimum criterion of 90 percent saturation for the period October 1 to March 31, for the Klamath River from Oregon-California state line (RM 214.1) to the Scott River (RM 145.1); see also Table 3.2-4.

hours once every other year. The temporary, brief increases in dissolved oxygen due to flushing flows also generally would occur before reservoirs stratify, so flushing releases would not alter the low dissolved oxygen downstream of Iron Gate Dam that occur under existing conditions during summer/late fall months. Dissolved oxygen concentrations in the Middle Klamath River under emergency dilution releases (3,000 to 4,000 cfs) would be similar to existing conditions since the increase in flow and associated mixing and aeration would be relatively small compared to existing conditions.

Increases in sediment transport due to flushing flows under this alternative would dislodge periphyton from the riverbed and decrease periphyton abundance downstream of Iron Gate Dam in the Middle Klamath River immediately after releases (see also Potential Impact 4.2.4-1). The relationship between flushing and emergency dilution releases, streambed scour and changes in periphyton abundance from the releases, and daily variations in summertime dissolved oxygen due to photosynthesis by periphyton is not fully understood, but seasonal periphyton abundance variations due to seasonal flow changes are a natural process in river systems and occur under existing conditions in the Klamath River. Periphyton naturally re-grow following high winter flows under existing conditions, so periphyton are anticipated to re-grow similarly after flushing flows. While the frequency of flushing flows (i.e., annually for surface flushing and every other year for deep flushing) and the rate of periphyton re-growth may result in a reduction in periphyton abundance downstream of Iron Gate Dam, these reductions in periphyton abundance are expected to have a less than significant impact on daily variations in summertime dissolved oxygen in the Klamath River and dissolved oxygen would be similar to existing conditions. Thus, there would be no significant impact on dissolved oxygen concentrations in the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment under the No Project Alternative due to 2017 court-ordered flushing and emergency dilution flows.

Significance

No significant impact

pH

pH existing conditions would not be altered by changes to the IMs implemented by PacifiCorp under the No Project Alternative (see Table 2.7-19). IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue implemented by PacifiCorp under the No Project Alternative, while IMs not incorporated into the ICP (non-ICP) would either cease or continue as listed in Table 2.7-19. The non-ICP IMs primarily relate to monitoring, funding, and hatcheries, so there would be no change from existing adverse conditions for pH from ending those IMs.

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description– Foreseeable Short-term Operations*, the long-term outcomes, including climate change and variations in pH from implementing nutrient reduction measures in Oregon and California as part of the Klamath TMDLs, are considered in the Proposed Project and other alternatives, thus long-term pH impacts are described in: Section 3.2.5.5 [*Water Quality*] *pH;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to pH in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-6 Seasonal high pH and daily pH fluctuations due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

The No Project Alternative would result in no change from the existing, adverse condition with respect to pH values that exceed the Basin Plan instantaneous maximum pH objective of 8.5 standard units (s.u.) and large daily fluctuations in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*). The reservoirs would remain in place under the No Project Alternative, so there would be no change in pH from existing, adverse conditions due to conversion of the reservoir areas to free-flowing river and there would be no significant impact on pH in the Hydroelectric Reach under the No Project Alternative.

Middle and Lower Klamath River and Klamath River Estuary

As discussed above, the No Project Alternative would continue to result in the same pH values that exceed the Basin Plan instantaneous maximum pH objective of 8.5 s.u and large daily fluctuations in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*). In the Middle and Lower Klamath River and Klamath River Estuary, pH exhibits large (0.5–1.5 pH units) daily fluctuations under existing conditions during periods of high photosynthesis and pH values also regularly exceed Basin Plan instantaneous maximum pH objective of 8.5 s.u. during late-summer and early-fall months (August–September), with the most extreme pH exceedances typically occurring from Iron Gate Dam to approximately Seiad Valley (see Section 3.2.2.6 *pH*). Under the No Project Alternative, existing conditions for pH would continue to occur for periods of high photosynthesis, particularly when large phytoplankton blooms are transported from Iron Gate Reservoir into the Middle and Lower Klamath River, with the most extreme pH exceedances typically occurring from Iron Gate Dam to approximately Seiad Valley (see Section 3.2.2.6 *pH*).

The pH in the Middle Klamath River likely would be similar to existing, adverse conditions with the 2017 court-ordered flushing and emergency dilution flows under the No Project Alternative since periphyton along the riverbed contributing to pH conditions would re-grow after reductions following releases and continue to alter pH in the river during summertime periods of high photosynthesis. Court-ordered flushing flows would mobilize sediment downstream of Iron Gate Dam between November 1 to May 31 (see Potential Impact 4.2.2-3) and dislodge periphyton from the riverbed and decrease periphyton abundance downstream of Iron Gate Dam in the Middle Klamath River immediately after releases (see Potential Impact 4.2.4-1). Emergency dilution releases (3,000 to 4,000 cfs) are below the flow recognized to mobilize sediment along the riverbed downstream of Iron Gate Dam, so there would be no change from existing conditions with respect to periphyton abundance due to these releases. While the relationship between flushing and emergency dilution releases, streambed scour and changes in periphyton abundance from the releases, and summertime increases in pH due to photosynthesis by periphyton is not fully understood, seasonal periphyton abundance variations due to seasonal flow changes are a natural process in river systems and occur under existing conditions in the Klamath River. Periphyton naturally re-grow following high winter flows under existing conditions, so periphyton are anticipated to re-grow similarly after flushing flows. While the frequency of flushing flows (i.e., annually for surface flushing and every other year for deep flushing) and the rate of periphyton re-growth may result in a reduction in periphyton abundance downstream of

Iron Gate Dam, these reductions in periphyton abundance are expected to have a less than significant impact on summertime increases in pH in the Klamath River due to periphyton photosynthesis. The Klamath River is a weakly buffered system and it is susceptible to photosynthesis-driven daily and seasonal swings in pH (see Section 3.2.2.6 *pH*), thus pH conditions in the Klamath River downstream of Iron Gate Dam are still anticipated to be similar to existing conditions even with reductions in periphyton abundance from flushing flows and there would be no significant impact to pH in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative.

Significance

No significant impact

Chlorophyll-*a* and Algal Toxins

There would be no change from existing conditions for chlorophyll-*a* and algal toxins, concentrations in the Klamath River under the No Project Alternative due to changes in IMs implemented since IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue under the No Project Alternative and IMs ending primarily relate to monitoring, funding, and hatcheries that would not alter chlorophyll-*a* and algal toxins concentrations compared to existing conditions.

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description – Foreseeable Short-term Operations*, the long-term outcomes, including climate change and decreases in chlorophyll-*a* and algal toxins from implementing nutrient reduction measures in Oregon and California as part of the Klamath TMDLs, are considered in the Proposed Project and other alternatives, thus long-term chlorophyll-*a* and algal toxin impacts are described in: Section 3.2.5.6 [*Water Quality*] *Chlorophyll-*a *and Algal Toxins;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to chlorophyll-a and algal toxins in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-7 Seasonal increases in chlorophyll-a and algal toxins due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

The No Project Alternative would continue to result in the same adverse, large, seasonal phytoplankton blooms, including blue-green algae, in Copco No. 1 and Iron Gate reservoirs, that occur under existing conditions and produce seasonally high chlorophyll-*a* concentrations and periodically high levels of algal toxins. In the Hydroelectric Reach, seasonal phytoplankton (including blue-green algae) blooms originating from Upper Klamath Lake (in Oregon) would still be able to enter J.C. Boyle Reservoir under this alternative, but the short residence time of this reservoir would not support substantial additional growth of algae similar to existing conditions (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). Further downstream in the Hydroelectric Reach, adverse, large, seasonal phytoplankton blooms, including blue-green algae, would continue to occur in Copco No. 1 and Iron Gate reservoirs under the No Project Alternative similar to existing conditions, resulting in chlorophyll-*a* concentrations exceeding the TMDL target of 10 ug/L during the May to October growth season, and periodically high levels of algal toxins (concentrations greater than 0.8 and/or 4 ug/L microcystin[181]) (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). Overall, the No Project Alternative would result in no change from existing, adverse conditions and would continue to cause exceedances of water quality standards in the Hydroelectric Reach. Thus, there would be no significant impact to chlorophyll-a and algal toxins in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Hydroelectric Reach.

Middle and Lower Klamath River and Klamath River Estuary

Downstream of Iron Gate Dam, chlorophyll-*a* and algal toxin trends generally would be similar to existing conditions under the No Project Alternative, with releases of chlorophyll-*a* and algal toxins (i.e., microcystin) in the Lower Klamath Project reservoirs to the Middle and Lower Klamath River, and eventually the Klamath River Estuary. Longitudinal and temporal variations in microcystin concentrations from upstream of Copco No. 1 Reservoir to Turwar indicate that Iron Gate Reservoir is the principal source of *Microcystis aeruginosa* cells to the Middle and Lower Klamath River (Otten et al. 2015) (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). There would be no change to the habitat conditions that promote growth of *Microcystis aeruginosa* in Iron Gate Reservoir under existing conditions (see also Section 3.4.2.3 *Hydroelectric Reach*), so the export of *Microcystis aeruginosa* cells from this reservoir would also continue to occur under the No Project Alternative similar to existing conditions.

The 2017 court-ordered flushing and emergency dilution flows would result in no change from existing conditions for chlorophyll-*a* or algal toxins downstream of Iron Gate Dam, since releases would not alter conditions in Copco No. 1 or Iron Gate reservoirs that produce high chlorophyll-*a* concentrations and periodically high levels of algal toxins under existing conditions, and the court-ordered flushing and emergency dilution flows would primarily occur during winter and spring when chlorophyll-*a* and algal toxin concentrations in Iron Gate Reservoir would be low (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). The 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would end by June 15, while monitoring data from the past five years (i.e., 2013 to 2018) indicates the abundance of blue-green algae and algal toxin concentrations (i.e., microcystin) in Iron Gate Reservoir increases above 0.8 ug/L or 4 ug/L after late June to early July (E&S Environmental Chemistry, Inc. 2013, 2014, 2015, 2016, 2018a, 2018b). Assuming blue-green algae cell counts and algal toxin concentrations from the past five years are representative of likely conditions in the reasonably foreseeable short-term (0−5 years), releases would end before elevated levels of chlorophyll-*a* or algal toxin concentrations occur in Iron Gate Reservoir, and there would be no changes from existing conditions for chlorophyll-a or algal toxin concentrations in the Middle and Lower Klamath River or the Klamath River Estuary. Overall, the No Project Alternative would result in no change from existing, adverse conditions and would continue to cause an exceedance of water quality standards in the Middle and Lower Klamath River and Klamath River Estuary. Thus, there would be no significant impact to chlorophyll-*a* and algal toxins due to flushing and

[181] Since the less than 4 ug/L criterion for microcystin in recreational waters is common to the California Klamath River TMDL, WHO, and Yurok Tribe criteria, and it is less than the Hoopa Valley Tribe recreational criterion, 4 ug/L microcystin is used as the threshold of significance for the Lower Klamath Project EIR water quality analysis. The current lowest CCHAB and Yurok Tribe posting limit for microcystin (0.8 ug/L) is also considered in the analysis although application of the lower threshold would in no case change the significance determinations in this EIR (see Section 3.2.3.1 *Thresholds of Significance – Chlorophyll-a and Algal Toxins*).

emergency dilution releases in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Middle and Lower Klamath River and the Klamath River Estuary.

Significance

No significant impact

Inorganic and Organic Contaminants

There would be no change from existing conditions for inorganic and organic contaminants in the Klamath River under the No Project Alternative due to changes in IMs implemented since IMs integrated into PacifiCorp's annual licenses as part of an ICP would continue under the No Project Alternative and IMs ending primarily relate to monitoring, funding, and hatcheries that would not alter inorganic and organic contaminants in the Klamath River compared to existing conditions.

Increases in human or freshwater aquatic species' exposure to inorganic and organic contaminants associated with sediment release under the Proposed Project (Potential Impacts 3.2-14 and 3.2-15) would not occur because the dams and sediment deposits would remain in place. Herbicide application during restoration of the former reservoir areas would not occur, as the reservoirs would remain in place (Potential Impact 3.2-16).

There would be no change from existing conditions in the reasonably foreseeable short-term (0−5 years) with respect to changes in Iron Gate Hatchery operations on Klamath River water quality since Iron Gate Hatchery would continue existing operations (Potential Impact 3.2-17). Fall Creek Hatchery would not be reopened under this alternative and thus there would be no effects of hatchery discharges on water quality and thus no significant impact (Potential Impact 3.2-17). There would be no significant impacts on water quality from short-term construction activities on Parcel B lands since land transfer would not occur (Potential Impact 3.2-18).

As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description– Foreseeable Short-term Operations*, the long-term outcomes are considered in the Proposed Project and other alternatives, thus inorganic and organic contaminants impacts are described in: Section 3.2.5.7 *[Water Quality] Inorganic and Organic Contaminants;* Section 4.3.2 *Water Quality*; Section 4.4.2 *Water Quality*; Section 4.5.2 *Water Quality*; Section 4.6.2 *Water Quality*; and Section 4.7.2 *Water Quality.*

Other potential impacts related to inorganic and organic contaminants in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.2-8 Human and freshwater aquatic species' exposure to inorganic and organic contaminants due to continued impoundment of water in the reservoirs.

The No Project Alternative would continue the existing condition with respect to human or freshwater aquatic species exposure to inorganic and organic contaminants (Section 3.2.2.7 *Inorganic and Organic Contaminants*). Implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would have no effect on exposure pathways for inorganic and organic contaminants because the flow changes would not alter the Lower Klamath Project reservoir sediment deposits nor would they alter physical, chemical, or biological conditions within the river or reservoir reaches that would change the potential for exposure to inorganic or organic contaminants compared with existing conditions. Overall, there would be no change in human or freshwater aquatic species' exposure to inorganic and organic contaminants relative to existing conditions, thus there would be no significant impact due to inorganic or organic contaminants in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Hydroelectric Reach, the Middle and Lower Klamath River and the Klamath River Estuary.

Significance

No significant impact

4.2.3 Aquatic Resources

4.2.3.1 Key Ecological Attributes

Suspended Sediment

As described in Section 3.3.4.1 *Suspended Sediment*, the potential effects of suspended sediment on anadromous fish species were assessed using SRH-1D (Huang and Greimann 2010, as summarized in USBR 2012). Suspended sediment effects under the No Project Alternative are described in detail in Appendix E and summarized below. Under the No Project Alternative, suspended sediment would be the same as under existing conditions. Most suspended sediment is supplied by tributaries; Iron Gate Dam currently interrupts both fine and coarse sediment transport, so suspended sediment generally increases in a downstream direction. The Lower Klamath River downstream from the Trinity River confluence (RM 43.3) to the estuary mouth (RM 0) is listed as sediment impaired under Section 303(d) of the Clean Water Act (CWA).

Daily durations of SSC concentrations were modeled assuming the No Project Alternative occurred within each of the 49 years in the available hydrology record (1961–2009).

For each simulation year in the 49-year record, the duration of SSCs over a given threshold was calculated for each species and life-history stage (e.g., duration of SSC over 1,000 mg/L during spring-run Chinook salmon adult upstream migration). Species selected for the suspended sediment analysis included Chinook salmon (fall- and spring-runs), coho salmon, steelhead (summer and fall/winter runs), Pacific lamprey, and green sturgeon. The results of modeling all potential years were summarized for each life-stage of each species assessed. This information was used assess the impacts of SSCs on fish under a No Project Alternative, based on the concentration and duration of exposure using an approach described by Newcombe and Jensen's (1996). As described in Appendix E, Newcombe and Jensen (1996) reviewed and synthesized 80 published reports of fish responses to suspended sediment in laboratories, streams, and estuaries and established a set of equations to calculate "severity of ill effect" (SEV) indices. A suite of six equations were developed that evaluate the effects of suspended sediment (at various concentrations, durations of exposure, and particle sizes) on various taxonomic groups of fishes and life stages of species within those groups.

Because the suspended sediment varies with hydrology, and in order to account for (and compare) the range of results and impacts that might occur under the No Project Alternative, three scenarios were analyzed for the No Project Alternative with the goal of predicting the potential impacts to fish that has either a 90 percent (mild conditions for fish), 50 percent (median conditions for fish) or 10 percent (extreme conditions for fish) probability of occurring, defined as follows:

- **Median conditions for fish:** This scenario represents the conditions that most often occur for each species and life stage—that is to say, SSCs and durations with a 50 percent exceedance probability for the mainstem Klamath River downstream from Iron Gate Dam. This means that under existing conditions there is an equal chance that the SSCs will be higher or lower than described. Exceedance probabilities were based on modeling SSCs for all water years from 1961 to 2009 with facilities in place.
- **Mild conditions for fish:** This scenario represents mild conditions of the potential sediment-related impacts to a species and life stage. It uses suspended sediment concentrations and durations with a 90 percent exceedance probability. This means that under these rare mild conditions for fish scenario the probability of these concentrations and durations being equal to or less than this level for each assessed species and life-stage in any one year is 10 percent, and the probability of them being exceeded is 90 percent.
- **Extreme conditions for fish:** This scenario represents extreme conditions for fish from potential sediment-related impacts. It uses SSCs and durations with a 10 percent exceedance probability. This means that under these rare extreme conditions for fish scenario the probability of these concentrations and durations being equal to or greater than this level for each assessed species and life-stage in any one year is 10 percent, and the probability of them being less than this level is 90 percent.

Under mild, median, or extreme conditions for fish, the magnitude and duration of the SSCs modeled for the No Project Alternative are expected to cause major stress to migrating adult and juvenile salmonids (SEV greater than 8) primarily during winter (see Appendix E for detailed analysis).

Bed Elevation and Grain Size Distribution

Under the No Project Alternative, reasonably foreseeable short-term (0−5 years) bed elevation and grain size distribution conditions downstream of Iron Gate Dam are expected to remain the same as existing conditions, since Lower Klamath Project dams will continue to trap sediment, as described in Appendix F and summarized in Section 3.11.2.2 *Geomorphology*.

Water Quality

Upper Klamath River—Hydroelectric Reach

Under the No Project Alternative, continued high rates of algal photosynthesis in the two largest reservoirs in the Hydroelectric Reach (Copco No. 1 and Iron Gate) would result in dissolved oxygen and pH values that would not consistently meet California Basin Plan water quality objectives (see Section 3.2 *Water Quality*). The bottom waters (i.e., hypolimnion) of Copco No. 1 and Iron Gate reservoirs would continue to have very low dissolved oxygen levels (< 1 mg/L to 5 mg/L) during summer stratification periods. Based on existing conditions, pH during summer through fall in Copco No. 1 and Iron Gate reservoirs would continue to range from just above neutral (7) to greater than 9 (slightly basic), with the highest values occurring during algal blooms. The ongoing presence of Copco No. 1 and Iron Gate reservoirs, the two largest reservoirs in the Hydroelectric Reach, would also continue to provide the conditions necessary for large seasonal blue-green algae blooms, including *Microcystis aeruginosa*, which can produce a toxin and contribute to reduced health and increased mortality rates for fish and other aquatic resources both within the reservoirs and in areas downstream.

Middle and Lower Klamath River

Ongoing efforts to improve water quality conditions in this reach are underway through the TMDL process and considerable efforts to improve habitat are also underway (Hamilton et al. 2011). Once fully implemented, these efforts could reduce existing water quality degradation that contribute to reduced health and increased mortality rates for aquatic resources (described below) to some extent, but this process would be slower and more challenging than with the dams removed (Section 4.2.1 *Introduction*). In the interim, water quality conditions that may reduce survival of fish and other aquatic resources would persist downstream from Iron Gate Dam.

Modeling conducted for development of the California Klamath River TMDL indicates that under the No Project Alternative, dissolved oxygen concentrations immediately downstream from Iron Gate Dam would not meet the North Coast Basin Plan water quality objective of 85 percent saturation during August–September and the 90 percent saturation objective from October–November (Section 3.2.2.5 *Dissolved Oxygen*, Figure 3.2-20). Further downstream, near the confluence with the Shasta River, dissolved oxygen concentrations under the No Project Alternative would not meet the 90 percent saturation objective from October–November (Section 3.2.2.5 *Dissolved Oxygen*, Figure 3.2-21). In the Klamath River at Seiad Valley, concentrations would be mostly in compliance, with the exception of modeled values in November that would not meet the 90 percent saturation objective (Section 3.2.2.5 *Dissolved Oxygen*, Figure 3.2-21). By the Salmon River (RM 66) confluence, with full attainment of TMDL allocations, predicted dissolved oxygen concentrations would remain at or above the 85 percent saturation objective (as well as the 90 percent saturation objective, where applicable), meeting the Water Quality Control Plan for the North Coast Region (California Basin Plan) requirements.

Under the No Project Alternative, continued high rates of algal photosynthesis in the reservoirs would result in high pH values in the Lower Klamath River downstream from Iron Gate Dam. Under the No Project Alternative, pH would continue to be elevated with high diurnal variability during summer and early fall months.

The overall anticipated effect on dissolved oxygen in the Lower Klamath River under the No Project Alternative would be an increasing trend toward compliance with water quality objectives and support of designated beneficial uses, but with possible continued seasonally low dissolved oxygen downstream from Iron Gate Dam. The seasonally low dissolved oxygen levels in this reach would not consistently meet California Basin Plan and Hoopa Valley Tribe water quality objectives. The No Project Alternative would continue to periodically result in dissolved oxygen levels that may be deleterious to aquatic resources downstream from Iron Gate Dam, but adverse effects would be similar to or less than under existing conditions.

Water Temperature

Upper Klamath River—Hydroelectric Reach

Under the No Project Alternative, the effects of ongoing and future upstream water quality improvements under the TMDLs would improve water temperatures downstream of Keno Dam, as described in Section 3.2.2.2 *Water Temperature*. The river's thermal regime downstream from the reservoirs would continue to be out of phase with the natural temperature regime (Hamilton et al. 2011). Unnatural temperature fluctuations would continue downstream from the J.C. Boyle Bypass Reach, from the mixture of cold-water inflow from Big Springs and the warmer water discharge from the J.C. Boyle Powerhouse (Hamilton et al. 2011).

Middle and Lower Klamath River

Under the No Project Alternative, the Lower Klamath River downstream from Iron Gate Dam would continue to have elevated water temperatures in the summer and fall in the near term. The reservoirs have the effect of changing the timing and magnitude of the thermal regime by increasing water temperatures in the fall as a result of the increased hydraulic residence time and thermal mass (Bartholow et al. 2005). Bartholow et al. (2005) and PacifiCorp (2004b) showed that the reservoirs delay seasonal thermal signatures by 18 days.

Dams would continue to increase late summer and early fall water temperatures in the Klamath River downstream from Iron Gate Dam (3.2.2.2 *Water Temperature*). Under the No Project Alternative in the fall, the dams would not decrease temperatures of water that is transported downstream from Upper Klamath Lake. This is due to the fact that powerhouse withdrawals for Copco No. 1 and Iron Gate Dams are primarily from the epilimnion (surface waters) (see Appendix C, Section C.1.1.4) which is heated by ambient air under existing reservoir operations. Unlike Shasta Dam or other deep reservoirs that support downstream tailwater fisheries by release of cold water from low level outlets, the location of dam outlets in the Klamath River cannot be adjusted to access large volumes of cold water in the bottom of the reservoirs (hypolimnion).

Under this alternative, the current phase shift and lack of temporal temperature diversity in the middle and lower Klamath River would persist, including current warm temperatures in late summer and fall (Hamilton et al. 2011). Juvenile and adult salmonids migrating in late summer and fall would continue to experience warm temperatures that could be deleterious to health and survival, including increased risk of disease, and high rates of delayed spawning and pre-spawn mortality (Hetrick et al. 2009). This phase shift and the resulting warm fall temperatures results in delayed adult upstream salmonid migration, which is believed to delay fall spawning (Dunsmore and Huntington 2006). Under the No Project Alternative, the existing cold-water temperatures in spring would likely continue to delay emergence and reduce growth rates of juveniles (Hardy et al. 2006).

In addition, the decrease in diel temperature variation compared with historical conditions is deleterious for salmonids. Historically, diel temperature variation would result in regular nighttime cooling of water, offering daily relief with significant bioenergetic benefits that helped fish persist under marginal water temperature conditions (NRC 2004). Under the No Project Alternative, the current lack of diel temperature variation would continue to reduce the value of thermal refuge habitat (Dunsmoor and Huntington 2006) and reduce the suitability of rearing habitat in the mainstem Klamath River (NRC 2004).

In addition to direct thermal stress, the potential for continued elevated water temperatures in the late summer/fall under the No Project Alternative could result in indirect stressors on salmonids including an increased intensity and duration of algal blooms, decreased dissolved oxygen levels, and conditions conducive to disease

(Bartholomew and Foott 2010). These effects would adversely impact cold-water fish communities and would be deleterious to warm-water fish communities as well.

Klamath River Estuary and Pacific Ocean Nearshore Environment
Under the No Project Alternative, water temperatures in the Klamath River Estuary and Pacific Ocean would remain similar to the existing conditions and climate change would continue to play a role in future temperatures as described above.

Fish Disease and Parasites
As described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Fish Disease and Parasites]*, The ongoing presence of the dams under the No Project Alternative would continue to contribute to the static flows, immobile substrate, seasonally warm water temperatures, and planktonic food sources in the mainstem Klamath River that are favorable for polychaetes and for *C. shasta* and *P. minibicornis* (Hetrick et al. 2009). Salmon carcasses would continue to concentrate downstream from Iron Gate Dam, where the polychaete hosts are abundant, facilitating the cross infection between the fish and the polychaetes. Under the No Project Alternative, mortality associated with *C. shasta* and *P. minibicornis* would be expected to worsen or remain similar to existing conditions. These conditions would continue to adversely affect salmon outmigrating from tributaries downstream from Iron Gate Dam, including those from the Shasta and Scott rivers. However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments. In addition, court ordered emergency dilution flows were required in 2018. As described in Section 3.1.6, the 2017 court-ordered flows include a requirement to ensure that certain high flows are reached each winter, and also include an emergency dilution requirement if juvenile fish disease reaches high levels in the infection nidus. The emergency dilution flows were used in 2018. While the flushing flows have not been occurring over a long enough time to allow collection of enough data on the efficacy of the flushing flows, the necessity to use the emergency dilution flows in 2018 suggest that the addition of the flushing flows is insufficient on its own to resolve the issue of fish disease downstream of Iron Gate Dam. Therefore, the No Project Alternative would result in continued substantial deleterious effects on salmon because of fish disease and parasites.

Algal Toxins
Upper Klamath River - Hydroelectric Reach
Continued impoundment of water at the Lower Klamath Project reservoirs under the No Project Alternative would continue to support suitable growth conditions for toxin-producing nuisance algal species such as *Microcystis aeruginosa* in Copco No. 1 and Iron Gate reservoirs, resulting in high seasonal concentrations of algal toxins in the Hydroelectric Reach. This would result in continued bioaccumulation of microcystin in fish tissue for species in the Hydroelectric Reach and could be deleterious to fish health (Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*).

Middle and Lower Klamath River

Continued impoundment of water within the Lower Klamath Project reservoirs under the No Project Alternative would continue to support suitable growth conditions for toxin-producing nuisance algal species such as *Microcystis aeruginosa* in Copco No. 1 and Iron Gate reservoirs and subsequent transport of high seasonal concentrations of algal toxins to the Klamath River downstream from Iron Gate Dam. This would also support continued bioaccumulation of microcystin in fish and muscle tissue for species downstream from the dam (3.2.2.7 *Chlorophyll-a and Algal Toxins*).

Aquatic Habitat and Instream Flows

Under the No Project Alternative, hydrology and aquatic habitat of the Klamath River from its headwaters to the estuary would generally remain the same as under existing conditions. However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam.
