Activities currently underway to improve aquatic habitat and recover salmonid populations within the Klamath Basin would continue at their current levels. Recovery actions to improve aquatic habitat under the Klamath River Coho Salmon Recovery Plan (NMFS 2014) would continue, depending on available funding. These actions are anticipated to improve aquatic habitat conditions over time relative to current conditions within the areas that anadromous fish currently have access to. However, anadromous fish would continue to be blocked by Lower Klamath Project dams from access to a substantial quantity of historical habitat (described in Section 3.3.5.8 *Aquatic Habitat*).

4.2.3.2 Aquatic Resource Potential Impacts, Impacts, and Mitigation

Potential Impact 4.2.3-1 Effects on coho salmon critical habitat quality and quantity due to continued operations of the Lower Klamath Project.

In the short term, under the No Project Alternative, habitat conditions that support Primary Constituent Elements (PCEs) of designated critical habitat for coho salmon would continue to be impaired (NMFS 1999, 2010). Spawning habitat would continue to be impaired by sediment and instream flows within tributary streams, with little occurrence of mainstem spawning. Rearing habitat would continue to be impaired as result of habitat degradation, high water temperatures, and disease within tributaries and the mainstem. Flows would continue to be regulated by the existing 2013 BiOp, but they also would include the winter-spring surface and deep flushing flows as well as emergency dilution flow requirements (see Section 4.2.1.1 *[Alternative Description] Summary of Available Hydrology Information for the No Project Alternative*). In general, flows that support PCEs would continue to be depleted, both within tributaries and within the mainstem Klamath River, similar to existing conditions. While the quality of PCEs would likely improve gradually over time through the actions undertaken under the Klamath River Coho Salmon Recovery Plan (NMFS 2014), potential variations in the implementation schedule for recovery actions, and the time until recovery actions have a measurable effect, means that in the short term, recovery actions would not be likely to improve PCE's. Additionally, in the short term under the No Project Alternative, coho salmon access to upstream tributaries such as Jenny Creek, Fall Creek, and Shovel Creek would remain inaccessible by Lower Klamath Project facilities. Overall, under the

No Project Alternative, there would be no change from existing adverse conditions for coho salmon critical habitat in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-2 Effects on Southern Resident Killer Whale critical habitat quality due to alterations to salmon populations due to continued operations of the Lower Klamath Project.

The Klamath River may affect PCEs of critical habitat for Southern Resident Killer Whales through its potential contribution of Chinook salmon to the food supply for Southern Resident Killer Whales, the survival and fecundity of which appears dependent upon the abundance of this species (Ward et al. 2009, Ford et al. 2009). However, data on the Southern Resident Killer Whale diet indicate that based on the migratory range and behavior of the population, the Klamath River salmon are anticipated to provide less than one percent of the diet of Southern Resident Killer Whales in most months under current and future conditions. While Southern Resident Killer Whales have been shown to consume Klamath River Chinook Salmon, the Klamath River is considered by NMFS and WDFW tenth out of the top ten priority Chinook Salmon populations for Southern Resident Killer Whales (NMFS 2018b, NMFS and WDFW 2018). Under the No Project Alternative, there would be no change in Klamath-origin Chinook salmon as compared to existing conditions, and therefore no significant impact.

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-3 Effects on eulachon critical habitat quality due to continued operations of the Lower Klamath Project.

Under the No Project Alternative, there are no major actions that are likely to alter PCEs of critical habitat for eulachon in the Klamath River Estuary. In the reasonably foreseeable short-term (0−5 years), there would be no change from existing conditions for eulachon critical habitat, and therefore no significant impact.

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-4 Effects on Chinook and coho salmon Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.

Under the No Project Alternative, EFH for Chinook and coho salmon would be expected to remain similar to current conditions. Access to habitat would be limited to current levels. Conditions under the No Project Alternative would continue to contribute to elevated concentrations of disease parasites and would provide the conditions required for the cross infection of fish and polychaetes (Hetrick et al. 2009, Hamilton et al. 2011). These interacting factors could decrease the viability of Chinook and coho salmon populations in the future (Hetrick et al. 2009, Hamilton et al. 2011). Under the No Project Alternative, there would be no change from existing adverse conditions for Chinook and coho salmon EFH in the reasonably foreseeable short-term (0−5 years).

Significance
No change from existing adverse conditions in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-5 Effects on groundfish Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.
Under the No Project Alternative, sediment and habitat conditions in the estuary are not substantially altered by the Lower Klamath Project, and nearshore ocean would remain the same as they are under existing conditions. Under the No Project Alternative, there would be no change from existing conditions for groundfish EFH in the reasonably foreseeable short-term (0−5 years), and therefore no significant impact.

Significance
No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-6 Effects on pelagic fish Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.
Under the No Project Alternative, sediment and habitat conditions in the estuary and nearshore ocean would not be altered by the Lower Klamath Project, and they would continue to be the same as they are under existing conditions. Under the No Project Alternative, there would be no change from existing conditions for pelagic fish EFH in the reasonably foreseeable short-term (0−5 years), and therefore no significant impact.

Significance
No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-7 Effects on the fall-run Chinook salmon population due to continued operations of the Lower Klamath Project.
To help determine if the Proposed Project would advance restoration of the salmonid fisheries of the Klamath Basin, a Chinook Salmon Expert Panel was convened to attempt to answer specific questions that had been formulated by the project stakeholders to assist with assessing the effects of the Proposed Project compared with existing conditions (Goodman et al. 2011). In response to comments the Panel stated with certainty that under the No Project Alternative, fall-run Chinook salmon within the Klamath River will continue to decline[182]. However, as described in detail in Section 3.3.2.1 *Aquatic Species [Chinook salmon]*, although abundances are low compared to historical numbers (Table 3.3-2), in a recent review of the population status of Chinook salmon, the BRT (Williams et al. 2011) concluded that the current Klamath Basin population (which includes hatchery fish) appears to have been fairly stable for the past 30 years and is not currently in decline.

As described in Section 3.2.2 *Water Temperature*, under the No Project Alternative, the thermal regimes downstream from Iron Gate Dam would continue to be altered as a result of the Lower Klamath Project reservoirs and operations, particularly retention time of water in the reservoirs. Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary regularly exceed the range of chronic effects temperature thresholds (55.4–68°F) for full salmonid support in California (North Coast Regional Board 2010, Sinnott 2010a, 2011a, 2012a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Hanington

[182] Page 69 of Appendix C of the July 20, 2011 Addendum to Goodman et al. 2011.

2013; Hanington and Ellien 2013) (see Appendix C for more detail). These detrimental temperature exceedances would continue under the No Project Alternative.

Under the No Project Alternative, Iron Gate Dam would continue to block fall-run Chinook salmon access to hundreds of miles of historical habitat, which used to extend upstream to the Sprague, Williamson, and Wood Rivers (Hamilton et al. 2005, Hamilton et al. 2016). This includes around 76 miles of potential habitat within the Lower Klamath Project, based on approximately 54 miles of potential anadromous fish (steelhead) habitat in the Project Reach (NMFS 2006a, DOI 2007)[183], reduced in consideration of the more limited distribution of Chinook salmon relative to steelhead (DOI 2007), and including over 22 miles inundated by Klamath Hydroelectric Project reservoirs (Cunanan 2009). The current reservoirs inundate sections of the river that had high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009). The consequences of this ongoing loss of habitat to the population could include reduced resilience to recover from catastrophic disturbances of natural or anthropogenic origin, such as wildfire or chemical spills. Under the No Project Alternative, access to cold water habitat would continue to be severely limited, reducing opportunities for the fall-run Chinook salmon of all life stages to access refuge habitat that would increase resiliency of the population to disturbance. Under the No Project Alternative, the system of reservoirs and dams in the hydroelectric reach would continue to create conditions conducive to the spread of parasites among the fall-run Chinook salmon population downstream from Iron Gate Dam, especially where adults (and carcasses) tend to congregate in high numbers, just downstream from Iron Gate Dam (Stocking and Bartholomew 2007, Bartholomew and Foott 2010), but also in other locations further downstream. Additional factors related to the Lower Klamath Project would continue to exacerbate the risk of disease downstream from Iron Gate Dam, including increased water temperatures and dampened flow and thermal variability, reduced dissolved oxygen concentrations, loss of sediment transport through the reach due to capture of sediment by the dams, and reservoirs contributing plankton to the filter-feeding polychaete hosts of the myxozoan parasites (as discussed above in Section 4.2.3.1 *Key Ecological Attributes [Fish Disease and Parasites]*). Under the No Project Alternative, downstream-migrating juvenile Chinook salmon may continue to have high disease infection rates (Bartholomew and Foott 2010) during summer months in some years. Heavy parasite loads may increase disease-related mortality in outmigrant smolts, particularly when water temperatures are high, or may reduce ocean survival by affecting growth or fitness (Scheuerell et al. 2009).

However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments. In addition, court ordered emergency dilution flows were required in 2018. As described in Section 3.1.6, the 2017 court-ordered flows include a requirement to ensure that certain high flows are reached each winter, and also include an emergency dilution requirement if juvenile fish disease

[183] This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

reaches high levels in the infection nidus. The emergency dilution flows were used in 2018. While the flushing flows have not been occurring over a long enough time to allow collection of enough data on the efficacy of the flushing flows, the necessity to use the emergency dilution flows in 2018 suggest that the addition of the flushing flows is insufficient on its own to resolve the issue of fish disease downstream of Iron Gate Dam. Therefore, the No Project Alternative would result in continued substantial deleterious effects on fall-run Chinook salmon because of fish disease and parasites.

Effects of suspended sediment on fall-run Chinook salmon under the No Project Alternative and existing conditions are described in Appendix E.3.1.1. Overall, fall-run Chinook salmon use the mainstem Klamath River for spawning, rearing, and as a migratory corridor. Although SSCs under existing conditions and the No Project Alternative are relatively high in the mainstem downstream from Orleans, and even more so downstream from the Trinity River (State Water Resources Control Board 2006, North Coast Regional Board 2010) (Appendix E and Section 3.2.2.3 *Suspended Sediments*), they are relatively low in the reach downstream from Iron Gate Dam where most mainstem spawning occurs. Suspended sediment concentrations and durations during upstream and downstream migration, even under extreme conditions for fish, are low enough that they have limited effects on fish, although physiological stress and reduced growth rates are possible. In general, fall-run Chinook salmon under the No Project Alternative would be relatively unaffected by SSCs, because smolt outmigration primarily occurs when SSCs are naturally low (similar to existing conditions).

Under the No Project Alternative, ongoing hatchery operations would continue to mitigate for habitat lost due to construction of Iron Gate Dam by releasing millions of juvenile and yearling Chinook salmon annually. These fish may compete with the progeny of natural-origin fish for food and other limited resources, such as thermal refugia, as described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Fish Hatcheries]*. In addition, hatchery releases can increase disease infection rates through crowding and, where mortality occurs, concentrated release of myxospores on top of the area of highest polychaete densities. Data from Ackerman et al. (2006) indicate that substantial straying of Iron Gate Hatchery fish may be occurring into important tributaries of the Middle Klamath River. Straying has the potential to reduce the reproductive success of natural salmonid populations (Mclean et al. 2003, Chilcote 2003, Araki et al. 2007) and negatively affect the diversity of the populations via outbreeding depression[184] (Reisenbichler and Rubin 1999).

Under the No Project Alternative, the interruption of sediment transport processes by the dams would continue, reducing spawning gravel supply to downstream reaches and changing the dynamics of channel morphology and riparian vegetation communities that create and maintain rearing habitats for fry and juvenile fall-run Chinook salmon. Lack of sediment transport is also likely to be contributing to the high densities of polychaetes downstream from Iron Gate Dam that host salmonid parasites, through reduction of scour that would otherwise help limit periphyton growth (FERC 2007, Hetrick et al. 2009). Under the No Project Alternative, there would be no change from existing conditions for fall-run Chinook salmon in the reasonably foreseeable short-term (0−5 years).

[184] Outbreeding depression is the displacement of locally adapted genes in a wild population.

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-8 Effects on the spring-run Chinook salmon population due to continued operations of the Lower Klamath Project.

In a recent review of the population status of Chinook salmon, the Biological Review Team (BRT) (Williams et al. 2011) concluded that the current Chinook population (which includes hatchery fish) appears to have been fairly stable for the past 30 years and is not currently in decline, despite dramatic reductions in comparison to historical abundance (Table 3.3-2). However, the BRT was concerned about the relatively few populations of spring-run Chinook salmon in the Upper Klamath Trinity River ESU and the low numbers of spawners within those populations (Williams et al. 2011).

Under the No Project Alternative, poor water quality conditions caused partly by nutrient enrichment through release of blue-green algae from Lower Klamath Project reservoirs, during spring-run Chinook salmon upstream and downstream migration may cause high stress to adults and juveniles. Water quality in the mainstem Klamath River downstream from Iron Gate Dam is adversely affected by Lower Klamath Project facilities (Section 3.2.2.2 *Water Temperature*) including altered seasonal water temperature patterns, low dissolved oxygen, and increased nutrient input, as well occasional blooms of the toxic blue-green algae *Microcystis aeruginosa*. Although water quality tends to improve downstream of Iron Gate Dam to the Salmon River (the current upstream extent of spring-run Chinook distribution in the Klamath River), the effect of water quality alterations caused by Lower Klamath Project facilities is that conditions (especially water temperature and dissolved oxygen) during much of the summer are critically stressful for spring-run Chinook salmon that are present during the period June through September. Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary regularly exceed the range of chronic effects temperature thresholds (55.4–68°F) for full salmonid support in California (North Coast Regional Board 2010, Sinnott 2010a, 2011a, 2012a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Hanington 2013; Hanington and Ellien 2013) (see Appendix C for more detail). These detrimental temperature exceedances would continue under the No Project Alternative. Spring Chinook salmon that are stressed by high temperatures, whether adults or juveniles, likely have lower survival rates, especially when challenged by additional water quality factors, such as low dissolved oxygen, the presence of toxic blue-green algae (*Microcystis aeruginosa*) and fish diseases, and high pH and un-ionized ammonia (3.2.2.6 *pH*). Under the No Project Alternative, downstream-migrating juvenile Chinook salmon may continue to have high disease infection rates (Bartholomew and Foott 2010) during summer months in some years. Heavy parasite loads may increase disease-related mortality in outmigrant smolts, particularly when water temperatures are high, or may reduce ocean survival by affecting growth or fitness (Scheuerell et al. 2009).

However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments. In addition, court ordered emergency dilution flows were required in 2018. As described in Section 3.1.6, the 2017 court-ordered flows include a requirement to ensure that certain high flows are reached each winter, and also include an emergency dilution requirement if juvenile fish disease reaches high levels in the infection nidus. The emergency dilution flows were used in 2018. While the flushing flows have not been occurring over a long enough time to allow collection of enough data on the efficacy of the flushing flows, the necessity to use the emergency dilution flows in 2018 suggest that the addition of the flushing flows is insufficient on its own to resolve the issue of fish disease downstream of Iron Gate Dam. Therefore, the No Project Alternative would result in continued substantial deleterious effects on spring-run Chinook salmon because of fish disease and parasites.

Under the No Project Alternative high water temperatures during summer may also reduce the growth of juvenile spring-run Chinook salmon juveniles that are rearing and migrating downstream to the ocean due to greater metabolic requirements. Because size is correlated with ocean survival (Scheuerell et al. 2009), this could lead to reduced smolt survival and subsequently, reduced escapement under the No Project Alternative. Finally, high temperatures can selectively reduce the survival of fish expressing the life history of migrating later in the summer (the "summer-run"), thus reducing genetic and life-history diversity. High water temperatures likely limit adult holding and summer rearing habitat for spring-run Chinook salmon in the main spawning tributaries, the Salmon and Trinity Rivers, which would likely reduce overall production under the No Project Alternative. Low flows in dry years can cause migration barriers to form, reducing habitat available to spawning and rearing fish.

Under the No Project Alternative, Iron Gate Dam would continue to block spring-run Chinook salmon access to their historical habitat, which used to extend upstream to the Sprague, Williamson, and Wood Rivers (Hamilton et al. 2005). This includes around 76 miles of potential habitat within the Lower Klamath Project, based on approximately 54 miles of potential anadromous fish (steelhead) habitat in the Project Reach (NMFS 2006a, DOI 2007)[185], reduced in consideration of the more limited distribution of Chinook salmon relative to steelhead (DOI 2007), and including over 22 miles inundated by Klamath Hydroelectric Project reservoirs (Cunanan 2009). The current reservoirs inundate sections of the river that had high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009). In addition, access would continue to be blocked to hundreds of miles of habitat upstream of J.C. Boyle Reservoir (Hamilton et al. 2005). The consequences of ongoing blockage of Spring-run Chinook habitat under the No Project Alternative could include reduced resilience to Spring-run Chinook population for recovery from catastrophic disturbances of natural or anthropogenic origin, such as wildfire or chemical spills. Because areas upstream of Iron Gate Dam include cold-water refugia, opportunities for the population to adapt to changing climate are reduced, whether these changes are a result of short- or long-term cycles or trends.

Effects of suspended sediment on spring-run Chinook salmon under the No Project Alternative and existing conditions are described in Appendix E.3.1.2. Overall, spring-run Chinook salmon mostly use the mainstem Klamath River as a migratory corridor during adult migration, and downstream smolt migration. Although suspended sediment under existing conditions is relatively high in the mainstem Klamath River downstream

[185] This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

from Orleans, and especially downstream from the Trinity River (Appendix E.3.1.2), increases in suspended sediment in the mainstem Klamath River during critical migratory periods are currently low enough in concentration and short enough in duration that effects are limited to physiological stress and possibly inhibited growth, even during extreme conditions for fish. Current suspended sediment conditions and timing would remain unchanged under the No Project Alternative.

One of the main spawning streams for spring-run Chinook salmon, the Salmon River, has dramatically increased course sediment production over historical conditions as a result of legacy mining, road construction, timber harvest, and wildfire disturbance which leads to habitat degradation (Elder et al. 2002). Habitat degradation, much of which is a direct result of increased sedimentation, is believed to be the primary cause of the decline of the spring-run salmon population in the Klamath River system. Under the No Project Alternative, spawning and rearing habitat would remain in a degraded condition in both quantity and quality, and salmon production may be low in some years.

Under this alternative, dams would continue to block access to historical habitat, and spring-run Chinook salmon are likely to remain at significantly suppressed levels over the years of analysis (50 years). Under the No Project Alternative, there would be no change from existing conditions for spring-run Chinook salmon in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-9 Effects on coho salmon populations due to continued operations of the Lower Klamath Project.

Under the No Project Alternative, Iron Gate Dam would continue to block access by coho salmon to historical habitat which used to extend upstream at least as far as Spencer Creek (Hamilton et al. 2005), including an estimated 76 miles of potential habitat within the Lower Klamath Project, based on approximately 54 miles of potential anadromous fish (steelhead) habitat in the Project Reach (NMFS 2006a, DOI 2007),[186] reduced in consideration of the more limited distribution of coho salmon relative to steelhead (DOI 2007), and including over 22 miles inundated by Klamath Hydroelectric Project reservoirs (Cunanan 2009), and habitat within the bypass reaches. The current reservoirs inundate sections of the river that had high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009). The consequences of this ongoing loss of habitat to the population would include reduced resilience to recover from catastrophic disturbances of natural or anthropogenic origin, such as wildfire or chemical spills (Hamilton et al. 2011). Under the No Project Alternative access to cold water habitat would continue to be severely limited. Because areas upstream of the Iron Gate Dam include cold-water refugia for adult salmon and outmigrating smolts, opportunities for the population to adapt to changing temperatures would continue to be reduced. The above factors, which would continue under the No Project Alternative, reduce the natural genetic and life-history diversity found in Klamath Basin subpopulations of coho salmon that provide adaptive capacity and a sufficient number of subpopulations so that the population can withstand catastrophic events (NMFS 2014).

[186] This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

Under the No Project Alternative, upstream-migrating adult coho salmon would continue to be exposed to high water temperatures and poor water quality in part caused by Lower Klamath Project facilities (Section 3.2.2.2 *Water Temperature*) in the mainstem Klamath River, which can cause physiological stress, delay migration, reduce coldwater refugia, and increase mortality from disease. Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary regularly exceed the range of chronic effects temperature thresholds (55.4–68°F) for full salmonid support in California (North Coast Regional Board 2010, Sinnott 2010a, 2011a, 2012a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Hanington 2013; Hanington and Ellien 2013) (see Appendix C for more detail). High water temperatures may promote higher incidence of disease or parasitism, which may increase direct and indirect mortality (Stutzer et al. 2006, NMFS 2010a). During a 2008 PIT-tag study of juvenile coho salmon in the Shasta River, Chesney et al. (2009) found juvenile coho salmon only in areas where temperatures were moderated by cold springs; the remainder of potential rearing habitat was too warm (>68°F). These detrimental temperature exceedances would continue under the No Project Alternative.

Effects of suspended sediment on coho salmon under the No Project Alternative and existing conditions are described in Appendix E.3.1.3. Under the No Project Alternative, SSCs in the mainstem would be sufficiently high and of long enough duration that coho salmon would continue to experience major physiological stress and reduced growth in most years.

Under the No Project Alternative, additional factors related to the Lower Klamath Project would continue to exacerbate the risk of disease downstream from Iron Gate Dam, including increased water temperatures and dampened flow and thermal variability, reduced dissolved oxygen concentrations, loss of sediment transport through the reach due to capture of sediment by the dams, and reservoirs contributing plankton to the filter-feeding polychaete hosts of the myxozoan parasites (as discussed above in Section 4.2.3.1 *Key Ecological Attributes [Fish Disease and Parasites]*). Under the No Project Alternative, downstream-migrating juvenile coho salmon may continue to have high disease infection rates (Bartholomew and Foott 2010) during summer months in some years. Heavy parasite loads may increase disease-related mortality in outmigrant smolts, particularly when water temperatures are high, or may reduce ocean survival by affecting growth or fitness (Holtby et al. 1990).

However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments. In addition, court ordered emergency dilution flows were required in 2018. As described in Section 3.1.6, the 2017 court-ordered flows include a requirement to ensure that certain high flows are reached each winter, and also include an emergency dilution requirement if juvenile fish disease reaches high levels in the infection nidus. The emergency dilution flows were used in 2018. While the flushing flows have not been occurring over a long enough time to allow collection of enough data on the efficacy of the flushing flows, the necessity to use the emergency dilution flows in 2018 suggest that the addition of the flushing flows is insufficient on its own to resolve the issue of fish disease downstream of Iron Gate Dam. Therefore, the No Project Alternative would result in continued substantial deleterious effects on coho salmon because of fish disease and parasites.

Under the No Project Alternative hatchery operations would continue. High numbers of hatchery fish may continue to impact the genetics and conditions for wild coho salmon (Noakes et al. 2000) in the Klamath Basin, as described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Fish Hatcheries]*. Data from Ackerman et al. (2006) indicate that substantial straying of Iron Gate Hatchery fish may be occurring into important tributaries of the Middle Klamath River. Straying has the potential to reduce the reproductive success of natural salmonid populations (Mclean et al. 2003, Chilcote 2003, Araki et al*.* 2007) and negatively affect the diversity of the populations via outbreeding depression[187] (Reisenbichler and Rubin 1999).

Coho salmon populations in the Klamath Basin are in decline; less than 70 percent of streams historically used by coho salmon in the Basin still contain small populations (NRC 2004). The No Project Alternative would likely support the continuation of blocked habitat access, water temperature impacts, and disease risk in the Klamath River that have helped to cause this decline (NMFS 2014). More detail on current conditions for coho salmon can be found in the NMFS (2010a) *BO on operation of the Klamath Project between 2010 and 2018*. Under the No Project Alternative, there would be no change from existing adverse conditions for coho salmon from all populations within the Klamath River watershed in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short term (0−5 years)

Potential Impact 4.2.3-10 Effects on the steelhead population due to continued operations of the Lower Klamath Project.

Summer steelhead use the mainstem Klamath River primarily as a migration corridor because most spawning and rearing occurs in Klamath River tributaries. Under the No Project Alternative, summer steelhead spawning and rearing habitat availability and distribution would continue to be restricted during summer and fall to reaches downstream from Seiad Valley by high water temperatures farther upstream (NRC 2004). Conditions in the mainstem are generally suitable for adult upstream migration during the peak of migration (March through June); however, high water temperatures in the summer may restrict upstream migration of adults arriving towards the end of the typical migration season (FERC 2007). Prior to dams and major flow regulation, temperatures would have been cooler in the summer and fall months for adult migrating steelhead, potentially supporting a broader migratory period (Bartholow et al. 2005, FERC 2007). Altered flow patterns downstream from Iron Gate Dam associated with Lower Klamath Project facilities may thus be affecting the population by selecting for earlier-arriving fish, potentially reducing life-history diversity in the population. The effects to population dynamics experienced in existing conditions would continue under the No Project Alternative. In addition, under the No Project Alternative the altered flow and water temperature patterns would continue to cause an ongoing loss of habitat that might otherwise be contributing to smolt production, survival, and escapement.

[187] Outbreeding depression is the displacement of locally adapted genes in a wild population.

Fall and winter steelhead are more widely distributed than any other anadromous salmonid downstream from Iron Gate Dam. Under the No Project Alternative, steelhead would continue to be restricted from accessing 360 miles of historical habitat along the mainstem Klamath River upstream to the Sprague, Williamson, and Wood Rivers (Huntington 2006), including cold-water refugia that could buffer the population from the warming effects of climate change (Hamilton et al. 2005). In addition, there are around 80 miles of potential habitat for steelhead within the Klamath Hydroelectric Project that are currently inaccessible, comprising approximately 58 miles of anadromous habitat with the Project reach (NMFS 2006a, DOI 2007), that includes over 22 miles inundated by Klamath Hydroelectric Project reservoirs (Cunanan 2009) and habitat within the bypass reaches. The current reservoirs inundate sections of the river that had high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009). As with summer steelhead, fall and winter steelhead use the mainstem primarily as a migration corridor to access tributaries for spawning. Under the No Project Alternative, high summer water temperatures in the summer months would continue to cause density-independent mortality on juveniles that have left spawning tributaries to rear in the mainstem.

Effects of suspended sediment on steelhead under the No Project Alternative and existing conditions are described in Appendix E.3.1.4. Overall, steelhead use the mainstem Klamath River as a migratory corridor during adult migration, and downstream smolt migration, and for juvenile rearing. SSCs under the No Project Alternative would continue to be relatively high in the mainstem Klamath River downstream from Orleans, and especially downstream from the Trinity River (State Water Control Board 2006, North Coast Regional Board 2010) (see Appendix E.3.1.4, and Section 3.2.2.3). However, SSCs in the mainstem Klamath River during critical migratory periods, even during extreme conditions for fish, would continue to be low enough with short exposure times that effects on steelhead would likely be limited to physiological stress and possibly reduced growth rates (Appendix E.3.1.4). Conditions for juvenile steelhead rearing in the mainstem would likely be worse and include mortality of up to 20 percent during extreme conditions for fish, but in general steelhead appear resilient to the suspended sediment regimes that occur under existing conditions and would persist under the No Project Alternative.

Under the No Project Alternative, additional factors related to the Lower Klamath Project would continue to exacerbate the risk of disease downstream from Iron Gate Dam, including increased water temperatures and dampened flow and thermal variability, reduced dissolved oxygen concentrations, loss of sediment transport through the reach due to capture of sediment by the dams, and reservoirs contributing plankton to the filter-feeding polychaete hosts of the myxozoan parasites (as discussed above in Section 4.2.3.1 *Key Ecological Attributes [Fish Disease and Parasites]*). Under the No Project Alternative, downstream-migrating juvenile steelhead may continue to have high disease infection rates (Bartholomew and Foott 2010) during summer months in some years (although steelhead are generally resistant to *C. shasta)*. Heavy parasite loads may increase disease-related mortality in outmigrant smolts, particularly when water temperatures are high, or may reduce ocean survival by affecting growth or fitness (FERC 2007).

However, additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath*

River Salmonids: A Guidance Document and U.S. District Court Filing 111 (U.S. District Court 2017a–c; described in Section 4.2.3) is predicted to help reduce juvenile salmon disease below Iron Gate Dam. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing flows were required in 2017 and 2018, with the intent of reducing disease in the Lower Klamath River by mobilizing bedload sediments. In addition, court ordered emergency dilution flows were required in 2018. As described in Section 3.1.6, the 2017 court-ordered flows include a requirement to ensure that certain high flows are reached each winter, and also include an emergency dilution requirement if juvenile fish disease reaches high levels in the infection nidus. The emergency dilution flows were used in 2018. While the flushing flows have not been occurring over a long enough time to allow collection of enough data on the efficacy of the flushing flows, the necessity to use the emergency dilution flows in 2018 suggest that the addition of the flushing flows is insufficient on its own to resolve the issue of fish disease downstream of Iron Gate Dam. Therefore, the No Project Alternative would result in continued substantial deleterious effects on steelhead because of fish disease and parasites.

Habitat conditions for juvenile steelhead rearing in the mainstem below Iron Gate Dam are generally suitable, except for reaches upstream of Seiad Valley where summer water temperatures are considered stressful. Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary regularly exceed the range of chronic effects temperature thresholds (55.4–68°F) for full salmonid support in California (North Coast Regional Board 2010, Sinnott 2010a, 2011a, 2012a; Watercourse Engineering, Inc. 2011a, 2011b, 2012, 2013, 2014, 2015, 2016; Hanington 2013; Hanington and Ellien 2013) (see Appendix C for more detail). These detrimental temperature exceedances would continue under the No Project Alternative. Juvenile outmigration peaks in the spring and extends through the summer and fall. Growth during their rearing and outmigration may be reduced by high temperatures (unless food availability is high) due to increased metabolism, which can reduce ocean survival (Scheuerell et al. 2009). High summer water temperatures causing physiological stress to fish can also make them more vulnerable to mortality from disease or other compounding factors. These conditions, and the resulting effects on juvenile steelhead in the mainstem Klamath River, would remain unchanged under the No Project Alternative. Under the No Project Alternative, there would be no change from existing conditions for steelhead in the reasonably foreseeable short-term (0−5 years).

<u>Significance</u>

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-11 Effects on the Pacific lamprey population due to continued operations of the Lower Klamath Project.

Pacific lamprey populations appear to have been in decline since the late 1980s in the Klamath Basin (Larson and Belchik 1998 as cited in Hamilton et al. 2011), and are considered “vulnerable” throughout their range by the American Fisheries Society (Jelks et al. 2008, as cited in Hamilton et al. 2011). Major factors believed to be affecting their populations include barriers to upstream migration at dams; dewatering of larval habitat through flow regulation; reducing larval habitat by increasing water velocity and/or reducing sediment deposition areas; and susceptibility to contaminants in the larval stage (Close et al. 2002, as cited in Hamilton et al. 2011).

Under the No Project Alternative, Iron Gate Dam would continue to form a barrier to Pacific lamprey migration, which represents an ongoing loss of available habitat and productive capacity. Although the exact upstream extent of suitable habitat for Pacific lamprey prior to the completion of the Lower Klamath Project dams and associated facilities is unknown, it is believed that Pacific lamprey would have migrated at least as far as Spencer Creek (Hamilton et al. 2005), including an estimated 80 miles of potential habitat within the Lower Klamath Project, based on approximately 58 miles of potential anadromous fish (steelhead) habitat in the Project Reach (NMFS 2006a, DOI 2007),[188] and including over 22 miles inundated by Klamath Hydroelectric Project reservoirs (Cunanan 2009), and habitat within the bypass reaches. The loss of this portion of spawning and larval rearing habitat reduces the viability of the Klamath Basin population by contracting its distribution within the watershed and reducing abundance.

Under the No Project Alternative, the dams would continue to reduce sediment supply to the mainstem Klamath River downstream from Iron Gate Dam, which may limit availability of gravel-cobble substrates for nest building and fine sediment for burrowing. Armoring of substrate would continue to occur downstream of Iron Gate Dam and would continue to also reduce spawning habitat quality. Despite these effects, in part caused by Lower Klamath Project facilities, the overall effect to Pacific lamprey populations in the Klamath Basin is likely to be small because (1) the effects of the dam on fine sediment and gravel/cobble substrates diminish with distance downstream because of input from tributaries and become less significant downstream from Cottonwood Creek (RM 185.1) (which is approximately 8 RM downstream of Iron Gate Dam), and (2) a large proportion of the population may spawn and rear in large tributaries to the mainstem, such as the Trinity, Salmon, Shasta, and Scott rivers.

Effects of suspended sediment on Pacific lamprey under the No Project Alternative and existing conditions are described in Appendix E.3.1.5. Overall, under all conditions, Pacific lamprey under the No Project Alternative are anticipated to suffer from stressful levels of suspended sediment while rearing and migrating through the mainstem Klamath River during winter, with exposure durations generally much longer under extreme conditions for lamprey. Because there are multiple year-classes of lamprey with a broad spatial distribution in the Klamath River Basin at any given time, and since adults may migrate upstream throughout the year (and thus some adults avoid peaks in SSC), Pacific lamprey populations may be well-adapted to persisting through years when SSCs are high in the mainstem.

The effects of Lower Klamath Project dams and reservoirs would continue to affect water quality downstream from Iron Gate Dam under the No Project Alternative, which may reduce habitat quality for spawning and rearing Pacific lamprey, as well as reproductive success. Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary regularly exceed the range of chronic effects temperature thresholds (64.4–71.6°F) for Pacific lamprey spawning and rearing (Meeuwig et al. 2005) (see Appendix C for more detail). These detrimental temperature exceedances would continue under the No Project Alternative.

Flow management under the No Project Alternative would continue to modify temperature and instream flow patterns relative to pre-project conditions which would

[188] This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

continue to alter the migration of patterns of adult, ammocoete, and macropthalmia Pacific lamprey (Stone et al. 2002, Luzier and Miller 2009), and may reduce survival (Stone et al. 2002). Under the No Project Alternative, regulated flow patterns and their potential effect on Pacific lamprey would remain the same as under existing conditions.

Under the No Project Alternative, Pacific lamprey populations in the Klamath Basin may remain at current levels or population numbers may continue to decline over the long term (Close et al. 2010). Because so little is known of Pacific lamprey life history and habitat requirements compared to those of anadromous salmonids, it is more difficult to predict the potential effects of alternatives on their abundance and distribution. Under the No Project Alternative, there would be no change from existing conditions for Pacific lamprey in the reasonably foreseeable short term (0−5 years).

Significance
No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-12 Effects on the green sturgeon population due to continued operations of the Lower Klamath Project.
Green sturgeon spend a majority of their lives in estuaries, bays, and nearshore waters, with adults only returning to fresh water to spawn after more than 15 years and spawning every 4 years on average (Klimley et al. 2007).

Northern green sturgeon spawn in the Rogue, Klamath, and Umpqua rivers. The Klamath Basin supports the largest spawning population of Northern Green Sturgeon (Moyle 2002), so it plays a critically important role in the viability and persistence of the entire DPS. In the Klamath River mainstem, green sturgeon spawn and rear in the lower 67 miles, downstream from Ishi Pishi Falls which forms a natural migratory barrier to green sturgeon. Concentration of spawning in only a very few areas renders these spawning populations vulnerable to local catastrophic impacts. A loss of any of the few spawning areas would have much greater effects than the loss of a spawning population of salmon that spawn in many other streams throughout their range.

Under existing conditions maximum temperatures in the Klamath River downstream from Iron Gate Dam to the Klamath River Estuary (including downstream of Ishi Pishi Falls) regularly exceed the range of temperature thresholds for green sturgeon spawning and egg incubation (62.6–78.8°F) (Van Eenennaam et al. 2005, Cech et al. 2000) (see Appendix C for more detail), especially during low water years. These detrimental temperature exceedances reducing the reproductive success of green sturgeon would continue under the No Project Alternative.

Effects of suspended sediment on green sturgeon under the No Project Alternative and existing conditions are described in Appendix E.3.1.6. Under existing conditions, green sturgeon in the Klamath River mainstem are regularly exposed to SSCs documented to cause major physiological stress, reduced growth, and mortality in other fish species, especially during their egg and larval stages, and the year-round juvenile rearing period. Exposure of green sturgeon to these SSCs would continue under the No Project Alternative. However, based on the persistence of their population under these conditions, these metrics likely overestimate effects on green sturgeon. Under the No Project Alternative, there would be no change from existing conditions for green sturgeon in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-13 Effects on Lost River and shortnose sucker populations due to continued operations of the Lower Klamath Project.

Under current conditions, Lost River and shortnose suckers in the Area of Analysis suffer mortality by entrainment in hydroelectric turbines at all Lower Klamath Project hydroelectric facilities (PacifiCorp 2013). Additionally, suckers would continue to be stranded due to peaking operations downstream of J.C. Boyle Dam (PacifiCorp 2013).

Under the No Project Alternative, there would be no change from existing conditions for Lost River and shortnose sucker populations in the reasonably foreseeable short term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-14 Effects on the redband trout population due to continued operations of the Lower Klamath Project.

Resident trout upstream of Iron Gate Dam are considered to be redband trout. Before construction of the Lower Klamath Project dams and associated facilities, redband trout in the area belonged to one population, with no migration barriers isolating populations from one another (NMFS 2006a). Under the No Project Alternative, genetic exchange and movement by redband trout between reaches would continue to be limited by the partially functional J.C. Boyle fish ladder (NMFS 2006a) and lack of fish ladders at the Copco No. 1 and 2 Dams, as would access to productive spawning habitat in Spencer Creek in the J.C. Boyle Bypass and Peaking Reaches (NMFS 2006a). The fragmentation of this population into several smaller, isolated subpopulations renders each more vulnerable to extinction due to stochastic events (wildfire, landslides, disease outbreaks, etc.) and limits genetic exchange among subpopulations.

Under the No Project Alternative, habitat connectivity for redband trout in the Klamath River would continue to be compromised by structural features of the Lower Klamath Project dams and associated facilities developments as well as by project operations. Fish downstream from J.C. Boyle Dam would continue to be hindered or obstructed from migrating to spawning grounds in Spencer Creek by the ineffective fish ladder at J.C. Boyle Dam, which poses a partial passage barrier (Hamilton et al. 2011). Spencer Creek is a highly productive spawning and rearing habitat for rainbow/redband trout (Hamilton et al. 2011). The stock of rainbow/redband trout in the bypass and peaking reaches below J.C. Boyle Dam is currently restricted from Spencer Creek and other suitable habitat upstream of the J.C. Boyle Dam (NMFS 2006a). Migration over the Copco No. 1 and 2 dams is in the downstream direction only, as there is no fishway. These conditions would remain unchanged under the No Project Alternative and the redband trout population would continue to suffer the effects of restricted habitat connectivity.

Under existing conditions, the lack of fully functioning fish screens at Iron Gate, Copco No. 1, and Copco No. 2 dams results in entrainment and loss of juvenile redband trout and reduces recruitment of redband trout to downstream reaches (DOI 2007). All Lower Klamath Project hydropower facilities use Francis turbines. A 1987 report prepared by the Electric Power Research Institute (EPRI 1987) concluded that fish mortality from entrainment at hydroelectric projects using Francis turbines averaged 24 percent. It is estimated that “several tens of thousands of resident fish” are annually entrained at “each of the Projects” facilities (NMFS 2006a), and it is likely that these entrainment and mortality rates would continue under the No Project Alternative.

The health and productivity of redband trout in the J.C. Boyle Peaking Reach and J.C. Boyle Bypass Reach would continue to be affected under the No Project Alternative. Obstruction of sediment transport at J.C. Boyle Dam has altered substrates and channel features in the peaking and bypass reaches (FERC 2007). High flows have mobilized and removed sediment from storage sites and transported it downstream, reducing habitat quality for redband trout as well as for the macroinvertebrates they feed on (NMFS 2006a). These effects would continue under the No Project Alternative. In the J.C. Boyle Peaking Reach, redband trout numbers would continue to be subject to large fluctuations in flows that would: (1) cause fluctuations in water temperature and pH, (2) strand fish, (3) displace fish downstream, (4) reduce fry habitat along channel margins, (5) reduce access to suitable gravels where they are affected by flow fluctuations, and (6) reduce macroinvertebrate food production by reducing the area of the channel suitable for their survival (City of Klamath Falls 1986, Addley et al. 2005, as cited in Hamilton et al. 2011). All of these conditions could result in substantial declines in redband trout abundance in this reach.

Under the No Project Alternative, diversion of water at continue to alter flows downstream, as occurs under existing conditions. Reduced flows in the 1.4-mile-long Copco No. 2 Bypass Reach would continue to prevent redband trout from using what would otherwise be habitat suitable for spawning and rearing. Productivity of redband trout in the bypass and peaking reaches downstream of J.C. Boyle Dam would continue to be suppressed by Lower Klamath Project effects that limit spawning and rearing habitat in these reaches (Hamilton et al. 2011). Under existing conditions, spawning of redband trout downstream of J.C. Boyle Dam appears limited to an area just downstream from the emergency canal spillway (Hamilton et al. 2011). Patches of gravel that might otherwise be suitable for spawning are rendered inaccessible to redband trout by reductions in instream flows (NMFS 2006a, Hamilton et al. 2011). These conditions would continue under the No Project Alternative.

Reduced redband trout abundance and distribution upstream of Iron Gate Dam attributable to Lower Klamath Project features and operations would continue under the No Project Alternative. Habitat connectivity and suitability are substantially reduced in the Hydroelectric Reach due in part to Lower Klamath Project facilities isolating population units by limiting migration and reducing habitat suitability. Apparent phenotypic changes in the redband trout in these reaches would likely be maintained or continue under the No Project Alternative, such as declines in size (Jacobs et al. 2007, as cited in Hamilton et al. 2011) and condition factor (ODFW 2003, as cited in Hamilton et al. 2011). The effect of the No Project Alternative would be no change from existing conditions for redband trout in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-15 Effects on the eulachon population due to continued operations of the Lower Klamath Project.

Under the No Project Alternative, habitat conditions in the estuary for eulachon would remain the same as they are under existing conditions. Although very little is known about the factors leading to decline of the eulachon, there is no evidence that the No Project Alternative would contribute to a continued decline of the population. The No Project Alternative would therefore have no significant impact on eulachon in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-16 Effects on the longfin smelt population due to continued operations of the Lower Klamath Project.

Longfin smelt populations in the Klamath River are discussed in Section *3.3.2.1 Aquatic Species [Longfin smelt]* of this EIR. The No Project Alternative would have no effect on longfin smelt and there would be no change from existing conditions in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-17 Effects on species interactions between introduced resident fish species and native aquatic species due to continued operations of the Lower Klamath Project.

Introduced fish species threaten the diversity and abundance of native fish species through competition for resources, predation, interbreeding with native populations, and causing potential physical changes to the invaded habitat (Moyle 2002). Introduced resident species occur within reservoirs upstream of Iron Gate Dam, and infrequently downstream from Iron Gate Dam. Under the No Project Alternative, conditions favorable for introduced species would continue to occur within the Lower Klamath Project reservoirs (Buchanan et al. 2011). The No Project Alternative would not change habitat conditions or alter populations of introduced resident fish species. The impacts of these introduced species on native aquatic species would remain unchanged in the short term relative to existing conditions.

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-19 Effects on freshwater mollusks populations due to continued operations of the Lower Klamath Project.

Freshwater mollusk populations in the Klamath River are discussed in Section *3.3.2.1 Aquatic Species [Freshwater mollusks]* of this EIR. Four species of native freshwater mussels have been observed within the Klamath Basin, including Oregon floater (*A. oregonensis*), California floater (*A. californiensis*), western ridged mussel (*G. angulata*), and western pearlshell mussel (*M. falcata*). Seven to eight species of fingernail clams and peaclams (Family: Sphaeriidae) also occur in the Hydroelectric Reach and from Iron Gate Dam to Shasta River. Based on freshwater mollusk life history and habitat preferences, freshwater mollusks are strongly affected by alterations to instream flows, suspended sediment, and bedload sediment. Under the No Project Alternative there would be no change in instream flows, suspended sediment, or bedload sediment, and thus under the No Project Alternative there would be no change from existing conditions for freshwater mussels in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-20 Effects on fish species from alterations to benthic macroinvertebrates due to continued operations of the Lower Klamath Project.

Under existing conditions, J.C. Boyle peaking operations kill, through stranding, large numbers of young fish and aquatic invertebrates that are the primary prey food for resident trout (NMFS 2006a). Current peaking operations reduce the production of sessile organisms, like macroinvertebrates, by 10 to 25 percent (Administrative Law Judge (2006). Fluctuations in the peaking reach are considered to be a contributing factor to the lower macroinvertebrate drift rates (NMFS 2006a). Under the No Project Alternative, there would be no change from existing adverse conditions on effects of alterations to benthic macroinvertebrates on fish species in the reasonably foreseeable short-term (0−5 years).

Significance

No significant impact in the reasonably foreseeable short-term (0−5 years)

Potential Impact 4.2.3-21 Alterations to aquatic habitat from implementation of California Klamath Restoration Fund/Coho Enhancement (IM2)

Under the No Project Alternative, in the short term, PacifiCorp would continue to provide funding for the California Klamath Restoration Fund/Coho Enhancement Fund as an Interim Measure (IM2) (Table 4.2-1). This would continue to fund the implementation of specific projects or actions that would create, maintain, and improve access by coho salmon to important tributary habitats downstream from Iron Gate Dam that are within the potential range of the Upper Klamath coho salmon population. The PacifiCorp IM2 projects involve removal of existing fish passage barriers, improving/maintaining habitat cover and complexity at coldwater refugia sites, providing livestock exclusion, increasing the duration and/or extent of coldwater refugia sites, enhancing habitat in rearing tributaries, restoring connectivity of juvenile rearing habitat in tributaries of the Upper Klamath, Scott, and Shasta Rivers, funding a program to provide flow augmentation in key reaches used for coho spawning and juvenile rearing in the Upper Klamath, Scott, and Shasta Rivers, enhancing habitat in rearing tributaries of the Upper Klamath, Scott, and Shasta Rivers, and protecting summer rearing habitat in tributaries of the Upper Klamath, Scott, and Shasta Rivers (PacifiCorp 2012).

Based on anticipated improvements in habitat availability and habitat quality, continued implementation of the Coho Enhancement Fund under the No Project Alternative would continue to provide benefits to fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, freshwater mussels, and benthic macroinvertebrates in the short term. These actions are also beneficial for coho salmon (particularly from the Upper Klamath River Population Unit). Implementation of the Coho Enhancement Fund under the No Project Alternative would have no significant impact (no change from existing conditions) on redband trout, shortnose and Lost River suckers, green sturgeon, eulachon, and Southern Resident Killer Whales, since these species are not found in or near the river reaches associated with IM2 projects or actions.

Significance

Beneficial for coho salmon, fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, freshwater mussels, and benthic macroinvertebrates in the reasonably foreseeable short-term (0−5 years)

No significant impact for redband trout, shortnose and Lost River suckers, green sturgeon, eulachon, and Southern Resident Killer Whales in the reasonably foreseeable short-term (0−5 years)

4.2.4 Phytoplankton and Periphyton

4.2.4.1 Phytoplankton

As discussed in more detail in Section 3.4 *Phytoplankton and Periphyton*, phytoplankton are aquatic microscopic organisms, including algae, bacteria, protists, and other single-celled plants, that obtain energy through photosynthesis and float in the water column of still or slowly flowing waters such as lakes or reservoirs. Excess growth of these organisms can cause nuisance water quality conditions, such as extreme diel (daily) fluctuations in dissolved oxygen and pH (see Section 3.4.2.1 *Phytoplankton*). Under the No Project Alternative, phytoplankton existing conditions, including adverse, large, seasonal blue-green algae blooms, would continue to occur in the Klamath River. In the Hydroelectric Reach, seasonal phytoplankton (including blue-green algae) blooms originating from Upper Klamath Lake in Oregon would still be able to enter J.C. Boyle Reservoir under this alternative, but the short residence time of this reservoir would not support substantial additional growth of phytoplankton similar to existing conditions (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). Further downstream in the Hydroelectric Reach, adverse, large, seasonal phytoplankton blooms, including blue-green algae, would continue to occur in Copco No. 1 and Iron Gate reservoirs under the No Project Alternative similar to existing conditions (see also Section 3.4.2.3 *Hydroelectric Reach*) since the reservoirs would remain in place. Overall, the No Project Alternative would result in no change from existing adverse conditions, so there would be no significant impact to phytoplankton in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Hydroelectric Reach.

The Lower Klamath Project reservoirs would remain in place under the No Project Alternative, so Copco No. 1 and Iron Gate reservoirs would continue to provide ideal habitat conditions for the proliferation of large seasonal blooms of *Aphanizomenon flos-aquae*, *Anabaena flos-aquae*, and *Microcystis aeruginosa*, which subsequently become the source of these species to the Middle and Lower Klamath River, and eventually the Klamath River Estuary (see also Section 3.4.2.3 *Hydroelectric Reach* and Section 3.4.2.4 *Middle and Lower Klamath River*). Genetic analysis of *Microcystis aeruginosa* variations at Klamath River locations upstream of Copco No. 1 Reservoir, within Copco No. 1 and Iron Gate reservoirs, and at multiple Klamath River locations from downstream of Iron Gate Dam to Turwar indicate that Iron Gate Reservoir is the principal source of *Microcystis aeruginosa* cells to the Middle and Lower Klamath River (Otten et al. 2015) (see also Section 3.4.2.4 *Middle and Lower Klamath River*). There would be no change to the habitat conditions that promote growth of *Microcystis aeruginosa* in Iron Gate Reservoir under existing conditions (see also Section 3.4.2.3 *Hydroelectric Reach*), so the export of *Microcystis aeruginosa* cells from this reservoir would also continue to occur under the No Project Alternative similar to existing conditions.

The 2017 court-ordered flushing and emergency dilution flows would result in no change from existing conditions for phytoplankton in the Klamath River. In the Hydroelectric Reach, habitat conditions in Copco No. 1 or Iron Gate reservoirs that result in adverse, large, seasonal phytoplankton blooms, including blue-green algae, would continue to be the same as existing conditions under these releases. In the Middle Klamath River and further downstream in the Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment, court-ordered flushing and emergency dilution flows would result in no change from existing conditions for phytoplankton since the releases would primarily occur during winter and spring when phytoplankton abundance in Iron Gate Reservoir would be low (see also Section 3.4.2.3 *Hydroelectric Reach*). Court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would end by June 15, while monitoring data from the past five years (i.e., 2013 to 2018) indicates the abundance of blue-green algae in Iron Gate Reservoir increases after late June to early July (E&S Environmental Chemistry, Inc. 2013, 2014, 2015, 2016, 2018a, 2018b). Assuming blue-green algae cell counts and algal toxin concentrations from the past five years are representative of likely conditions in the reasonably foreseeable short-term (0−5 years), releases would end before elevated levels of blue-green algae occur in Iron Gate Reservoir. There would be no changes from existing conditions for blue-green algae abundance in the reasonably foreseeable short-term (0−5 years), thus there would be no significant impact to phytoplankton in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment.

Under the No Project Alternative, reservoir sediment deposits would not be mobilized in the Hydroelectric Reach, Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment, so there would be no short-term increases in sediment-associated nutrients that could potentially stimulate nuisance and/or noxious phytoplankton growth in those reaches (Potential Impact 3.4-1). Thus, there would be no significant impact.

As described under the Proposed Project (Potential Impact 3.2-1), climate change would be anticipated to only significantly influence existing conditions in the long term (5+ years), so climate change is not discussed further for phytoplankton under the No Project Alternative. Similarly, other long-term processes that would potentially alter phytoplankton abundance such as the gradual increase in nutrients and organic matter in reservoir sediments (i.e., reservoir aging [USGS 2018]) and implementation of nutrient reduction or other measures in Oregon and California to meet Klamath River TMDLs are not analyzed as part of the reasonably foreseeable short-term (0−5 years). As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description– Foreseeable Short-term Operations*, the long-term outcomes are considered in the Proposed Project and other alternatives, thus the long-term potential impacts to phytoplankton are described in: Section 3.4.5.1 *Phytoplankton;* Section 4.3.4.1 *Phytoplankton*; Section 4.4.4.1 *Phytoplankton*; Section 4.5.4.1 *Phytoplankton*; Section 4.6.4.1 *Phytoplankton*; and Section 4.7.4.1 *Phytoplankton.*

4.2.4.2 Periphyton

As discussed in more detail in Section 3.4, periphyton are aquatic organisms including aquatic plants, algae, and bacteria that live attached to underwater surfaces such as rocks on a riverbed. Some degree of periphyton growth is an important part of stream ecosystem function. Excess growth of these organisms can cause nuisance water quality conditions, such as extreme diel (daily) fluctuations in dissolved oxygen and pH (see Section 3.4.2.2 *Periphyton* for detail. Under the No Project Alternative, periphyton existing conditions would continue to occur in the Klamath River, since there would be no substantial change to the periphyton habitat conditions along the margins and riverbed of the Klamath River. In the Hydroelectric Reach from J.C. Boyle Reservoir through the J.C. Boyle Bypass and Peaking Reach to Copco No. 1 Reservoir, the flows and hydropower peaking operations would continue, thus there would be no change from existing conditions that do not currently support excessive periphyton mats in the J.C. Boyle Peaking Reach due to the generally high gradient and velocity (see Section 3.4.2.2 *Periphyton*). Further downstream from Copco No. 1 Reservoir to Iron Gate Dam, the reservoirs would remain in place, so there would be no change in the limited habitat conditions for periphyton growth that occur under existing conditions. Thus, there would be no significant impact to periphyton in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative in the Hydroelectric Reach.

Under the No Project Alternative, reservoir sediment deposits would not be mobilized in the reasonably foreseeable short-term (0−5 years) to the Hydroelectric Reach, Middle and Lower Klamath River, or the Klamath River Estuary, and there would be no increases in sediment-associated nutrients in these river reaches that could stimulate nuisance periphyton growth. Additionally, there would be no conversion of the reservoir areas to free-flowing river or elimination of hydropower peaking operations under the No Project Alternative, so there would be no change in periphyton abundance from existing conditions due to increased low-gradient channel margin habitat conditions. While nutrients do not appear to be limiting periphyton growth in the Klamath River from Iron Gate Dam to approximately Seiad Valley (RM 132.7) (and potentially farther downstream) (see also Potential Impact 3.4-5), nutrients would be similar to existing conditions under the No Project Alternative (see Section 4.2.2 *Water Quality, Nutrients*), so periphyton growth or abundance would be the same relative to existing conditions due to nutrients conditions under this alternative. There would be no change in nutrient transport from existing conditions in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative, since the reservoirs would continue to intercept upstream nutrients and phytoplankton cells containing nutrients generated in the reservoirs and seasonal export of nutrients from reservoir sediments would continue to occur.

As described under the Proposed Project (Potential Impact 3.2-1), climate change would be anticipated to only significantly influence existing conditions in the long term (5+ years), so climate change is not discussed further for periphyton under the No Project Alternative. Similarly, other long-term processes that would potentially alter periphyton abundance such as implementation of nutrient reduction or other measures in Oregon and California to meet Klamath River TMDLs are not analyzed as part of the reasonably foreseeable short-term (0−5 years). As noted in Section 4.2.1.1 *[No Project Alternative] Alternative Description– Foreseeable Short-term Operations*, the long-term outcomes, including nutrient build-up in the reservoirs and the basin response to the nutrient reduction measures, are considered in the Proposed Project and other alternatives, thus the long-term potential impacts to phytoplankton are described in: Section 3.4.5.2 *Periphyton;* Section 4.3.4.2 *Periphyton*; Section 4.4.4.2 *Periphyton*; Section 4.5.4.2 *Periphyton*; Section 4.6.4.2 *Periphyton*; and Section 4.7.4.2 *Periphyton.*

Other potential impacts related to periphyton in the foreseeable short-term (0−5 years) under the No Project Alternative are discussed under a new impact heading, below.

Potential Impact 4.2.4-1 Variations in nuisance periphyton species abundance downstream of Iron Gate Dam due to implementation of 2017 court-ordered flushing and emergency dilution flows.
In the Middle and Lower Klamath River, seasonal shifts in water temperature downstream of the reservoirs and flow modification due to the continuing presence of the Lower Klamath Project dams would continue to support periphyton growth, including nuisance periphyton species, in the Middle and Lower Klamath River similar to existing conditions, but court-ordered flushing flows and emergency dilution releases would reduce periphyton abundance in the Middle Klamath River downstream of Iron Gate Dam relative to existing conditions. Higher fall water temperatures occurring under existing conditions due Iron Gate Dam (see Section 3.2.2.2 *Water Temperature*) would continue in the Middle Klamath River to the confluence with the Salmon River under the No Project Alternative (see Section 4.2.2 *Water Quality*), thus periphyton growth would continue to be promoted in this reach of the Middle Klamath River similar to existing conditions. Water temperature downstream of the confluence with the Salmon River, including the Klamath River Estuary and the Pacific Ocean nearshore environment, and its influence on periphyton growth and abundance would be the same as under existing conditions under the No Project Alternative, since there is no influence of the dams on water temperature downstream of the confluence with the Salmon River.

While the presence of the Lower Klamath Project dams would continue to support periphyton growth in the Middle and Lower Klamath River as described for existing conditions (Section 3.4.2.4 *[Periphyton] Middle and Lower Klamath River*), 2017 court-ordered flushing releases downstream of Iron Gate Dam under the No Project Alternative would increase mobilization of riverbed sediment downstream of Iron Gate Dam between November 1 to May 31 (see Potential Impact 4.2.2-3). Emergency dilution releases (3,000 to 4,000 cfs) are below the flow recognized to mobilize sediment along the riverbed downstream of Iron Gate Dam. Increases in sediment transport due to flushing flows under this alternative would dislodge periphyton from the riverbed and decrease periphyton abundance downstream of Iron Gate Dam in the Middle Klamath River immediately after releases. Currently, there are not sufficient data to determine how far downstream of Iron Gate Dam the effect of bed turnover and scouring on periphyton would extend under the 2017 court-ordered flushing flows. This analysis assumes that periphyton scouring potential would extend from Iron Gate Dam until approximately the Shasta River (RM 179.5), as the first major tributary that would contribute additional flows to the mainstem river. While periphyton naturally re-establish and re-grow following high winter flows under existing conditions and periphyton are anticipated to re-establish and re-grow similarly after flushing flows, the frequency of flushing flows (i.e., annually for surface flushing and every other year for deep flushing) would result in a reduction in periphyton abundance downstream of Iron Gate Dam in the Middle Klamath River to approximately the confluence with the Salmon River. Overall, flushing releases under this alternative would reduce dense growth of periphyton relative to existing conditions, and would be beneficial in the reasonably foreseeable short-term (0−5 years) under the No Project Alternative.

Significance

Beneficial for the Middle Klamath River from Iron Gate Dam to the Shasta River (RM 179.5)

No significant impact for the Middle Klamath River from the confluence with the Shasta River (RM 179.5) and the Lower Klamath River

4.2.5 Terrestrial Resources

Except for the potential impacts to foothill yellow-legged frogs and Western Pond Turtles due to 2017 flow requirements (see Potential Impact 4.2.5-1, below) there would be no change to terrestrial resources in the short term under the No Project Alternative. Thus, except for Potential Impact 4.2.5-1, under the No Project Alternative short term conditions for terrestrial resources would be the same as the existing conditions described in Section 3.5.2 *Terrestrial Resources, Environmental Setting,* including the subsections: 3.5.2.1 *Vegetation Communities,* 3.5.2.2 *Invasive Plant Species,* 3.5.2.3 *Culturally Significant Plant Species*, 3.5.2.4 *Non-special-status Wildlife,* 3.5.2.4 *Special-status Species*, and 3.5.2.6 *Wildlife Corridors and Habitat Connectivity.*

4.2.5.1 Vegetation Communities

Under the No Project Alternative, in the short term (0−5 years), there would be no habitat loss or gain for wetland or riparian vegetation as compared with existing conditions, since ground-disturbing construction activities, reservoir drawdown, and dam removal would not occur. Thus, there would be no significant impacts to wetland or riparian vegetation in the short term (0−5 years) under the No Project Alternative.

4.2.5.2 Culturally Significant Species

Under the No Project Alternative, in the short term (0−5 years), there would be no habitat loss or gain for culturally significant plant species as compared with existing conditions since the Lower Klamath Project reservoirs and associated riparian habitat would remain unchanged and would continue to provide habitat for these species. Thus, there would be no significant impacts to culturally significant plant species in the short term (0−5 years) under the No Project Alternative.

4.2.5.3 Special-status Species

Under the No Project Alternative, in the short term (0−5 years), there would be no habitat loss or gain for special-status plant and wildlife species as compared with existing conditions since the Lower Klamath Project reservoirs would remain and would continue to provide habitat for western pond turtle, multiple bird species, including waterfowl and bald eagles, bats, and other special-status wildlife and plants that are supported by the Lower Klamath Project reservoirs and Iron Gate Hatchery. Populations of special-status plant and wildlife species and rare natural vegetation communities would continue to be influenced by various stressors in the Klamath Basin, including habitat degradation from the Lower Klamath Project and invasive species.

Klamath River hydrology in the short term (0−5 years) would be similar to existing conditions under the No Project Alternative with the addition of the 2017 court-ordered flushing and emergency dilution flows released from Iron Gate Dam to the Middle Klamath River; these flows are described in detail in Section 4.2.1.1 *[No Project Alternative] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative*. Potential Impact 4.2.5-1 (below) assesses the potential for the additional court-ordered flow releases from Iron Gate Dam to affect breeding foothill yellow-legged frog in the short term (0−5 years).

Since Iron Gate Hatchery would continue to obtain water from Iron Gate Reservoir, no flow diversion would occur in Bogus Creek to supply water to Iron Gate Hatchery; therefore, there would be no significant impact to aquatic amphibians and reptiles in the short term (0−5 years) under the No Project Alternative.

Since no dewatering of the reservoirs or sediment would be released from behind the dams during the dam removal process, no elevated suspended sediment concentrations (SSCs) would occur nor would they have the potential to affect special-status amphibians and reptiles. Thus, there would be no SSC-associated impacts to special-status amphibians and reptiles in the short term (0−5 years) under the No Project Alternative.

Under the No Project Alternative, there would be no construction-related impacts on special-status plant and wildlife species, including nesting birds or bats, as no construction activities with the potential to remove suitable nesting/roosting habitat would occur in the short term. Thus, there would be no significant impacts to special-status plant and wildlife species in the short term (0−5 years) under the No Project Alternative.

Potential Impact 4.2.5-1 Effects of 2017 court-ordered flushing and emergency dilution flows released from Iron Gate Dam on foothill yellow-legged frog and western pond turtle breeding.
To manage the fish parasite *C. shasta*, mandatory surface flushing flows in the winter-spring, deep flushing flows, and emergency dilution flows would occur in the short-term (0−5 years) in the Middle Klamath River downstream of Iron Gate Dam under the No Project Alternative (see Section 4.2.1.1 *[No Project Alternative] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative*).

The winter-spring surface flushing flow of 6,030 cfs is designed to occur for a 72-hour period between November 1 and April 30 (U.S. District Court 2017). This flow would be sufficient to move surface sediments (i.e., sand and potentially pea-sized gravel). The beginning of the foothill yellow-legged frog breeding season (typically April 22 through early July) overlaps with this flushing flow for about one week (April 22 through April 30). Mean daily flows in April are generally 2,000–3,000 cfs (Figure 3.6-4, Section 3.6.2.2 *Basin Hydrology*). Foothill yellow-legged frogs are known to time their egg-laying with the flow pattern of a given year, initiating egg-laying on the descending limb of the spring hydrograph (i.e., when flows are trending down) (Seltenrich and Pool 2002). If the winter-spring surface flushing flows were to occur early in the foothill yellow-legged frog breeding season, individuals may delay breeding (Gonsolin 2010 and GANDA 2008); otherwise there is a potential for eggs to be scoured, if present, during the winter-spring surface flushing flows.

The deep flushing flows are designed to occur in one 24-hour period at least every other year (U.S. District Court 2017). This one-day flow will consist of an average flow of 11,250 cfs and occur any time between February 15 and May 31. Mean daily flows observed between April and May at Iron Gate Dam are typically between about 2,500–3,500 (Figure 3.6-4 Section 3.6.2.2 *Basin Hydrology*). This deep flushing flow may scour or damage eggs attached to submerged rocks and pebbles during the one-month period that egg-laying overlaps with the deep flushing flows (April 22–May 31). Tadpoles, which hatch between 5–37 days following egg-laying, could be present in May and could be displaced by the deep flushing flows, which would likely result in injury or mortality because the species is not adapted to high flows.

Both the annual surface flushing and deep flushing flows are implemented through flow augmentation when the required flows are not met naturally (i.e., in the case of a dry water year). The flows are timed, where possible, to occur during high precipitation events, in order to reduce the impact on water supplies. This means that any foothill yellow-legged frogs in the area would already be exposed to high flows, though supplementation would make these flows higher. Because the flows are designed to cause bed mobilization, the supplementation would be more likely to cause an impact than the precipitation event alone.

The emergency dilution flows of 3,000–4,000 cfs are designed to occur between April 1 and June 15 if certain disease thresholds are present in the river (U.S. District Court 2017). Existing flows are typically at or above 3,000 cfs for approximately 50 percent of April, 25 percent of May, and 5 percent of June (Figure 3.1-1; Section 3.1.6.2 *Comparison of Klamath River Flows under 2013 Biological Opinion and KBRA*). The emergency dilution flows may scour or damage any eggs that are present between April 22 and June 15, when the flows overlap with the typical foothill yellow-legged frog breeding season. Additionally, direct impacts may result from stranding of eggs if breeding occurs along the river edge during the emergency dilution flows, and the subsequent receding flows reduce the wetted channel and dewatered egg masses. Tadpoles, which hatch between 5 and 37 days following egg-laying, could also be displaced by the emergency dilution flows.

Although survey data are limiting for characterizing the presence of foothill yellow-legged frog in the Klamath River (i.e., this species has not been documented since 1976), occurrences are known in tributaries and presumably individuals have the potential to be present in the mainstem river as well. Due to the listing status of the foothill yellow-legged frog (i.e., State Candidate Threatened), direct mortality or harm to an individual would result in a significant impact. Thus, if eggs, juvenile and/or adult foothill yellow-legged frogs are present in the Middle Klamath River immediately downstream of Iron Gate Dam, direct impacts from scouring and displacement due to the court-ordered flushing and dilution flows may occur. The likelihood of this occurring is not high, because of the lack of certainty that individuals are present in the upper Middle Klamath River and the timing of flow supplementation to occur with natural high flows. However, if present and affected, this would be a significant impact.

Due to the low likelihood of locating eggs during high flow events, mitigation typically employed to reduce impacts to this species (i.e., rescuing and relocating eggs) would be ineffective. Modification of the flows to avoid the potential presence of foothill yellow-legged frog is not feasible. The USBR, which is responsible for the court-ordered flow releases, is a federal agency with a mandate to maximize agricultural deliveries as possible. Therefore, it is not feasible for the agency to adjust its decision-making to accommodate a candidate state-listed and state species of special concern that it does not have a particular obligation to protect. Thus, this would be a significant and unavoidable impact.

Since western pond turtles' nest on land and usually above the floodplain, up to several hundred meters from water (Ashton et al. 1997), there would be no significant impacts to their nests due to the 2017 court-ordered flushing and emergency dilution flows. While the flushing and dilution flows may disperse juvenile and adult western pond turtles, this would be a less than significant impact because although this species is considered an aquatic species, they are known to spend a considerable portion of their lives in upland habitats and may move to upland habitats during high winter flows.

Significance

Significant and unavoidable for foothill yellow-legged frog breeding populations, if present, in the Middle Klamath River immediately downstream of Iron Gate Dam in the short term (0−5 years)

No significant impact for western pond turtle in the Middle Klamath River immediately downstream of Iron Gate Dam in the short term (0−5 years)

4.2.5.4 Wildlife Corridors and Habitat Connectivity

In the short term under the No Project Alternative, the reservoirs and dams would continue to present a barrier to movement for some terrestrial wildlife species (Section 3.5.5.4). Salmon and other fish species would not be able to migrate to reaches upstream of Iron Gate Dam, and thus they would not provide nutrient-rich food for terrestrial species located upstream of Iron Gate Dam. Marine-derived nutrients would not be subsequently deposited into terrestrial habitats and productivity of the terrestrial ecosystem as a whole would not change from existing conditions. There would be no significant impact in the short term compared with existing conditions.

4.2.6 Flood Hydrology

Under the No Project Alternative, there would be no changes to the Lower Klamath Project facilities or operations that would affect flood hydrology in the short term (0−5 years). The existing condition, as described in Section 3.6.2 *Flood Hydrology, Environmental Setting,* would continue. Specifically, there would be no increases in downstream surface water flows during reservoir drawdown that could change flood risks, no changes to flood hydrology due to removal of recreational facilities currently located along the banks of the existing reservoirs, and no changes to flood risks due to downstream sediment deposition as compared with existing conditions, since reservoir drawdown and dam removal would not occur. Thus, there would be no significant impacts to the aforementioned aspects of flood hydrology in the Area of Analysis in the short term (0−5 years) under the No Project Alternative. Potential impacts to the 100-year floodplain inundation extent downstream of Iron Gate Dam, and the potential for dam failure, under the No Project Alternative are discussed further below.

Potential Impact 4.2.6.1 The FEMA100-year floodplain inundation extent downstream from Iron Gate Dam could change due to 2017 flow requirements, potentially exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.

Under the No Project Alternative, the dams would remain in place and the Lower Klamath Project would continue to operate in the short term (0−5 years) under annual licenses issued by FERC. The 2013 BiOp requirements for the upstream USBR Klamath Irrigation Project and the 2017 court-ordered flushing and emergency dilution flows would determine how instream flows through the Lower Klamath Project and releases from Iron Gate Dam are managed (NMFS and USFWS 2013, U.S. District Court 2017).

The 100-year floodplain inundation extent in the Klamath River between RMs 193 and 174 (i.e., from Iron Gate Dam to Humbug Creek) was modeled by USBR (2012), including a "WithDams_100yr" scenario that assumes 2010 BiOp flows and Lower Klamath Project dams remain in place. Floodplain inundation maps illustrating the USBR (2012) model results are presented in Appendix K of this EIR. Because the overall magnitude of the 2010 BiOp flows is consistent with that of the 2013 BiOp flows, and the 2017 court-ordered flushing and emergency dilution flows are within the range of historical Klamath River flows evaluated in 2013 BiOp studies (see also Section 4.2.1.1 *[No Project Alternative] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative*), the 100-year floodplain inundation extent previously modeled by USBR (2012) also serves as the Lower Klamath Project EIR No Project Alternative 100-year floodplain inundation extent. The USBR (2012) 100-year floodplain inundation extent corresponds closely with the current FEMA 100-year flood boundary, however there are some differences between the two modeled inundation extents. These differences are attributable to the use of different hydrographic base data for flood events and the use of enhanced elevation data by USBR (2012). The USBR (2012) analysis is based on LiDAR data with elevation values sufficient to support 2-foot contours along the reach of the Klamath River from Iron Gate Dam (RM 193) to Happy Camp (RM 108.3).

Based on a review of detailed 2010 and 2009 aerial imagery under the USBR (2012) "WithDams_100yr" scenario, 671 structures including mobile homes, houses, farm sheds, bridges, and other features large enough to cast a shadow, are potentially at risk of flooding in a 100-year storm event if the dams remain in place. Many of the structures are mobile homes that move annually or seasonally. Within the FEMA 100-year floodplain, there are 481 structures at risk, including bridges (USBR and CDFG 2012), if the dams remain in place. As described in Section 3.6.5 *Flood Hydrology, Potential Impacts and Mitigation*, the KRRC has determined that there are 34 legally-established habitable structures located within the existing 100-year floodplain between Iron Gate Dam (RM 193) and Humbug Creek (RM 174) (Appendix B: *Definite Plan*). Under the No Project Alternative, these 34 structures would be exposed to a substantial risk of damage or loss involving flooding.

Overall, in the short term (0−5 years), flows under the No Project Alternative would not change from existing adverse conditions, thus the extent of 100-year floodplain inundation in the Klamath River downstream of Iron Gate Dam as modeled by USBR (2012) would not change (see Appendix K for 100-year floodplain inundation maps).

Significance

No significant impact in the short term (0−5 years)

Potential Impact 4.2.6.2 The FEMA 100-year floodplain inundation extent downstream from J.C. Boyle Dam could change due to 2017 flow requirements between the California-Oregon state line and Copco No. 1 Reservoir, potentially exposing people and/or structures to a substantial risk of damage, loss, injury, or death involving flooding.

As part of prior flood-inundation hydrologic and hydraulic modeling conducted for dam removal analyses, USBR (2012) did not conduct 100-yr floodplain mapping within the

Hydroelectric Reach; however, FEMA (2016) mapping includes an existing conditions 100-yr floodplain boundary for the Klamath River, including the Hydroelectric Reach (see Appendix K).

As described for the Proposed Project analysis of Potential Impact 3.6-4 (see Section 3.6.5.2), J.C. Boyle Reservoir provides no storage and the dam typically operates in spill mode at flows above plant capacity (i.e., approximately 6,000 cfs; Table 2-1 in USBR 2012). Existing-conditions peak flows in the Hydroelectric Reach are not attenuated as a result of J.C. Boyle Dam. As is the case for the Middle Klamath River downstream of Iron Gate Dam, flows under the No Project Alternative would not change from existing conditions in the short term (0−5 years), and thus the 100-year floodplain inundation extent in the Klamath River from the Oregon-California state line downstream to Copco No. 1 Reservoir as modeled by FEMA (2016) would also not change from existing conditions (see Appendix K for 100-year floodplain inundation maps). Therefore, there would be no significant impact.

Significance

No significant impact in the short term (0−5 years)

Potential Impact 3.6-6 Dam failure could flood areas downstream of the Lower Klamath Project.

The Lower Klamath Project dams collectively store over 169,000 acre-feet of water when they are full. The dams are inspected regularly and the probability of failure has been found to be low. In the short term (0−5 years), if a dam failed, it could inundate a portion of the downstream watershed. The risk of failure in the next 0−5 years under the No Project Alternative remains the same low risk as under existing conditions. The 0−5 year period is a small fraction of the expected lifetime of the facilities, and the facilities would continue to undergo the same requirements for continuing inspection and maintenance.

Significance

No significant impact in the short term (0−5 years)

4.2.7 Groundwater

Under the No Project Alternative, in the short term (0−5 years), there would be no change in groundwater/ surface water interactions related to the Lower Klamath Project reservoirs as compared with existing conditions, since reservoir drawdown and dam removal would not occur. Groundwater conditions would remain as described in Section 3.7.2 *Groundwater, Environmental Setting*. Thus, there would be no significant impacts to groundwater in the Area of Analysis in the short term (0−5 years) under the No Project Alternative.

4.2.8 Water Supply/Water Rights

Under the No Project Alternative, in the short term (0−5 years), there would be no change in the amount of surface water flow available for diversion under existing water rights in the Middle or Lower Klamath River or Upper Klamath Lake/Keno Reservoir due to operations of the Lower Klamath Project. Thus, except for the changes due to 2017 flow requirements described in Potential Impact 4.2.8-1 below, the existing conditions, as described in Section 3.8.3 *Water Supply/Water Rights, Environmental Setting,* would remain in the short term.

Potential Impact 4.2.8-1 Water availability changes from coordinated operations under 2017 flow requirements
With Iron Gate Dam continuing to block fish passage, it is assumed that the 2017 flushing and emergency dilution flow requirements will continue under the No Project Alternative in the short term. The 2017 flow requirements determine how instream flows through the Lower Klamath Project and releases from Iron Gate Dam are managed (NMFS and USFWS 2013, U.S. District Court 2017; see Section *[No Project] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative*). The 2017 flow requirements require use of more water than the 2013 flow requirements, in that the USBR must guarantee at Iron Gate Dam, annual flushing flows and bi-annual deep flushing flows. Additionally, USBR must maintain an additional 50,000 acre feet of water until approximately June 15 annually, as a reserve in case emergency dilution flows are needed. The amount of water required to maintain the flow requirements is not fixed, because the requirements work in tandem with available high flows. Thus, the amount of water that USBR must withhold from deliveries in order to ensure the flow minimums are met will vary each year. Additionally, in some years, the 50,000 acre-feet of water held in reserve for dilution flows will be available for delivery to the Klamath Irrigation Project later in the year, while in other years it will not. While it is not possible to quantify the reduction in water available for Klamath Irrigation Project deliveries, it is reasonable to assume that there will be some level of reduced deliveries in most, if not all, years. In 2018, the amount of Klamath Irrigation Project Supply water required to meet 2017 flow requirements was 76,713 acre-feet. As noted in Potential Impact 3.8-2, the potential for the Lower Klamath Project dams to somewhat ameliorate reductions in water deliveries would be uncertain in light of stated operational changes. Despite this uncertainty, there would remain some potential for coordinated operations to reduce the amount of supply by up to 20,000 acre-feet in drought situations. As discussed in Section 3.8 *Water Supply/Water Rights*, coordinated efforts do not affect releases downstream of Iron Gate Dam, and therefore do not impact water rights downstream. The Lower Klamath Project is not required to operate in such a manner as to extend USBR deliveries.

The potential for coordinated operations under the 2017 flow requirements has no significant impact as compared to the exiting condition.

Significance
No significant impact in the short term (0−5 years)

4.2.9 Air Quality

In the short term under the No Project Alternative, there would be no additional construction above existing conditions. Therefore, unlike under the Proposed Project (Potential Impacts 3.9-1−3.9-6), short-term impacts associated with increased air emissions due to dam removal and construction activities would not occur. Conditions would remain consistent with the operation of existing Lower Klamath Project facilities and there would be no air quality impacts in the reasonably foreseeable period (0−5 years), relative to existing conditions described in Section 3.9.3 *Air Quality, Environmental Setting*.

4.2.10 Greenhouse Gas Emissions

In the short term under the No Project Alternative, there would be no change to the level of power production, and no additional construction above existing conditions, described in Section 3.10.2 *Greenhouse Gas Emissions, Environmental Setting*. Therefore, unlike under the Proposed Project (Potential Impacts 3.10-1–3.10-5), there would be no impacts related to greenhouse gas emissions in the short term (0−5 years) relative to existing conditions.

4.2.11 Geology, Soils, and Mineral Resources

In the short term under the No Project Alternative (0−5 years), there would be no changes in the operations or facilities of the Lower Klamath Project, so the existing conditions would continue, as described in Section 3.11 *[Geology, Soils, and Mineral Resources] Environmental Setting*. Specifically, there would be no changes in geologic hazards, the hillslope stability of reservoir slopes, or the stability of the earthen dam embankments at J.C. Boyle or Iron Gate dams as compared with existing conditions, since reservoir drawdown and dam removal would not occur. There would also be no soil disturbance associated with dam removal construction activities. In the short term, the No Project Alternative would continue existing operations and, therefore, would have no significant impact on the aforementioned aspects of geology and soils within the Hydroelectric Reach compared to existing conditions.

Since reservoir drawdown and dam removal would not occur, erosion of the sediment deposits stored within the Lower Klamath Project reservoirs, downstream sedimentation, and downstream bank erosion due to the release of these sediment deposits would not occur, and there would be no significant impact . Rather, in the short term under the No Project Alternative, J.C. Boyle, Iron Gate, and Copco No. 1 reservoirs would continue to trap sediment at rates similar to historical rates. Based on historical sediment trapping rates and sediment levels in each reservoir, an estimated 2.4 million cubic yards of sediment would be deposited in the reservoirs over the next 5 years. Studies indicate that the trapping efficiency of J.C. Boyle Dam may decrease slightly as the reservoir capacity decreases, but this is not expected to be a factor over the next five years (USBR 2012).

The continued interception of sand, gravel and coarser sediment supplied by sources upstream of Iron Gate Dam would continue to coarsen the channel bed and reduce the size and frequency of mobile coarse sediment deposits in the Hydroelectric Reach and in the Middle Klamath River from Iron Gate Dam to approximately the Scott River, limiting the amount and quality of spawning gravel deposits in these reaches (see also Appendix F). While the winter-spring surface flushing flows and deep flushing flow requirements at Iron Gate Dam (Section 4.2.1.1 *[No Project Alternative] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative)* would increase the mobility of existing surficial fine sediment deposits and infilled fine sediment from the armor layer, with potential for slight mobilization of the armor layer in some locations, new sediment supply would not occur. Overall, maintenance of static channel features would represent no change from existing adverse conditions for the Middle Klamath River between Iron Gate Dam and the confluence with the Scott River.

In the short term under the No Project Alternative, the presence of Copco No. 1 Reservoir would continue to prevent access to the known mineral resource of diatomite beds located at the southern shore near Copco No. 1 Dam (see Section 3.11.2.1 *Regional Geology, Mineral Resources* and Potential Impact 3.11-7). Because of their location in the reservoir and existing erosion resulting from wave action, the diatomite resources are currently inaccessible for extraction purposes. In the short term there would be no change from existing conditions with respect to the diatomite beds under the No Project Alternative because the resources would continue to be inaccessible. The No Project Alternative would have no significant impact on mineral resources relative to existing conditions in the short term.

4.2.12 Historical Resources and Tribal Cultural Resources

In the short term under the No Project Alternative, dam removal construction and reservoir drawdown would not occur, and Lower Klamath Project operations would continue and there would be no change from existing conditions for historical resources and tribal cultural resources, as described in section 3.12.2 *Historical Resources and Tribal Cultural Resources*. Thus, there would be no construction- or restoration-related impacts to known, or as yet unknown, tribal cultural resources (Potential Impacts 3.12-1, 3.12-4, and 3.12-5), no potential shifting and exposure of existing tribal cultural resources within the Lower Klamath Project reservoir footprints or located along the Klamath River (Potential Impacts 3.12-2, 3.12-3, 3.12-7), nor increased potential for looting (Potential Impacts 3.12-6, 3.12-8), since reservoir drawdown would not occur. The potential for impacts to tribal cultural resources due to wave erosion in the annual reservoir fluctuation zone would continue, as described under Potential Impacts 3.12-2 and 3.12-8 of the Proposed Project. The potential beneficial effects on the Klamath Cultural Riverscape related to Proposed Project implementation (including the beneficial effects of the contributing factors of fisheries improvement and improved cultural use of riverine waters through water quality improvements—see Potential Impacts 3.12-9 and 3.12-10) would not occur under the No Project Alternative. Additionally, there would be no impacts to Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and the Klamath River Hydroelectric Project District (Potential Impact 3.12-11), because the Lower Klamath Project would remain in place. Potential impacts to submerged historic-period archaeological resources (Potential Impacts 3.12-12 through 3.12-16) within the reservoir footprints and along the Klamath River would not occur. Overall, conditions for historical resources and tribal cultural resources would remain consistent with existing conditions, and there would be no significant impacts in the short-term period (0−5 years).

4.2.13 Paleontologic Resources

Under the No Project Alternative, there would be no change in construction or operations of the facilities that could affect paleontologic resources in the short term (0−5 years), thus there would be a continuation of existing conditions as described in 3.13.2 *Paleontologic Resources, Environmental Setting*. Specifically, there would be no downcutting or erosion of the Hornbrook Formation located downstream of Iron Gate Dam due to drawdown of the Lower Klamath Project reservoirs. Therefore, relative to existing conditions, there would be no significant impact to paleontologic resources.

4.2.14 Land Use and Planning

In the short term under the No Project Alternative, there would be no change to ongoing project operations, practices, or land uses, or facilities that would affect Land Use and Planning; therefore, the existing condition would continue, as described in Section 3.14.2 *Land Use and Planning, Environmental Setting.* In the short term under the No Project Alternative, there would be no additional construction above existing conditions, and no changes of land use under KHSA section 7.6.4, which relates to disposition of Parcel B lands. Specifically, there would be no significant impacts to established communities associated with dam removal, or conflicts with applicable land use plans, policies, or regulations. In contrast to the Proposed Project, road maintenance changes would not occur, and fencing would not be needed as the Lower Klamath Project reservoirs would remain in place. Conditions would remain consistent with the existing operation of Lower Klamath Project facilities.

4.2.15 Agriculture and Forestry Resources

In the short term under the No Project Alternative, agriculture and forestry resource management would continue to be implemented as per existing conditions described in Section 3.15.2 *Agriculture and Forestry Resources, Environmental Setting*. No farmland would be directly or indirectly converted to non-agricultural use. No forest lands would be converted to non-forest use and, in general, the No Project Alternative would maintain the status quo with regard to Williamson Act contracts and zoning. Thus, there would be no reasonably foreseeable short-term (0−5 years) impacts to agriculture and forestry resources relative to existing conditions.

4.2.16 Population and Housing

In the short term under the No Project Alternative, there would be no changes that would alter the existing trends in population and housing as described in Section 3.16.2 *Population and Housing, Environmental Setting*. No short-term potential impacts to population and housing associated with construction for dam removal would occur. Thus, unlike under the Proposed Project (Potential Impacts 3.16-1 and 3.16-2), there would be no influx of temporary workers relative to the existing conditions. Population and housing would follow current trends, and there would be no significant impact.

4.2.17 Public Services

In the short term under the No Project Alternative, there would be no increase in construction related to the Lower Klamath Project facilities in the reasonably foreseeable period (0−5 years). Thus, the potential public services impacts associated with dam removal and construction activities under the Proposed Project would not occur for the No Project Alternative, and the existing condition as described in Section 3.17.2 *Public Services, Environmental Setting* would continue. Relative to existing conditions, public services response times for emergency fire, police, and medical services would not increase due to construction and demolition activities, there would be no increased risk of wildfires and need for firefighting measures due to construction and demolition activities, and there would be no potential effects on schools services and facilities. Conditions would remain consistent with the existing operation of Lower Klamath Project facilities, and there would be no significant impact to public services.

4.2.18 Utilities and Service Systems

In the short term under the No Project Alternative, there would be no increase in construction related to operations of the Lower Klamath Project facilities in the reasonably foreseeable period (0−5 years). Therefore, the potential Utilities and Service Systems impacts associated with dam removal construction activities would not occur, and the existing condition as described in Section 3.18 *Utilities and Service Systems, Environmental Setting* would continue. Relative to existing conditions, there would be no need for construction of new wastewater treatment facilities, or expansion of existing facilities to serve new recreational facilities or construction work crews, no need for construction of new stormwater drainage facilities, or expansion of existing facilities, no generation of large volumes of waste due to dam removal and construction activities requiring landfill capacity. Conditions would remain consistent with the operation of existing Lower Klamath Project facilities, and there would be no significant impact to utilities and service systems in the short term.

4.2.19 Aesthetics

Under the No Project Alternative, the operations and facilities of the Lower Klamath Project would remain the same for the short term. Therefore, visual impacts resulting from project construction and reservoir drawdown would not occur, and the existing condition would continue, as described in Section 3.19.2 *Aesthetics, Environmental Setting*. There would be no loss of open water vistas, no changes in flows and channel morphology, no changes in visual water quality due during periods of elevated SSCs, and no exposure of bare areas of sediment and rock, all due to reservoir drawdown. In addition, there would be no long-term visual changes from either removal of the Lower Klamath Project facilities, or construction of new infrastructure and improvements to existing infrastructure. There would also be no construction equipment, staging areas, and demolition areas that could detract from the natural surroundings, and no nighttime construction or security lighting that would adversely affect nighttime views under the No Project Alternative. The existing Lower Klamath Project facilities and their operations are already a part of the environmental baseline. Aesthetic conditions would remain consistent with surrounding recreational, agricultural, open space and rural residential land uses, and visual presence of the Lower Klamath Project facilities, and there would be no significant impacts to aesthetics in the short term (0−5 years).

4.2.20 Recreation

In the short term under the No Project Alternative, there would be no change to existing recreation facilities and opportunities, as dam removal construction, recreation facilities removal (and potential construction of additional facilities) and reservoir drawdown would not occur. The existing condition as described in Section 3.20.2 *Recreation, Environmental Setting,* would continue. Thus, there would be: no restrictions, noise, dust, and/or sediment release due to dam removal activities that would impact existing recreational facilities; no changes to, or loss of, local or regional reservoir-based recreation activities and facilities due to reservoir drawdown; no increase in the use of regional recreational facilities due to the loss facilities at the Lower Klamath Project reservoirs; and no construction of new or expanded recreational facilities due to dam removal. There would also be no changes to, or loss of, river conditions that support whitewater boating, or other river-based recreation, including fishing; and no potential impacts to Wild and Scenic River resources, designations, or eligibility for listing due to dam removal activities. Conditions for recreation would remain consistent with existing conditions, and there would be no significant impact in the short term (0−5 years) .

4.2.21 Hazards and Hazardous Materials

In the short term under the No Project Alternative, there would be no change to the current operations of the Lower Klamath Project, and therefore no change related to hazards and hazardous materials. Therefore, the existing condition as described in Section 3.21.2 *Hazards and Hazardous Materials, Environmental Setting,* would continue. There would not be significant dam removal and construction impacts associated with the transport and use of hazardous materials during project construction activities, and there would not be a need for implementation of an emergency response plan associated with construction activities. The existing hazardous materials that have been identified at the Lower Klamath Project dams and associated facilities would remain. Since reservoirs would remain, there would be no increased risk from wildfires under the No Project Alternative. Conditions would remain consistent with the operation of existing Lower Klamath Project facilities, and there would be no significant impacts related to hazards and hazardous materials in the short term (0−5 years), as compared to existing conditions.

4.2.22 Transportation and Traffic

In the short term under the No Project Alternative, there would be no change to the operations or facilities of the Lower Klamath Project that would potentially impact transportation and traffic, and therefore the existing conditions would continue, as described in Section 3.22.2 *Transportation and Traffic, Environmental Setting*. No potential impacts associated with increased vehicular traffic, or increases in potential conflicts with vehicular and non-vehicular traffic, as part of construction-related activities would occur. No improvements to roads, bridges or culverts would occur beyond the typical levels of maintenance already occurring under existing conditions. Conditions would remain consistent with the operation of existing Lower Klamath Project facilities and there would be no significant impacts to Transportation and Traffic in the short term (0−5 years) compared with existing conditions.

4.2.23 Noise

In the short term under the No Project Alternative, there would be no change to the operations or facilities of the Lower Klamath Project that would potentially impact noise. Therefore, the existing condition as described in Section 3.23.2 *Noise, Environmental Setting,* would continue. No potential impacts associated with noise and vibration levels from dam removal construction and reservoir restoration would occur. Therefore, there would be no significant impact related to noise under the No Project Alternative compared with existing conditions.

4.3 Partial Removal Alternative

4.3.1 Introduction

4.3.1.1 Alternative Description

In the Partial Removal Alternative, sufficient portions of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dam complexes would be removed to ensure a free-flowing Klamath River and year-round volitional fish passage under all river stages and flow conditions in the Hydroelectric Reach. Ancillary facilities associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dam complexes that do not affect Klamath River flows or volitional fish passage would be abandoned in place. In general, the ancillary facilities to be retained under the Partial Removal Alternative include the Copco No. 1 Powerhouse, penstocks, and intake structure, the Copco No. 2 Powerhouse, steel penstocks and supports, and intake structure, and the lower portion of the Iron Gate Powerhouse (Table 4.3-1, Table 4.3-3, Table 4.3-5). The mechanical and electrical equipment associated with each of the powerhouses would also remain. Penstock openings and powerhouse intakes would be sealed and security fences would be installed around the remaining structures to ensure public safety. Some of the remaining features would likely require ongoing maintenance, including periodic repair and replacement of fencing and repainting/recoating facilities. Detailed lists of features to be retained and new or different construction activities that would be undertaken for the Partial Removal Alternative as compared with the Proposed Project are presented in Table 4.3-2 and Table 4.3-4, and Table 4.3-6.

Other than the aforementioned portions of the Lower Klamath Project dam complexes that would remain under this Partial Removal Alternative, all other aspects would occur as described under the Proposed Project: dam and powerhouse deconstruction, reservoir drawdown, erosion of reservoir sediment deposits during drawdown, restoration within the reservoir footprint, restoration of upland areas, hatchery operations, City of Yreka water supply pipeline relocation, aquatic and terrestrial resource measures, road and bridge improvements/replacements, culvert replacements, recreation facilities removal, traffic management, groundwater well monitoring and replacement, fire management, hazardous material management, emergency response, and noise and vibration control measures (see also Section 2.7 *Proposed Project*).

Table 4.3-1. Copco No. 1 Dam and Powerhouse Removal Under the Partial Removal Alternative.

Feature[1]	National Register Eligibility Recommendation and Reference		Proposed Project (see also Table 2.7-2)	Partial Removal Alternative
	Kramer (2003)	2012 KHSA EIS/EIR		
Concrete Dam	Historic Contributing	Historic Contributing	Remove to elevation 2,463.5 feet, which is 20 feet below original river channel bottom	Same as the Proposed Project
Spillway Gates and Operators, Deck, Piers	No information	No information	Remove	Same as the Proposed Project
Penstocks	Historic Contributing	Historic Contributing	Remove	**Seal openings but retain penstocks, install security fence[2]**
Powerhouse Intake Structure	No information	No information	Remove	**Seal openings but retain powerhouse intake structure, install security fence[2]**
Gate Houses on Right Abutment	Historic Contributing	Historic Contributing	Remove	Same as the Proposed Project [3]
Diversion Control Structure	No information	No information	Remove	Same as the Proposed Project[4]
Tunnel Portals[5]	No information	No information	Retain the tunnel, plug the tunnel portals with reinforced concrete[5]	Same as the Proposed Project[5]
Powerhouse (including mechanical and electrical equipment)	Historic Contributing	Historic Contributing	Remove	**Retain, install security fence. Powerhouse would remain in the 100-year floodplain[2,6]**
Powerhouse Hazardous Materials (including transformers, batteries, insulation)	No information	No information	Remove	Same as the Proposed Project
Four 69-kv Transmission Lines (3.03 miles total) (including poles and transformers)	No information	No information	Remove	Same as the Proposed Project
Switchyard	No information	No information	Remove	Same as the Proposed Project
Warehouse and Residence[7]	Historic Contributing	Historic Contributing	Remove	Same as the Proposed Project

5 Feature as presented in Appendix B: *Definite Plan – Table 5.3-1*.

6 Some of the features proposed to be retained under the Partial Removal Alternative may have coatings that contain heavy metals (such as the penstocks) and that could be exposed during or following construction activities. These features would require preservation under the Partial Removal to reduce the risk of environmental contamination.

7 While it would be possible to partially remove the gate houses, they are likely to be fully removed to facilitate construction access (e.g., to allow a large crane to access the site). For the purposes of this CEQA analysis, it is assumed that the gate houses would be fully removed.

8 The existing diversion control structure includes gate hoists, stems, and wire ropes, which would be demolished along with unstable concrete as part of modifying the diversion structure prior to reservoir drawdown. Proposed features to modify the diversion control structure (i.e., new downstream tunnel gate and portal, new upstream blind flanges) to facilitate reservoir drawdown would be removed as part of dam deconstruction activities.

9 Refers to the Diversion Tunnel shown in Figure 2.7-2.

10 Retention of the Copco No. 1 Powerhouse under the Partial Removal Alternative would require the structure to be sealed and fenced, unless developed for public benefit as a historic structure (using an alternative funding source).

11 Refers to the Maintenance Building and the North and South Residences shown in Figure 2.7-2.

Table 4.3-2. Copco No. 1 Features[1] to be Retained and New or Different Construction Activities Under the Partial Removal Alternative as Compared with the Proposed Project.

Retain concrete intake structure on right abutment	Retain station service 600-volt switchgear
Retain diversion tunnel control structure concrete	Retain unit and plant control switchboard
Retain three sections of 23-foot by 72-inch diameter steel lining	Retain raceways, conduit and cable
Retain three 72-inch butterfly valves	Retain miscellaneous power and control boards
Retain powerhouse concrete down to top of rock under the powerhouse	Retain indoor, oil-filled, step-up, 1-phase, 5000 kilo-volt ampere (kVA) transformers
Retain powerhouse structural steel	Retain seven 40-ton indoor travelling crane motors
Retain two governor oil systems	Retain 40-ton indoor travelling crane control
Retain cooling water and bearing oil systems	Retain 40-ton indoor travelling crane festoon cable
Retain four horizontal tandem Francis turbines	Retain four 15-ton overhead crane motors
Retain two 40-ton indoor travelling cranes	Retain 15-ton overhead crane control
Retain compressed air system	Retain 15-ton overhead crane festoon
Retain two CO2 systems	Retain concrete items associated with 10 foot-diameter penstock
Retain plant water and fire protection	No plugging of the 14-foot diameter penstock with concrete
Retain transformer oil fire protection	Retain 8 screens
Retain unwatering piping	Retain 8 water gates
Retain drainage piping	Retain three 30-inch diameter by 25-foot stand pipes
Retain horizontal 12 mega-volt ampere (MVA) generator	Retain 14-foot diameter penstock pipe
Retain excitation equipment for 12 MVA generator	Retain 10-foot diameter penstock pipe
Retain surge protection equipment for 12 MVA generator	Seal openings in the penstocks, powerhouse intake structure, and powerhouse
Retain neutral grounding equipment for 12 MVA generator	Install security fencing around penstocks, powerhouse intake structure, and powerhouse

Table 4.3-3. Copco No. 2 Dam and Powerhouse Removal Under the Partial Removal Alternative.

Feature[1]	National Register Eligibility Recommendation and Reference		Proposed Project (see also Table 2.7-4)	Partial Removal Alternative
	Kramer (2003)	2012 KHSA EIS/EIR		
Concrete Dam	Historic Contributing	Historic Contributing	Remove	Same as Proposed Project
Spillway Gates, Structure	Historic Contributing	No Information	Remove	Same as Proposed Project
Power Penstock Intake Structure and Gate	Historic Contributing	Historic Contributing	Remove	**Seal openings but retain power penstock intake structure and gate, install security fence[2]**
Tunnel Portals[3]	Historic Contributing	Historic Contributing	Retain the tunnel, plug the tunnel portals with reinforced concrete[2]	**Same as Proposed Project but retain and close intake structure gate[2]**
Embankment Section and Right Sidewall	No Information	No Information	Remove	Same as Proposed Project
Basin Apron and End Sill	No Information	No Information	Remove	Same as Proposed Project
Remnant Cofferdam Upstream of Dam	Historic Contributing	Historic Contributing	Remove	Same as Proposed Project
Wood-stave Penstock	Historic Contributing	Historic Contributing	Remove	Same as Proposed Project
Concrete Pipe Cradles	No Information	No Information	Remove	Same as Proposed Project
Steel Penstock, Supports, Anchors	Historic Contributing[4]	Historic Contributing[4]	Remove	**Seal openings but retain penstock, supports, and anchors, install security fence[2]**
Powerhouse (including mechanical and electrical equipment)	Historic Contributing	Historic Contributing	Remove	**Retain, seal openings, install security fence[2,5]**
Powerhouse Hazardous Materials (including transformers, batteries, insulation)	No Information	No Information	Remove	Same as Proposed Project
Powerhouse Control Center Building and Maintenance Building	Non-Contributing	No Information	Remove	Same as Proposed Project
Oil and Gas Storage Building	Historic Contributing	No Information	Remove	Same as Proposed Project
69-kV Transmission Line, 0.14 mile	No Information	No Information	Remove	Same as Proposed Project

Feature[1]	National Register Eligibility Recommendation and Reference		Proposed Project (see also Table 2.7-4)	Partial Removal Alternative
	Kramer (2003)	2012 KHSA EIS/EIR		
Switchyard	Non-Contributing[6]	No Information	Retain – the switchyard is not part of the Proposed Project	Same as Proposed Project
Tailrace Channel	No Information	No Information	Backfill[2]	Same as Proposed Project[2]
Copco Village, Copco No. 2 Cookhouse/Bunkhouse	Historic Contributing	No Information	Remove	Same as Proposed Project
Copco Village, Bungalow Housing (bungalow and garage)	Historic Contributing	No Information	Remove	Same as Proposed Project
Copco Village (including modern bunkhouse, garage/ storage building, three modular houses, four ranch-style houses, and schoolhouse/community center)[7]	Non-Contributing	No Information	Remove	Same as Proposed Project

1 Feature as presented in Appendix B: *Definite Plan – Table 5.4-1*.
2 Some of the features proposed to be retained under the Partial Removal Alternative may have coatings that contain heavy metals (such as the penstocks) and that would be exposed during or following construction activities. These features would require preservation under the Partial Removal to reduce the risk of environmental contamination.
3 Refers to Conveyance Tunnel and Overflow Spillway Tunnel shown in Figure 2.7-2.
4 Supports and anchors not specified as part of the National Register Eligibility Recommendation.
5 Located within the FEMA designated 100-year floodplain under existing conditions (FEMA 2011a).
6 Switchyard labeled as the Copco No. 2 Substation in Kramer (2003).
7 For the purposes of this CEQA analysis, Copco Village facilities also includes the water tower shown in Figure 2.7-2.

Table 4.3-4. Copco No. 2 Features[1] to be Retained and New or Different Construction Activities Under the Partial Removal Alternative as Compared with the Proposed Project.

No removal of water from behind tailrace cofferdam	Retain indoor, vertical alternating current generator
No dewatering behind tailrace cofferdam	Retain excitation equipment for 15 milli-volt ampere (MVA) generator
No construction of embankment cofferdam across tailrace	Retain surge protection equipment for 15 MVA generator
Retain right abutment random fill	Retain neutral grounding equipment for 15 MVA generator
Retain right abutment hand-placed riprap	Retain switchgear for equipment for 15 MVA generator
Retain right abutment gunite curtain wall	Retain station service 600-volt switchgear
Retain copper shingles from roof of powerhouse	Retain unit and plant control switchboard
Retain powerhouse concrete down to spring-line of turbine	Retain battery system
Retain structural steel items associated with powerhouse	Retain raceways, conduit and cable
Retain shop building	Retain miscellaneous power and control boards
Retain two governor oil systems	Retain seven 40-ton travelling crane motors hoists
Retain cooling water and bearing oil systems	Retain 40-ton travelling crane controls
Retain oil/water separator tank and piping	Retain 40-ton travelling crane festoon cables
Retain 12 cast iron columns	Retain intake structure concrete
Retain two Francis turbines	Retain concrete items associated with 16-foot inner diameter wood penstock
Retain two 40-ton indoor cranes	Retain concrete items associated with penstocks
Retain compressed air systems	Retain steel caterpillar gate
Retain two CO2 systems	Retain steel trash rack and trash rake
Retain plant water and fire protection	Retain steel stop logs and slots for intake
Retain transformer oil fire protection	Retain penstock after bifurcation to butterfly
Retain unwatering piping	Retain bifurcated vent pipes and support
Retain drainage piping	Retain two 138-inch butterfly valves
Seal openings in the penstocks, powerhouse intake structure, and powerhouse	Install security fencing around penstocks, powerhouse intake structure, and powerhouse

1 Feature description using information presented in Appendix B: *Definite Plan – Appendix P – Attachments A.1 and A.2.*

Table 4.3-5. Iron Gate Dam and Powerhouse Removal Under the Partial Removal Alternative.

Feature[1]	National Register Eligibility Recommendation and Reference		Proposed Project (see also Table 2.7-6)	Partial Removal Alternative
	Kramer (2003)	2012 KHSA EIS/EIR		
Embankment Dam, Cutoff Walls	Non-Contributing	Historic Contributing	Remove	Same as Proposed Project
Penstock Intake Structure and Footbridge	Non-Contributing	Historic Contributing	Remove	Same as Proposed Project
Penstock	Non-Contributing	Historic Contributing	Remove	Same as Proposed Project
Water Supply Pipes and Aerator	No Information	No Information	Remove	Same as Proposed Project
Spillway Structure	Non-Contributing	Historic Contributing	Retain and bury to extent practicable[2]	Same as Proposed Project[2]
Powerhouse (including mechanical and electrical equipment)	Non-Contributing	Historic Contributing	Remove	**Retain lower portion of the powerhouse and seal openings, remove upper portion of the powerhouse[3]**
Powerhouse Hazardous Materials (transformers, batteries, insulation)	No Information	No Information	Remove	Same as Proposed Project
Powerhouse Tailrace Area	No Information	No Information	Backfill[2]	Same as Proposed Project[2]
Fish Facilities on Dam (fish ladder and trapping and holding facilities)	Non-Contributing	Historic Contributing	Remove	Same as Proposed Project
Fish Hatchery	Non-Contributing	No Information	Fish ladder and holding tanks at the toe of the dam would be removed, as would the cold-water supply for the hatchery; these facilities would be relocated such that the hatchery remains operational for eight years after the removal of Iron Gate Dam (see also Section 2.7.6)	Same as Proposed Project

Feature[1]	National Register Eligibility Recommendation and Reference		Proposed Project (see also Table 2.7-6)	Partial Removal Alternative
	Kramer (2003)	2012 KHSA EIS/EIR		
Switchyard	No Information	No Information	Remove	Same as Proposed Project
69-kV Transmission Line, 0.5 mi	No Information	No Information	Remove	Same as Proposed Project
Diversion Tunnel Intake Structure and Footbridge	Non-Contributing	No Information	Remove	Same as Proposed Project
Diversion Tunnel and Portals	Non-Contributing	No Information	Retain the tunnel, plug the tunnel portals with reinforced concrete[2]	Same as Proposed Project[2]
Diversion Tunnel Control Tower, Hoist, and Gate	Non-Contributing	No Information	Remove above finished-grade portion and retain below finished-grade portion[2]	Same as Proposed Project[2]
Additional Ancillary Facilities (e.g., communication buildings, restrooms and two residences)[4]	Non-Contributing	Historic Contributing[5]	Remove	Same as Proposed Project

[1] Feature as presented in Appendix B: *Definite Plan – Table 5.5-1*.
[2] Some of the features proposed to be retained under the Partial Removal Alternative may have coatings that contain heavy metals (such as the penstocks) and that could be exposed during or following construction activities. These features would require preservation under the Partial Removal to reduce the risk of environmental contamination.
[3] Located within the FEMA designated 100-year floodplain under existing conditions (FEMA 2011b).
[4] These facilities are discernible in Figure 2.7-4 although they not itemized in Appendix B: *Definite Plan – Table 5.5-1.*
[5] National Register Eligibility Recommendation only applies to the communication building and restroom. No recommendation made for the two residences.

Table 4.3-6. Iron Gate Features[1] to be Retained and New or Different Construction Activities Under the Partial Removal Alternative as Compared with the Proposed Project.

No furnishing, installing, and then removing temporary air vent hose from barge to diversion tunnel intake structure	Retain drainage piping
No removal of water from behind tailrace cofferdam	Retain transformer oil and fire protection
No dewatering behind tailrace cofferdam	Retain compressed air system
No construction of embankment cofferdam across tailrace	Retain outdoor horizontal generator
Retain powerhouse concrete	Retain excitation equipment for 18.975 milli-volt ampere (MVA) generator
Retain turbine unit	Retain surge protection equipment for 18.975 MVA generator
Retain draft tube bulkheads	Retain neutral grounding equipment for 18.975 MVA generator
Retain crane	Retain station service 600-volt switchgear
Retain governor oil system	Retain unit and plant control switchboard
Retain bearing oil system and cooling water system	Retain raceways, bus, conduit and cable
Retain CO2 systems	Retain miscellaneous power and control boards
Retain plant water and fire protection	Retain 3-phase, 275-kilo-volt ampere (kVA) transformer
Retain sump pumps	Retain governor oil pump motors
Retain pumps	Seal openings in the penstocks, powerhouse intake structure, and powerhouse
Retain exposed piping around the powerplant	Install security fencing around penstocks, powerhouse intake structure and powerhouse
Retain unwatering piping	

[1] Feature description using information presented in Appendix B: *Definite Plan – Appendix P – Attachments A.1 and A.2.*

4.3.1.2 Alternative Analysis Approach

Like the Proposed Project analysis in Section 3, the potential impacts of the Partial Removal Alternative are analyzed in comparison to existing conditions. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the Partial Removal Alternative are the same as those described for the Proposed Project (see Section 3.1 *Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures*). Most potential impacts for each environmental resource area are analyzed both in the short term and the long term, and unless otherwise indicated, use the same definitions of short term and long term as described for each resource area analyzed for the Proposed Project.

Based upon the detailed list of features that would be retained under the Partial Removal Alternative (Table 4.3-2 and Table 4.3-4, Table 4.3-6), the analysis of this alternative assumes that deconstruction techniques are the same as for the Proposed Project, with no specialized means or methods necessary. The analysis also assumes that the Partial Removal Alternative would use the same equipment as the Proposed Project. This alternative would require time to secure retained facilities by removing hazardous materials and installing fences and similar security features to prevent unwanted entry, such that the Partial Removal Alternative would adhere to the same schedule as the Proposed Project (Table 2.7-1).

The Definite Plan (Appendix B: *Definite Plan*) does not describe how openings in the penstocks, powerhouse intake structures, and powerhouse would be sealed, or how much security fencing would be needed under the Partial Removal Alternative. This alternative assumes that penstock openings would be sealed with reinforced concrete to eliminate trespass concerns.
Assuming a 100-foot buffer around each of the retained structures, approximately 3,100 linear feet of fencing would be installed. There would be an estimated six openings to seal for the three Copco No. 1 steel penstock pipes, and an estimated two openings to seal for the Copco No. 2 steel penstock. There would be an unknown number of openings to seal for the powerhouses; however, combined with the penstock openings, the total amount of area to be sealed and the construction-related effort to do so, including waste disposal and materials import, would be considerably less than the construction-related effort saved by not demolishing and processing waste from the numerous features listed in Table 4.3-2, Table 4.3-4, and Table 4.3-6, and in particular the multiple 40-ton travelling indoor cranes and 15-ton overhead cranes from Copco No. 1 and Copco No. 2 powerhouses, approximately 1,400 feet of steel penstocks for Copco No. 1 and Copco No. 2 powerhouses, and the concrete for the bottom portion of the Iron Gate Powerhouse.

This analysis also assumes that excavation and cut/fill activities associated with the Partial Removal Alternative would be lower than the Proposed Project because the footprint on which equipment would be operating is smaller (Appendix N – *Section N.3.2 Emissions from the Partial Removal Alternative*). However, emissions associated with the other construction-related activities would be relatively unaffected because the peak number of truck trips, construction equipment, and temporary workers would not substantially change between the Proposed Project and this alternative because the remaining structures will require sealing of penstocks, intake structures, and powerhouses, and security fence installation.

4.3.2 Water Quality

The Partial Removal Alternative would have the same level of significance for potential impacts on water quality as those identified under the Proposed Project. While partial removal of the Lower Klamath Project dam complexes would reduce construction activities due to some structures remaining in place (Table 4.3-1 through Table 4.3-6), the majority of the Lower Klamath Project dam complexes would still be removed under this alternative, including the entirety of each dam. Sealing of openings in the penstocks, powerhouse intake structures, and powerhouses, and installation of security fencing around the remaining features would require some degree of materials import (i.e., sealing materials, fencing). Compared with the Proposed Project, the same degree of mobilization of Lower Klamath Project reservoir sediment deposits would occur. Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to some Lower Klamath Project structures remaining in place, the degree of difference would not be sufficient to significantly reduce water quality impacts identified for the Proposed Project or any potential mitigation measures. Water quality impacts under the Partial Removal Alternative (i.e., water temperature-related: Potential Impact 3.2-1 and 3.2-2; suspended sediment-related: Potential Impact 3.2-3 through to 3.2-6; nutrient-related: Potential Impact 3.2-7 and 3.2-8; dissolved oxygen-related: Potential Impact 3.2-9 and 3.2-10; pH-related: Potential Impact 3.2-11; chlorophyll-a and algal toxins-related: Potential Impact 3.2-12; and inorganic and organic contaminant-related: Potential Impact 3.2-13 to 3.2-16; general water quality-related: Potential Impact 3.2-17 and 3.2-18) would be the same as the Proposed Project.

4.3.3 Aquatic Resources

4.3.3.1 Key Ecological Attributes

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the degree of difference would not be sufficient to significantly reduce the potential effects of dam removal on key aquatic ecological attributes (e.g., suspended sediment, bedload, water quality, disease and parasites, algal toxins, aquatic habitat, and instream flows). Thus, effects on key ecological attributes under the Partial Removal Alternative would be indistinguishable from those described for the Proposed Project.

4.3.3.2 Aquatic Resource Impacts

Like under the Proposed Project, reservoir drawdown associated with dam removal under the Partial Removal Alternative could directly impact aquatic species. In addition, the removal of dams and reservoirs could alter the availability and quality of habitat, resulting in direct and indirect effects on aquatic species. Although the Partial Removal Alternative would leave some Lower Klamath Project structures in place (Table 4.3-1 through Table 4.3-6), the entirety of each dam would be removed to ensure a free-flowing Klamath River and year-round volitional fish passage under all river stages and flow conditions. Under the Partial Removal Alternative, hatchery operations would continue with reduced production for eight years following dam removal, as described for the Proposed Project (Section 2.7.6 *Hatchery Operations*). Although there would be some decrease in construction-related activities under the Partial Removal Alternative due to some Lower Klamath Project structures remaining in place, the degree of difference would not be sufficient to significantly reduce water quality impacts identified for the Proposed Project. Therefore, the potential impacts to aquatic resources, and the potential mitigation measures, would be the same as those described for the Proposed Project (Potential Impacts 3.3-1 through 3.3-24).

4.3.4 Phytoplankton and Periphyton

Although the Partial Removal Alternative would leave some Lower Klamath Project structures in place (Table 4.3-1 through Table 4.3-6), the entirety of each dam would be removed to ensure a free-flowing Klamath River under all river stages and flow conditions. The hydrologic processes, suspended sediment transport, and nutrient conditions affecting phytoplankton and periphyton growth will therefore be the same under the Proposed Project and the Partial Removal Alternative. As such, the potential impacts to phytoplankton and periphyton (Potential Impact 3.4-1 through 3.4-5) due to implementation of the Partial Removal Alternative would be the same as those described for the Proposed Project.

4.3.5 Terrestrial Resources

4.3.5.1 Vegetation Communities

Under the Partial Removal Alternative there would be less construction activity as compared to the Proposed Project, since some structures would remain in place (see Table 4.3-1 through Table 4.3-6); however, there would still be construction activities in areas where there are sensitive habitats under existing conditions (Section 3.5.2.1 *Vegetation Communities*). Consequently, short-term impacts on sensitive habitats would be similar to those described for the Proposed Project (Potential Impacts 3.5-1 and 3.5-2), including impacts on wetlands and riparian habitats along the Lower Klamath Project reservoirs, river reaches (i.e., Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam), and locations associated with bridges to be replaced or upgraded prior to reservoir drawdown. Implementation of Mitigation Measure TER-1 would reduce these potential short-term impacts to less than significant.

Additionally, under the Partial Removal Alternative, there may be short- and long-term impacts on wetland and riparian habitat due to reservoir drawdown and dam removal, similar to those of the Proposed Project (Potential Impacts 3.5-3 through 3.5-6). Proposed activities contained within the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*), in combination with natural recruitment of riparian habitat along newly-formed tributary reaches within the former reservoir footprint, may result in a net increase in the areal extent of riparian habitat within the terrestrial resources Area of Analysis (Potential Impact 3.5-5). Furthermore, as with the Proposed Project, loss of riparian habitat from sedimentation downstream of the dams would be short-term in nature. Overall, short-term and long-term impacts on wetland and riparian habitat from implementation of the Partial Removal Alternative would be less than significant.

4.3.5.2 Culturally Significant Species

Similar to the Proposed Project, many of the species identified by the Native American Tribes in the Klamath River region as culturally significant occur in riparian and wetland habitats. The goal of no net loss of wetland or riparian habitat acreage and functions would still apply under the Partial Removal Alternative, and the revegetation mixes would be developed based on updated inventories of existing wetland and riparian vegetation around the reservoir perimeters; therefore, culturally significant species would be documented and incorporated as part of the revegetation effort. In addition, Mitigation Measure TER-1 (see Potential Impact 3.5-1) includes wetland buffers to prevent intrusion in wetland habitats, deter heavy machinery from traversing the wetland, prevent runoff pollution from directly entering the wetland, and avoid substantial degradation in these areas. These measures would reduce short- and long-term impacts on culturally significant species to less than significant under this alternative.

4.3.5.3 Special-status Species

Under the Partial Removal Alternative there would be less construction activity as compared to the Proposed Project as some structures would remain in place (see Table 4.3-1 through Table 4.3-6); however, short-term construction-related noise would still be generated due to the removal of the large majority of the dam complexes, including the entirety of each dam, and sealing of remaining structures and installation of security fencing. Thus, retaining some structures under the Partial Removal Alternative would not reduce noise-related impacts on special-status bats or birds to a less than significant level. Although bats are known to use some of the structures that would be retained (i.e., Copco No. 1, Copco No. 2, and Iron Gate powerhouses, see Section 3.5.5.3 *Special-status Species and Rare Natural Communities*), the Partial Removal Alternative would seal openings in the structures that remain, which would prevent bats from accessing the inside of the structures.

The structures that currently support the largest of the known bat roosts (e.g., Copco No. 1 and Iron Gate diversion tunnels) would be removed under this alternative. Birds may be nesting on the exterior of the structures that would be retained and potentially affected by facility preservation. As such, short- and long-term construction-related potential impacts (Potential Impacts 3.5-9, 3.5-10, 3.5-11, 3.5-12, 3.5-13, 3.5-14, 3.5-15, and 3.5-28) on terrestrial resources would be the same as those described for the Proposed Project. The mitigation measures and recommended terrestrial measures also would be the same as those identified for the Proposed Project.

Similarly, even though there would be less construction activity under the Partial Removal Alternative as compared to the Proposed Project, special-status plants and rare natural communities may be present in the areas where construction activities may be performed. Consequently, short-term impacts on special-status plants and rare natural communities may would be similar to those of the Proposed Project (Potential Impacts 3.5-7 and 3.5-8). The same terrestrial resource measures would apply as under the Proposed Project, which would include surveys for special-status species and rare natural communities, implementation of avoidance measures and invasive species control (Appendix B: *Definite Plan – Appendix J*). There may be significant impacts on special-status plants where avoidance is infeasible and if replanting does not succeed in re-establishment of new populations; therefore, recommended measures would be the same as those identified for the Proposed Project.

Short-term impacts of high SSCs and flows, as they relate to special-status amphibian and reptile species (Potential Impacts 3.5-16 and 3.5-18), would also be the same under the Partial Removal Alternative as those described under the Proposed Project, since retaining some structures would not affect proposed reservoir drawdown rates or the degree of mobilization of Lower Klamath Project reservoir sediment deposits.

For the same reasons as described under the Proposed Project, there would be the potential short- and long-term impacts due to loss of aquatic reservoir, wetland, and riparian habitats (Potential Impact 3.5-8) under the Partial Removal Alternative. However, as discussed under the Proposed Project, implementation the Reservoir Area Management Plan (Appendix B: *Definite Plan – Appendix H*) in combination with natural recruitment along newly-formed tributary reaches within the former reservoir footprint may result in a net increase in the areal extent of riparian habitat within the terrestrial resources Area of Analysis (Potential Impact 3.5-5). The extent of both impacts and remediation would be functionally the same under both the Proposed Project and the Partial Removal Alternative. Therefore, short- and long-term potential impacts on special-status plants (Potential Impacts 3.5-9) and special-status wildlife (Potential Impacts 3.5-15, 3.5-17, 3.5-19–22, and 3.5-24) would be similar to those described for the Proposed Project and recommended measures would be the same.

Under this alternative, Iron Gate Hatchery would operate with reduced production goals, Fall Creek Hatchery would be reopened, and water would be diverted from Bogus Creek and Fall Creek as described under the Proposed Project; thus, potential construction-related impacts, impacts from loss of hatchery production on wildlife, and flow diversion impacts would be the same as those described under the Proposed Project (Potential Impacts 3.5-10 3.5-25, 3.5-26, and 3.5-27).

4.3.5.4 Wildlife Corridors and Habitat Connectivity

Retaining some structures (Table 4.3-1 through Table 4.3-6) under the Partial Removal Alternative would result in no change from existing conditions. Effects on wildlife corridors and habitat connectivity would be slightly less beneficial in terms of opening migration opportunities than those described for the Proposed Project because the steel penstocks would remain and may impede wildlife migration. The largest length of parallel penstocks that would remain at Copco No. 1 is approximately 230 feet and at Copco No. 2 is approximately 410 feet. Powerhouses and intake structures that would remain do not present a migration barrier under existing conditions. There would be long-term benefits to wildlife from gains in upland and riparian habitat following establishment of newly planted areas, which would include monitoring and control of invasive plants (see Reservoir Area Management Plan [Appendix B: *Definite Plan – Appendix H*]). Drawdown of the reservoirs and removing the dams would benefit some terrestrial species by eliminating migration barriers, as described above (Potential Impacts 3.5-23, 3.5-29, and 3.5-30).

4.3.6 Flood Hydrology

Although the Partial Removal Alternative would leave some Lower Klamath Project structures in place (see Table 4.3-1 through Table 4.3-6), the entirety of each dam would be removed to ensure a free-flowing Klamath River under all river stages and flow conditions. The retained Copco No. 1, Copco No. 2, and Iron Gate powerhouses would likely remain within the 100-year floodplain after dam removal, based on their position within the current FEMA designated 100-year floodplain (FEMA 2011a,b) and there would be no change from existing conditions with respect to flood risk for the remaining powerhouse structures. Overall, the potential flood hydrology impacts of the Partial Removal Alternative would be the same as those described for the Proposed Project and there would be no significant impacts for Potential Impacts 3.6-1, 3.6-2, and 3.6-4 through 3.6-6 (short term). For reasons described under the Proposed Project, the long-term effect of this alternative would be beneficial for Potential Impact 3.6-6. There would be significant and unavoidable impacts related to exposing structures to a substantial risk of damage due to flooding downstream of the location of Iron Gate Dam (Potential Impact 3.6-3).

4.3.7 Groundwater

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different impacts to groundwater resources compared with those described for the Proposed Project. Thus, the potential impacts of the Partial Removal Alternative on groundwater would be the same as those described for the

Proposed Project (Potential Impacts 3.7-1 and 3.7-2) and there would be no significant impacts.

4.3.8 Water Supply/Water Rights

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different impacts to water supply/water rights compared with those described for the Proposed Project. Thus, the potential impacts of the Partial Removal Alternative on water supply/water rights, and the potential mitigation measures, would be the same as those described for the Proposed Project. Potential Impacts 3.8-1, 3.8-2, and 3.8-5 would result in no significant impacts.

Under the Partial Removal Alternative, the same degree of mobilization of Lower Klamath Project reservoir sediment deposits would occur as under the Proposed Project, such that release of stored sediment during reservoir drawdown could still impact water intake pumps downstream from Iron Gate Dam (Potential Impact 3.8-3). As under the Proposed Project, implementation of Mitigation Measure WSWR-1 would reduce this potential impact to less than significant.

The City of Yreka's municipal water supply pipeline would still need to be relocated following drawdown of Iron Gate Reservoir (Potential Impact 3.8-4), and there would still be potential for disruption to the City's water supply. Implementation of Mitigation Measure WSWR-2 would reduce this potential impact to less than significant.

4.3.9 Air Quality

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the degree of difference would not be sufficient to significantly reduce the potential effects of dam removal on construction-related air quality impacts described for the Proposed Project (Potential Impacts 3.9-1 through 3.9-5). With respect to potential exceedances of the Siskiyou County Air Pollution Control District (SCAPCD) emissions thresholds in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants) (Potential Impact 3.9-2), estimated total daily emissions from the Partial Removal Alternative would still exceed the SCAPCD's significance thresholds for NOx, PM_{10}, and $PM_{2.5}$ (Table 4.3-7). While there would be less excavation and cut/fill activities than the Proposed Project due to the smaller construction footprint, emissions associated with the other project activities would be relatively unaffected because the peak number of truck trips, amount of construction equipment, and number of temporary workers does not substantially change between the Proposed Project and this alternative. As such, the construction emissions from the Partial Removal Alternative would be significant.

As with the Proposed Project, since the Yreka water pipeline relocation would occur prior to initiating drawdown of the Iron Gate Reservoir, the construction emissions from this activity do not have the potential to occur at the same time as the other activities and should be considered separately. As shown in Table 4.3-7, the emissions from the relocation of the Yreka water supply pipeline as an isolated activity would be below the significance criteria.

Table 4.3-7. Uncontrolled Daily Emissions for the Partial Removal Alternative.[1]

Project Activity	Peak Daily Emissions (pounds per day)[2]					
	VOC	CO	NO_x	SO_x	PM_{10}	$PM_{2.5}$
Dam and Powerhouse Deconstruction	128	570	625	9	484	244
Restoration Activities	19	62	168	20	3	3
Recreation Facilities	12	77	85	0	17	7
Yreka Water Supply Pipeline Relocation	3	16	18	0	10	3
Total Maximum Daily	162	725	**896**	29	**514**	**257**
Significance Criterion[2]	250	2,500	250	250	250	250

Source: Appendix N

Notes:

[1] Values shown in grey highlight exceed the Siskiyou County Air Pollution Control District's (SCAPCD) thresholds of significance in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).

Key:

VOC = volatile organic compounds
CO = carbon monoxide
NO_x = nitrogen oxides
SO_2 = sulfur dioxide
PM_{10} = inhalable particulate matter
$PM_{2.5}$ = fine particulate matter

As discussed for the Proposed Project (Potential Impact 3.9-2), the KRRC's current proposal lacks sufficient detail concerning construction activities and it is too speculative to determine whether the air quality mitigation measures proposed in the 2012 KHSA EIS/EIR are feasible and enforceable. As such, the analysis of the Partial Removal Alternative does not include mitigation to minimize impacts from construction emissions generated by the alternative's activities. Since similar minimization measures may be implemented during project construction, it is assumed that the emissions generated by the Partial Removal Alternative would fall somewhere in the range between the uncontrolled and mitigated emissions estimates contained in Appendix N. Due to this uncertainty, the emissions of NOx, PM_{10}, and $PM_{2.5}$ from the Partial Removal Alternative are found to be significant and unavoidable.

4.3.10 Greenhouse Gas Emissions

The Partial Removal Alternative would result in few direct operational greenhouse gas (GHG) emissions. As noted for the Proposed Project (see Potential Impact 3.10-1), direct GHG emissions associated with operation of the Iron Gate Hatchery and Fall Creek Hatchery are assumed to be the same as existing baseline GHG emissions associated with current hatchery operations. Appreciable direct GHG emissions would occur only for a limited time as a result of construction related to dam deconstruction, restoration, relocation and demolition of recreational facilities, Yreka supply pipeline relocation. Since uncontrolled direct total GHG emissions from construction-related and restoration activities under the Proposed Project would be approximately 9,455 MTCO2e (Table 3.10-2), which is below the SCAQMD's 10,000 MTCO2e significance threshold, any decrease in emissions due to less construction-related and restoration activity emissions under the Partial Removal Alternative, however small, would also result in a less than significant impact.

The removal of power production is the same under both the Proposed Project and the Partial Removal Alternative. The potential for indirect production of GHG emissions under the Partial Removal Alternative would be less than significant because this alternative would not affect PacifiCorp plans to add new sources of renewable power or purchase renewable energy credits (RECs) to comply with the California Renewable Portfolio Standard (RPS) (PacifiCorp 2017b), and removal of the reservoirs would still occur which would result in a reduction in methane production (Potential Impact 3.10-2).

4.3.11 Geology, Soils, and Mineral Resources

Under the Partial Removal Alternative, removal of the Lower Klamath Project embankment/earth-filled dam and concrete dam structures would still occur to ensure a free-flowing Klamath River under all river stages and flow conditions. Thus, compared with the Proposed Project, the same degree of mobilization of Lower Klamath Project reservoir sediment deposits would occur under the Partial Removal Alternative. The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different impacts related to geology and soils compared with those described for the Proposed Project. Therefore, potential impacts under the Partial Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.11-1, 3.11-2, 3.11-3, 3.11-4, 3.11-5, 3.11-6, 3.11-7). As with the Proposed Project, Mitigation Measure GEO-1 would be required to be implemented as part of the Partial Removal Alternative to reduce potential impacts due to short-term hillslope instabilities during reservoir drawdown (Potential Impact 3.11-3).

4.3.12 Historical and Tribal Cultural Resources

The potential impacts of the Partial Removal Alternative on Copco No. 1 Dam, Copco No. 2 Dam, and Iron Gate Dam, their associated hydroelectric facilities, and the Klamath River Hydroelectric Project District as a whole, would be less than those described for the Proposed Project (Potential Impact 3.12-11) because some of the Lower Klamath Project structures would be retained. The Partial Removal Alternative would retain (entirely or partially) the following structures of potential historical significance: Copco No. 1 powerhouse and penstocks; Copco No. 2 power penstock intake structure and gate, tunnel portals, steel penstock (including supports and anchors[189]), and powerhouse; and the lower portion of the Iron Gate Dam powerhouse (Table 4.3-1 through Table 4.3-6). Leaving these structures in place would reduce potential impacts to the proposed Klamath River Hydroelectric Project District relative to those described for the Proposed Project. However, impacts to the other structures of potential historical significance within the proposed Klamath River Hydroelectric Project District would still occur under this alternative. The Copco No. 1 Dam, gate houses [190], warehouse and residence (Table 4.3-1), the Copco No. 2 Dam, spillway gates and structure, remnant cofferdam, wooden-stave penstock, concrete pipe cradles, oil and gas storage building, and certain features of the Copco Village, which are considered to be features of potential historical significance (Table 4.3-3), and the Iron Gate embankment dam,

[189] Supports and anchors not specified as part of the National Register Eligibility Recommendation.

[190] While it would be possible to partially remove the gate houses, they are likely to be fully removed to facilitate construction access (e.g., to allow a large crane to access the site). For the purposes of this CEQA analysis, it is assumed that the gate houses would be removed.

penstock intake structure, penstock, spillway structure, fish facilities on the dam, and certain features of the additional ancillary facilities (Table 4.3-5), would still be removed under the Partial Removal Alternative. Removal of these features, or any others within the Klamath Hydroelectric Historic District that are determined to have potential historical significance through the FERC process, would result in the physical destruction of the resource or its immediate surroundings in a way that would materially impair the significance of the historical resource. Thus, while the impact to historical resources would be reduced as compared to the Proposed Project, the Partial Removal Alternative would still result in a significant impact on the historical built environment (Potential Impact 3.12-11). Further, for reasons described under the Proposed Project, the impact to the Klamath Hydroelectric Historical District would be significant and unavoidable even with inclusion of the KRRC's proposed mitigation measure (i.e., implementation of a final Historic Properties Management Plan and Programmatic Agreement).

The retention of the aforementioned structures under the Partial Removal Alternative would not result in different effects related to either historic-period archaeological resources or tribal cultural resources compared with those described for the Proposed Project. Therefore, potential impacts and beneficial effects on these resources and any associated mitigation measures under the Partial Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.12-1 through 3.12-10 and 3.12-12 through 3.12-16).

4.3.13 Paleontologic Resources

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different impacts to paleontologic resources compared with those described for the Proposed Project. There would be no significant impact of the Partial Removal Alternative on paleontologic resources (Potential Impact 3.13-1).

4.3.14 Land Use and Planning

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different potential impacts to land use and planning resources compared with those described for the Proposed Project. Thus, under the Partial Removal Alternative, potential impacts on land use and planning would be the same as those described for the Proposed Project (Potential Impacts 3.14-1 and 3.14-2) and there would be no significant impacts.

4.3.15 Agriculture and Forestry Resources

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see also Table 4.3-1 through Table 4.3-6) would not result in different impacts to agriculture and forestry resources compared with those described for the Proposed Project. Thus, under the Partial Removal Alternative, potential impacts on agriculture and forestry resources would be the same as those described for the Proposed Project and there would be no significant impacts (Potential Impacts 3.15-1 through 3.15-3).

4.3.16 Population and Housing

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the number of temporary workers would not substantially change between the Proposed Project and this alternative since workers would still be needed for sealing and security fence installation around the structures that remain. Additionally, this alternative would adhere to the same schedule as the Proposed Project (Table 2.7-1) since it would require time to secure retained facilities by removing hazardous materials and installing fences (Section 4.3.1 *[Partial Removal Alternative] Introduction – Alternative Analysis Approach*). Thus, potential impacts to population and housing under the Partial Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.16-1 and 3.16-2) and this alternative would not induce substantial population growth or displace substantial numbers of people or existing housing. Implementation of the Partial Removal Alternative would have no significant impacts on population and housing.

4.3.17 Public Services

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (see Table 4.3-1 through Table 4.3-6), the degree of difference would not be enough to significantly change the assessment of dam removal effects on public services compared with those described for the Proposed Project (Potential Impacts 3.17-1 through 3.17-3). This alternative would still result in significant impacts due to short-term increased response times for emergency fire, police, and medical services, increased risk of wildfires and the need for firefighting measures, increased need of police protection, and personal and public health and safety risks and need for medical services (Potential Impact 3.17-1). Implementation of Mitigation Measure HZ-1 (Section 3.21 *Hazards and Hazardous Materials*) would reduce impacts for reasons described under the Proposed Project. However, the KRRC is developing a Traffic Management Plan to identify mitigation and other protective measures that would be implemented to reduce impacts to public services. Overseeing development and implementation of a Traffic Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that the Traffic Management Plan will be finalized and implemented, at this time the plan is not finalized, and the State Water Board cannot require its implementation. Accordingly, while the State Water Board anticipates that implementation of HZ-1 and Recommended Measure TR-1 would reduce impacts to public services, because it cannot require implementation of Recommended Measure TR-1, it is analyzing the impacts under this alternative as significant and unavoidable.

Under the Partial Removal Alternative, elimination of the Lower Klamath Project reservoirs as a long-term water source for wildfire services and the associated increase in response times for fighting wildfires (Potential Impact 3.17-2) would result in the same impacts as described for the Proposed Project because removal of the Lower Klamath Project reservoirs would still occur to ensure a free-flowing Klamath River under all river stages and flow conditions. The KRRC is working on an updated Fire Management Plan to identify mitigation and other protective measures that would be implemented to reduce impacts to wildfire services. Overseeing development and implementation of the Fire Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that it will be finalized and implemented, at this time the plan is not finalized, and the State Water Board cannot require its implementation. Accordingly, while the State Water Board anticipates that implementation of the Fire Management Plan and its incorporation of Recommended Measure PS-1 would reduce impacts to wildfire services, because it cannot require implementation, it is analyzing the impacts under this alternative as significant and unavoidable.

Potential impacts on school services and facilities (Potential Impact 3.17-3) under this alternative would be the same as described for the Proposed Project and would be less than significant.

4.3.18 Utilities and Service Systems

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the degree of difference would not be sufficient to significantly change the assessment of dam removal activities on the need for wastewater treatment (Potential Impact 3.18-1) or the need for stormwater drainage facilities (Potential Impact 3.18-2) under the Proposed Project, and there would be no significant impacts to these service systems.

Under the Partial Removal Alternative, there would be a reduction in waste disposal as compared to the Proposed Project since numerous features listed in Table 4.3-2, Table 4.3-4, and Table 4.3-6 would not be demolished and would instead be either disposed of onsite or offsite, depending on the material (see also Potential Impacts 3.18-3 and 3.18-4). For example, the Copco No. 1 and 2 powerhouse cranes (multiple 40-ton travelling indoor cranes and 15-ton overhead cranes), and 1,400 feet of steel penstocks would remain under the Partial Removal Alternative, but would be demolished under the Proposed Project. Likewise, the concrete from the bottom portion of the Iron Gate Powerhouse would remain under the Partial Removal Alternative, but would be demolished under the Proposed Project. Since the anticipated volume of waste generation for the Proposed Project is less than the identified capacities for local landfill facilities (described in Section 3.18.2.4 *Solid Waste*), and the Partial Removal Alternative would result in less construction-related waste, there would be sufficient capacity to accommodate the solid waste disposal needs of the Partial Removal Alternative, and potential waste disposal impacts would be less than significant.

4.3.19 Aesthetics

Although the Partial Removal Alternative would leave some Lower Klamath Project structures in place (see Table 4.3-1 through Table 4.3-6), the entirety of each dam would be removed to ensure a free-flowing Klamath River under all river stages and flow conditions. Thus, under the Partial Removal Alternative, the long-term change from open water lake vistas to river, canyon, and valley vistas would still occur and would not result in a significant impact (Potential Impact 3.19-1). In the short term, there would still be significant and unavoidable aesthetic impacts due to barren areas within the reservoir footprints, which would be created during reservoir drawdown and would remain until vegetation in previously inundated areas establishes (Potential Impact 3.19-4). As described for the Proposed Project, there would be no significant impacts to scenic resources resulting from changes in flows and channel morphology (Potential Impact

3.19-2) or increased turbidity and reduced clarity during reservoir drawdown (Potential Impact 3.19-3). Long-term changes in visual water quality (reduced algal blooms) would be beneficial (Potential Impact 3.19-3) under the Partial Removal Alternative for the reasons described under the Proposed Project.

The retention of some structures under the Partial Removal Alternative (e.g., powerhouse elements, penstocks, some buildings, see Table 4.3-1 through Table 4.3-6) would mean that the visual character of the Lower Klamath Project area would continue to be affected by the remaining man-made features. However, as the remaining features are already part of the existing conditions (i.e., environmental baseline), the aesthetic effect of removing the other large existing structures (e.g., dams, some buildings) the would be beneficial as compared with existing conditions, even though the benefits would be of a slightly lesser degree than those described for the Proposed Project (Potential Impact 3.19-5). Visual impacts due to construction of new infrastructure and improvements to existing infrastructure would be less than significant for the reasons described for the Proposed Project (Potential Impact 3.19-5). In general, short-term construction-related impacts to visual resources under the Partial Removal Alternative would be slightly less than those described for the Proposed Project and as such would be less than significant (Potential Impact 3.19-6). The exception to this is short-term lighting impacts; because construction would still occur at night over a period of several months, the potential impact due to construction lighting would also be significant for this alternative (Potential Impact 3.19-7). The Proposed Project currently does not include measures that would reduce impacts to nighttime views cause by temporary construction lighting. KRRC proposes that KRRC and the appropriate state or local agency would work together to develop recommended terms and conditions that should be adopted by FERC as conditions of approval for the Lower Klamath Project. This is consistent with FERC's preference for licensees to be 'good citizens' of the communities in which projects are located and thus to comply, where possible, with state and local requirements. It would be appropriate for any such terms to include measures to reduce nighttime light and glare on surrounding residences during construction. However, overseeing development and implementation of measures to reduce impacts to nighttime views does not fall within the scope of the State Water Board's water quality certification authority. While the KRRC has stated its intention to reach enforceable good citizen agreements that will be finalized and implemented, at this time these agreements are not finalized and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the final FERC terms and conditions for the Proposed Project would reduce potential impacts to nighttime views to less than significant, because the State Water Board cannot ensure implementation of any associated measures, it is analyzing the impact in this Draft EIR as significant and unavoidable.

4.3.20 Recreation

Since none of the structures that would be retained under the Partial Removal Alternative are related to recreation (see Table 4.3-1 through Table 4.3-6), and since the reservoirs themselves would not be retained, the potential impacts of the Partial Removal Alternative on recreational opportunities would be the same as those described for the Proposed Project and there would be no significant impacts in the short term (Potential Impacts 3.20-1, 3.20-2, 3.20-3, and 3.20-4). For reasons described under the Proposed Project, while there would be no short-term and long-term significant impacts to whitewater boating recreational activities in most Klamath River reaches, there would be significant and unavoidable changes to Hell's Corner area in the upper Hydroelectric Reach in the short and long term (Potential Impact 3.20-5). In the short term, there would be no significant impact on non-boating river-based recreation (e.g., fishing) and in the long term there would be a beneficial effect (Potential Impact 3.20-6). Similarly, there would also be beneficial effects on the designated California Klamath River wild and scenic river segment, and eligible and suitable California Klamath River wild and scenic river section (Potential Impact 3.20-7).

4.3.21 Hazards and Hazardous Materials

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (see Table 4.3-1 through Table 4.3-6), the degree of difference would not be enough to change the potential for hazard-related impacts due to transport or use of hazardous materials during construction activities, as compared with those described under the Proposed Project. Some of the features proposed to be retained under the Partial Removal Alternative may have coatings that contain heavy metals (such as the penstocks) and that would be exposed during or following construction activities. These features would require preservation under the Partial Removal to reduce the risk of environmental contamination. Overall, the hazards and hazardous materials-related potential impacts and mitigation would be the same as those described for the Proposed Project (Potential Impacts 3.21-1 through 3.21-7).

4.3.22 Transportation and Traffic

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the degree of difference would not be enough to significantly reduce the potential effects of dam removal on construction-related traffic described for the Proposed Project (Potential Impacts 3.22-1 through 3.22-5). This is because while there would be less excavation and cut/fill activities than anticipated for the Proposed Project (due to the smaller construction footprint), the peak number of truck trips, construction equipment, or temporary workers would not substantially change between the Proposed Project and this alternative to allow for sealing of and fencing installation around structures that remain. Overall, transportation and traffic potential impacts would be the same as those described for the Proposed Project (Potential Impacts 3.22-1 through 3.22-5) and would be significant. The KRRC is working on developing a Traffic Management Plan and an Emergency Response Plan to identify mitigation and other protective measures that would be implemented to reduce potential impacts to transportation and traffic. Overseeing development and implementation of the Traffic Management Plan and the Emergency Response Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that these plans will be finalized and implemented, at this time the plans are not finalized, and the State Water Board cannot require their implementation. Accordingly, while the State Water Board anticipates that implementation of the Traffic Management Plan and the Emergency Response Plan would reduce impacts to transportation and traffic, because it cannot require implementation, it is analyzing the impacts as significant and unavoidable.

For reasons described under the Proposed Project (Potential Impact 3.22-6), this alternative would not require a change in air traffic that would result in substantial safety risks, and there would be no significant impact.

4.3.23 Noise

Although there would be a decrease in construction-related activities under the Partial Removal Alternative due to several of the Lower Klamath Project structures remaining in place (Table 4.3-1 through Table 4.3-6), the degree of difference would not be sufficient to significantly reduce the potential effects of dam removal related to noise and vibration. Short-term construction related noise impacts due to any use of dozers, jackhammers, and/or tractors during the Partial Removal Alternative would constitute an exceedance of Siskiyou County maximum allowable noise levels and this would be a significant impact (Potential Impact 3.23-1). Deconstruction of Copco No. 1 Dam (Potential Impact 3.23-2), deconstruction of Iron Gate Dam (Potential Impact 3.23-4), restoration activities at Copco No. 1 and Iron Gate reservoirs (Potential Impact 3.23-5), and blasting at Copco No. 1 Dam (Potential Impact 3.23-6) would remain significant and unavoidable under the Partial Removal Alternative.

The analysis of the Partial Removal Alternative assumes that deconstruction techniques for this alternative are the same as for the Proposed Project, with no specialized means or methods necessary. The analysis also assumes that the Partial Removal Alternative would use the same equipment as the Proposed Project. Thus, as described for the Proposed Project, there would be no significant impacts from the Partial Removal Alternative due to construction activities associated with deconstruction of Copco No. 2 Dam (Potential Impact 3.23-3), the Downstream Flood Control project component (moving or elevating legally established structures located within the altered 100-year floodplain, where feasible) (Potential Impact 3.23-8), Mitigation Measure WSWR-1 (modify water intakes) (Potential Impact 3.23-9), and construction activities associated with the deepening or replacement of existing groundwater wells adjacent to the reservoirs (Potential Impact 3.23-10).

Under the Partial Removal Alternative, waste disposal would be somewhat reduced as compared to the Proposed Project since numerous features listed in Table 4.3-2, Table 4.3-4, and Table 4.3-6 would not be demolished, and would either disposed of on-site or off-site, depending on the material (Compare with Potential Impacts 3.18-3 and 3.18-4). As the Partial Removal Alternative would result in less construction-related waste than the Proposed Project (see Potential Impact 3.18-7), the need to transport waste to off-site landfills and construction worker commutes would likely be reduced under the Partial Removal Alternative. Transporting waste off-site and construction worker commutes would result in less than significant noise impacts for receptors 50 feet or more from all local roadways under the Proposed Project. Since there would be a reduction of this impact under the Partial Removal Alternative as compared to the Proposed Project, there would be a less than significant impact.

4.4 Continued Operations with Fish Passage Alternative

4.4.1 Introduction

4.4.1.1 Alternative Description

In the Continued Operations with Fish Passage Alternative, the J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dam complexes would be relicensed by FERC for continued operations with changes to allow for upstream and downstream fish passage and updated flow requirements. More specifically, the Continued Operations with Fish Passage Alternative assumes mandatory conditions issued by the USFWS, NMFS, and BLM, and FERC staff for the relicensing of PacifiCorp's Klamath Hydroelectric Project described in the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative*[191]. The primary conditions under the Continued Operations with Fish Passage Alternative are:

- *Fishways Prescriptions* – volitional year-round upstream and downstream fish passage at J.C. Boyle, Copco No.1, Copco No. 2, and Iron Gate dams consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007) and upheld in a trial-type administrative hearing, and specific fishway facility design and construction details included in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*[191], including fishway (i.e., fish ladder and screens) installation for both upstream and downstream migrations at all four Lower Klamath Project dam complexes and barriers to prevent juvenile salmonid entrainment into turbines;
- *Changes to J.C. Boyle Operations* – at least 40 percent of J.C. Boyle Reservoir inflow to be released downstream through the J.C. Boyle Bypass to increase minimum flows in the Bypass Reach. The generation of peaking power at J.C. Boyle Power Plant would be limited to one day per week, as water supplies allow, with the weekly peaking power flows also being used for recreation (whitewater boating) flows. Power generation would be suspended and all inflow to J.C. Boyle Reservoir would be released down the Bypass Reach under a seasonal high flow event that would occur for seven full days in later winter/spring when inflows to J.C. Boyle first exceed 3,300 cfs (DOI 2007, NMFS 2007, FERC 2007); and
- *Changes to Copco No. 2 Operations* – increase in minimum flows for the Copco No. 2 Bypass Reach, with a release of 70 cfs or inflow, whichever is less, to the bypass reach. Inflow would be computed as a 3-day running average of flows at the J.C. Boyle Powerhouse gage added to the flow from Shovel Creek, as measured by a new gage (FERC 2007).

The following conditions under the Continued Operations with Fish Passage Alternative are modifications to the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative*:

- Flows specified in the NMFS and USFWS 2013 BiOp for the USBR Klamath Irrigation Project, which are currently being considered under reinitiated consultation (see also 3.1.6.1 *Klamath River Flows under the Klamath Irrigation Project's 2013 BiOp*);

[191] The KHSA 2012 EIS/EIR's *Section 2.4.5 Fish Passage at Four Dams Alternative* (included in Appendix U of this EIR) include fishway facility design and construction details beyond what are specifically required in the FERC prescriptions and that are based on designs of similar fishway facilities used at other hydroelectric facilities. The 2012 alternative is essentially the *Staff Alternative with Mandatory Conditions* in the 2007 FERC EIS (see 2007 FERC EIS Section 2.3.3).

- Court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam, which became required after February 2017 (U.S. District Court 2017) (see also Section 4.2.1.3 *Summary of Available Hydrology Information for the No Project Alternative*); and
- Design and implementation of a Reservoir Management Plan, as described in the 2014 water quality certification application for Klamath Hydroelectric Project operations.

This alternative does not make any assumptions about potential Oregon or California water quality certification conditions.

Additionally, this section includes a short discussion of differences in the potential impact of using fishways described in the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative* compared to passage using trap and haul. For such additional analysis, this EIR generally assumes that trap and haul would be as described by FERC (2007) and would consist of trapping adult upstream migrants downstream of Iron Gate Dam and releasing them in J.C. Boyle Reservoir. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir and released downstream of Iron Gate Dam. This alternative assumes that trap and haul, like fishways prescriptions, would cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007).

The aforementioned flow-related measures would reduce overall power generation at the Lower Klamath Project dam development. This alternative assumes that installation of fish passage facilities would follow the schedule prescribed in the FERC relicensing process, which would allow downstream facilities to be installed prior to upstream passage facilities. Although the duration of construction for any individual facility would range from approximately four months to one year (Table 4.4-1), the entire process of installing fish passage at each of the four Lower Klamath Project dams would take place over a four- to eight-year period (FERC 2007). The level of construction would be consistent with that estimated for development of the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative*. Fish ladder construction would include building upstream fish ladders, spillway modifications, tailrace barriers, screens, and bypass structures (see Appendix U of this EIR for more details) and would require work in wet conditions (i.e., in-water) in areas that cannot be dewatered or dried. Construction would include the use of heavy equipment, and blasting as necessary (e.g., removal of the existing J.C. Boyle fish ladder structure). Workforce estimates for the Continued Operations with Fish Passage Alternative are provided in Table 4.4-1 and are generally less than workforce estimates for the Proposed Project (Table 2.7-8).

Table 4.4-1. Workforce Projections for Continued Operations with Fish Passage Alternative.

Dam	Estimated Average Construction Workforce	Construction Duration
J.C. Boyle*	10 to 20 people	4 to 6 months
Copco No. 1	15 to 25 people	9 months
Copco No. 2	10 to 20 people	4 to 6 months
Iron Gate	15 to 30 people	12 months

* J.C. Boyle Dam is included in this analysis as some of the traffic flow may use roads in California (e.g., I-5 to OR 66)
Source: 2012 KHSA EIS/EIR (USBR and CDFW 2012)

If instead of fish ladders, trap and haul were used, there would be the potential for reduced construction compared to the aforementioned activities for fish ladders. While trap and haul facilities differ by site, common features include a trap holding pool, diffusers or gates to guide fish into the trap, a channel or port for discharge of attraction flows, a lift mechanism for truck-loading fish, a truck loading station, and a discharge platform. Much of the trap and haul facility would be located in-stream, with only the truck loading station and discharge platform potentially requiring upland grading or other earthwork. Although trap and haul construction activities would be limited to the same construction period described above for fish ladders, hauling operations (i.e., truck trips to move fish) would be ongoing.

Under Continued Operations with Fish Passage, no KHSA Interim Measures (IMs) would continue, although actions consistent with IMs designed for water quality improvements are analyzed in this alternative as part of the Reservoir Management Plan (Section 4.4.2 *Water Quality*). Additionally, the “California Klamath Restoration Fund/Coho Enhancement Fund” restoration actions, described under the No Project Alternative (see also Table 4.2-1), would continue.

Under this alternative, Iron Gate Hatchery would continue to target current annual production goals as described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project – Fish Hatcheries*.

4.4.1.2 Alternative Analysis Approach

As for the Proposed Project, the potential impacts of the Continued Operations with Fish Passage Alternative are analyzed in comparison to existing conditions. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the Continued Operations with Fish Passage Alternative are the same as those described for the Proposed Project (see Section 3.1 *Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures*). The potential impacts for each environmental resource area are analyzed both in the short term and the long term, and unless otherwise indicated, use the same definitions of short term and long term as described for each resource area analyzed for the Proposed Project.

4.4.2 Water Quality

4.4.2.1 Water Temperature

In general, existing ongoing alterations to water temperatures caused by the reservoirs and by Lower Klamath Project operations (as described in Section 3.2.2.2 *Water Temperature*) would continue to occur under the Continued Operations with Fish Passage Alternative. Short-term and long-term potential impacts to water temperature due to implementation of the 2017 court-ordered flushing and emergency dilution flows under this alternative would be similar to the potential short-term impacts to water temperature described for the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-1). Flushing and emergency dilution releases could temporarily accentuate existing fall or spring shifts in water temperature that occur in the Middle Klamath River downstream of Iron Gate Dam, but this would be a less than significant impact on water temperatures since it would only promote the existing seasonal water temperature shift for the brief time period corresponding to the flow releases.

However, there are three actions under the Continued Operations with Fish Passage Alternative that would potentially modify water temperatures in the Klamath River and the Lower Klamath Project reservoirs relative to existing conditions in both the short term and long term: 1) increased minimum flows in the J.C. Boyle Bypass Reach and limited peaking operations at J.C. Boyle Powerhouse; 2) increased minimum flows for the Copco No. 2 Bypass Reach; 3) and implementation of a Reservoir Management Plan. These actions would alter water temperature relative to existing conditions in both the short term (0–5 years) and long term (5+ years). Changes to water temperature in the Klamath River and reservoirs from these three actions would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions and they are discussed below in Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1.

The 2007 FERC EIS found that PacifiCorp's proposal for relicensing of the Klamath Hydroelectric Project failed to address the project's water quality impairments within and downstream of the Hydroelectric Reach (FERC 2007). The Klamath River TMDLs later assigned water temperature and dissolved oxygen dual (i.e., co-occurring) load allocations to Copco No. 1 and Iron Gate reservoirs for the stratification period (May through October) to ensure compliance with the dissolved oxygen and water temperature targets (i.e., dissolved oxygen consistent with 85 percent saturation or better through September, and 90 percent or better in October [see also Table 3.2-5], and natural water temperatures, where natural baseline summer mean water temperature is approximately 18.7ºC) within the reservoirs and to ensure support of cold freshwater habitat (COLD), which is a designated beneficial use. The Klamath River TMDLs created a physical "compliance lens" where both dissolved oxygen and temperature conditions meet Basin Plan objectives in a layer of water stretching from the point of entry to the reservoirs throughout the reservoir (the depth of the compliance lens within the reservoir is not fixed) (North Coast Regional Board 2010). Since 2007, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including water temperature. Study results, including those under IM 11 (see Table 4.2-1), have indicated that while proposed reservoir management techniques can improve some of the project impacts to water quality (e.g., transport of nuisance and/or noxious blue-green algae downstream of Iron Gate Dam [Austin et al. 2016, PacifiCorp 2018]), the various techniques have not resulted in water quality improvements at Copco No. 1 or Iron Gate reservoirs that create the TMDL compliance lens nor have they otherwise sufficiently improved Klamath Hydroelectric Project impacts to water temperature (PacifiCorp 2017, 2018). Results from testing of a powerhouse intake barrier/thermal curtain in Iron Gate Reservoir under IM 11 indicate that modest water temperature improvement is possible using this technique; Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1 below discusses these results.

As described under the Proposed Project (Potential Impact 3.2-1), in the long-term (5+ years), climate change models for the Klamath Basin suggest that as the western United States warms, air temperatures will increase, there will be a slight increase in overall precipitation, winter snowfall will likely shift to higher elevations, and snowpack will be diminished as more precipitation falls as rain (Oregon Climate Change Research Institute [OCCRI] 2010). Bartholow (2005) predicted that in the Klamath Basin as a whole, increasing air temperatures and decreasing flows in the summer months would be expected to cause general increases in summer and fall water temperatures on the order of 2–3°C (3.6–5.4°F). Long-term water temperature trends relevant to consideration of effects of the Continued Operations with Fish Passage Alternative are also discussed below.

For the Continued Operations with Fish Passage Alternative, there would be no sediment release due to removal of the Lower Klamath Project. Thus, there would be no sediment-related morphological changes in the Klamath River Estuary due to dam removal that would be likely to increase estuary water temperatures in a manner that would cause or substantially exacerbate an exceedance of water quality standards or would result in a failure to maintain existing beneficial uses currently supported (Potential Impact 3.2-2) and there would be no significant impact.

Potential Impact 4.2.2-1 Seasonal alterations in water temperature due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

Under the Continued Operations with Fish Passage Alternative, J.C. Boyle Reservoir would remain in place but increased minimum flows in the J.C. Boyle Bypass Reach and limitation of peaking operations at J.C. Boyle Powerhouse would decrease the large daily water temperature range that occurs under existing conditions when warmer reservoir water is diverted around the Bypass Reach to produce power (Section 3.2.2.2 *Water Temperature*). Areas adjacent to the cold water springs in the Bypass Reach would continue to serve as thermal refugia for aquatic species because the springs themselves would not be affected by the Continued Operations with Fish Passage Alternative.

The primary decrease in daily and seasonal flow fluctuations relative to existing conditions would occur in the J.C. Boyle Bypass Reach in Oregon because flow fluctuations in the downstream J.C. Boyle Peaking Reach in California (i.e., from the Oregon-California state line to Copco No. 1 Reservoir) are attenuated with distance downstream due to tributary inputs and accretion flows. With the limitation of peaking operations under this alternative, the temperature effects downstream from J.C. Boyle are similar to those described by removal of the facility, as described in Proposed Project (Potential Impact 3.2-1 *Hydroelectric Reach*). Maximum water temperatures at the Oregon-California state line would be slightly lower and temperatures would be less artificially variable relative to existing conditions due to higher overall flows and lower frequency of peaking operations at the J.C. Boyle Powerhouse (i.e., weekly peaking under this alternative as compared to daily peaking under existing conditions). The decrease in maximum daily water temperatures and temperature variability would be less than described under the Proposed Project, because there would still be peaking operations occurring one day per week in conjunction with recreational flows (see Section 4.4.1 *[Continued Operations with Fish Passage Alternative] Introduction*). Relative to existing conditions, the slight decreases in long-term maximum summer/fall water temperatures and less artificial diel temperature variation in the J.C. Boyle Peaking Reach would return the river to a more natural thermal regime, although the degree of benefit would be slightly lower than under the Proposed Project (Potential Impact 3.2-1). Elimination of the artificial temperature signal under existing conditions would better conform with the California Thermal Plan's prohibition on elevated temperature discharges (Table 3.2-4) and would be beneficial.

In the remainder of the Hydroelectric Reach (i.e., Copco No. 1 and Iron Gate reservoirs) water temperatures would be the same as those described under the existing condition (see Section 3.2.2.2 *Water Temperature*), where spring, summer, and fall water temperatures would continue to be influenced by the thermal mass of Copco No. 1 and Iron Gate reservoirs, and the seasonal stratification patterns of the two reservoirs. It is unclear what, if any, steps could reduce the impact of the reservoirs on the thermal regime within the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam and comply with the Thermal Plan's ban on elevated temperature discharges into COLD interstate waters (Table 3.2-4). Of the seven water quality improvement actions described in the Reservoir Management Plan[192], selective withdrawal and intake control is most focused on water temperature improvements. With respect to this approach, PacifiCorp has estimated that the maximum useable cool water volume in Copco No. 1 Reservoir in summer (approximately 3,100 acre-feet at less than 14°C and 4,800 acre-feet at less than 16°C) (PacifiCorp 2014b), which if selectively withdrawn from the reservoirs, would decrease water temperatures immediately downstream of Copco No. 1 Reservoir. It is currently unclear whether selective withdrawal from Copco No. 1 Reservoir alone would be sufficient to allow compliance with the Thermal Plan or to meet the Klamath TMDLs temperature requirement in the Hydroelectric Reach (see also below discussion in *Middle and Lower Klamath River and Klamath River Estuary*).

The increase in minimum flows in the Copco No. 2 Bypass Reach under this alternative would be expected to result in decreases in maximum summer/fall water temperatures and less artificial diel temperature variation than under existing conditions, returning the river to a more natural thermal regime, although the degree of benefit would be slightly lower than under the Proposed Project (Potential Impact 3.2-1). As for the J.C. Boyle Peaking Reach, elimination of any artificial temperature signal in the Copco No. 2 Bypass Reach under existing conditions would better conform with the California

[192] Water quality management techniques in the Reservoir Management Plan (PacifiCorp 2014b) for application in Copco No. 1 and Iron Gate reservoirs include the following techniques to control nutrients, algae, dissolved oxygen and pH: (1) constructed wetlands conceptual design and implementation planning; (2) further evaluation of tailrace aeration and oxygenation systems; (3) design and implementation planning of in-reservoir oxygenation systems; (4) evaluation of epilimnion (surface water) mixing and circulation; (5) further evaluation of selective withdrawal and intake control; (6) modeling and testing of deeper seasonal drawdown and fluctuation of the reservoirs; and (7) additional testing and controlled applications of SCP algaecide to treat localized areas (e.g., coves, embayments) in the reservoirs.

Thermal Plan's prohibition on elevated temperature discharges (Table 3.2-4) and would be beneficial.

As described under the Proposed Project (Potential Impact 3.2-1), for part of the Klamath Dam Removal Secretarial Determination studies, the effects of climate change were included in model projections for long-term water temperatures, including model runs assuming that the Lower Klamath Project dams remain in place. RBM10 model results using climate change predictions from five global circulation models (GCMs) (see also Section 3.2.4.1 *Water Temperature* and Appendix D) indicate that future water temperatures would be 1–2.3°C (1.8–4.1°F) warmer than historical temperatures in the Klamath Basin (Perry et al. 2011). While this temperature range is slightly lower than that estimated by Bartholow (2005), within the general uncertainty of climate change projections, the two modeling efforts correspond reasonably well and indicate that water temperatures in the Hydroelectric Reach are expected to increase within a 50-year period on the order of 1–3°C (1.8–5.4°F). RBM10 model results also show that with dams remaining in place, the thermal lag associated with the Lower Klamath Project reservoirs would continue to result in decreased river temperatures in the spring and increased river temperatures in the late summer/fall in the Hydroelectric Reach (Perry et al. 2011; USBR 2016), consistent with the general trend under existing conditions (3.2.2.2 *Water Temperature*).

The anticipated increases in water temperatures due to climate change would occur over a timescale of decades and would act in opposition to improvements expected from actions taken in furtherance of TMDL implementation throughout the Upper Klamath Basin, such as increased riparian shading and decreased diversion from cold springs (ODEQ 2010). While full implementation of the Klamath TMDLs is anticipated to result in late summer/fall reductions in water temperature in the range of 2–10°C immediately downstream from Iron Gate Dam (North Coast Regional Board 2010), there is currently no reasonable proposal to achieve the temperature allocations in the Klamath TMDLs with the Lower Klamath Project dams remaining in place, despite the modest improvements exhibited through implementation of the Reservoir Management Plan during the past several years (PacifiCorp 2017, 2018). Thus, this EIR assumes that reasonably foreseeable late summer/fall water temperature improvements under the Continued Operations with Fish Passage Alternative would be on the lower end of the 2–10°C range, such that any improvements in late summer/fall water temperatures due to partial TMDL implementation would be completely offset by climate change increases of 1–3°C, and overall, under the Continued Operations with Fish Passage Alternative, late summer/fall water temperature conditions would not move towards a condition that supports designated beneficial uses, including cold freshwater habitat (COLD), rare, threatened, or endangered species (RARE), and migration of aquatic organisms (MIGR) annually during late summer/early fall (North Coast Regional Board 2010).

In summary, continued impoundment of water in Copco No. 1 and Iron Gate reservoirs under the Continued Operations with Fish Passage Alternative would maintain existing adverse late summer/fall water temperatures in the Hydroelectric Reach downstream of Copco No. 1 Reservoir (Section 3.2.2.2 *Water Temperature*). There is currently no reasonable proposal to achieve the temperature allocations in the Klamath TMDLs with the Lower Klamath Project dams remaining in place, despite the modest improvements achieved to date through implementation of the Reservoir Management Plan. Further, long-term climate change-induced increases in water temperatures would partially offset any TMDL improvements. Overall, the Continued Operations with Fish Passage

Alternative would result in no change from existing adverse conditions in the Hydroelectric Reach and would continue to cause an exceedance of water quality standards as set forth in the Thermal Plan.

Middle and Lower Klamath River and Klamath River Estuary

The Continued Operations with Fish Passage Alternative would have similar effects on water temperature in the Middle and Lower Klamath River Estuary as those described under the existing condition (see Section 3.2.2.2 *Water Temperature*), where spring, summer, and fall water temperatures would continue to be influenced by the thermal mass of Copco No. 1 and Iron Gate reservoirs, and the seasonal stratification patterns of the two reservoirs. It is unclear what, if any, steps could reduce the impact of the reservoirs on the thermal regime within the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam and comply with the Thermal Plan's ban on elevated temperature discharges into COLD interstate waters (Table 3.2-4). As discussed above, short-term and long-term potential impacts on water temperature due to implementation of the 2017 court-ordered flushing and emergency dilution flows under this alternative would be similar to the potential short-term impacts on water temperature under the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-1). Flushing and emergency dilution releases could temporarily accentuate the existing fall or spring shifts in water temperature that occur in the Middle Klamath River downstream of Iron Gate Dam, but this would be a less than significant change to existing water temperatures since it would only promote the existing seasonal water temperature shift for the brief time period of the flow releases.

Of the seven water quality improvement actions described in the Reservoir Management Plan[192], selective withdrawal and intake control is most focused on water temperature improvements. PacifiCorp has estimated that the maximum useable cool water volume in Copco No. 1 Reservoir in summer (approximately 3,100 acre-feet at less than 14°C and 4,800 acre-feet at less than 16°C) and the maximum volume of cold water (8°C or less) in Iron Gate Reservoir in summer (8,000 to 10,000 acre-feet) could, if selectively withdrawn from the reservoirs, decrease water temperatures immediately downstream of Iron Gate Dam by 1 to 2°C for up to 1.5 months in late summer/early fall, with larger releases resulting in cooler water temperatures in the tailrace of the dam, but depleting the reservoir cool water pools more rapidly (PacifiCorp 2014). PacifiCorp has also noted that the water supply for Iron Gate Hatchery withdraws cold water from the deeper portion of Iron Gate reservoir, and depleting or exhausting this cold water pool during the summer would have effects on the hatchery that would need to be addressed (PacifiCorp 2014). In 2015, PacifiCorp installed a powerhouse intake barrier/thermal curtain in Iron Gate Reservoir under IM 11. One of the purposes of the curtain is to isolate warmer, less dense near-surface waters while withdrawing cooler, denser, and deeper waters from the reservoir for release to the Klamath River downstream (PacifiCorp 2018). The other purpose is to isolate surface waters that have high concentrations of blue-green algae (cyanobacteria) such that extensive summer and fall blooms are not readily released downstream to the Middle and Lower Klamath River (see further discussion in Potential Impact 4.2.2-4). Results from the intake barrier/thermal curtain indicate that modest 1–2°C (1.8–3.6°F) water temperature improvement is possible (PacifiCorp 2017), although data do not indicate that this measure could achieve compliance with the Thermal Plan or to meet the Klamath TMDLs temperature requirement in the Middle Klamath River (North Coast Regional Board (2010).

In the long term, the Klamath River TMDL model indicates that, absent climate change, as implementation of the TMDL progresses under a Continuing Operations with Fish Passage Alternative (the “TMDL dams-in” [T4BSRN] scenario), water temperatures from Iron Gate Dam (RM 193.1) to the Klamath River Estuary (RM 0−2) would improve towards modeled natural conditions (the “TMDL natural conditions” [T1BSR] scenario) (North Coast Regional Board 2010). However, some delayed warming of springtime water temperatures (February–March) and delayed cooling of late summer/fall (August–November) water temperatures would still occur under a dams-in scenario due to the large thermal mass of Copco No. 1 and Iron Gate reservoirs. With dams in-place, this temporal shift would continue to occur from downstream of Iron Gate Dam to approximately the confluence of the Salmon River (RM 66). This is because while full attainment of the Klamath River TMDLs would improve water temperature, the model is unable to demonstrate full temperature compliance in the spring and fall downstream from Iron Gate Dam to the Salmon River with the Lower Klamath Project complexes in place. The Klamath TMDL model also predicts that, with full implementation, reduced diel variation in water temperature downstream from Iron Gate Dam would continue to occur should the dams remain in place due to the thermal mass of the reservoirs. The magnitude of diel variation would increase with distance downstream from Iron Gate Dam as the river approaches equilibrium with ambient air temperatures (North Coast Regional Board 2010, Dunsmoor and Huntington 2006).

In the long term, climate change is expected to cause general increases in water temperatures. The historical data record indicates that mainstem water temperatures have increased, on average, approximately 0.05ºC (0.09ºF) per year between 1962 and 2001 (Bartholow 2005) such that climate change may already be affecting Klamath River water temperatures. Projecting the Bartholow (2005) estimate of an average annual temperature increase 50 years into the future, water temperatures would increase approximately 2–3°C (3.6–5.4°F). As part of the Klamath Dam Removal Secretarial Determination studies, the effects of climate change were included in model projections for future water temperatures under dams in and dams out scenarios. RBM10 model results using climate change predictions from five global circulation models (GCMs) indicate that future water temperatures in the Middle and Lower Klamath River under a scenario where the Lower Klamath Project dams remain in place (where simulated flows are subject to the 2010 Biological Opinion mandatory flow regime [NOAA Fisheries Service 2010]) would be 1–2.3°C (1.8–4.1 °F) warmer than historical temperatures at the end of the 50-year analysis period (Perry et al. 2011). While this temperature range is slightly lower than that suggested using the Bartholow (2005) historical estimates, within the general uncertainty of climate change projections, the two projections correspond reasonably well. Considering together the available sources for climate change predictions, annual average water temperatures in the Middle and Lower Klamath River are expected to increase within the period of analysis on the order of 1–3 °C (1.8–5.4 °F).

The anticipated increases in water temperatures due to climate change would also occur over a timescale of decades and would act in opposition to improvements expected from actions taken in furtherance of TMDL implementation in upstream reaches (see also discussion above in *Hydroelectric Reach*). While full implementation of the Klamath TMDLs is anticipated to result in late summer/fall reductions in water temperature in the range of 2–10ºC immediately downstream from Iron Gate Dam (North Coast Regional Board 2010), there is currently no reasonable proposal to achieve the temperature allocations in the Klamath TMDLs with the Lower Klamath Project dams remaining in place.

In light of the ability of the thermal curtain/intake barrier to result in modest temperature improvements downstream of Iron Gate Dam during the past several years (PacifiCorp 2017, 2018), this analysis assumes that reasonably foreseeable late summer/fall water temperature improvements under the Continued Operations with Fish Passage Alternative would be on the lower end of the 2–10ºC range. Any improvements in late summer/fall water temperatures due to partial TMDL implementation would be completely offset by climate change increases of 1–3°C, and overall, under the Continued Operations with Fish Passage Alternative, late summer/fall water temperature conditions would not move towards a condition that supports designated beneficial uses, including cold freshwater habitat (COLD), rare, threatened, or endangered species (RARE), and migration of aquatic organisms (MIGR) (North Coast Regional Board 2010) in the Middle Klamath River to approximately the confluence of the Salmon River.

In summary, continued impoundment of water in Copco No. 1 and Iron Gate reservoirs under the Continued Operations with Fish Passage Alternative would maintain existing adverse late summer/fall water temperatures in the Middle Klamath River from Iron Gate Dam to the Salmon River (Section 3.2.2.2 *Water Temperature*). There is currently no reasonable proposal to achieve the temperature allocations in the Klamath TMDLs with the Lower Klamath Project dams remaining in place, despite the modest improvements achieved to date through implementation of the Reservoir Management Plan (see discussion in Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1). Further, long-term climate change-induced increases in water temperatures would partially offset any TMDL improvements. Overall, the Continued Operations with Fish Passage Alternative would result in no significant change from existing adverse conditions in the Middle Klamath River from Iron Gate Dam to the Salmon River and would continue to cause an exceedance of water quality standards as set forth in the Thermal Plan.

Temperature effects of the dams do not extend downstream of the Salmon River confluence (see Section 3.2.2.2 *Water Temperature*). Therefore, there would be no change in the impact of the Continuing Operations with Fish Passage Alternative in the Middle and Lower Klamath River reaches downstream from the confluence with the Salmon River, including the Klamath River Estuary and the Pacific Ocean nearshore environment.

Significance

Beneficial in the short term and long term for the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir

No significant impact in the short term and long term for the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, the Middle Klamath River, the Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment

4.4.2.2 Suspended Sediments

The Continued Operations with Fish Passage Alternative would not release sediments stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams. Potential Impacts 3.2-3 and 3.2-4, as discussed under the Proposed Project, would not occur and there would be no significant impacts.

The Continued Operations with Fish Passage Alternative would result in no change from the existing condition with respect to interception and retention of mineral (inorganic) suspended material in the Lower Klamath Project reservoirs (Potential Impact 3.2-6), in either the short or the long term.

J.C. Boyle gravel placement and/or habitat enhancement (IM7) (Table 4.2-1) would not continue under the Continued Operations with Fish Passage Alternative. Thus, any incidental sediment release occurring under the existing condition as a result of this activity would cease. Because of construction management practices employed, this currently does not cause a meaningful degree of sedimentation in the river, and so ceasing this practice would be unlikely to cause a substantial benefit in reducing suspended sediments.

Nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions with respect to long-term seasonal increases in algal-derived (organic) suspended material due to algal blooms in the reservoirs. There are two exceptions to this general expectation. The first is that nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions. The second is that PacifiCorp intends to design and implement a Reservoir Management Plan. These differences are discussed under a new impact heading below (Potential Impact 4.2.2-2), along with consideration of flow changes under this alternative.

The Continued Operations with Fish Passage Alternative also includes 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam that would increase SSCs compared to existing conditions during these releases. Potential short-term and long-term impacts to suspended sediments under this alternative due to these flow releases would be the same as the potential short-term impacts discussed for the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-3) and there would be no significant impact.

Additionally, the Continued Operations with Fish Passage Alternative would include upstream and downstream fish passage construction at all four Lower Klamath Project dams over a four- to eight-year period, and potential impacts related to these construction activities are discussed under a new impact heading below (Potential Impact 4.4.2-1).

Potential Impact 4.2.2-2 Seasonal increases in algal-derived (organic) suspended material due to continued impoundment of water in the reservoirs.

The Continued Operations with Fish Passage Alternative would result in no change from existing conditions with respect to interception, decomposition, retention, and/or dilution[193] of algal-derived (organic) suspended material originating from Upper Klamath Lake (in Oregon) within J.C. Boyle Reservoir and the Hydroelectric Reach to Copco No. 1 Reservoir (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). With its shallow depth and short residence time, J.C. Boyle Reservoir does not provide suitable habitat for seasonal phytoplankton (including blue-green algae) blooms (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). Increased minimum flows in the J.C.

[193] Dilution from coldwater springs downstream of J.C. Boyle Dam.

Boyle Bypass Reach and limitation of peaking operations at J.C. Boyle Powerhouse under this alternative would not affect the ongoing mechanical breakdown of algal remains in the turbulent river reaches between J.C. Boyle and Copco No. 1 reservoirs or dilution by the coldwater springs located there. The breakdown and dilution of algal-derived (organic) suspended material in this portion of the Hydroelectric Reach is not an adverse existing condition and there would be no significant impact of the Continued Operations with Fish Passage Alternative on algal-derived (organic) suspended material in this reach.

However, the Continued Operations with Fish Passage Alternative would continue to result in the same adverse seasonal increases in algal-derived (organic) suspended material in Copco No. 1 and Iron Gate reservoirs as existing conditions, with subsequent release of suspended material to the Middle and Lower Klamath River, and eventually the Klamath River Estuary (Section 3.2.2.3 *Suspended Sediments*). Note that the increase in minimum flows for the Copco No. 2 Bypass Reach under this alternative could increase summertime algal-derived (organic) suspended material in the Bypass Reach relative to existing conditions if the water were to be withdrawn from the Copco No. 1 Reservoir surface waters during an intensive bloom period. However, there is no information indicating whether the water would be withdrawn from surface waters, and therefore this potential is too speculative to evaluate further.

The 2007 FERC EIS found that PacifiCorp's proposal for relicensing of the Klamath Hydroelectric Project failed to address the project's water quality impairments within and downstream of the Hydroelectric Reach (FERC 2007). Since 2007, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including large seasonal phytoplankton blooms. Of the seven water quality improvement actions described in the Reservoir Management Plan[192], surface water mixing and application of algaecides are focused on reduction of seasonal algae blooms in the reservoirs. Study results from physical mixing to reduce phytoplankton growth within Mirror Cove in Iron Gate Reservoir indicated that the combination of a barrier curtain, aeration, and pumping, reduced summertime phytoplankton growth in the localized area of the cove (Austin et al. 2016, PacifiCorp 2018). Treatment of blue-green algae blooms in Long Gulch Cove in Iron Gate Reservoir using a hydrogen-peroxide-based algaecide resulted in short-term reductions in phytoplankton and chlorophyll-*a* in the localized area of the cove; however, nutrient release following algaecide application may have supported a later season bloom (PacifiCorp 2013, 2014, 2015). In 2015, PacifiCorp installed a powerhouse intake barrier/thermal curtain in Iron Gate Reservoir under IM 11. One of the purposes of the curtain is to isolate surface waters that have high concentrations of blue-green algae (cyanobacteria) such that extensive summer and fall blooms are not readily released downstream to the Middle and Lower Klamath River (PacifiCorp 2018). The other purpose is to isolate warmer, less dense near-surface waters while withdrawing cooler, denser, and deeper waters from the reservoir for release to the Klamath River downstream (see further discussion in Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1). Results from the intake barrier/thermal curtain indicate that the curtain reduces entrainment of blue-green algae into the Iron Gate Powerhouse intake and subsequent release downstream into the Klamath River (PacifiCorp 2017), although data do not indicate that this measure could improve algal-derived (organic) suspended material in the reservoirs such that they would no longer cause an exceedance of water quality standards (Table 3.2-4) or achieve the Klamath TMDLs phytoplankton chlorophyll-*a* target of 10 ug/L for Copco No.1 and Iron Gate reservoirs during the May to October growth season (North Coast Regional Board 2010).

Nutrient reduction measures in Oregon's Upper Klamath River and Lost River TMDLs could, over time, decrease algal-derived (organic) suspended material in Copco No.1 and Iron Gate reservoirs due to decreased nutrient availability. Similarly, nutrient reduction measures in California's Lower Lost River TMDLs and Klamath River TMDLs for organic enrichment/low dissolved oxygen, nutrients, and microcystin water quality impairments, could decrease algal-derived (organic) suspended material in Copco No.1 and Iron Gate reservoirs and could, in the long term, be beneficial to water quality. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions and subsequent effects on the Lower Klamath Project reservoirs are likely to require decades to achieve. Further, continuing seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that subsequently die and settle to the bottom, would continue to build up nutrients and organic matter in the reservoir sediments. This layer of nutrients would continue to be recycled into the water column (through internal nutrient loading, see Figure 3.2-2) during periods of stratification and low dissolved oxygen and would continue to stimulate large seasonal phytoplankton blooms in the reservoirs that are then released to the Middle and Lower Klamath River. Warmer water temperatures under climate change (Perry et al. 2011, Bartholow 2005; see discussion in Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1) would further exacerbate increases in algal-derived suspended material under the Continued Operations with Fish Passage Alternative through earlier reservoir water column stratification in the spring, which provides more favorable conditions for the growth of blue-green algae.

Overall, despite the modest improvements achieved to date for localized reductions in seasonal phytoplankton blooms within Iron Gate Reservoir and reduced release of blue-green algae blooms downstream into the Klamath River, there is currently no reasonable proposal to achieve the Klamath TMDLs phytoplankton chlorophyll-*a* target of 10 ug/L for the Lower Klamath Project Reservoirs during the May to October growth season (North Coast Regional Board 2010). Overall, the Continued Operations with Fish Passage Alternative would result in no meaningful change from existing adverse conditions and would continue to cause an exceedance of water quality standards in the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, the Middle and Lower Klamath River, and the Klamath River Estuary.

Significance

No significant impact in the short term and long term for the Hydroelectric Reach, Middle and Lower Klamath River, and the Klamath River Estuary

Potential Impact 4.4.2-1 Short-term increases in suspended material and contaminants from stormwater runoff due to construction activities associated with replacement and construction of new fish passage facilities.

Under the Continuing Operations with Fish Passage alternative, there is the potential for impacts to water quality from construction activities associated with building new fish passage facilities, including upstream fish ladders, spillway modifications, tailrace barriers, screens, and bypass structures (see Appendix U of this EIR for more details). This alternative also includes removal of the existing J.C. Boyle fish ladder structure, construction of a new fishway at or near the same location as the existing fish ladder (Figure 2.3-1), and construction of downstream fish passage. All these construction activities could result in the disturbance of soil within the Limits of Work and result in loose sediment that could then be suspended during rainfall events in stormwater runoff. Additionally, use of heavy construction equipment and construction-related vehicles involves gasoline, other petroleum fuels, hydraulic and lubricating fluids and other materials that have the potential to contaminate waters should they be captured in stormwater runoff or due to accidents. Further, because some of the construction activities under this alternative would occur directly in the river channel (i.e., "in-water") or on the banks immediately surrounding the river, the potential for discharges to the Klamath River are greater than for work conducted in areas that can be dewatered or dried. Potential water quality impacts would occur over a four- to eight-year period (see also Section 4.4.1 *[Continued Operations with Fish Passage Alternative] Introduction*) and would be likely to cause an exceedance in water quality standards for suspended material, sediment, turbidity, and/or chemical constituents (Table 3.2-4), which would be a significant impact. Implementation of mitigation measures WQ-1, TER-1, and HZ-1 would reduce impacts to less than significant for fish passage construction-related activities in the Hydroelectric Reach throughout the four- to eight-year construction period under the Continued Operations with Fish Passage Alternative. If instead of fish ladders, trap and haul were used, there would be the potential for reduced construction compared to the aforementioned activities for fish ladders.

Significance
No significant impact with mitigation in the short term for the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam

4.4.2.3 Nutrients

The Continued Operations with Fish Passage Alternative would not release sediment-associated nutrients stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams (Potential Impact 3.2-7) and there would be no significant impact.

The Continued Operations with Fish Passage Alternative would generally result in no change from the existing condition with respect to interception and retention of nutrients in the Lower Klamath Project reservoirs, in either the short term or the long term. There are two exceptions to this general statement. The first is that nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions. The second is that PacifiCorp intends to design and implement a Reservoir Management Plan. These differences are discussed under a new impact heading below (Potential Impact 4.2.2-4), along with consideration of flow changes under this alternative.

Potential Impact 4.2.2-4 Annual interception and retention of nutrients and seasonal release of nutrients due to continued impoundment of waters in the reservoirs.
The Continued Operations with Fish Passage Alternative would continue to result in the same small annual decreases in total phosphorus (TP) and total nitrogen (TN) across the Hydroelectric Reach as occur under existing conditions, due to settling of particulate matter and retention of associated nutrients originating from upstream reaches, including Upper Klamath Lake (in Oregon), in J.C. Boyle, Copco No. 1, and Iron Gate reservoirs, and dilution by the coldwater springs located downstream of J.C. Boyle Reservoir

(Section 3.2.2.4 *Nutrients*). Increased minimum flows in the J.C. Boyle Bypass Reach and limitation of peaking operations at J.C. Boyle Powerhouse under this alternative would not be expected to change the longitudinal decrease in total particulate nutrients on an annual basis from J.C. Boyle Reservoir to Iron Gate Reservoir (i.e., the Hydroelectric Reach).

However, this alternative would also continue to support the same seasonal increases in TP, and to a lesser degree TN, in the Hydroelectric Reach due to the release (export) of dissolved forms of phosphorus (ortho-phosphorus) and nitrogen (ammonium) from Copco No. 1 and Iron Gate reservoir sediments during summer and fall, when reservoir bottom waters are anoxic (through internal nutrient loading, see Figure 3.2-2). These nutrients can stimulate large seasonal blooms of phytoplankton, including blue-green algae, that are then released to the Middle and Lower Klamath River, and eventually the Klamath River Estuary (Section 3.4.2.1 *Phytoplankton*). Seasonal TP can also be transported downstream to the Middle Klamath River where it can stimulate excessive growth of periphyton (aquatic freshwater organisms attached to river bottom surfaces) (Section 3.4.2.2 *Periphyton*). Further downstream, the nutrient effects of the Lower Klamath Project diminish due to both tributary dilution and nutrient retention, such that effects are likely to be small in the Lower Klamath River and Klamath River Estuary (see Potential Impact 3.2-9). Thus, this impact focuses on seasonal nutrient trends in the Hydroelectric Reach and the Middle Klamath River under the Continued Operations with Fish Passage Alternative. Increasing minimum flows for the Copco No. 2 Bypass Reach would not change existing conditions with respect to annual or seasonal nutrient trends in this reach.

The 2007 FERC EIS found that PacifiCorp's proposal for relicensing of the Klamath Hydroelectric Project failed to address the project's water quality impairments within and downstream of the Hydroelectric Reach (FERC 2007). Since 2007, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams. Of the seven water quality improvement actions described in the Reservoir Management Plan[194], conceptual design and implementation of constructed wetlands and design and implementation of in-reservoir oxygenation systems have potential to reduce the seasonal release of nutrients from reservoir bottom sediments by intercepting incoming nutrients from upstream sources before they can enter the reservoirs, and by changing the chemistry of reservoir bottom waters (by physically adding oxygen) to inhibit (dissolved) nutrient release from the sediments.

PacifiCorp has conducted studies to determine the feasibility and effectiveness of constructing treatment wetlands upstream along the Upper Klamath River (e.g., along Lake Ewauna/Keno Impoundment) (Lyon et al. 2009, CH2M HILL 2012, PacifiCorp 2013), as well as along Copco No. 1 and Iron Gate reservoirs. PacifiCorp proposed a

[194] Water quality management techniques in the Reservoir Management Plan (PacifiCorp 2014b) for application in Copco No. 1 and Iron Gate reservoirs include the following techniques to control nutrients, algae, dissolved oxygen and pH: (1) constructed wetlands conceptual design and implementation planning; (2) further evaluation of tailrace aeration and oxygenation systems; (3) design and implementation planning of in-reservoir oxygenation systems; (4) evaluation of epilimnion (surface water) mixing and circulation; (5) further evaluation of selective withdrawal and intake control; (6) modeling and testing of deeper seasonal drawdown and fluctuation of the reservoirs; and (7) additional testing and controlled applications of SCP algaecide to treat localized areas (e.g., coves, embayments) in the reservoirs.

design for a demonstration wetlands facility adjacent to the Upper Klamath River, evaluated five potential sites, and developed construction costs and a monitoring plan (PacifiCorp 2018). To date PacifiCorp has not implemented the demonstration facility, although PacifiCorp has continued to fund pilot studies of diffuse source (i.e., small distributed) treatment wetlands for reducing nutrient transport into Upper Klamath Lake, which would eventually help to improve water quality conditions downstream in the Klamath River. PacifiCorp has also tested chemical coagulants at the laboratory scale to assess the potential for binding and removing phosphorus from waters entering the Lower Klamath Project reservoirs. While some of the coagulants were effective, potential toxicity to aquatic organisms was indicated in the laboratory tests due to elevated dissolved aluminum levels (PacifiCorp 2018). Other Reservoir Management Plan studies have included consideration of in-reservoir oxygenation systems for Keno, J.C. Boyle, and Iron Gate reservoirs (MEI 2007, PacifiCorp 2014, 2018); however, results of the aforementioned studies do not indicate that these approaches, either individually or in combination, would allow the reservoirs to meet Klamath TMDL targets for nutrients (TP and TN) for the tailraces of Copco No. 2 and Iron Gate dams, where these targets numerically interpret the narrative biostimulatory substances objective for the Klamath River (see Section 3.2.3.1 *Thresholds of Significance – Nutrients*).

Nutrient reduction measures in Oregon's Upper Klamath River and Lost River TMDLs would, over time, decrease nutrient input to the Lower Klamath Project reservoirs. Similarly, nutrient reduction measures in California's Lower Lost River TMDLs and Klamath River TMDLs for nutrients would decrease nutrient inputs and would, in the long term, be beneficial to water quality. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions, along with the corresponding reductions in nutrient inflows to the Lower Klamath Project are likely to require decades to achieve. Further, continuing seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that subsequently die and settle to the bottom, would continue to build up nutrients and organic matter in the reservoir sediments. This layer of nutrients would continue to be recycled into the water column (through internal nutrient loading, see Figure 3.2-2) during periods of stratification and low dissolved oxygen and would continue to stimulate large seasonal phytoplankton blooms in the reservoirs that are then released to the Middle Klamath River. Warmer water temperatures under climate change (Perry et al. 2011, Bartholow 2005; see discussion in Section 4.4.2 *Water Quality*, Potential Impact 4.2.2-1) would further exacerbate seasonal nutrient internal loading by supporting earlier reservoir water column stratification in the spring and later water column mixing in the fall, for an overall longer period of anoxia in bottom waters and opportunity for seasonal nutrient release to the Hydroelectric Reach and the Middle Klamath River.

With respect to the potential impact of 2017 court-ordered flushing and emergency dilution flows on nutrients downstream of Iron Gate Dam under the Continued Operations with Fish Passage Alternative, since suspended sediments transported by these releases would be primarily mineral (inorganic) sediments there would be no change from existing conditions for nutrients due to implementation of these flows. Flushing and emergency dilution releases downstream of Iron Gate Dam would end by June 15, which is generally before large phytoplankton (e.g., blue-green algae) blooms occur in Iron Gate Reservoir under existing conditions (E&S Environmental Chemistry, Inc. 2013, 2014, 2015, 2016, 2018a, 2018b), so releases would result in a less than significant increase in the export phytoplankton cells and associated nutrients downstream of Iron Gate Dam for the reasons described for the No Project Alternative

(Section 4.2.2, Potential Impact 4.2.2-4 and Section 4.2.4.1 *Phytoplankton*). Increasing minimum flows for the Copco No. 2 Bypass Reach under this alternative also would not change existing conditions with respect to annual or seasonal nutrient trends in the Hydroelectric Reach or the Klamath River downstream of Iron Gate Dam.

There is currently no reasonable proposal to achieve the Klamath TMDLs targets for nutrients (TP and TN) for the tailraces of Copco No. 2 and Iron Gate dams, where these targets numerically interpret the narrative biostimulatory substances objective. Overall, the Continued Operations with Fish Passage Alternative would result in no significant change from existing adverse conditions with respect to seasonal release of nutrients and would continue to cause an exceedance of water quality standards in the Hydroelectric Reach and the Middle Klamath River in the short term and long term.

Significance

No significant impact in the short term and long term for annual interception and retention of nutrients in the Hydroelectric Reach

No significant impact in the short term and long term for seasonal release of nutrients to the Hydroelectric Reach and the Middle Klamath River

4.4.2.4 Dissolved Oxygen

The Continued Operations with Fish Passage Alternative would not release sediments stored behind the Lower Klamath Project dams because this alternative would not remove the existing dams. Thus, there would be no short-term depletion of oxygen from the river due to resuspension of unoxidized organic matter during drawdown (Potential Impact 3.2-10) and there would be no significant impact.

The Continued Operations with Fish Passage Alternative would result in no change from the existing adverse condition with respect to large summertime variations in dissolved oxygen in the Hydroelectric Reach and dissolved oxygen concentrations in the Middle Klamath River immediately downstream of Iron Gate Reservoir that fall below the Basin Plan minimum dissolved oxygen criteria (Section 3.2.2.5 *Dissolved Oxygen*), in either the short or the long term. There are two exceptions to this general expectation. The first is that nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions. The second is that PacifiCorp intends to design and implement a Reservoir Management Plan. The 2007 FERC EIS found that PacifiCorp's proposal for relicensing of the Klamath Hydroelectric Project failed to address the project's water quality impairments within and downstream of the Hydroelectric Reach (FERC 2007). The Klamath River TMDLs later assigned water temperature and dissolved oxygen dual (i.e., co-occurring) load allocations to Copco No. 1 and Iron Gate reservoirs for the stratification period (May through October) to ensure compliance with the dissolved oxygen and water temperature targets (i.e., dissolved oxygen consistent with 85 percent saturation or better through September, and 90 percent or better in October [see also Table 3.2-5]) within the reservoirs and to ensure support of COLD. The Klamath River TMDLs created a physical "compliance lens" where both dissolved oxygen and temperature conditions meet Basin Plan objectives in a layer of water stretching from the point of entry to the reservoirs throughout the reservoir (the depth of the compliance lens within the reservoir is not fixed) (North Coast Regional Board 2010). Since 2007, PacifiCorp has developed several iterations of a

Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including dissolved oxygen. Study results, including those under IM 11 (see Table 4.2-1), have indicated that while proposed reservoir management techniques can improve some of the project impacts to water quality (e.g., transport of nuisance and/or noxious blue-green algae downstream of Iron Gate Dam [Austin et al. 2016, PacifiCorp 2018]), the various techniques have not resulted in water quality improvements at Copco No. 1 or Iron Gate reservoirs that create the TMDL compliance lens nor have they otherwise sufficiently improved Lower Klamath Project impacts to dissolved oxygen (Section 3.2.2.5 *Dissolved Oxygen*). Results from operation of a turbine venting system at Iron Gate Dam indicate that dissolved oxygen improvement is possible using this technique; Potential Impact 4.2.2-5 below discusses these results, along with consideration of flow changes under this alternative.

Potential Impact 4.2.2-5 Seasonal low dissolved oxygen concentrations due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

The Continued Operations with Fish Passage Alternative would continue to result in the same large summertime variations in dissolved oxygen in J.C. Boyle Reservoir, especially at depth, where summer/late fall concentrations can fall below 5 mg/L, releasing water with low dissolved oxygen concentrations to the Klamath River immediately downstream of J.C. Boyle Dam (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.1*). Increased minimum flows in the J.C. Boyle Bypass Reach and limitation of peaking operations at J.C. Boyle Powerhouse under this alternative would result in more natural flow conditions, which could have no effect or potentially a small effect on average dissolved oxygen concentrations in the Hydroelectric Reach downstream of J.C. Boyle Dam and at the Oregon-California state line, and somewhat reduced variability in daily dissolved oxygen for this same reach. These results are predicted by the Klamath River TMDL model, which is useful for informing impacts associated with the Proposed Project and alternatives, although it includes as a starting assumption that there will be full implementation of the TMDLs (see further discussion of TMDLs below). Overall, since daily variability in dissolved oxygen is not currently an issue in the J.C. Boyle Peaking Reach, slightly reducing this variability under future conditions where there is full implementation of the TMDLs would not be considered a beneficial effect under this alternative. Instead, there would be no change from existing adverse conditions for dissolved oxygen during summer months immediately downstream of J.C. Boyle Dam.

In Copco No. 1 and Iron Gate reservoirs, this alternative would continue to result in the same adverse seasonal anoxia (0 mg/L dissolved oxygen) in reservoir bottom waters, which often occurs by May and lasts through October to early November (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.1*). Of the seven water quality improvement actions described in the Reservoir Management Plan[192], in-reservoir oxygenation of J.C. Boyle Reservoir or the upstream Lake Ewauna/Keno Impoundment have potential to increase seasonal dissolved oxygen in J.C. Boyle Reservoir bottom waters indirectly, by reducing oxygen demand of waters entering J.C. Boyle Reservoir, or directly, by adding oxygen to J.C. Boyle Reservoir (PacifiCorp 2014, 2018). Further downstream in Iron Gate Reservoir, in-reservoir oxygenation could directly increase seasonal dissolved oxygen without depleting or exhausting the cold water pool in Iron Gate Reservoir that is used for the Iron Gate Hatchery water supply (see also discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1). PacifiCorp undertook a feasibility study for this reservoir, which indicated that placement of a hypolimnetic (bottom water) bubble-type oxygenation system near Iron Gate Dam could result in well-oxygenated conditions in the Iron Gate Powerhouse releases to the Middle Klamath River (PacifiCorp 2014, MEI 2007); however, this approach did not demonstrate creation of the TMDL compliance lens compliance within the remainder of the reservoir and the study raised questions regarding financial feasibility. To date implementation of in-reservoir oxygenation in the Lower Klamath Project reservoirs has not occurred. In 2015, PacifiCorp installed a powerhouse intake barrier/thermal curtain in Iron Gate Reservoir under IM 11. One of the purposes of the curtain is to isolate warmer, less dense near-surface waters while withdrawing cooler, denser, and deeper waters from the reservoir for release to the Klamath River downstream (PacifiCorp 2018). The other purpose is to isolate surface waters that have high concentrations of blue-green algae (cyanobacteria) such that extensive summer and fall blooms are not readily released downstream to the Middle and Lower Klamath River (see further discussion in Section 4.4.2 *[Continued Operations with Fish Passage] Suspended Sediments*, Potential Impact 4.2.2-2). Results from deployment of the intake barrier/thermal curtain in 2016 indicate that the presence of the curtain can reduce mixing of reservoir surface waters near the curtain such that moderate (5 to 6 mg/L) to low (approximately 2 to 5 mg/L) dissolved oxygen concentrations occur at depths from 2 to 12 meters due to respiration of dense phytoplankton blooms (PacifiCorp 2017). Overall, while results from the Reservoir Management Plan feasibility investigations of in-reservoir oxygenation and deployment of an intake barrier/thermal curtain suggest that improvement in dissolved oxygen is possible in the reservoirs (PacifiCorp 2017, 2018), these studies have not resulted in water quality improvements at Copco No. 1 or Iron Gate reservoirs that meet TMDL requirements for dissolved oxygen in the reservoirs, nor have they otherwise sufficiently improved Lower Klamath Project impacts to dissolved oxygen in the Middle Klamath River immediately downstream of Iron Gate Dam (see below discussion under *Middle and Lower Klamath River and Klamath River Estuary*). There would be no change from existing conditions with respect to dissolved oxygen due an increase in the minimum flows for the Copco No. 2 Bypass Reach.

Nutrient reduction measures in Oregon's Upper Klamath River and Lost River TMDLs would, over time, decrease nutrient input to the Lower Klamath Project reservoirs which would reduce the prevalence of anoxic conditions in reservoir bottom waters during periods of stratification under existing conditions (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*). Similarly, nutrient reduction measures in California's Lower Lost River TMDLs and Klamath River TMDLs for nutrients would decrease nutrient inputs and would, in the long term, be beneficial to water quality by improving seasonal dissolved oxygen in the reservoirs. However, it is anticipated that full attainment of the Oregon and California TMDLs would require decades to achieve. Further, continuing seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs, which subsequently die and settle to the bottom, would continue to result in zero to low dissolved oxygen in bottom waters during periods of stratification (see Figure 3.2-2), which is then released to the Middle Klamath River (see below discussion under *Middle and Lower Klamath River and Klamath River Estuary*). Warmer water temperatures under climate change (Perry et al. 2011, Bartholow 2005; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1) would further exacerbate low dissolved oxygen concentrations in reservoir bottom waters by supporting earlier reservoir water column stratification in the spring and later water column mixing in the fall, for an overall longer period of anoxia in bottom waters and releases of water with low dissolved oxygen concentrations to the Middle Klamath River.

There is currently no reasonable proposal to achieve the Klamath TMDLs compliance lens for dissolved oxygen in Copco No. 1 and Iron Gate reservoirs or Basin Plan minimum dissolved oxygen criteria (minimum dissolved oxygen criteria of 85 percent saturation for the period April 1 through September 30, and below the minimum criterion of 90 percent saturation for the period October 1 to March 31, for the Klamath River from Oregon-California state line [RM 214.1] to the Scott River [RM 145.1]; Table 3.2-4) with the dams remaining in place, despite the modest improvements achieved to date through implementation of the Reservoir Management Plan. Overall, the Continued Operations with Fish Passage Alternative would not resolve the existing adverse conditions and would continue to cause an exceedance of water quality standards in the Hydroelectric Reach.

Middle and Lower Klamath River and Klamath River Estuary

As discussed above, the Continued Operations with Fish Passage Alternative would continue to result in the same seasonal anoxia (0 mg/L dissolved oxygen) in reservoir bottom waters during periods of stratification (July through October/November) in Copco No. 1 and Iron Gate reservoirs as existing conditions (see also Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.1*). Immediately downstream of Iron Gate Dam, this alternative would continue to result in low dissolved oxygen in waters released from Iron Gate Reservoir during summer/late fall months, where concentrations regularly fall below 8.0 mg/L and the current Basin Plan minimum dissolved oxygen criteria based on percent saturation[195] (see also Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*). Alterations in dissolved oxygen concentrations due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would result in no significant impacts for the reasons described under the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-5). Further downstream, the effects of the Lower Klamath Project on dissolved oxygen diminish due to natural stream re-aeration, such that effects are not generally discernable by Seiad Valley (RM 132.7) (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*). Thus, this impact focuses on dissolved oxygen trends in the Hydroelectric Reach and the Middle Klamath River from Iron Gate Dam to Seiad Valley (RM 132.7) under the Continued Operations with Fish Passage Alternative. For the Middle Klamath River downstream of Seiad Valley (RM 132.7), the Lower Klamath River, and the Klamath River Estuary, there would be no significant impact of the Continued Operations with Fish Passage Alternative.

Of the seven water quality improvement actions described in the Reservoir Management Plan[194], tailrace aeration and oxygenation, in-reservoir oxygenation, and selective withdrawal and intake control have potential to increase seasonal dissolved oxygen in the Middle Klamath River immediately downstream of Iron Gate Dam by physically adding oxygen to reservoir waters or pulling higher oxygen water from selected depths in the water column for downstream release, while avoiding low oxygen water. In-reservoir oxygenation is described above for the *Hydroelectric Reach*. With respect to tailrace

[195] Minimum dissolved oxygen criteria of 85 percent saturation for the period April 1 through September 30, and below the minimum criterion of 90 percent saturation for the period October 1 to March 31, for the Klamath River from Oregon-California state line (RM 214.1) to the Scott River (RM 145.1); see also Table 3.2-4.

aeration/oxygenation, PacifiCorp currently (since 2009), and on a year-round basis, automatically operates a turbine venting system with a blower that mechanically adds oxygen as water is passed through the powerhouse turbines, with the goal of improving dissolved oxygen concentrations immediately downstream from the dam during periods of reservoir stratification. The system is automatically turned on when dissolved oxygen levels drop below 87 percent saturation and is automatically turned off when dissolved oxygen levels exceed 87 percent saturation. Despite improvements reported during 2008 and 2011, dissolved oxygen immediately downstream of Iron Gate Dam has continued to exhibit percent saturation values below the Basin Plan minimum dissolved oxygen criteria of 85 percent saturation for the period April 1 through September 30, and below the minimum criterion of 90 percent saturation for the period October 1 to March 31 for the Klamath River from Oregon-California state line (RM 214.1) to the Scott River (RM 145.1) (see also Table 3.2-4), with the majority of measured low dissolved oxygen saturation values occurring from August through November (see Appendix C – *Section C.4*). Dissolved oxygen concentrations improve with natural aeration as water moves downstream such that within approximately 6 miles downstream of the dam, the effect of turbine venting is no longer discernable (PacifiCorp 2011).

In 2015, PacifiCorp installed a powerhouse intake barrier/thermal curtain in Iron Gate Reservoir under IM 11. One of the purposes of the curtain is to isolate warmer, less dense near-surface waters while withdrawing cooler, denser, and deeper waters from the reservoir for release to the Klamath River downstream (PacifiCorp 2018). The other purpose is to isolate surface waters that have high concentrations of blue-green algae (cyanobacteria) such that extensive summer and fall blooms are not readily released downstream to the Middle and Lower Klamath River (see further discussion in Section 4.4.2.2 *[Continued Operations with Fish Passage] Suspended Sediments,* Potential Impact 4.2.2-2). Results from deployment of the intake barrier/thermal curtain in 2016 indicate that the presence of the curtain can reduce mixing of reservoir surface waters near the curtain such that low dissolved oxygen concentrations are entrained in the powerhouse intake, and to date turbine venting does not sufficiently improve dissolved oxygen concentrations in the Middle Klamath River immediately downstream of Iron Gate Dam (PacifiCorp 2018).

Overall, while results from the Reservoir Management Plan techniques employed indicate thus far that improvement is possible (PacifiCorp 2017, 2018), they have not resulted in water quality improvements at Copco No. 1 or Iron Gate reservoirs that create the TMDL compliance lens nor have they otherwise sufficiently improved Lower Klamath Project impacts to dissolved oxygen in the Middle Klamath River immediately downstream of Iron Gate Dam (North Coast Regional Board (2010).

Nutrient reduction measures in Oregon's Upper Klamath River and Lost River TMDLs would, over time, decrease nutrient input to the Lower Klamath Project reservoirs which would reduce the prevalence of anoxic conditions in reservoir bottom waters during periods of stratification under existing conditions and improve dissolved oxygen in waters discharged to the Middle Klamath River (Section 3.2.2.5 *Dissolved Oxygen* and Appendix C – *Section C.4.2*). Similarly, nutrient reduction measures in California's Lower Lost River TMDLs and Klamath River TMDLs for nutrients would decrease nutrient inputs and would, in the long term, be beneficial to water quality by improving seasonal dissolved oxygen in the reservoirs and the downstream river. However, it is anticipated that full attainment of the Oregon and California TMDLs would require decades to achieve. Further, continuing seasonal phytoplankton blooms in Copco No. 1

and Iron Gate reservoirs, which subsequently die and settle to the bottom, would continue to result in low to zero dissolved oxygen in bottom waters during periods of stratification (see Figure 3.2-2) that is then released to the Middle Klamath River. Warmer water temperatures under climate change (Perry et al. 2011, Bartholow 2005; see discussion in 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature,* Potential Impact 4.2.2-1) would further exacerbate low dissolved oxygen concentrations in reservoir bottom waters by supporting earlier reservoir water column stratification in the spring and later water column mixing in the fall, for an overall longer period of anoxia in bottom waters and potential release to the Middle Klamath River.

There is currently no reasonable proposal to achieve the Klamath TMDLs compliance lens for dissolved oxygen in Copco No. 1 and Iron Gate reservoirs or Basin Plan minimum dissolved oxygen criteria (minimum dissolved oxygen criteria of 85 percent saturation for the period April 1 through September 30, and below the minimum criterion of 90 percent saturation for the period October 1 to March 31, for the Klamath River from Oregon-California state line [RM 214.1] to the Scott River [RM 145.1]; Table 3.2-4) with the dams remaining in place, despite the modest improvements achieved to date through implementation of the Reservoir Management Plan. Overall, the Continued Operations with Fish Passage Alternative would not resolve existing adverse conditions and would continue to cause an exceedance of water quality standards in the Middle Klamath River immediately downstream of Iron Gate Dam to Seiad Valley (RM 132.7).

Significance

No significant impact in the long term for the Hydroelectric Reach, Middle and Lower Klamath River, and the Klamath River Estuary

4.4.2.5 pH

The Continued Operations with Fish Passage Alternative would result in no change from the existing adverse condition with respect to pH values that exceed the Basin Plan instantaneous maximum pH objective of 8.5 s.u and large daily fluctuations in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*). In the Middle and Lower Klamath River and Klamath River Estuary, pH exhibits large (0.5–1.5 pH units) daily fluctuations during periods of high photosynthesis and pH values also regularly exceed Basin Plan instantaneous maximum pH objective of 8.5 s.u. during late-summer and early-fall months (August–September), with the most extreme pH exceedances typically occurring from Iron Gate Dam to approximately Seiad Valley (see Section 3.2.2.6 *pH*). There are two exceptions to the general expectation that these adverse existing conditions would continue under this alternative. The first is that nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions. The second is that PacifiCorp intends to design and implement a Reservoir Management Plan. These differences are discussed under Potential Impact 4.2.2-6 below. Note that while the Hydroelectric Reach is not currently identified as being impaired for pH specifically and the California Klamath River TMDLs do not include specific allocations or targets for pH itself, pH is identified as a secondary indicator of biostimulation, and pH impacts (i.e., exceedances of Basin Plan numeric pH objectives, see Table 3.2-4) are closely related to excessive nutrient inputs to the Klamath River (North Coast Regional Board 2010).

Potential Impact 4.2.2-6 Seasonal high pH and daily pH fluctuations due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

The Continued Operations with Fish Passage Alternative would continue to result in the same pH values that exceed the Basin Plan instantaneous maximum pH objective of 8.5 s.u and large daily fluctuations in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*).

As discussed in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality*, Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including large seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that would affect pH. The improvement actions described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5 do not indicate that this measure could improve phytoplankton blooms in the reservoirs such that they would no longer cause an exceedance of pH standards (Table 3.2-4). Also as described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5, nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial to pH. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions are likely to require decades to achieve. Warmer water temperatures under climate change would further exacerbate seasonal phytoplankton blooms in the Hydroelectric Reach and overall there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated pH in the surface waters of Copco No. 1 and Iron Gate reservoirs during summer and fall months. Overall, the Continued Operations with Fish Passage Alternative would result in no change from existing adverse conditions and would continue to cause an exceedance of water quality standards in the Hydroelectric Reach. There would be no change from existing conditions with respect to pH due an increase in the minimum flows for the Copco No. 2 Bypass Reach.

Middle and Lower Klamath River and Klamath River Estuary

As discussed above, the Continued Operations with Fish Passage Alternative would continue to result in continuation of pH values that exceed the Basin Plan instantaneous maximum pH objective of 8.5 s.u and large daily fluctuations in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*). Downstream of Iron Gate Dam, this alternative would continue to result in similar pH trends for periods of high photosynthesis, particularly when large phytoplankton blooms are transported from Iron Gate Reservoir into the Middle and Lower Klamath River, with the most extreme pH exceedances typically occurring from Iron Gate Dam to approximately Seiad Valley (see Section 3.2.2.6 *pH*). Alterations in pH due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would result in no significant impacts for the reasons described under the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-6).

As discussed in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including large seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that would affect pH. The improvement actions described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5 do not indicate that this measure could improve phytoplankton blooms in the reservoirs such that they would no longer cause an exceedance of pH standards in the Middle Klamath River (Table 3.2-4). Also as described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, and 4.2.2-5, nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial to pH. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions are likely to require decades to achieve. Warmer water temperatures under climate change would further exacerbate seasonal phytoplankton blooms in the Hydroelectric Reach and overall there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated pH in the Middle Klamath River, potentially extending downstream of Seiad Valley into the Lower Klamath River and Klamath River Estuary during summer and fall months. Overall, the Continued Operations with Fish Passage Alternative would result in no meaningful change from existing adverse conditions and would continue to cause an exceedance of water quality standards in the Middle and Lower Klamath River and Klamath River Estuary.

Significance

No significant impact in the long term for the Hydroelectric Reach, Middle and Lower Klamath River, and the Klamath River Estuary

4.4.2.6 Chlorophyll-*a* and Algal Toxins

The Continued Operations with Fish Passage Alternative would continue to result in the same adverse, large, seasonal phytoplankton blooms, including blue-green algae, in Copco No. 1 and Iron Gate reservoirs, chlorophyll-*a* concentrations exceeding the TMDL target of 10 ug/L during the May to October growth season, and periodically high levels of algal toxins (concentrations greater than 0.8 and/or 4 ug/L microcystin[196]) (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*) as existing conditions. This alternative would also continue to result in release of chlorophyll-a and microcystin to the Middle and Lower Klamath River, and eventually the Klamath River Estuary, where longitudinal and temporal variations in microcystin concentrations from upstream of Copco No. 1 Reservoir to Turwar indicate that Iron Gate Reservoir is the principal source of *Microcystis aeruginosa* cells to the Middle and Lower Klamath River (Otten et al. 2015) (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). There are two exceptions to the general expectation that these adverse existing conditions would continue under this alternative. The first is that nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations

[196] Since the less than 4 ug/L criterion for microcystin in recreational waters is common to the California Klamath River TMDL, WHO, and Yurok Tribe criteria, and it is less than the Hoopa Valley Tribe recreational criterion, 4 ug/L microcystin is used as the threshold of significance for the Lower Klamath Project EIR water quality analysis. The current lowest CCHAB and Yurok Tribe posting limit for microcystin (0.8 ug/L) is also considered in the analysis although application of the lower threshold would in no case change the significance determinations in this EIR (see Section 3.2.3.1 *Thresholds of Significance – Chlorophyll-a and Algal Toxins*).

with Fish Passage Alternative and existing conditions. The second is that PacifiCorp intends to design and implement a Reservoir Management Plan. These differences are discussed under Potential Impact 4.2.2-7 below, along with consideration of flow changes under this alternative.

Potential Impact 4.2.2-7 Seasonal increases in chlorophyll-a and algal toxins due to continued impoundment of water in the reservoirs.

Hydroelectric Reach

While seasonal phytoplankton (including blue-green algae) blooms originating from Upper Klamath Lake (in Oregon) can enter J.C. Boyle Reservoir, the short residence time of this reservoir does not support substantial additional growth of algae (Section 3.2.2.3 *Suspended Sediments* and Appendix C.2.1.1). Increased minimum flows in the J.C. Boyle Bypass Reach and limitation of peaking operations at J.C. Boyle Powerhouse under this alternative would not be expected to significantly affect this condition and there would be no significant impact of the Continued Operations with Fish Passage Alternative on chlorophyll-*a* and algal toxin concentrations in the Hydroelectric Reach from J.C. Boyle Reservoir to the upstream end of Copco No. 1 Reservoir. However, the Continued Operations with Fish Passage Alternative would continue to result in chlorophyll-*a* concentrations exceeding the TMDL target of 10 ug/L during the May to October growth season, and periodically high levels of algal toxins (concentrations greater than 0.8 and/or 4 ug/L microcystin), in Copco No. 1 and Iron Gate reservoirs and would result in no change from existing adverse conditions (see also Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*).

As discussed in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including large seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that result in elevated chlorophyll-*a* concentrations and periodically high algal toxin concentrations. The improvement actions described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6 do not indicate that this measure could reduce the extent of phytoplankton blooms in the reservoirs such that they would no longer cause exceedances of chlorophyll-*a* and algal toxin standards. Also as described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6, nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial with respect to decreasing these water quality constituents, although the measures to achieve such reductions remain unclear, and the improvements could require decades. Warmer water temperatures under climate change would further exacerbate seasonal phytoplankton blooms in the Hydroelectric Reach and overall there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated chlorophyll-*a* concentrations and periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs during summer and fall months. Overall, the Continued Operations with Fish Passage Alternative would result in no change from existing adverse conditions and would continue to cause an exceedance of water quality standards in the Hydroelectric Reach. There would be no change from existing conditions with respect to chlorophyll-*a* and algal toxins due an increase in the minimum flows for the Copco No. 2 Bypass Reach.

Middle and Lower Klamath River and Klamath River Estuary

As discussed above, the Continued Operations with Fish Passage Alternative would continue to result in the same elevated chlorophyll-*a* concentrations (i.e., exceeding the TMDL target of 10 ug/L during the May to October growth season), and periodically high levels of algal toxins (concentrations greater than 0.8 and/or 4 ug/L microcystin) in the Hydroelectric Reach in Copco No. 1 and Iron Gate reservoirs during summertime periods of intense algal blooms (see Section 3.2.2.6 *pH*). Downstream of Iron Gate Dam, this alternative would continue to result in similar chlorophyll-*a* and algal toxin trends when large phytoplankton blooms are transported from Iron Gate Reservoir into the Middle and Lower Klamath River and Klamath River Estuary.

As discussed in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including large seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs that increase chlorophyll-*a* and algal toxin concentrations when they are transported from Iron Gate Reservoir into the Middle and Lower Klamath River. The improvement actions described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6 do not indicate that this measure could reduce the extent of phytoplankton blooms in the upstream Lower Klamath Project reservoirs such that they would no longer cause exceedances of chlorophyll-*a* or algal toxin standards in the Middle and Lower Klamath River. Alterations in chlorophyll-a and algal toxins due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would result in no significant impacts for the reasons described under the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-7).

Also as described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6, nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial with respect to decreasing these water quality constituents, although the measures to achieve such reductions remain unclear, and the improvements could require decades. Warmer water temperatures under climate change would further exacerbate seasonal phytoplankton blooms in the Hydroelectric Reach, which would then be transported downstream, and overall there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated chlorophyll-*a* concentrations and periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs during summer and fall months. Overall, the Continued Operations with Fish Passage Alternative would result in no change from existing adverse conditions and would continue to cause an exceedance of water quality standards in the Middle and Lower Klamath River and Klamath River Estuary.

Significance

No significant impact in the long term for the Hydroelectric Reach, Middle and Lower Klamath River, and the Klamath River Estuary

4.4.2.7 Inorganic and Organic Contaminants

The Continued Operations with Fish Passage Alternative would continue the existing condition with respect to short-term and long-term freshwater aquatic species' or human exposure to inorganic and organic contaminants (Section 3.2.2.8 *Inorganic and Organic Contaminants*).

The short-term increases in freshwater aquatic species' or human exposure to inorganic and organic contaminants associated with sediment release under the Proposed Project (Potential Impacts 3.2-13 through 3.2-15) would not occur because the dams and sediment deposits would remain in place and there would be no significant impact. There would be no significant impact to aquatic biota in the short term from herbicide application during restoration of the former reservoir areas, as the reservoirs would remain in place (Potential Impact 3.2-16). There would be no change from existing conditions in the short term or long-term with respect to changes in Iron Gate Hatchery operations on Klamath River water quality since Iron Gate Hatchery would continue existing operations (Potential Impact 3.2-17). Fall Creek Hatchery would not be reopened under this alternative and thus there would be no effects of hatchery discharges on water quality and thus no significant impact (Potential Impact 3.2-17). There would be no significant impacts on water quality from short-term construction activities on Parcel B lands since land transfer would not occur (Potential Impact 3.2-18). The potential for increases in inorganic and organic contaminants from hazardous materials associated with construction of fishways is discussed in Potential Impact 4.4.2-1.

Alterations in human and freshwater aquatic species' exposure to inorganic and organic contaminants due to implementation of the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would result in no significant impacts for the reasons described under the No Project Alternative (Section 4.2.2, Potential Impact 4.2.2-8). Increased minimum flows in the J.C. Boyle Bypass Reach, limitation of peaking operations at J.C. Boyle Powerhouse, and increased minimum flows in the Copco No. 2 Bypass Reach would have no effect on exposure pathways for inorganic and organic contaminants because the flow changes would not alter the Lower Klamath Project reservoir sediment deposits nor would they alter physical, chemical, or biological conditions within the river or reservoir reaches that would change the potential for exposure to inorganic or organic contaminants compared with existing conditions.

4.4.3 Aquatic Resources

4.4.3.1 Suspended Sediment

Under the Continued Operations with Fish Passage Alternative, the Lower Klamath Project dams would not be removed, and sediment would continue to be trapped and stored behind the dams. This evaluation assumes that the Continued Operations with Fish Passage Alternative would result in similar SSCs to the model runs for existing conditions. This model scenario provides the closest evaluation of the long-term suspended sediments effects of Continued Operations with Fish Passage Alternative. It results in no change to algal-derived (organic) suspended material as compared to existing condition over the long term, as the dams would continue to exert the same influence on algal-derived (organic) suspended material as under existing conditions (see also Potential Impact 4.2.2-2).

However, the modeling for the No Project Alternative somewhat underestimates the short-term SSC impacts of the Continuing Operations with Fish Passage Alternative, as it does not have SSC impacts related to the construction of fish passage facilities. As discussed in Section 4.4.2 *Water Quality – Suspended Sediments*, and specifically in Potential Impact 4.4.2-1, implementation of mitigation measures WQ-1, TER-1, and HZ-1 would reduce the potential significance of the short-term construction-related impacts to less than significant. Thus, there would be no significant impact in the short term of suspended sediment on any aquatic species under the Continued Operations with Fish Passage Alternative with mitigation. This alternative would have no long-term effects associated with suspended sediment transport for any aquatic species, relative to existing conditions.

4.4.3.2 Bed Elevation and Grain Size Distribution

Under the Continued Operations with Fish Passage Alternative, the Lower Klamath Project dams would not be removed and sediment would continue to be stored behind Lower Klamath Project dams, as described for existing conditions in Section 3.11.2.5 Reservoir Sediment Storage and Composition. As described for existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project–Suspended Sediment*), the Lower Klamath Project dams would continue to trap fine and coarse sediment which, when transported as bedload sediments and deposited downstream, are necessary for the long-term maintenance of aquatic habitats. As of the interception of sand, gravel and coarser sediment supply from sources upstream of Iron Gate Dam the channel downstream from Iron Gate Dam would continue to coarsen and decrease in mobility (USBR 2012), providing fewer components of habitat, in particular spawning habitat, and decreased habitat quality over time. This effect would continue to gradually decrease in the downstream direction as coarse sediment is resupplied by tributary inputs (Hetrick et al. 2009) and would be substantially reduced at the Cottonwood Creek confluence (PacifiCorp 2004a). As occurs under existing conditions, the coarser bed material is mobilized at higher flows that occur less frequently, resulting in channel features that are unnaturally static and provide lower value aquatic habitat (Buer 1981), and provide stable substrate favorable for polychaetes and for C. shasta and P. minibicornis (Hetrick et al. 2009). Additionally, as described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, in 2017, the United States District Court ordered USBR to change operations to meet court-ordered flushing flows below Iron Gate Dam. These are not modeled as part of existing conditions hydrology. These flows increase bedload mobilization during the years in which they are ordered by the court.

4.4.3.3 Water Quality

Under the Continued Operations with Fish Passage Alternative, water quality would be the same as described for existing conditions (Section 3.2.2 *Water Quality*) with the modifications described in Section 4.4.2 *Water Quality*. However, unlike under existing conditions, anadromous fish would be able to move through the Hydroelectric Reach and would be seasonally exposed to poor water quality during upstream and downstream migration, and for long durations if rearing were to occur in the mainstem river. Diminished dissolved oxygen concentrations within reservoirs can be seasonally stressful for anadromous fish from June to September (FERC 2007), high levels of the cyanotoxin microcystin also occur during summer months (see Section 3.2.2.7 *Chlorophyll-a and Algal Toxins* and discussion below for more detail) and continued high rates of algal photosynthesis in the reservoirs would result in pH values that would not consistently meet applicable ODEQ and California Basin Plan water quality objectives (see Section 3.2.2.6 *pH*).

Under the Continued Operations with Fish Passage Alternative, the effects on water temperature are predicted to be similar to those described for existing conditions (Section 3.2.2.2 *Water Temperature*), with the modifications described in Section 4.4.2 *Water Quality – Water Temperature*. Under the Continued Operations with Fish Passage Alternative, the 40 percent bypass requirement at J.C. Boyle Dam would result in more reservoir water entering the J.C. Boyle Bypass Reach and correspondingly warmer water temperatures during summer and early fall, and cooler water temperatures in late fall and winter. These effects would be similar to those under the Proposed Project and would move this short reach away from consistently cooler water temperatures during summer and early fall months; however, as with the Proposed Project, areas adjacent to the cold-water springs in the Bypass Reach would continue to serve as thermal refugia for aquatic species because the springs themselves would not be affected by the Continued Operations with Fish Passage Alternative. If volitional fishways were implemented (rather than trap and haul; as described below in Section 4.4.3.7 *Fish Passage*) anadromous fish would be able to move through the Hydroelectric Reach and might be seasonally exposed to high temperatures during upstream and downstream migration. Water temperature in Copco No. 1 and Iron Gate reservoirs can be high from June to September (Section 3.2.2.2 *Water Temperature*) and surface layers may seasonally exceed thermal tolerances for salmonids or resident fish. During late spring through summer, early fall-run Chinook salmon adult migrants could be exposed to high water temperatures, as well as spring-run Chinook salmon adults not already holding in tributary habitat; for spring-run Chinook salmon, peak migration would occur outside of the period of high water temperatures, and most juvenile outmigration occurs earlier in the spring or later in the fall. However, fall-run Chinook salmon migrating upstream through Iron Gate Reservoir and Copco No. 1 Reservoir during the primary period of their migration (August and September) would be limited to waters exhibiting suitable dissolved oxygen concentrations; under existing conditions, these concentrations are located within the top approximately 10 meters of depth in these two reservoirs where water temperatures are greater than approximately 23ºC in most years (see Appendix C – *Section C.1* and *C.4*.) The combination of warm water temperatures in surface waters and low dissolved oxygen below approximately 10 meters would potentially limit upstream migration of a proportion of fall-run Chinook salmon through the Hydroelectric Reach, unless migrating fish are able to remain within a water depth shallow enough to provide suitable dissolved oxygen and deep enough to avoid unsuitable water temperatures. If the trap and haul fish passage option was implemented consistent with FERC (2007), these water quality migration impediments would be avoided (as described in Section 4.4.3.7 *Fish Passage*).

Since J.C. Boyle Reservoir, with its large thermal mass, would remain in place under the Continued Operations with Fish Passage Alternative, effects on diel temperature variation in the Bypass Reach would be similar to those described for existing conditions (i.e., reduced diel temperature variation). Maximum water temperatures in the Peaking Reach would be slightly cooler and temperatures would be less artificially variable compared to existing conditions due to higher overall flows and the lower frequency of peaking operations at the J.C. Boyle Powerhouse.

Under existing conditions, there is a delay in the normal progression of water temperatures downstream from Iron Gate Dam (or Phase Shift from historical timing) (Bartholow et al. 2005). Under this alternative, the current phase shift and lack of temporal temperature diversity would persist, including current warm temperatures in late summer and fall (Hamilton et al. 2011). Juveniles and adults migrating later in the year would continue to experience warm temperatures in late summer and fall that could be deleterious to health and survival, including increased risk of disease, and high rates of delayed spawning and pre-spawn mortality (Hetrick et al. 2009). As there is currently no reasonable proposal to achieve the temperature allocations in the Klamath River TMDLs with the Lower Klamath Project dams remaining in place, and long-term climate change-induced increases in water temperatures would partially offset any TMDL improvements (see Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1), overall the Continued Operations with Fish Passage Alternative would maintain existing adverse late summer/fall water temperatures in the reach downstream from Iron Gate Dam.

4.4.3.4 Fish Disease and Parasites

As discussed in detail in Section 3.3.2.3, *Habitat Attributes Expected to be Affected by the Proposed Project [Fish Disease and Parasites],* under the existing condition, fish diseases, specifically the myxozoan parasites *Ceratomyxa shasta* (*C. shasta*) and *Parvicapsula minibicornis (P. minibicornis),* regularly result in substantial mortality of Klamath River salmon (Fujiwara et al. 2011, True et al. 2013). Additional diseases that may affect fish in the Klamath Basin include *Ichthyophthirius multifis* (Ich) and *Flavobacterium columnare* (columnaris). These parasites and diseases occur throughout the watershed but appear to cause the most severe mortality in the Lower Klamath Basin where *C. shasta* has been observed to result in high rates of mortality in salmon (True et al. 2013). Ich and columnaris occasionally result in substantial mortality (e.g., the 2002 fish kill of primarily adult Chinook salmon)

As discussed in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Fish Disease and Parasites],* there is currently an infection nidus (reach with the highest disease infection) for *C. shasta* and *P. minibicornis* in the Klamath River in the reach from the Shasta River downstream to Seiad Valley. With fish passage, there would be the potential that in addition to the current infection nidus downstream of Iron Gate Dam, an additional nidus could be created in upstream areas where salmon spawning congregations occur (Foott et al. 2012). Any creation of a new infection zone upstream, or the continuation of the existing infection zone (or zones) would be the result of the synergistic effect of numerous factors, such as those that occur within the current disease zone (FERC 2007, Bartholomew and Foott 2010).

Under the Continued Operations Alternative with Fish Passage Alternative, some of these conditions would persist relatively unchanged, while others would be reduced. The conditions promoting infection zones which would continue to occur under this alternative include an altered hydrograph and altered sediment transport rates below Iron Gate Dam (Hetrick et al. 2009). Additionally, altered water temperatures driven by Lower Klamath Project reservoirs would continue.

However, this alternative also has the potential to reduce crowding downstream of Iron Gate Dam, through the provision of upstream fish passage. FERC's (2007) analysis concluded that restoring access to reaches above Iron Gate Dam for anadromous fish would allow adult fall-run Chinook salmon to distribute over a greater length of the river, reducing crowding and the concentration of disease pathogens that currently occur in the reach between Iron Gate Dam and the Shasta River. This would be a reduction in conditions that promote infection zones. However, provision of fish passage alone will not eliminate crowding at Iron Gate Dam or some of the conditions to contribute to high infection rates. Concentrations of myxospore-infected salmon carcasses downstream from Iron Gate Dam are likely to still be elevated in association with two factors. First, the continued operation of Iron Gate Hatchery will continue to promote congregations of adult salmonids near the base of Iron Gate Dam. Second, congregations of adults at the entrance to fish passage facilities are likely to occur. Thus, crowding would be ameliorated, but not eliminated as a contributing factor to high disease rates.

Additionally, as described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, in 2017, the United States District Court ordered USBR to change operations to meet court-ordered flushing and dilution flows below Iron Gate Dam. These are not modeled as part of existing conditions hydrology. These flows are aimed at reducing fish disease downstream of Iron Gate Dam. This alternative assumes that these flows would continue to be required, because the addition of habitat alone is unlikely to eliminatethe current nidus downstream of Iron Gate Dam under the Continued Operations with Fish Passage Alternative.

Therefore, under this alternative, fish disease would potentially be reduced by the addition of habitat and associated reduction in crowding below Iron Gate Dam, and the continued operation of 2017 flow requirements. The flow and dilution requirements alone have not been successful in eliminating the disease nidus. Although the conditions leading to nidus downstream of Iron Gate Dam will be ameliorated by reduced crowding, and by flushing and dilution flows as required by the 2017 court order, the nidus is anticipated to continue to occur to some degree.

As discussed in detail for the Proposed Project in Section 3.3.5.5 *Fish Disease and Parasites*, available information indicates that fish passage under the Continued Operations with Fish Passage Alternative would not increase the risk of disease for resident species that occur upstream of Iron Gate Dam (NMFS 2006a).

4.4.3.5 Algal Toxins

Upper Klamath River—Hydroelectric Reach

Continued impoundment of water in the Lower Klamath Project reservoirs under the Continued Operations with Fish Passage Alternative would continue to support growth conditions for toxin-producing nuisance algal species such as *Microcystis aeruginosa* in Copco No. 1 and Iron Gate reservoirs, resulting in high seasonal concentrations of algal toxins in the Hydroelectric Reach and downstream for decades into the future. As described for existing conditions in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Algal Toxins]*, this would result in continued bioaccumulation of microcystin in fish tissue for species in the Hydroelectric Reach and could be deleterious to fish health. As there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated chlorophyll-*a* concentrations and periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs during summer and fall months with the Lower Klamath Project dams remaining in place (see Potential Impact

4.2.2-7), overall the Continued Operations with Fish Passage Alternative would maintain existing adverse high seasonal concentrations of algal toxins in the Hydroelectric Reach. For salmonids, impacts would be similar to those currently observed downstream from Iron Gate Dam.

Middle and Lower Klamath River

Continued impoundment of water in the Lower Klamath Project reservoirs under the Continued Operations with Fish Passage Alternative would continue to support the seasonal transport of toxin-producing nuisance algae and microcystin to the Klamath River downstream from Iron Gate Dam. This would result in continued bioaccumulation of microcystin in muscle tissue for aquatic species in the river and could be deleterious to fish health. As there is currently no reasonable proposal to achieve TMDL targets and meet applicable water quality standards for water temperature, nutrients and dissolved oxygen, which would also continue to result in elevated chlorophyll-*a* concentrations and periodically high algal toxin concentrations transported to the Klamath River downstream from Iron Gate Dam during summer and fall months (see Potential Impact 4.2.2-7), overall the Continued Operations with Fish Passage Alternative would maintain existing adverse high seasonal concentrations of algal toxins in the Klamath River downstream of Iron Gate Dam. For aquatic species, impacts would be similar to those currently observed downstream from Iron Gate Dam (described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Algal Toxins]*).

4.4.3.6 Aquatic Habitat and Instream Flows

Under the Continued Operations with Fish Passage Alternative, access to historical anadromous fish habitat would be restored to some degree. Volitional fishways would provide anadromous fish access to 58 miles of habitat upstream of Iron Gate Dam not inundated by Lower Klamath Project reservoirs (and downstream of Keno Dam) (DOI 2007). This is considered historical habitat for coho salmon, Pacific lamprey, fall-run Chinook salmon, spring-run Chinook salmon, and steelhead (Hamilton et al. 2005, 2016). Volitional fishways would also provide 360 miles of habitat upstream of Upper Klamath Lake and Keno Impoundment/Lake Ewauna (Huntington 2006, DOI 2007, NMFS 2007). This is considered historical habitat for fall-run Chinook salmon, spring-run Chinook salmon, and steelhead (Hamilton et al. 2005, 2016). The number of miles of fish habitat made potentially available under this alternative may also be impaired by high water temperatures in during some seasons in association with Lower Klamath Project reservoirs, as described above in *Water Quality*.

If fish passage were provided by trap and haul (as described below), the amount of habitat upstream of Upper Klamath Lake and Keno Impoundment/Lake Ewauna would be the same, but of the 58 miles of habitat between Iron Gate Dam and Keno Dam, only approximately 25 miles of habitat would be available on the mainstem Klamath River between J.C. Boyle and Keno, and within Spencer Creek (Huntington 2006, FERC 2007).

Hydrology of the Klamath River from Iron Gate Dam to the Klamath River Estuary would generally remain the same as under existing conditions. Additional winter-spring surface flushing flows and deep flushing flow requirements outlined in *Measures to Reduce Ceratanova Shasta Infection of Klamath River Salmonids: A Guidance Document* and U.S. District Court Filing 111 (U.S. District Court 2017a–c; see also Section 4.4.1

[Continued Operations with Fish Passage Alternative] Introduction – Alternative Description) is predicted to help reduce juvenile salmon disease below Iron Gate Dam, as discussed in Section 4.4.3.4 *Fish Disease and Parasites*. However, as described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing and dilution flows required to be released from Iron Gate Dam are not modeled as part of existing conditions hydrology.

Activities currently underway to recover salmonid and sucker populations within the Klamath Basin would likely continue at their current levels. See Section 5, *Cumulative Impacts* for information on salmonid and sucker recovery activities.

Under this alternative, there would be substantial changes to hydroelectric operations. J.C. Boyle Powerhouse would no longer generate in peaking mode, and higher flow releases would be made through the J.C. Boyle Bypass Reach than under existing conditions. Higher base flows would also be provided in the Copco No. 2 Bypass Reach. Peaking operations would only occur one day a week to coincide with recreation flows, at least 40 percent of flow would go into the Bypass Reach (and not enter the powerhouse), and ramping rates would be slower than they are currently. Seasonal high flows would contribute to improving the quality of riparian habitat in the J.C. Boyle Bypass Reach by increasing the sediment deposited within the channel and decreasing reed canary grass (NMFS 2006a). The more normative flow regime associated with this alternative would provide these seasonal high flows. These modifications would benefit fish in this reach, including redband trout and anadromous fish.

As discussed in Section 4.2.3.2, Potential Impact 4.2.3-21, continued implementation of the Coho Enhancement Fund under the Continued Operations with Fish Passage Alternative would continue to provide benefits to fall-run Chinook salmon, spring-run Chinook salmon, steelhead, Pacific lamprey, freshwater mussels, and benthic macroinvertebrates. These actions are also beneficial for coho salmon (particularly from the Upper Klamath River Population Unit). Implementation of the Coho Enhancement Fund under the No Project Alternative would have no significant impact (no change from existing conditions) on redband trout, shortnose and Lost River suckers, green sturgeon, eulachon, and Southern Resident Killer Whales, since these species are not found in or near the river reaches associated with IM2 projects or actions.

4.4.3.7 Fish Passage

Under the Continued Operations with Fish Passage Alternative, fish migrating upstream and downstream past Lower Klamath Project dams and reservoirs would have fishways for the provision of safe and timely passage, consistent with FERC (2007). Under the Continued Operations with Fish Passage Alternative upstream and downstream fish passage at all four Lower Klamath Project dams would be provided consistent with the prescriptions from the U.S. Department of Interior (DOI) and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007), and in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*, including barriers to prevent juvenile salmonid entrainment into turbines. This alternative assumes fish passage is consistent with the general prescriptions (DOI 2007) that cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007). As noted, this alternative also provides information on where trap and haul would result in different impacts, although that process would not comply with the mandatory conditions.

Fish migrating through fishways may experience delay, injury, and mortality, beyond what would occur from natural migration in the absence of dams and reservoirs (FERC 2007). In the relicensing proceeding for the Klamath Hydroelectric Project, NMFS (2006) recommended dam removal as the preferred alternative to provide the least mortality and injury to migrating fish. NMFS' mandatory fishway prescription (DOI 2007) was submitted in the event that FERC chose to reject NMFS' recommendation to removal all Lower Klamath Project mainstem dams. In the FERC (2007) analysis, potential mortality occurring during fish passage was considered for fall-run Chinook salmon adults and juveniles, for both volitional fishways (e.g., fish ladders and screened turbines), as well as for trap and haul. In analyzing volitional fishways FERC (2007) considered potential sources of mortality for upstream and downstream migrating fish, such as poor water quality conditions, predatory fish in Lower Klamath Project reservoirs, and injuries while passing through multiple fish ladder and screening facilities. As described in Section 4.4.3.3 *Water Quality*, poor water quality conditions in Iron Gate and Copco No. 1 reservoirs would likely limit migration of a proportion of the adult fall-run Chinook salmon migration through the Hydroelectric Reach during most years if fish passage were provided from volitional fishways at each of the Lower Klamath Project facilities, unless migrating fish are able to remain within a water depth shallow enough to provide suitable dissolved oxygen and deep enough to avoid unsuitable water temperatures.

Based on the reservoir dynamics and the predator population that currently occurs, predation of outmigrating salmonids above Iron Gate Dam is anticipated to be low (NMFS 2006a). In restoration efforts elsewhere in the Pacific Northwest, anadromous juveniles successfully pass through reservoirs under similarly difficult circumstances (NMFS 2006a). These potential sources of mortality were estimated based on Oosterhout (2005, cited from PacifiCorp 2006). FERC (2007) predicted that average cumulative (migration in reservoirs and through fishways) mortality for adult Chinook salmon migrating upstream from Iron Gate Dam to upstream of J.C. Boyle Dam would be 28 percent with volitional fish ladders. The prediction for juveniles migrating downstream from Upper Klamath Lake to downstream of Iron Gate was 58 percent mortality for passage through the reservoirs and volitional fishways. For this analysis, it is assumed that effects of passage through volitional fishways would be equivalent for other migratory species, which appears to be a reasonable assumption based on available data (DWR 2013) for fishways designed and constructed to modern agency criteria as required by DOI (2007).

Trap and haul fish passage facilities are described by FERC (2007) and are addressed under the Continued Operations with Fish Passage Alternative to the extent the impacts of trap and haul would be different from those considered under mandatory fishway conditions. However, trap and haul facilities do not provide volitional fish passage, and thus are not considered by NMFS or USFWS to be equivalent to volitional fishways, such as fish ladders and downstream bypass facilities. The trap and haul alternative described by FERC (2007), would consist of trapping upstream adult migrants downstream of Iron Gate Dam and releasing them in J.C. Boyle Reservoir. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Iron Gate Dam (potentially far enough downstream to avoid disease issues). In addition, the trap and haul option avoids water quality impediments to upstream migration for adult fall-run Chinook salmon described in Section 4.4.3.3 *Water Quality*. Therefore, trap and haul was predicted to have lower cumulative mortality than volitional ladders, since this option would avoid mortality associated with passage through the Lower Klamath Project reservoirs and riverine habitat that would be bypassed. FERC (2007) predicted that average cumulative mortality for adult Chinook salmon migrating upstream from Iron Gate Dam to upstream of J.C. Boyle Dam would be 21 percent for trap and haul. The prediction for juveniles migrating downstream from Upper Klamath Lake to downstream of Iron Gate was 46 percent for trap and haul. However, the FERC analysis did not consider the impacts of the trap and haul operation itself, such as handling and trucking stress and mortality. The recent review of Lusardi and Moyle (2017) note that adults trapped and hauled upstream experience high (> 20 percent) pre-spawn mortality rates, and juvenile salmonids transported downstream are observed to experience delayed mortality, reduced growth rates, and increased predation. Therefore, for purposes of comparing the impacts of the Continued Operations with Fish Passage alternative with the impacts of trap and haul, this analysis does not assume that mortality would be different from that estimated for volitional fishways reported by FERC (2007). In addition, for this analysis, it is assumed that effects of passage through trap and haul facilities would be equivalent for other migratory species, which is a reasonable assumption for modern fishways designed to accommodate all species (including Pacific lamprey).

Potential Impact 4.2.3-1 Effects on coho salmon critical habitat quality and quantity due to continued operations of the Lower Klamath Project.

Under the Continued Operations with Fish Passage Alternative, coho salmon would be able to access habitat in the Hydroelectric Reach by ascending the fishways associated with each of the dams. Available habitat for coho salmon would be approximately 54 miles with volitional fishways. If trap and haul were implemented to actively transport coho salmon migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat. The estimate of 54 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[197], reduced in some part for the propensity of coho salmon to remain in lower gradient habitat than steelhead (DOI 2007), habitat in the bypass reaches, and the continued inundation of approximately 22 miles of spawning and rearing habitat by the Lower Klamath Project reservoirs (Cunanan 2009). The upstream boundary of critical habitat for coho salmon in the Klamath Basin is Iron Gate Dam; any newly accessible areas would be outside of their currently designated critical habitat. NMFS may want to consider including the newly accessible reaches as critical habitat as part of their 5-year status review or in a separate decision (J. Simondet, NOAA Fisheries Service, pers. comm., 2011). The areas inundated by the reservoirs would not provide suitable spawning or rearing habitat for coho salmon, but coho salmon would regain access to the riverine reaches on the mainstem and to the tributaries, although the downstream ends of most of the tributaries would remain inundated by the reservoirs. It is anticipated that adults will migrate upstream through inundated reservoir habitat, and that juveniles will migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*.

[197] This also takes into consideration slight differences in the Administrative Law Judge (2006) definition of the Project Reach from what is used in this report.

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through elimination of peaking operation flows and increased base flows.

Water temperatures would continue to be seasonally affected by the reservoirs. Similar to existing conditions, temperatures would be warmer in the summer and fall when adults are migrating upstream and may pose a degree of seasonal risk to adult that are located downstream from Iron Gate Dam, migrating within reservoirs or in bypass reaches. As under existing conditions, this thermal stress may continue to contribute to coho salmon being more susceptible to disease downstream of Iron Gate Dam. Relative to existing conditions, the slight decreases in long-term maximum summer/fall water temperatures and less artificial diel temperature variation in the J.C. Boyle Peaking Reach would return the river to a more natural thermal regime (see also Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1).

As described above in Section 4.4.3.4 *Fish Disease and Parasites*, overall incidence of fish disease in salmon under the Continued Operations with Fish Passage Alternative may be reduced but is unlikely to be eliminated.

In terms of Primary Constituent Elements (PCEs) of coho salmon critical habitat, this alternative would provide access to additional spawning habitat upstream of currently designated critical habitat, including in Fall, Jenny, Shovel, and Spencer creeks, although the downstream ends of these streams would continue to be inundated by the reservoirs and would not provide suitable spawning or rearing habitat. Delay, injury, and mortality could occur for upstream migrating adults, and downstream migrating juveniles. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be approximately 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs and spawned in Fall or Jenny creeks for example, would have much lower morality (e.g., 10 percent for adults, FERC 2007). The same is true for downstream migrating juveniles; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality.

The food resources in these tributaries would also become available to fry and juvenile coho salmon rearing in those streams. Despite the modest water quality improvements achieved to date through implementation of actions contained within PacifiCorp’s Reservoir Management Plan (see also Section 4.4.2 *Water Quality*), there is currently no reasonable proposal to achieve water quality standards important to coho salmon within or downstream of the Hydroelectric Reach. Based on the current designation of critical habitat, the effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for coho salmon critical habitat in the short term and long term.

Significance

No significant impact to coho salmon critical habitat in the short term and long term

Potential Impact 4.2.3-2 Effects on Southern Resident Killer Whale critical habitat quality due to alterations to salmon populations due to continued operations of the Lower Klamath Project.

Klamath River contributes to critical habitat for Southern Resident Killer Whales through its contribution of salmon to their food supply (included as a PCE). The Continued Operations with Fish Passage Alternative would not affect the geographic extent of critical habitat for this species, as it is located in the state of Washington. Implementation of this alternative is expected to increase production of salmon (as described in Potential Impacts 4.2.3-7, 4.2.3-8, and 4.2.3-9), which could increase food supply for Southern Resident Killer Whales. However, data on the Southern Resident Killer Whale diet indicate that based on the migratory range and behavior of the population, the Klamath River salmon are anticipated to provide less than one percent of the diet of Southern Resident Killer Whales in most months under current and future conditions. While Southern Resident Killer Whales have been shown to consume Klamath River Chinook salmon, the Klamath River is considered by NMFS and Washington Department of Fish and Wildlife (WDFW) tenth out of the top ten priority Chinook salmon populations for Southern Resident Killer Whales (NMFS 2018b, NMFS and WDFW 2018). Under this alternative, Iron Gate Hatchery would continue to operate and target existing production levels of hatchery Chinook salmon and contribution to ocean stocks. Due to the low proportion of the Sothern Resident Killer Whale diet being composed of Klamath River salmon, the Continued Operations with Fish Passage Alternative would result in no significant impact in the short term and long term.

<u>Significance</u>

No significant impact to Southern Resident Killer Whale critical habitat in the short term and long term

Potential Impact 4.2.3-3 Effects on eulachon critical habitat quality due to continued operations of the Lower Klamath Project.

Implementation of the Continued Operations with Fish Passage Alternative would not affect eulachon critical habitat. The Continued Operations with Fish Passage Alternative would not cause an alteration to habitat conditions in the Klamath River Estuary and Pacific Ocean nearshore environment compared to the existing conditions.

<u>Significance</u>

No significant impact to eulachon critical habitat in the short term and long term

Potential Impact 4.2.3-4 Effects on Chinook and coho salmon Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.

Implementation of the Continued Operations with Fish Passage Alternative would increase habitat for Chinook and coho salmon (upstream of currently designated EFH) by providing access to habitat upstream of Iron Gate Dam. As described above for Potential Impact 4.2.3-1, water quality, sediment dynamics, and fish disease affecting EFH would not change substantially from the existing conditions detailed in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project*. Under this alternative, designated EFH for Chinook and coho salmon would be expected to remain similar to its current condition, as described for existing conditions (Section 3.3.2.1 *Aquatic Species*). The effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for Chinook and coho salmon designated EFH in the short term and long term.

Significance
No significant impact for Chinook and coho salmon EFH in the short term and long term

Potential Impact 4.2.3-5 Effects on groundfish Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.
Implementation of the Continued Operations with Fish Passage Alternative would not affect groundfish EFH. Habitat conditions within the estuary and nearshore environment would not be altered as result of this alternative. The effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for groundfish EFH in the short term and long term.

Significance
No significant impact to groundfish EFH in the short term and long term

Potential Impact 4.2.3-6 Effects on pelagic fish Essential Fish Habitat (EFH) quality due to continued operations of the Lower Klamath Project.
Implementation of the Continued Operations with Fish Passage Alternative would not affect pelagic fish EFH. Habitat conditions within the estuary and nearshore environment would not be altered as result of this alternative. The effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for pelagic fish EFH in the short term and long term.

Significance
No significant impact to pelagic fish EFH in the short term and long term

Potential Impact 4.2.3-7 Effects on the fall-run Chinook salmon population due to continued operations of the Lower Klamath Project.
Upper Klamath River and Connected Waterbodies
Under the Continued Operations with Fish Passage Alternative, fish passage facilities installed at the Lower Klamath Project dams within the Hydroelectric Reach would allow fall-run Chinook salmon to regain access to 360 miles of habitat upstream of J.C. Boyle Reservoir. The access would expand the Chinook salmon's current habitat to include historical habitat along the mainstem Klamath River upstream to the Sprague, Williamson, and Wood rivers (Hamilton et al. 2005, Hamilton et al. 2016). This would be a potential increase in access to 49 significant tributaries in the Upper Klamath Basin, comprising hundreds of miles of additional potentially productive habitat (DOI 2007), including access to groundwater discharge areas relatively resistant to effects of climate change (Hamilton et al. 2011).

Water quality problems (e.g., excessive water temperatures and low dissolved oxygen) that currently occur in the Keno Impoundment/Lake Ewauna during late spring, summer, and early autumn, may challenge fall-run Chinook salmon accessing these areas under the Continued Operations with Fish Passage Alternative. As discussed under Section 3.3.5.3 *Water Quality*, the Keno Impoundment/Lake Ewuana has the potential to be a habitat barrier during most years for fall-run Chinook due to poor water quality during the late summer, and therefore NMFS and USFWS have prescribed fish passage measures for the Keno Impoundment/Lake Ewuana to be used during periods of poor water quality (DOI 2007). If fish passage were not provided, fall-run Chinook salmon would be limited to the additional habitat access in the Hydroelectric Reach, as described in detail below. While seasonal dissolved oxygen in the Keno Impoundment/Lake Ewauna would be expected to improve in furtherance of TMDL implementation throughout the Upper

Klamath Basin, it would be speculative at this point to identify either the mechanisms necessary to fully implement the TMDLs or the timing required to achieve full compliance, thus this EIR assumes that trap and haul around the Keno Impoundment/Lake Ewauna would be needed in years of poor water quality for fish to be able to access habitat upstream of Keno Dam.

Implementation of the Continued Operations with Fish Passage Alternative would result in no change from existing conditions for suspended sediments or bedload sediment, flow-related habitat, or algal toxins and disease in this reach.

Upper Klamath River – Hydroelectric Reach

Implementation of the Continued Operations with Fish Passage Alternative would restore fall-run Chinook salmon access to the Hydroelectric Reach by providing fishways associated with each of the Lower Klamath Project dams. Available habitat for fall-run Chinook salmon would be approximately 54 miles with volitional fishways. However, low DO and high-water temperatures in Iron Gate and Copco No. 1 reservoirs would likely limit upstream migration of fall-run Chinook salmon during the peak of their migration (as described in Section 4.4.3.3 *Water Quality*), potentially limiting their access to habitat upstream of Iron Gate Dam, unless migrating fish are able to remain within a water depth shallow enough to provide suitable dissolved oxygen and deep enough to avoid unsuitable water temperatures. If trap and haul were implemented to actively transport fall-run Chinook salmon migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat. The estimate of 54 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[198], reduced in some part for the propensity of fall-run Chinook salmon to remain in lower gradient habitat than steelhead (DOI 2007), habitat in the bypass reaches, and the continued inundation of approximately 22 miles of spawning and rearing habitat by Lower Klamath Project reservoirs (Cunanan 2009). It is anticipated juveniles would migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be approximately 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality in the reach.

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through elimination of peaking operation flows and increased base flows. Under this alternative, the expected overall higher flow releases would result in more reservoir water entering the J.C. Boyle Bypass Reach and correspondingly warmer water temperatures during summer and early fall, and cooler temperatures in late fall and winter. These effects would be similar to those under the Proposed Project and would move this short reach away from consistently cooler water temperatures during summer and early fall months; however, fishways would provide access to thermal refugia created by 200 to 250 cfs of spring flow accretion in the J.C.

198 This also takes into consideration slight differences in the Administrative Law Judge (2006) definition of the Project Reach from what is used in this report.

Boyle Bypass Reach (DOI 2007, FERC 2007). Under this alternative, suspended and bedload sediment, water quality, and algal toxins would be the same as under existing conditions.

Under this alternative fish migrating through reservoirs would be seasonally exposed to some degree to stressful water quality conditions including high temperatures in reservoir surface layers with low dissolved oxygen in reservoir surface layers in the summer and fall, changes in dissolved oxygen, pH, and ammonia associated with algal blooms, and exposure to microcystin from *Microcystis aeruginosa* blooms (Dunsmoor and Huntington 2006, FERC 2007). These conditions can become stressful in June through September, contributing to lower resistance to disease seasonally. Based on the reservoir dynamics and the predator population that currently occurs therein, predation of outmigrating salmonids above Iron Gate Dam is anticipated to be low (NMFS 2006a). In restoration efforts elsewhere in the Pacific Northwest, anadromous juveniles successfully pass through reservoirs under similarly difficult circumstances (NMFS 2006a).

The amount of time required for the fall-run Chinook salmon population to reach capacity under this alternative would be a function of adult returns that recolonize new habitat. Recolonization success and rate is a function of fish straying into newly available habitats (Pess 2009). For Chinook salmon, stray rates are approximately six percent (Hendry et al. 2004), and 95 percent of strays migrate less than 20 miles from their natal area (Quinn and Fresh 1984, Quinn et al. 1991). However, following major changes in environmental conditions (e.g., dam removal, high SSC), salmonid stray rates have been observed to increase above these average levels. The time period of colonization (historical or new habitat) has been reported to occur within five to thirty years, with most falling between one to two decades (Withler 1982, Bryant 1999, Burger et al 2000, Glen 2002, Pess et al. 2003, Milner et al. 2008, Kiffney et al. 2009). Rapid (less than one year) recolonization was observed for fall-run Chinook salmon following fish ladder installation at Landsburg Dam on the Cedar River, Washington (Kiffney et al. 2009). A ladder was placed on the Landsburg Dam in 2003, and Chinook salmon immediately (i.e., the first fall following ladder installation) accessed areas upstream of the dam, with juveniles being observed during snorkel surveys the following year. By 2011, Chinook salmon occurred throughout nearly all accessible habitat upstream of the dam. It is likely that under this alternative fall-run Chinook salmon would recolonize newly accessible habitat.

Middle and Lower Klamath River

Under the Continued Operations with Fish Passage Alternative, suspended sediment downstream of Iron Gate dam would be the same as described under existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Suspended Sediment]*). Lower Klamath Project dams would continue to trap fine and coarse sediment. The channel directly downstream from Iron Gate Dam would continue to be starved of fine sediment (leading to coarsening of the bed), but the effect would gradually decrease in the downstream direction as coarse sediment would be resupplied by tributary inputs (Hetrick et al. 2009, Stillwater Sciences 2010a). Coarsening of the bed could reduce spawning habitat for fall-run Chinook salmon downstream from the dam over time, but this impact would be limited to the area upstream of Cottonwood Creek. Rearing habitat would be expected to remain similar to existing conditions.

Under the Continued Operations with Fish Passage Alternative, the Lower Klamath River downstream from Iron Gate Dam reach would continue to have seasonally poor water quality because of the continued presence of the reservoirs with their increased hydraulic residence time and thermal mass (Section 3.2.2.2 *Water Temperature*). The continuation of warm water releases from Iron Gate Dam would contribute to delay adult upstream migration of fall-run Chinook salmon (Dunsmoor and Huntington 2006) and increase the risk of mortality prior to spawning (Hamilton et al. 2011). PacifiCorp's Reservoir Management Plan actions, such as further development and use of an intake barrier/thermal curtain, may slightly reduce water temperatures downstream of Iron Gate Dam, but recent data indicate that only modest 1–2°C (1.8–3.6°F) water temperature improvement is possible using this approach (PacifiCorp 2017). Further, the maximum useable cool water volume in Copco No. 1 Reservoir in summer and the maximum volume of cold water (8°C or less) in Iron Gate Reservoir in summer are limited, such that selective withdrawal from the reservoirs would be anticipated to decrease water temperatures immediately downstream of Iron Gate Dam by only 1 to 2°C in late summer/early fall. PacifiCorp has also noted that the water supply for Iron Gate Hatchery withdraws cold water from the deeper portion of Iron Gate Reservoir, and depleting or exhausting this cold water pool during the summer would have effects on the hatchery that would need to be addressed (PacifiCorp 2014) (see also discussion under Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1).

As described above in Section 4.4.3.4 *Fish Disease and Parasites*, overall incidence of fish disease in salmon under the Continued Operations with Fish Passage Alternative may be reduced but is unlikely to be eliminated.

Despite modest improvements in dissolved oxygen concentrations from implementation of actions contained within the Reservoir Management Plan (i.e., turbine venting system at Iron Gate Dam; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1 and Appendix C – *Section C.4.2*), dissolved oxygen concentrations during August through October immediately downstream from Iron Gate Dam would continue to be low (less than 85 percent saturation during August through September and 90 percent saturation from October and November (see Section 3.2.2.5 *Dissolved Oxygen*). In addition, the presence of microcystin, associated with the dense blooms of *Microcystis aeruginosa* in Iron Gate and Copco reservoirs, would continue to occur downstream from Iron Gate Dam, as there is currently no reasonable proposal that would decrease periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs to concentrations that would not exceed water quality standards (see also Potential Impact 4.2.2-7).

Klamath River Estuary and Pacific Ocean Nearshore Environment

Habitat conditions within the estuary and nearshore environment would not be altered as result of this alternative. The Continued Operations with Fish Passage Alternative is not expected to substantially alter fall-run Chinook salmon estuarine habitat.

Summary

In the short term, there would be no impact (no change relative to existing conditions) for fall-run Chinook salmon populations from the habitat attributes that would be anticipated to affect the population within a short (i.e., less than five years) time frame.

In the long term (i.e., more than five years*)*, under this alternative, fish passage would result in alterations in habitat availability for fall-run Chinook salmon. However, low DO and high-water temperatures in Iron Gate and Copco No. 1 reservoirs would likely limit upstream migration of fall-run Chinook salmon during the peak of their migration (as described in Section 4.4.3.3 *Water Quality*), potentially limiting their access to habitat upstream of Iron Gate Dam if fish passage was provided by volitional fishways rather than trap and haul, unless migrating fish are able to remain within a water depth shallow enough to provide suitable dissolved oxygen and deep enough to avoid unsuitable water temperatures. In addition, if fish passage is not provided a Keno Impoundment/Lake Ewuana, restored habitat access to the Hydroelectric Reach would be beneficial for fall-run Chinook salmon in the long term. If fish passage were provided at Keno (per DOI [2007] fish passage prescriptions), an even greater magnitude of restored habitat access to the Upper Klamath River Basin. Mortality could occur for migrants from passage through fishways, and from migration through Lower Klamath Project reservoirs.

This alternative would result in continuation of some of the stresses that currently affect Chinook salmon populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist. Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, although there is currently no reasonable proposal to improve water temperatures towards full support of cold freshwater habitat (COLD) (Section 4.4.2 *Water Quality*). These reservoir-related conditions would continue to have negative effects on fall-run Chinook salmon populations, as compared to a without-dams scenario under the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-7). The overall effect of the Continued Operations with Fish Passage Alternative on fish disease may be slightly improved but is unlikely to be substantially altered from existing conditions.

It is anticipated that increased habitat availability as a result of the Continued Operations with Fish Passage Alternative the fall-run Chinook salmon population within the Klamath River watershed would have an increase in abundance, population spatial structure, and genetic diversity if fish passage were to be provided by trap and haul rather than volitional fishways. Out-migrating smolts would continue to be subject to deleterious effects downstream from Iron Gate Dam. While the degree of harm may be reduced, the types of effects would be continued as under the existing condition. If fish passage were provided that avoided water quality barriers to adult upstream migration (i.e., trap and haul), increases in abundance, population spatial structure, and genetic diversity would confer greater population-level benefits than the expected mortality within the fishways, resulting in overall increases in the viability for fall-run Chinook salmon in the long term.

<u>Significance</u>

No significant impact for fall-run Chinook salmon in the short term

Beneficial for fall-run Chinook salmon in the long term

Potential Impact 4.2.3-8 Effects on the spring-run Chinook salmon population due to continued operations of the Lower Klamath Project.

Upper Klamath River and Connected Waterbodies

Under the Continued Operations with Fish Passage Alternative, fish passage facilities installed at the Lower Klamath Project dams within the Hydroelectric Reach would allow spring-run Chinook salmon to regain access to 360 miles of habitat in the upper Klamath River upstream of J.C. Boyle Reservoir. The access would expand the Chinook salmon's current habitat to include historical habitat along the mainstem Klamath River upstream to the Sprague, Williamson, and Wood rivers (Hamilton et al. 2005, Butler et al. 2010, Hamilton et al. 2016). Huntington (2006) reasoned that spring-run Chinook salmon likely accounted for the majority of the Upper Klamath Basin's actual salmon production under historical conditions. Overall, the Continued Operations with Fish Passage Alternative would provide spring-run Chinook access to 49 significant tributaries in the Upper Klamath Basin, comprising hundreds of miles of additional potentially productive anadromous fish habitat upstream of Iron Gate Dam (DOI 2007), including access to important thermal refugia within areas influenced by groundwater exchange that are more resistant to climate change (Hamilton et al. 2011). Some of these areas, such as the lower Williamson River, have habitat that would provide substantial holding areas for spring-run Chinook salmon (Hamilton et al. 2011). Other holding areas with suitable temperatures upstream of J.C. Boyle Reservoir include groundwater influenced areas on the west side of Upper Klamath Lake, and the Wood River (Gannett et al. 2007).

Poor water quality (e.g., severe hypoxia, temperatures exceeding 77°F, high pH) in the reach from Keno Dam to Link Dam might impede volitional fish passage at any time from late June through mid-November (Sullivan et al. 2009, USGS 2010; both as cited in Hamilton et al. 2011). However, available information indicates that Upper Klamath Lake habitat is presently suitable to support Chinook salmon for at least the period from October through May (Maule et al. 2009). Currently, adult spring-run Chinook migration takes place in approximately April through June. Historically, adult spring-run Chinook salmon migrated upstream of the current location of Iron Gate Dam perhaps as early as February and March (Fortune et al. 1966) and likely held over in large holding pools in the mainstem in tributaries fed by cool water, and in thermal refuge habitat upstream of Upper Klamath Lake (Snyder 1931, CDFG 1990c, Moyle 2002). One benefit of such early migration (similar to the spring-run Chinook salmon migration timing currently observed in the Klamath Basin) would be the avoidance of periods of poor water quality in the vicinity of Keno Impoundment/Lake Ewuana. Under the current migration timing, most or all of the spring-run Chinook salmon migrants would be able to pass upstream through the Keno Impoundment/Lake Ewuana area before seasonal water quality reductions would make passage restricted.

Upper Klamath River – Hydroelectric Reach

Implementation of the Continued Operations with Fish Passage Alternative would restore spring-run Chinook salmon access to the Hydroelectric Reach by providing fishways associated with each of the Lower Klamath Project dams. Available habitat for spring-run Chinook salmon would be approximately 54 miles with volitional fishways. (If trap and haul were implemented to actively transport spring-run Chinook salmon migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat.) The estimate of 54 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[199], reduced in some part for the propensity of spring-run Chinook salmon to remain in lower gradient habitat than steelhead (DOI 2007), habitat in the bypass reaches, and the continuation of approximately 22 miles of spawning and rearing habitat inundated by Lower Klamath Project reservoirs (Cunanan 2009). It is anticipated that adults will migrate upstream through inundated reservoir habitat, and that juveniles will migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be approximately 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007). As mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs and spawned in Fall or Jenny creeks for example, would have much lower morality (e.g., 10 percent for adults, FERC 2007). The same is true for downstream migrating juveniles; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality.

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through reduced (but not eliminated) peaking operations and increasing base flows. Under this alternative, the expected overall higher flow releases than under current conditions would result in more reservoir water entering the J.C. Boyle Bypass Reach and correspondingly warmer water temperatures during summer and early fall, and cooler temperatures in late fall and winter. These effects would be similar to those under the Proposed Project and would move this short reach away from the existing condition of consistently cooler water temperatures during summer and early fall months; however, passage structures would provide fish with some refuge from high temperatures due to access to cooler water from tributaries, in addition to that provided by 200 to 250 cfs of accretion from springs in the J.C. Boyle Bypass Reach (DOI 2007, FERC 2007, Hamilton et al. 2011). With the construction of fish passage facilities, flows and access would also be restored to the 1.4-mile Copco No. 2 Bypass Reach. Under this alternative, suspended and bedload sediment, water quality, and the occurrence of fish disease and algal toxins would be the same as under existing conditions.

This alternative would result in continuation of some of the stresses that currently affect Chinook salmon populations. The presence of J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist within reservoirs. Adult spring-run Chinook salmon in the Klamath River migrate upstream from April through June (and possibly earlier, Fortune et al. 1966), and most juveniles migrate from April through May or in the fall, as flows increase. Therefore, poor water quality in reservoirs is expected to have minor effects on this species, and only at the early and late ends of migration periods, outside peak migration times.

199 This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

There are a few basic mechanisms by which spring-run Chinook salmon could recolonize newly accessible habitat, including: (1) straying of adults, (2) adaptation of fall-run Chinook salmon to an early spring-run Chinook salmon life history, or (3) active reintroduction of spring-run Chinook salmon from another population. There are many examples of spring-run Chinook salmon rapidly recolonizing newly accessible habitat discussed in Potential Impact 4.2.3-7 above, and spring-run Chinook salmon were observed recolonizing habitat in the White Salmon River, Washington, following removal of Condit Dam (Allen et al. 2016). Following the removal of Condit Dam most of the observed spring-run Chinook salmon spawning was upstream of the location of the former Condit Dam. The current spring-run Chinook salmon abundance in the Salmon River is low (Table 3.3-10), and the rate of recolonization could be slow as a result.

The potential for adaptation of fall-run Chinook salmon to a spring-run Chinook salmon life history was assessed by Thompson et al. (2018), and they concluded that based on the genetics of the fall-run Chinook salmon currently downstream of Iron Gate Dam, it was unlikely that this would occur. Active reintroduction of Chinook salmon with genetics suited to adapt to an early spring-run Chinook salmon life history may be successful strategy for recolonization (Thompson et al. 2018). The Continued Operations with Fish Passage Alternative does not include an active reintroduction plan, although ODFW has been considering implementing active reintroduction of spring-run Chinook salmon following dam removal (T. Wise, ODFW, pers. comm., 2018). Such a strategy could be considered under this alternative as well.

Middle and Lower Klamath River

Under the Continued Operations with Fish Passage Alternative, suspended sediment downstream of Iron Gate Dam would be the same as described under existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Suspended Sediment]*). Lower Klamath Project dams would continue to trap fine and coarse sediment. The channel directly downstream from Iron Gate Dam would continue to be starved of fine sediment (leading to coarsening of the bed), but the effect would gradually decrease in the downstream direction as coarse sediment would be resupplied by tributary inputs (Hetrick et al. 2009, Stillwater Sciences 2010a).

Under the Continued Operations with Fish Passage Alternative, the Klamath River downstream from Iron Gate Dam would continue to have seasonally poor water quality related to temperature because of the continued presence of the reservoirs, with their increased hydraulic residence time and thermal mass (Section 3.2.2.2 *Water Temperature*). There is currently no reasonable proposal to achieve the temperature allocations in the Klamath TMDLs with the Lower Klamath Project dams remaining in place, despite the modest improvements achieved to date through implementation of actions contained within PacifiCorp's Reservoir Management Plan (see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1). Under this alternative, the current phase shift and lack of temporal temperature diversity will persist, including current warm temperatures in late summer and fall (Hamilton et al. 2011). Juveniles and adult migrants would continue to experience warm temperatures in late summer and fall that could be deleterious to health and survival, including increased risk of disease, and high rates of delayed spawning and pre-spawn mortality (Hetrick et al. 2009). These effects would be most pronounced for fish migrating through areas upstream of the Scott River, because tributary contributions dampen the temperature effect of the dams further downstream, as discussed in Section 3.2.2.2 *Water Temperature*.

As described above in Section 4.4.3.4 *Fish Disease and Parasites*, overall incidence of fish disease for spring-run Chinook salmon migrating from newly accessible habitat upstream of Iron Gate Dam under the Continued Operations with Fish Passage Alternative may be reduced but is unlikely to be eliminated.

Despite modest improvements in dissolved oxygen concentrations from implementation of actions contained within the Reservoir Management Plan (i.e., turbine venting system at Iron Gate Dam; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1 and Appendix C – *Section C.4.2*), dissolved oxygen concentrations during August through October immediately downstream from Iron Gate Dam would continue to be low (less than 85 percent saturation during August through September and 90 percent saturation from October and November (see Section 3.2.2.5 *Dissolved Oxygen*). In addition, the presence of microcystin, associated with the dense blooms of *Microcystis aeruginosa* in Iron Gate and Copco reservoirs, would continue to occur downstream from Iron Gate Dam, as there is currently no reasonable proposal that would decrease periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs to concentrations that would not exceed water quality standards (see also Potential Impact 4.2.2-7).

Klamath River Estuary and Pacific Ocean Nearshore Environment

The Continued Operations with Fish Passage Alternative is not expected to substantially alter spring-run Chinook salmon estuarine habitat.

Summary

In the short term, there would be no impact (no change relative to existing conditions) for spring-run Chinook salmon from the habitat attributes that would be anticipated to affect the population within a short (less than five years) time frame.

In the long term (more than five years), under this alternative, fishways could result in alterations in habitat availability for spring-run Chinook salmon. Under the Continued Operations with Fish Passage Alternative, spring-run Chinook salmon could regain access to approximately 414 miles of mainstem and tributary habitat in the upper Klamath River and Hydroelectric Reach, and thermal refugia within the Hydroelectric Reach, which would benefit the population. Mortality could occur for migrants from passage through fishways, and from migration through Lower Klamath Project reservoirs. The expansion of habitat opportunities will allow increased expression of life-history variation and the restoration of an additional population of spring-run Chinook salmon population to strengthen resiliency in the Klamath Basin, particularly because passage upstream of Iron Gate Dam would provide access to thermal refugia at groundwater areas (Hamilton et al. 2011).

Cool water temperatures (similar to existing conditions) during the spring would continue to benefit upstream migrating adult and downstream migrant juvenile spring-run Chinook salmon. Warm water temperatures in the fall would continue to be detrimental to juveniles and adults migrating at that time. These effects would be most pronounced for fish migrating through areas upstream of the Scott River.

This alternative would result in continuation of some of the stresses that currently affect Chinook salmon populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist. Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, although there is currently no reasonable proposal to improve water temperatures towards full support of cold freshwater habitat (COLD) (Section 4.4.2 *Water Quality*). These reservoir-related conditions would continue to have negative effects on spring-run Chinook salmon populations, as compared to a without-dams scenario under the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-8). The overall effect of the Continued Operations with Fish Passage Alternative on fish disease may be slightly improved but is unlikely to be substantially altered from existing conditions.

It is anticipated that increased habitat availability as a result of the Continued Operations with Fish Passage Alternative the spring-run Chinook salmon population within the Klamath River watershed would have an increase in abundance, population spatial structure, and genetic diversity. These increases would confer greater population-level benefits than the expected mortality within the fishways and upstream reservoirs, resulting in overall increases in the viability for spring-run Chinook salmon in the long term.

Significance

No significant impact for spring-run Chinook salmon in the short term

Beneficial for spring-run Chinook salmon in the long term

Potential Impact 4.2.3-9 Effects on coho salmon populations due to continued operations of the Lower Klamath Project.

Upper Klamath River and Connected Waterbodies

Available data suggest that coho salmon were in both mainstem and tributary reaches of the Klamath River upstream to and including Spencer Creek at RM 232.6 (Figure 3.3-1, NRC 2004, as cited in NMFS 2007a, Hamilton et al. 2005). It is not anticipated that under the Continued Operations with Fish Passage Alternative coho salmon would begin to occupy habitat within the Upper Klamath River and connected waterbodies, and therefore there would be no change from the existing condition.

Upper Klamath River – Hydroelectric Reach

Under the Continued Operations with Fish Passage Alternative, coho salmon would be able to access habitat in the Hydroelectric Reach by ascending the fishways associated with each of the dams. Available habitat for coho salmon would be approximately 54 miles with volitional fishways. If trap and haul were implemented to actively transport coho salmon migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat. The estimate of 54 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[200], reduced in some part for the propensity of coho salmon to remain in lower

[200] This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

gradient habitat than steelhead (DOI 2007), habitat in the bypass reaches, and the continuation of around 22 miles of spawning and rearing habitat inundated by Lower Klamath Project reservoirs (Cunanan 2009). It is anticipated that adults will migrate upstream through inundated reservoir habitat, and that juveniles will migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be around 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs and spawned in Fall or Jenny creeks for example, would have much lower morality (e.g., 10 percent for adults, FERC 2007). The same is true for downstream migrating juveniles; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality. Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007).

Coho salmon downstream from Iron Gate Dam belonging to the Upper Klamath River Population Unit would likely migrate above the dam if access was provided by fishways (NMFS 2006a). Over time, access to habitat above Iron Gate Dam would benefit the Upper Klamath River Population Unit by: (a) extending the range and distribution of the species thereby increasing the coho salmon's reproductive potential; (b) increasing genetic diversity in the coho stocks; (c) reducing the species' vulnerability to the impacts of degradation; and (d) increasing the abundance of the coho salmon population (NMFS 2006a).

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through reduced (but not eliminated) peaking operations and increasing base flows. Under this alternative, the expected overall higher flow releases would result in more reservoir water entering the J.C. Boyle Bypass Reach and correspondingly warmer water temperatures during summer and early fall, and cooler temperatures in late fall and winter. These effects would be similar to those under the Proposed Project and would move this short reach away from consistently cooler water temperatures during summer and early fall months; however, upstream passage would provide fish with some refuge from high temperatures because of access to cooler water from tributaries, in addition to the 200 to 250 cfs provided by coldwater springs in the J.C. Boyle Bypass Reach (DOI 2007, FERC 2007, Hamilton et al. 2011).

This alternative would result in continuation of some of the stresses that currently affect coho salmon populations. The presence of the Lower Klamath Project reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist within reservoirs. Although water temperature in the summer upstream of Iron Gate Dam is an issue, the available information shows that water temperature would not preclude coho salmon from successfully using the habitat within the Project Area while the Lower Klamath Project dams are in place (NMFS 2006a). Adult coho salmon enter the Klamath River between late September and mid-December, with peak upstream migration occurring between late October and mid-November, and juvenile coho outmigrate to the ocean beginning in late February, with most outmigration occurring in

April and May. As such, poor water quality (e.g., high water temperatures) in reservoirs would have minor effect on this species.

Under this alternative, suspended and bedload sediment, water quality, and the occurrence of algal toxins would be the same as under existing conditions.

Middle and Lower Klamath River

Under the Continued Operations with Fish Passage Alternative, suspended sediment downstream of Iron Gate Dam would be the same as described under existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Suspended Sediment]*). Lower Klamath Project dams would continue to trap fine and coarse sediment. The channel directly downstream from Iron Gate Dam would continue to be starved of fine sediment (leading to coarsening of the bed), but the effect would gradually decrease in the downstream direction as coarse sediment would be resupplied by tributary inputs (Hetrick et al. 2009, Stillwater Sciences 2010a). Most coho salmon spawning and rearing takes place within tributaries. Coarsening of the bed could reduce spawning habitat between Iron Gate Dam and Cottonwood Creek over time, which would have little effect on coho salmon except for the few coho salmon from the Upper Klamath River Population Unit that spawn in the mainstem downstream of Iron Gate Dam. Rearing habitat would be expected to remain similar to existing conditions.

Under the Continued Operations with Fish Passage Alternative, the Lower Klamath River downstream from Iron Gate Dam would continue to have seasonally poor water quality related to temperature because of the continued presence of the reservoirs, with their increased hydraulic residence time and thermal mass (Section 3.2.2.2 *Water Temperature*). PacifiCorp's Reservoir Management Plan actions, such as further development and use of an intake barrier/thermal curtain, may slightly reduce water temperatures downstream of Iron Gate Dam, but recent data indicate that only modest 1–2°C (1.8–3.6°F) water temperature improvement is possible using this approach (PacifiCorp 2017). Further, the maximum useable cool water volume in Copco No. 1 Reservoir in summer and the maximum volume of cold water (8°C or less) in Iron Gate Reservoir in summer are limited, such that selective withdrawal from the reservoirs would be anticipated to decrease water temperatures immediately downstream of Iron Gate Dam by only 1 to 2°C in late summer/early fall. PacifiCorp has also noted that the water supply for Iron Gate Hatchery withdraws cold water from the deeper portion of Iron Gate Reservoir, and depleting or exhausting this cold water pool during the summer would have effects on the hatchery that would need to be addressed (PacifiCorp 2014) (see also discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1).

As described above in Section 4.4.3.4 *Fish Disease and Parasites*, overall incidence of fish disease for coho salmon under the Continued Operations with Fish Passage Alternative may be reduced but is unlikely to be eliminated.

Despite modest improvements in dissolved oxygen concentrations from implementation of actions contained within the Reservoir Management Plan (i.e., turbine venting system at Iron Gate Dam; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1 and Appendix C – *Section C.4.2*), dissolved oxygen concentrations during August through October immediately downstream from Iron Gate Dam would continue to be low (less than 85 percent saturation during August through September and 90 percent saturation from October and November (see Section 3.2.2.5 *Dissolved Oxygen*). In addition, the presence of microcystin, associated with the dense blooms of *Microcystis aeruginosa* in Iron Gate and Copco reservoirs, would continue to occur downstream from Iron Gate Dam, as there is currently no reasonable proposal that would decrease periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs to concentrations that would not exceed water quality standards (see also Potential Impact 4.2.2-7).

Klamath River Estuary and Pacific Ocean Nearshore Environment
The Continued Operations with Fish Passage Alternative is not expected to substantially alter habitat in the estuary, and thus there would be no impact on coho salmon rearing in the estuary.

Summary
In the short term, there would be no impact (no change relative to existing conditions) for coho salmon from the habitat attributes that would be anticipated to affect the population within a short less than five years) time frame.

In the long term (more than five years), the Continued Operations with Fish Passage Alternative could result in alterations in habitat availability which could affect coho salmon. Under the Continued Operations with Fish Passage Alternative, coho salmon would regain access to approximately 54 miles (or 25 miles if trap and haul were used) of mainstem and tributary habitat in the upper Klamath River and Hydroelectric Reach, and thermal refugia within the Hydroelectric Reach, which would benefit the population. Mortality would occur for migrants from passage through fishways, and from migration through Lower Klamath Project reservoirs.

This alternative would result in continuation of some of the stresses that currently affect coho salmon populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, sediment and would continue to contribute to crowding (though to a lesser degree than under the current condition), allowing some conditions favorable for the transmission of fish disease to persist. Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, although there is currently no reasonable proposal to improve water temperatures towards full support of cold freshwater habitat (COLD) (Section 4.4.2 *Water Quality*). These reservoir-related conditions would continue to have negative effects on coho salmon populations, as compared to a without-dams scenario under the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-9). The overall effect on fish disease of the Continued Operations with Fish Passage Alternative is likely to improve somewhat but is unlikely to be substantially altered from existing conditions.

Despite the continuation of poor conditions for coho salmon downstream of Iron Gate Dam, the Continued Operations with Fish Passage Alternative would benefit the Upper Klamath River Coho Salmon Population Unit (described in Section 3.3.2.1 *Aquatic Species [coho salmon]*) by increasing habitat access. This population would experience a long-term increase in abundance, population spatial structure, and genetic diversity. These increases would confer greater population-level benefits than the expected mortality within the fishways, resulting in overall increases in the viability of coho salmon from the Upper Klamath River population unit in the long term. The Mid-Klamath River, Shasta River, Scott River, Salmon River population units would experience a continuation of existing effects, and the three Trinity River population units, and the Lower Klamath River population units would not be affected. Based on the continuation of existing conditions for populations downstream from Iron Gate Dam, this alternative would be no impact (no change from existing conditions) for the coho salmon from the Mid-Klamath River, Shasta River, Scott River, and Salmon River, three Trinity River population units, and the Lower Klamath River population units in the long term. Due to the benefit to the Upper Klamath River Population Unit, the Continued Operations with Fish Passage Alternative would provide an overall benefit to the Klamath River Basin coho salmon population in the long term.

Significance

No significant impact for coho salmon populations in the short term

Beneficial for coho salmon populations in the long term

Potential Impact 4.2.3-10 Effects on the steelhead population due to continued operations of the Lower Klamath Project.

Upper Klamath River and Connected Waterbodies

Under the Continued Operations with Fish Passage Alternative, steelhead would regain access to the Upper Klamath Basin upstream of J.C. Boyle Reservoir. This would expand the population's distribution to include historical habitat along the mainstem Klamath River upstream to the Sprague, Williamson, and Wood rivers (Hamilton et al. 2005). This would be a potential increase in access to 49 significant tributaries in the Upper Klamath Basin, comprising 360 miles of additional potentially productive habitat (Huntington 2006, DOI 2007, NMFS 2007a).

Water quality problems (e.g., excessive water temperatures and low dissolved oxygen) that currently occur in the Keno Impoundment/Lake Ewauna during late spring, summer, and early autumn, may challenge steelhead accessing these areas under the Continued Operations with Fish Passage Alternative. As discussed under Section 3.3.5.3 *Water Quality*, in some years poor water quality in the Keno Impoundment/Lake Ewuana reach may prevent the latest migrants of the summer steelhead run and the earlier migrants from the fall run from accessing upstream spawning habitat in these upper reaches. If no upstream trap and haul is provided at Keno, these fish would be likely to spawn in habitat downstream of Keno Dam in the Hydroelectric Reach (described below), or, in the case of fall-run steelhead, hold below the dam until conditions become passable. However, the majority of the summer steelhead adult migration, much of the fall-run adult steelhead migration, and all of the winter adult steelhead migration is anticipated to occur outside the mid-June to mid-November timeframe in which water quality in the Keno Impoundment/Lake Ewuana reach is typically so poor as to present a migration barrier to adult salmonids. Similarly, juvenile outmigration and run-backs also occur outside this timeframe. While seasonal dissolved oxygen in the Keno Impoundment/Lake Ewauna would be expected to improve in furtherance of TMDL implementation throughout the Upper Klamath Basin, it would be speculative at this point to identify either the mechanisms necessary to implement the TMDLs or the timing required to achieve full compliance, thus this EIR assumes that trap and haul around the Keno Impoundment/Lake Ewauna would be needed in years of poor water quality for fish to be able to access habitat upstream of Keno Dam.

This alternative would not result in changes to suspended or bedload sediment, flow-related habitat, or algal toxins in this reach.

Upper Klamath River – Hydroelectric Reach

Implementation of the Continued Operations with Fish Passage Alternative would restore steelhead access to the Hydroelectric Reach by providing fishways associated with each of the Lower Klamath Project dams. Available habitat for steelhead would be approximately 58 miles with volitional fishways. If trap and haul were implemented to actively transport steelhead migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat. The estimate of 58 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[201], habitat in the bypass reaches, and the continuation of around 22 miles of spawning and rearing habitat inundated by Lower Klamath Project reservoirs (Cunanan 2009). It is anticipated that adults will migrate upstream through inundated reservoir habitat, and that juveniles will migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be around 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs and spawned in Fall or Jenny creeks for example, would have much lower morality (e.g., 10 percent for adults, FERC 2007). The same is true for downstream migrating juveniles; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality.

It is likely that steelhead recolonization would occur rapidly, as was observed for similar steelhead populations following fish ladder installation at Landsburg Dam on the Cedar River, Washington (Kiffney et al. 2009), and following removal of Condit Dam on the White Salmon River, Washington (Allen et al. 2016).

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through reduced (but not eliminated) peaking operations and increased base flows, consistent with mandatory conditions (DOI 2007). Under this alternative, the expected overall higher flow releases would result in more reservoir water entering the J.C. Boyle Bypass Reach and correspondingly warmer water temperatures during summer and early fall, and cooler water temperatures in late fall and winter. Similar to the Proposed Project, the effect would be to increase water temperatures in the J.C. Boyle Bypass Reach during summer and early fall months relative to existing conditions.

Poor water quality conditions in reservoirs, such as high temperatures with low dissolved oxygen, fluctuations in dissolved oxygen, pH, ammonia associated with algal blooms, and microcystin from *Microcystis aeruginosa* blooms would continue to be stressful to fish from June through September (Dunsmoor and Huntington 2006, FERC 2007).

201 This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

Winter steelhead enter and migrate from August to March; thus, poor water quality could have an effect on these fish as they move through reservoirs. Steelhead generally spawn in tributaries, and juveniles typically outmigrate from April through November, but the peak migration occurs from April through June, so most individuals would be likely to avoid poor reservoir water quality.

Middle and Lower Klamath River

Under the Continued Operations with Fish Passage Alternative, suspended sediment downstream of Iron Gate Dam would be the same as described under existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Suspended Sediment]*). Lower Klamath Project dams would continue to trap fine and coarse sediment. The channel directly downstream from Iron Gate Dam would continue to be starved of fine sediment (leading to coarsening of the bed), but the effect would gradually decrease in the downstream direction as coarse sediment would be resupplied by tributary inputs (Hetrick et al. 2009, Stillwater Sciences 2010a). Current summer steelhead distribution extends from the mouth of the Klamath River upstream to Empire Creek, while winter steelhead are distributed throughout the Lower Klamath River up to Iron Gate Dam (Stillwater Sciences 2010b). Summer and winter steelhead do not spawn in the mainstem Klamath River, nor are they expected to in the future, so spawning habitat would not be affected by alterations to bedload composition downstream from Iron Gate Dam under the Continued Operations with Fish Passage Alternative. Changes to bedload sediment and effects on juvenile rearing and migration would be expected to remain similar to existing conditions.

As described above in Section 4.4.3.4 *Fish Disease and Parasites*, overall incidence of fish disease for steelhead under the Continued Operations with Fish Passage Alternative may be reduced but is unlikely to be eliminated.

Despite modest improvements in dissolved oxygen concentrations from implementation of actions contained within the Reservoir Management Plan (i.e., turbine venting system at Iron Gate Dam; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1 and Appendix C – *Section C.4.2*), dissolved oxygen concentrations during August through October immediately downstream from Iron Gate Dam would continue to be low (less than 85 percent saturation during August through September and 90 percent saturation from October and November (see Section 3.2.2.5 *Dissolved Oxygen*). In addition, the presence of microcystin, associated with the dense blooms of *Microcystis aeruginosa* in Iron Gate and Copco reservoirs, would continue to occur downstream from Iron Gate Dam, as there is currently no reasonable proposal that would decrease periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs to concentrations that would not exceed water quality standards (see also Potential Impact 4.2.2-7).

Klamath River Estuary and Pacific Nearshore Environment

The Continued Operations with Fish Passage Alternative is not expected to substantially alter steelhead estuarine habitat.

Summary

In the short term, there would be no impact (no change relative to existing conditions) for steelhead from the habitat attributes that would be anticipated to affect the population within a short (less than five years) time frame, such as substantial changes in suspended sediment like those predicted to occur under the Proposed Project (Section 3.3.5.1 *Suspended Sediment*).

In the long term (more than five years), under this alternative, fishways could result in alterations in habitat availability for steelhead. Under the Continued Operations with Fish Passage Alternative, steelhead could regain access to approximately 414 miles (or fewer if trap and haul were used) of mainstem and tributary habitat in the upper Klamath River and Hydroelectric Reach, and thermal refugia within the Hydroelectric Reach, which would benefit the population. FERC (2007) concluded that implementing fish passage would help to reduce adverse effects to steelhead associated with lost access to upstream spawning habitats. Hamilton et al. (2011) also concluded that access to additional habitat in the Upper Klamath River watershed would benefit steelhead runs. Mortality could occur for migrants from passage through fishways, and from migration through Lower Klamath Project reservoirs.

This alternative would result in continuation of some of the stresses that currently affect steelhead populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist (although steelhead are more resistant to *C. Shasta* than other salmonids). Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, although there is currently no reasonable proposal to improve water temperatures towards full support of cold freshwater habitat (COLD) (Section 4.4.2 *Water Quality*). These reservoir-related conditions would continue to have negative effects on steelhead populations, as compared to a without-dams scenario under the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-9). The overall effect of the Continued Operations with Fish Passage Alternative on fish disease may be slightly improved but is unlikely to be substantially altered from existing conditions.

It is anticipated that as a result of the increased habitat availability under the Continued Operations with Fish Passage Alternative, the summer and winter steelhead within the Klamath River watershed would have an increase in abundance, population spatial structure, and genetic diversity. These increases would confer greater population-level benefits than the expected mortality within the fishways, resulting in overall increases in the viability of summer and winter steelhead in the long term.

Significance

No significant impact for steelhead in the short term

Beneficial for steelhead in the long term

Potential Impact 4.2.3-11 Effects on the Pacific lamprey population due to continued operations of the Lower Klamath Project.

Upper Klamath River and Connected Waterbodies

Available data suggests that Pacific lamprey were in both mainstem and tributary reaches of the Klamath River upstream to and including Spencer Creek at RM 232.6 (Figure 3.3-1, Hamilton et al. 2005). It is not anticipated that under the Continued Operations with Fish Passage Alternative Pacific lamprey would begin to occupy habitat within the Upper Klamath River and connected waterbodies, and therefore there would be no change from the existing condition.

Upper Klamath River – Hydroelectric Reach

Under the Continued Operations with Fish Passage Alternative, Pacific lamprey would be able to access habitat in the Hydroelectric Reach by ascending the fishways associated with each of the dams. Available habitat for Pacific lamprey would be approximately 58 miles with volitional fishways. If trap and haul were implemented to actively transport Pacific lamprey migrants around the Lower Klamath Project reservoirs, there would be approximately 25 miles of newly accessible habitat. The estimate of 58 miles of additional habitat along the mainstem and within accessible tributaries is based on access to a maximum of 58 miles of anadromous fish (steelhead) habitat (NMFS 2006a)[202], habitat in the bypass reaches, and the continuation of around 22 miles of spawning and rearing habitat inundated by Lower Klamath Project reservoirs (Cunanan 2009). It is anticipated that adults will migrate upstream through inundated reservoir habitat, and that juveniles will migrate downstream with mortality from predation and poor water quality considered in the estimates of passage survival discussed in Section 4.4.3.7 *Fish Passage*. As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within fishways is predicted to be around 28 percent, and 58 percent for downstream migrating ammocoetes (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs and spawned in Fall or Jenny creeks for example, would have much lower morality (e.g., 10 percent for adults, FERC 2007). The same is true for downstream migrants; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality. Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007).

Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through reduced (but not eliminated) peaking operations and increased base flows. In addition, passage would provide Pacific lamprey with some refuge from high temperatures by allowing cooler tributaries to flow directly into the mainstem Klamath River, adding to the 200 to 250 cfs provided by coldwater springs in the J.C. Boyle Bypass Reach (DOI 2007, FERC 2007, Hamilton et al. 2011). Under this alternative, suspended and bedload sediment, water quality, water temperature, and the occurrence of algal toxins would continue to be the same as under existing conditions.

Poor water quality conditions in reservoirs, such as high temperatures with low dissolved oxygen, changes in dissolved oxygen, pH, and ammonia associated with algal blooms, and microcystin from *Microcystis aeruginosa* blooms would continue to be stressful from June to September (Dunsmoor and Huntington 2006, FERC 2007), although modest improvements in water quality are expected with continued implementation of Reservoir Management Plan actions (see Section 4.4.2 *Water Quality*). Pacific lamprey adults migrate from winter through spring, while juveniles (age 2 to age 10) outmigrate year-round, with peaks during late spring and fall. Seasonally poor reservoir quality would likely not affect migrating adults but could affect juveniles. Juveniles would be subject to

202 This also takes into consideration slight differences in the NMFS (2006a) definition of the Project Reach from what is used in this report.

some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch (FERC 2007).

Middle and Lower Klamath River

Under the Continued Operations with Fish Passage Alternative, suspended sediment downstream of Iron Gate Dam would be the same as described under existing conditions (Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project [Suspended Sediment]*). Lower Klamath Project dams would continue to trap fine and coarse sediment. The channel directly downstream from Iron Gate Dam would continue to be starved of fine sediment (leading to coarsening of the bed), but the effect would gradually decrease in the downstream direction as coarse sediment would be resupplied by tributary inputs (Hetrick et al. 2009, Stillwater Sciences 2010a). Spawning and rearing habitat for Pacific lamprey downstream of Iron Gate Dam would be expected to remain similar to existing conditions.

Despite modest improvements in dissolved oxygen concentrations from implementation of actions contained within the Reservoir Management Plan (i.e., turbine venting system at Iron Gate Dam; see discussion in Section 4.4.2.1 *[Continued Operations with Fish Passage] Water Temperature*, Potential Impact 4.2.2-1 and Appendix C – *Section C.4.2*), dissolved oxygen concentrations during August through October immediately downstream from Iron Gate Dam would continue to be low (less than 85 percent saturation during August through September and 90 percent saturation from October and November (see Section 3.2.2.5 *Dissolved Oxygen*). In addition, the presence of microcystin, associated with the dense blooms of *Microcystis aeruginosa* in Iron Gate and Copco reservoirs, would continue to occur downstream from Iron Gate Dam, as there is currently no reasonable proposal that would decrease periodically high algal toxin concentrations in the surface waters of Copco No. 1 and Iron Gate reservoirs to concentrations that would not exceed water quality standards (see also Potential Impact 4.2.2-7).

Klamath River Estuary and Pacific Ocean Nearshore Environment

The Continued Operations with Fish Passage Alternative is not expected to substantially alter Pacific lamprey estuarine habitat.

Summary

In the short term, there would be no impact (no change relative to existing conditions) for Pacific lamprey from the habitat attributes that would be anticipated to affect the population within a short (less than five years) time frame, such as substantial changes in suspended sediment like those predicted to occur under the Proposed Project (Section 3.3.5.1 *Suspended Sediment*).

In the long term (more than five years), under this alternative, fishways could result in alterations in habitat availability for Pacific lamprey. Under the Continued Operations with Fish Passage Alternative, Pacific lamprey would regain access to approximately 58 miles of mainstem and tributary habitat in the upper Klamath River and Hydroelectric Reach, and thermal refugia within the Hydroelectric Reach, which would benefit the population. FERC (2007) concluded that implementing fish passage would help to reduce adverse effects to Pacific lamprey associated with lost access to upstream spawning habitats. Mortality would occur for migrants from passage through fishways, and from migration through Lower Klamath Project reservoirs.

This alternative would result in continuation of some of the stresses that currently affect Pacific lamprey populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures. Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, although there is currently no reasonable proposal to improve water temperatures towards full support of cold freshwater habitat (COLD) (Section 4.4.2 *Water Quality*). These reservoir-related conditions would continue to have negative effects on Pacific lamprey populations, as compared to a without-dams scenario under the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-9).

It is anticipated that, as a result of the increased habitat availability under the Continued Operations with Fish Passage Alternative, the Pacific lamprey population within the Klamath River watershed would have an increase in abundance, population spatial structure, and genetic diversity (NMFS 2006a). These increases would confer greater population-level benefits than the expected mortality within the fishways, resulting in overall increases in the viability of Pacific lamprey in the long term.

Significance

No significant impact for Pacific lamprey in the short term

Beneficial for Pacific lamprey in the long term

Potential Impact 4.2.3-12 Effects on the green sturgeon population due to continued operations of the Lower Klamath Project.

Under the Continued Operations with Fish Passage Alternative, conditions in the area occupied by green sturgeon are unlikely to change relative to existing conditions as green sturgeon occur no further upstream than Ishi Pishi Falls, and this alternative does not have substantial effects relative to existing conditions that extend that far downstream (as described in Section 4.4.3.1 *Suspended Sediment* through Section 4.4.3.6 *Aquatic Habitat and Instream Flows*).

Significance

No significant impact for green sturgeon in the short term and long term

Potential Impact 4.2.3-13 Effects on Lost River and shortnose sucker populations due to continued operations of the Lower Klamath Project.

Under the Continued Operations with Fish Passage Alternative, shortnose and Lost River suckers would continue to be subject to seasonally poor water quality and high rates of predation from non-native fish species within Lower Klamath Project reservoirs, as described in Section 3.3.2.1 *Fish Species [Lost River and shortnose suckers]*. However, with little or no successful reproduction (Buettner et al. 2006), populations downstream from Keno Dam contribute minimally to conservation goals and insignificantly to recovery (Hamilton et al. 2011).

Under the Continued Operations with Fish Passage Alternative, Lost River and shortnose sucker would be able to migrate among habitats within Iron Gate, Copco No. 1, and J.C. Boyle Reservoirs. Since upstream migration at Keno Dam is currently possible to some degree with existing facilities (DOI 2007), suckers would potentially have migratory connectivity from the Lower Klamath Project reservoirs to Upper Klamath

Lake and connected waterbodies. Migratory opportunities may increase access to spawning habitat and increase the abundance and resiliency of the sucker populations (Buettner et al. 2006). However, Miller and Smith (1981) claimed that sucker hybridization was most pronounced in the Lower Klamath Project reservoirs, and Markle et al. (2005) reported hybridization between small scale sucker and both Lost River and shortnose suckers in the Hydroelectric Reach. Hybridization is considered by the sucker recovery plan (USFWS 2013) to be a predominate threat to the populations. Hybridization prompted Buettner et al. (2006) and others to caution against supporting migration of individuals from Iron Gate and Copco reservoirs into the Upper Klamath Lake population. If fish passage were to be provided, there is a potential deleterious effect on the population from increased hybridization (USFWS 2013). Under the Proposed Project, Aquatic Resource Measure AR-6 is included to rescue and salvage suckers from Lower Klamath Project reservoirs prior to their removal. However, AR-6 includes genetic testing for hybridization, and sucker salvage and release is to be only into waterbodies isolated from the Upper Klamath Lake Populations to prevent the risk of further hybridization. As the Continued Operations with Fish Passage Alternative would directly connect the reservoirs for fish, no such measures would be possible, and the risk of hybridization within the Upper Klamath Lake sucker population would be increased. No data are available to predict the extent of potential hybridization or whether it hybridization would have a long-term impact on the Lost River and shortnose sucker population. Overall, it is speculative to determine whether increased access to spawning habitat outweigh the increased risk of hybridization, or vice-versa.

The effect of the Continued Operations with Fish Passage Alternative would be no impact for Lost River and shortnose sucker populations in the short term and long term.

Significance

No significant impact for shortnose and Lost River suckers in the short term and long term

Potential Impact 4.2.3-14 Effects on the redband trout population due to continued operations of the Lower Klamath Project.

Upper Klamath River and Connected Waterbodies

Under existing conditions redband trout can migrate through a fish ladder at Keno Dam, and occasionally through a poorly functioning fish ladder at J.C. Boyle Dam (DOI 2007). Under the Continued Operations with Fish Passage Alternative, redband trout would be able to migrate more successfully from the Hydroelectric Reach to the Upper Klamath Basin (Hamilton et al. 2011) than under existing conditions. New fish passage facilities would improve access to Spencer Creek, which provides important spawning habitat and temperature refugia for redband trout (DOI 2007, Buchanan et al. 2011). New upstream fish passage would also improve connectivity of resident redband populations in the mainstem Klamath River to those in Lake Ewauna, the Link River, and Upper Klamath Lake (DOI 2007).

Redband trout under this alternative could be affected by the reintroduction of anadromous fish, including the potential for competition, predation, and exposure to disease, as described for the Proposed Project in Section 3.3.5.9.

Upper Klamath River – Hydroelectric Reach

Fish passage resulting from the Continued Operations with Fish Passage Alternative would allow redband trout to express the seasonal movements and migration patterns that were historically in place, restore population connectivity and genetic diversity, and allow greater use of existing habitat and refugia. Effective fishways at J.C. Boyle would greatly improve connectivity to Spencer Creek. Fish passage at Copco No. 1 and Copco No. 2 dams would restore connectivity throughout the Hydroelectric Reach to Shovel Creek, which provides spawning habitat and temperature refugia (DOI 2007). Passage at Iron Gate Dam would also restore connectivity between populations in the mainstem Klamath River and those in the Copco No. 2 Bypass Reach and in Slide, Scotch, Camp, Jenny, Salt, and Fall creeks, which also provide spawning habitat and temperature refugia (DOI 2007). The existing fish screen and ladder at the J.C. Boyle Dam do not meet current state and federal fish passage criteria and the ladder impairs upstream migration (Administrative Law Judge 2006). Improvements in efficiency to the fishway at J.C. Boyle Dam would result in significant trout population migration above the dam over time (Administrative Law Judge 2006). As described in Section 4.4.3.7 *Fish Passage*, upstream migrating adult mortality within all the fishways is predicted to be approximately 28 percent, and 58 percent for downstream migrating juveniles (FERC 2007). Since mortality estimates are cumulative assuming migration through all facilities past all dams and through all reservoirs, any upstream migrating adults that migrated past fewer facilities and reservoirs would have much lower morality. The same is true for downstream migrants; the fewer facilities and reservoirs required during downstream migration, the lower the cumulative mortality. This is especially true for redband trout, which may only migrate past one facility to gain access to spawning habitat, and thus may experience mortality during migration of less than 5 percent (FERC 2007). Increased production resulting from increased habitat access is anticipated to off-set losses from fish passage injury and mortality (FERC 2007).

Under the Continued Operations with Fish Passage Alternative, redband trout would continue to be subject to seasonally poor water quality and high rates of predation from non-native fish species within Lower Klamath Project reservoirs, as described in Section 3.3.2.1 *Fish Species [Redband trout]*. Habitat in the J.C. Boyle Bypass and Peaking reaches and the Copco No. 2 Bypass Reach would be improved through reduced (but not eliminated) peaking operations and increased base flows.

Summary

In the short term, there would be no meaningful impact (relative to existing conditions) for redband trout.

In the long term, fishways at the Lower Klamath Project dams and changes in operations could result in alterations in habitat availability and suitability which could affect redband trout. The Continued Operations with Fish Passage Alternative would improve habitat connectivity throughout the Hydroelectric Reach and to the upper Klamath River in the long term, increasing access to spawning habitat and temperature refugia. Redband trout would still be subject to seasonally poor water quality, and some level of predation within the reservoirs, but increases in connectivity and reduced effects of hydropower peaking operations would likely provide a benefit to redband trout populations. The habitat improvements and increased connectivity would confer greater population-level benefits than the expected mortality within the fishways, resulting in overall benefits to redband trout in the long term.

Significance

No significant impact for redband trout in the short term

Beneficial for redband trout in the long term

Potential Impact 4.2.3-15 Effects on the eulachon population due to continued operations of the Lower Klamath Project.

Under the Continued Operations with Fish Passage Alternative, the extent and quality of eulachon habitat would be expected to remain the same as existing conditions. As eulachon occur far downstream (more than 150 river miles downstream) in the river from the Hydroelectric Reach, mixing and inflows from intervening tributaries would continue to reduce seasonally poor water quality conditions originating in the Lower Klamath Project dams. The effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for eulachon in the short term and long term.

Significance

No significant impact for eulachon in the short term and long term

Potential Impact 4.2.3-16 Effects on the longfin smelt population due to continued operations of the Lower Klamath Project.

Under the Continued Operations with Fish Passage Alternative, the extent and quality of longfin smelt habitat would be expected to remain the same as existing conditions. As longfin smelt occur far downstream (more than 150 river miles downstream) in the river from the Hydroelectric Reach, mixing and inflows from intervening tributaries would continue to reduce seasonally poor water quality conditions originating in the Lower Klamath Project dams. The effect of the Continued Operations with Fish Passage Alternative would be no impact (no change from existing conditions) for longfin smelt in the short term and long term.

Significance

No significant impact for longfin smelt in the short term and long term

Potential Impact 4.2.3-17 Effects on species interactions between introduced resident fish species and native aquatic species due to continued operations of the Lower Klamath Project.

Introduced fish species threaten the diversity and abundance of native fish species through competition for resources, predation, interbreeding with native populations, and causing potential physical changes to the invaded habitat (Moyle 2002). Introduced resident species occur within reservoirs upstream of Iron Gate Dam, and infrequently downstream from Iron Gate Dam. . Adults yellow perch are opportunistic predators that feed on small fish, potentially including native fish species. Juvenile and adult largemouth bass tend to feed on larger invertebrates and fish as well, potentially including native species. Under the Continued Operations with Fish Passage Alternative, dams in the Hydroelectric Reach would not be removed, allowing reservoir habitat to remain the same as existing conditions. Additionally, anadromous fish that are now prevented from entering the reservoirs would be able to do so. However, connectivity between the reservoirs could increase access to available habitat area for introduced species as well as native species if they are able to migrate through volitional passage facilities. Migratory connectivity is more likely to increase the population abundance and resiliency of native species adapted to more riverine conditions, than reservoir-dependent non-natives. Juvenile native species migrating through reservoirs would be subject to some level of predation by introduced resident species resulting in mortality rates that would depend largely on their size (larger migrants would do better)

(NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018). Based on the reservoir dynamics and the predator population that currently occurs, predation of outmigrating salmonids above Iron Gate Dam is anticipated to be low (NMFS 2006a). In restoration efforts elsewhere in the Pacific Northwest, anadromous juveniles successfully pass through reservoirs under similarly difficult circumstances (NMFS 2006a). Overall, the effect of the Continued Operations with Fish Passage Alternative would be less than significant for the effects of introduced resident species on native aquatic species. If passage were provided through trap and haul, these interactions would be further reduced, as fewer juvenile anadromous fish would enter Copco No. 1, Copco No. 2 and Iron Gate reservoirs.

Significance

No significant impact for the effects of introduced resident species on native aquatic species

Potential Impact 4.2.3-18 Effects on aquatic species from interactions among fish species due to continued operations of the Lower Klamath Project.

The Continued Operations with Fish Passage Alternative would restore access for migratory fish species to habitat upstream of Iron Gate Dam, as described in detail above. As described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-18), restoration of access would result in Pacific lamprey, anadromous salmon, and steelhead potentially interacting with resident redband trout and bull trout, with the potential for competition and predation. These species evolved together in the Upper Klamath Basin of the Klamath River, and co-existed prior to the construction of dams (Goodman et al. 2011).

Anadromous salmonids currently co-exist with resident rainbow trout and resident cutthroat trout downstream from Iron Gate Dam, without any obvious detriment to these native species or the aquatic ecosystem in which they reside. While there is little information on the nature of any competitive interactions between steelhead and resident trout in the Klamath Basin, research does suggest that in some circumstances, resident trout may have a competitive edge over steelhead (NMFS 2006a). Conversely, research has shown that hatchery salmon supplementation can negatively impact resident trout abundance and salmonid biomass in a Washington watershed (Pearsons and Temple 2010). However, competition between steelhead and currently present indigenous species such as redband trout are not assumed to be a major limiting factor since these species historically co-evolved (Hooton and Smith 2008). There are many examples from nearby river systems in the Pacific Northwest that show wild anadromous steelhead and resident rainbow/redband trout can co-exist and maintain abundant populations without adverse consequences. The Deschutes River in Oregon, the Yakima River in Washington, and the river systems in Idaho are examples (NMFS 2006a). As noted by Buchanan et al. (2011a), existing trout and colonizing anadromous steelhead are expected to co-exist in the Klamath Basin, as they do in other watersheds, although there may be shifts in abundance related to competition for space and food. Overall, there is no predicted substantial short-term or long-term decrease in native aquatic species abundance of a year class, or substantial decrease in habitat quality or quantity, and there would not be a significant impact to the aquatic species populations under the Continued Operations with Fish Passage Alternative in the short term or long term.

Significance
No significant impact for effects to aquatic species from interactions among fish species in the short term and long term

Potential Impact 4.2.3-19 Effects on freshwater mollusks populations due to continued operations of the Lower Klamath Project.
Under the Continued Operations with Fish Passage Alternative, suspended sediment, algal toxins, and other dynamics that potentially affect freshwater mussels would not change substantially from existing conditions, since only modest improvements in water quality are expected with continued implementation of actions contained within PacifiCorp's Reservoir Management Plan (see Section 4.4.2 *Water Quality*). The Continued Operations with Fish Passage Alternative would therefore have no significant impact as compared to the existing condition on mussels in the short term and long term.

Significance
No significant impact for freshwater mussels in the short term and long term

Potential Impact 4.2.3-20 Effects on fish species from alterations to benthic macroinvertebrates due to continued operations of the Lower Klamath Project.
Benthic macroinvertebrates (BMI) are small aquatic animals and the aquatic larval stages of insects. BMI are the primary food source for most freshwater fish species, and therefore, changes in abundance, distribution, or community structure can affect fish populations. A diminished food supply can limit growth of salmonids, and this is especially true at higher temperatures because as water warms, a fish's metabolic rate increases, and it needs more food to sustain growth. Growth is critical to juvenile salmonids because a larger size fish often has a survival advantage during the overwintering period, smolt outmigration, and ocean residence.

Under the Continued Operations with Fish Passage Alternative, reduction in peaking operations in the Hydroelectric Reach would result in a reduction in periodic killing, through stranding, of large numbers of young fish and aquatic invertebrates that are the primary prey food for salmonids (Administrative Law Judge 2006). Increased minimum flows in the bypass reaches may increase BMI production. This would result in a benefit to food availability both for the trout and other fish currently in the reach, and for anadromous species gaining access to the reach.

While the additional flows under this alternative would periodically increase the mobility of existing surficial fine sediment deposits downstream of Iron Gate Dam, in general, suspended sediment, which can affect benthic macroinvertebrates as discussed for the Proposed Project in Section 3.3.5.9, Potential Impact 3.3-20, would also be the same as under existing conditions. Further, since only modest improvements in water quality are expected with continued implementation of actions contained within PacifiCorp's Reservoir Management Plan (see Section 4.4.2 *Water Quality*), the effect of the Continued Operations with Fish Passage Alternative would be no significant impact (no change from existing conditions) on fish species due to alterations to benthic macroinvertebrates in the short term and long term.

Significance
No significant impact for effects of alterations to benthic macroinvertebrates on fish species in the short term and long term

Potential Impact 4.4.3-1 Effects on aquatic resources due to short-term noise disturbance and water quality alterations from fishway construction activities. This analysis relates to the potential impacts to aquatic resources from various construction activities associated with fishways under the Continued Operations with Fish Passage Alternative.

Disturbance to the river channel during construction related to the Continued Operations with Fish Passage Alternative could affect aquatic species. This alternative would require removal of the existing J.C. Boyle fish ladder structure, construction of a new fishways at all dams (Figure 2.3-1), and construction of downstream fish passage at all dams. Fish ladder construction would include building upstream fish ladders, spillway modifications, tailrace barriers, screens, and bypass structures (see Appendix U of this EIR for more details). These actions would include the use of heavy equipment, and blasting as necessary, and have the potential to disturb aquatic species. Activities at the Lower Klamath Project dams would affect the riverine and reservoir species in the Hydroelectric Reach. At Iron Gate Dam and Iron Gate Hatchery, anadromous species could also be affected. These potential effects could include shockwaves associated with construction of fish ladders using heavy equipment, potential crushing of aquatic species from operation of heavy equipment in the river, sedimentation, and release of oil, gasoline, or other toxic substances from construction sites.

Although the duration of construction for any individual facility would range from approximately four months to one year (Table 4.4-1), the entire process of installing fish passage at each of the four Lower Klamath Project dams would take place over a four- to eight--year period (FERC 2007). Unlike under the Proposed Project, these construction activities would not necessarily be limited to the timeframe that generates the least impact on the various life stages of anadromous fish in the Klamath River (i.e., winter and spring months), although since downstream facilities would be installed prior to upstream passage facilities, anadromous fish potentially would not be exposed to construction impacts related to building the downstream facilities.

As some of the construction activities under this alternative would occur directly in the river channel (i.e., "in-water") or on the banks immediately surrounding the river, the potential for impacts to aquatic species are greater than for work conducted in areas that can be dewatered or dried. To minimize potential construction impacts from crushing, sediment release, toxins, noise, etc., construction areas would be isolated from the river where possible. Areas to be dewatered would be isolated, and fish rescue and relocation efforts would be undertaken to remove any native fish trapped in the work area. Fish would be relocated to an area of suitable habitat within the Klamath River.

Implementation of mitigation measures WQ-1 and HZ-1 would reduce impacts to less than significant for fish passage construction-related activities in the Hydroelectric Reach throughout the four- to eight-year construction period under the Continued Operations with Fish Passage Alternative. If instead of fish ladders, trap and haul, or some combination of fish passage methods were used, there would be the potential for reduced construction compared to the aforementioned activities for fish ladders (see also Section 4.4.1 *[Continued Operations with Fish Passage Alternative] Introduction*).

Based on no predicted substantial short- or long-term decrease in in the abundance of a year class of any aquatic species, or substantial decrease in habitat quality or quantity for any aquatic species, there would not be a significant impact to aquatic resources under the Continued Operations with Fish Passage Alternative in the short term or long term from fishway construction impacts.

Significance

No significant impact with mitigation in the short term or long term

4.4.4 Phytoplankton and Periphyton

4.4.4.1 Phytoplankton

As discussed in more detail in Section 3.4, phytoplankton are aquatic microscopic organisms, including algae, bacteria, protists, and other single-celled plants, that obtain energy through photosynthesis and float in the water column of still or slowly flowing waters such as lakes or reservoirs. Excess growth of these organisms can cause nuisance water quality conditions, such as extreme diel (daily) fluctuations in dissolved oxygen and pH (see Section 3.4.2.1 *Phytoplankton* for detail. Under the Continued Operations with Fish Passage Alternative, reservoir sediment deposits would not be mobilized in the Hydroelectric Reach, Middle and Lower Klamath River, or the Klamath River Estuary, and there would be no short-term increases in sediment-associated nutrients that could potentially stimulate nuisance and/or noxious phytoplankton growth in those reaches (Potential Impact 3.4-1), and thus there would be no significant impact.

Nutrient reduction measures in Oregon and California due to the Klamath TMDLs would result in some differences between the Continued Operations with Fish Passage Alternative and existing conditions with respect to long-term phytoplankton blooms in the reservoirs. Additionally, PacifiCorp intends to design and implement a Reservoir Management Plan, which would result in some differences between this alternative and existing conditions. These differences are discussed below (Potential Impact 4.4.4-1).

Potential Impact 4.4.4-1 Long-term occurrence of nuisance and/or noxious phytoplankton blooms in the reservoirs.

Because the Lower Klamath Project reservoirs would remain in place, Copco No. 1 and Iron Gate reservoirs would continue to provide beneficial habitat conditions for the proliferation of large seasonal blooms of *Aphanizomenon flos-aquae*, *Anabaena flos-aquae*, and *Microcystis aeruginosa*, which subsequently become the source of these species to the Middle and Lower Klamath River, and eventually the Klamath River Estuary (see also Section 3.4.2.3 *Hydroelectric Reach*). Note that the increase in minimum flows for the Copco No. 2 Bypass Reach under this alternative could increase summertime phytoplankton concentrations in the Bypass Reach relative to existing conditions if the water were to be withdrawn from the Copco No. 1 Reservoir surface waters during an intensive bloom period, however this potential is too speculative to evaluate further.

As discussed in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impact 4.2.2-4, PacifiCorp has developed several iterations of a Reservoir Management Plan that proposed solutions to addressing water quality impairments associated with J.C. Boyle, Copco No. 1, Copco No. 2, and Iron Gate dams, including seasonal increases in TP, and to a lesser degree TN, in the Hydroelectric Reach due to the release (export) of dissolved forms of phosphorus (ortho-phosphorus) and nitrogen (ammonium) from Copco No. 1 and Iron Gate reservoir sediments during summer and fall, when reservoir bottom waters are anoxic (through internal nutrient loading, see

Figure 3.2-2). The improvement actions described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6 do not indicate that this measure could reduce the extent of phytoplankton blooms in the reservoirs such that they would no longer cause large seasonal blooms of *Microcystis aeruginosa*. Also as described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impacts 4.2.2-2, 4.2.2-4, 4.2.2-5, and 4.2.2-6, nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial with respect to decreasing nuisance phytoplankton blooms. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions are likely to require decades to achieve. Warmer water temperatures under climate change would further exacerbate seasonal phytoplankton blooms in Copco No. 1 and Iron Gate reservoirs and overall there is currently no reasonable proposal to substantially reduce nuisance and/or noxious phytoplankton blooms, including *Microcystis aeruginosa*, in the surface waters of Copco No. 1 and Iron Gate reservoirs during summer and fall months (Potential Impact 3.4-2), which subsequently become the source for the Middle and Klamath River, and Klamath River Estuary. The Continued Operations with Fish Passage Alternative would result in no change from existing adverse conditions in the short term and long term for these reaches. With respect to the Pacific Ocean nearshore environment, the latter is not suitable habitat for the freshwater phytoplankton species of concern (i.e., *Aphanizomenon flos-aquae, Anabaena flos-aquae, Microcystis aeruginosa*) (Potential Impact 3.4-2), and leaving the dams in place under the Continued Operations with Fish Passage Alternative would result in no significant impact relative to existing conditions.

<u>Significance</u>
No significant impact in the long term for the Hydroelectric Reach, Middle and Lower Klamath River, and the Klamath River Estuary

4.4.4.2 Periphyton

As discussed in more detail in Section 3.4 *Phytoplankton and Periphyton*, periphyton are aquatic organisms including aquatic plants, algae, and bacteria that live attached to underwater surfaces such as rocks on a riverbed. Some degree of periphyton growth is an important part of stream ecosystem function. Excess growth of these organisms can cause nuisance water quality conditions, such as extreme diel (daily) fluctuations in dissolved oxygen and pH (see Section 3.4.2.2 *Periphyton* for detail). Under the Continued Operations with Fish Passage Alternative, reservoir sediment deposits would not be mobilized in the Hydroelectric Reach, Middle and Lower Klamath River, or the Klamath River Estuary, and there would be no short-term increases in sediment-associated nutrients that could potentially stimulate nuisance periphyton growth in those reaches (Potential Impact 3.4-4), and thus there would be no significant impact.

The Continued Operations with Fish Passage Alternative would change the flow regime downstream of J.C. Boyle Dam, Copco No. 2 Dam, and Iron Gate Dam. These differences are discussed below (Potential Impact 4.4.4-2).

Potential Impact 4.4.4-2 Long-term colonization of nuisance periphyton in riverine reaches.
The Continued Operations with Fish Passage Alternative would change the flow regime downstream of J.C. Boyle Dam. This alternative would have the same or similar potential short-term and long-term impacts on periphyton in the Hydroelectric Reach

from the Oregon-California state line to Copco No. 1 Reservoir as those identified for the Proposed Project (Potential Impact 3.4-4). This is because increased minimum flows in the J.C. Boyle Bypass Reach and reduction of peaking operations at J.C. Boyle Powerhouse to one day per week, would result in a similar flow regime in the California portion of the Peaking Reach as that described under the Proposed Project, and it is these flow regime changes that have the potential to increase periphyton habitat. There would be less artificial diel (24-hour) temperature variation during summer and early fall in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir relative to existing conditions (see also Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality,* Potential Impact 4.2.2-1). J.C. Boyle Reservoir retains relatively little nutrients under existing conditions (see Appendix C, Section C.3.1.1 *Hydroelectric Reach*), and therefore nutrient conditions in this reach would be the same under the Continued Operations with Fish Passage Alternative as under existing conditions since there would be no change in nutrient interception or retention with J.C. Boyle Dam remaining in place (see also Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impact 4.2.2-4). The less diel (24-hour) temperature variations and slight decrease in the maximum water temperature in this reach is not anticipated to affect periphyton colonization. Additionally, the generally high gradient and velocity in the J.C. Boyle Peaking Reach does not currently support excessive periphyton mats and it is not anticipated this reach would support excessive periphyton mats under higher minimum flows and reduce peaking flows. In the short term and long term, increases in periphyton biomass from reduction of peaking flows along with the change in water temperature in this reach are expected to be limited under the Continued Operations with Fish Passage Alternative and any potential increase in periphyton would not result in new or further impairment of designated beneficial uses. For the reasons described above, increased minimum flows and reductions in peaking flows in the Copco No. 2 Bypass Reach under this alternative also would not result in new or further impairment of designated beneficial uses due to periphyton growth. Overall, in the Hydroelectric Reach there would be no significant impact.

Further downstream, the continuing presence of the Lower Klamath Project dams would continue to support periphyton growth in the Middle and Lower Klamath River as described for existing conditions (Section 3.4.2.4 *Middle and Lower Klamath River*), with the exception that the 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam under this alternative would scour the streambed more regularly than under simply the 2013 BiOp Flows that characterize the existing condition. This is likely to reduce dense growth of periphyton in the Middle Klamath River from Iron Gate Dam to approximately the Shasta River confluence (RM 179.5) relative to existing conditions, even as the contribution of the hydroelectric facilities to such nuisance growth remains unchanged, and would be beneficial (see also Potential Impact 4.2.4-1).

PacifiCorp intends to design and implement a Reservoir Management Plan to reduce water quality impairments in the Hydroelectric Reach and immediately downstream of Iron Gate Dam, including seasonal release of nutrients from Copco No. 1 and Iron Gate reservoir sediments during summer and fall, when reservoir bottom waters are anoxic. As described in Section 4.4.2 *[Continued Operations with Fish Passage] Water Quality* Potential Impact 4.2.2-4, results of Reservoir Management Plan studies to date do not indicate that reduced seasonal nutrient releases from the reservoirs would occur under this alternative. Nutrient reduction measures in Oregon and California’s TMDLs would, over time, be beneficial with respect to decreasing overall nutrient concentrations in the

Middle and Lower Klamath River. However, the measures necessary to achieve significant reductions are, at this point, unknown and reductions are likely to require decades to achieve. However, because nutrients do not appear to be limiting periphyton growth in the Klamath River from Iron Gate Dam to approximately Seiad Valley (RM 132.7) (and potentially farther downstream) (see also Potential Impact 3.4-5), nutrient dynamics associated with the Continued Operations with Fish Passage Alternative are not likely to have an effect on periphyton growth in the Middle and Lower Klamath River, such that there would be no new or further impairment of designated beneficial uses.

Overall, the increased scouring of the streambed due to 2017 court-ordered flushing and emergency dilution flows downstream of Iron Gate Dam would reduce dense growth of periphyton in the Middle Klamath River relative to existing conditions, and would be beneficial.

Significance

No significant impact for the Hydroelectric Reach

Beneficial for the Middle Klamath River from Iron Gate Dam to the Shasta River (RM 179.5)
No significant impact for the Middle Klamath River downstream of the confluence with the Shasta River (RM 179.5) and the Lower Klamath River

4.4.5 Terrestrial Resources

4.4.5.1 Vegetation Communities

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to facilitate upstream and downstream fish ladders, at all four Lower Klamath Project dam complexes. These activities would have a reduced construction footprint as compared to that necessary for removal of the Lower Klamath Project dam complexes under the Proposed Project, as fewer structures would be removed and less debris created. These activities would take place within the Limits of Work for the Proposed Project, thus construction-related impacts on wetland and riparian vegetation would generally be similar to, but less than those described for the Proposed Project. As described in Section 3.5.5.1, construction activities resulting in ground disturbance would have short-term impacts on sensitive habitats, including wetlands and riparian habitats along reservoirs and river reaches. Within the construction footprint of the fishways, implementation of Mitigation Measure TER-1 described in Potential Impact 3.5-1 and Mitigation Measure TER-5, would reduce potential short-term construction impacts on sensitive habitats to less than significant.

Implementation of mitigation measures TER-1 and TER-5 would be enforceable through inclusion in a water quality certification and construction-related impacts on wetlands and riparian vegetation communities with mitigation would be reduced for the reasons described in Section 3.5.5.1 *Terrestrial Resources Potential Impacts and Mitigation*. Therefore, construction impacts on wetlands and riparian communities, would be less than significant with mitigation.

Under the Continued Operations with Fish Passage Alternative there would be no impact on wetland and riparian vegetation resulting from short- or long-term habitat loss or gain as compared with existing conditions, since reservoir drawdown and dam removal activities would not occur (Potential Impacts 3.5-2, 3.5-3, 3.5-4, 3.5-5, and 3.5-8).

Mitigation Measure TER-5 – Identification, protection, and restoration of wetland and riparian habitats.
The KRRC shall conduct a wetland delineation within the limits of construction in accordance with the 1987 U.S. Army Corps of Engineers (USACE) Wetland Delineation Manual (USACE 1987) and applicable Regional Supplements (i.e., Western Mountains, Valleys, and Coast Region [USACE 2010] and Arid West [USACE 2008]). The results of the wetland delineation shall be incorporated into the Continued Operations with a Continued Operations with Fish Passage Alternative design to avoid and minimize direct impacts on wetlands to the maximum extent feasible, and wetland areas adjacent to the construction Limits of Work shall be fenced to prevent inadvertent entry. Where avoidance is not feasible the KRRC shall develop a restoration plan to re-vegetate all areas disturbed during construction with a goal of no net loss of wetland or riparian habitat acreage and functions. The restoration plan shall include details on revegetation native seed mixes based on existing species that will be impacted and installation techniques for container plants and seeds. Wetlands established in restored areas would be monitored for five years or until the performance criteria, as defined in the restoration plant that shall be developed, have been met.

4.4.5.2 Culturally Significant Species

As described in Section 3.5.2.3 many of the species identified by the Native American Tribes in the Klamath River region as culturally significant occur in riparian and wetland habitats. Under the Continued Operations with Fish Passage Alternative, required construction activities including facility development for the fishway prescriptions would result in less ground disturbance than those needed for removal of the Lower Klamath Project dam complexes under the Proposed Project as a result of removing less structures and creating less debris; however, because ground disturbance would occur, the types of potential short- and long-term construction-related impacts on culturally significant species would be similar to those described for the Proposed Project (Potential Impact 3.5-6). Mitigation Measure TER-1 (see Potential Impact 3.5-1) and TER-5 includes wetland buffers to prevent intrusion in wetland habitats, avoid substantial degradation in these areas, and restore with a goal of no net loss of wetland or riparian habitat acreage and function. These measures would reduce short- and long-term impacts on culturally significant species to less than significant under this alternative. Implementation of the TER-1 and TER-5 measures would be enforceable through inclusion in a water quality certification. Therefore, the TER-1 and TER-5 measures are feasible and Potential Impact 3.5-6 would result in no significant impacts from impacts on culturally significant species in riparian and wetland habitats with mitigation for the reasons described in Section 3.5.5.2 *Terrestrial Resources Potential Impacts and Mitigation*.

4.4.5.3 Special-status Species

Under the Continued Operations with Fish Passage Alternative, construction activities for fish passage facilities would constitute major construction in the Limits of Work described in Section 4.4.1. Special-status plant and wildlife species in the Primary Area of Analysis are listed/described in Tables 3.5-4 and 3.5-5. The types of potential short- and long-term construction-related impacts on terrestrial resources would be similar to those described for the Proposed Project (Potential Impacts 3.5-7, 3.5-9, 3.5-10, 3.5-11, 3.5-12, 3.5-13, 3.5-14, 3.5-28), but would be somewhat less than under the Proposed Project, as there would be less construction-related ground disturbance from the development of fish ladders or trap and haul as compared with removing the dam complexes. As a result, there would be relatively less overall habitat modification and less intensive construction noise due to modifying fewer structures under this alternative as compared with the Proposed Project. However, the entire process may take place over a four- to eight-year period which would result in noise disturbance (potentially from blasting) over a longer period of time to affect terrestrial resources.

Even though there would be less construction activity under the Partial Removal Alternative as compared to the Proposed Project, special-status plants and rare natural communities may be present in the areas where construction activities may be performed. Consequently, short-term impacts on special-status plants and rare natural communities may would be similar to those of the Proposed Project (Potential Impact 3.5-7), though at a reduced scale. Within the construction footprint of the fishways, Recommended Terrestrial Resource Measure TER-1 and measures similar to those described in Appendix B: *Definite Plan – Appendix J* would be required to reduce potential impacts, including surveys for special-status species and rare natural communities, implementation of avoidance measures and invasive species control. To the extent the special-status plants and rare natural communities are a part of wetland or riparian areas, these measures can be feasibly imposed through water quality certification. For other such communities, however, it is not clear whether the hydroelectric project owner or operator would implement the Recommended Terrestrial Measures TER-1 (Potential Impact 3.5-7) or measures similar to those described in the Appendix B: *Definite Plan – Appendix J* through 'good citizen' agreements, as described in the Definite Plan, and it is unclear how these recommended terrestrial measures would be enforced in light of Federal Power Act preemption. Without an enforcement mechanism, these restoration activities cannot be deemed feasible for the purposes of CEQA. Therefore, construction impacts on special-status plants and rare natural communities would be significant and unavoidable.

A reduction in the impacted area as compared to the impacts of the Proposed Project, could reduce the significance of the impact to special-status wildlife species, specifically state species of special concern or BLM sensitive species on BLM lands, because it would reduce the number of potentially affected individuals in a population (Potential Impact 3.5-9). However, for other special-status wildlife species (state listed, state proposed, USFWS listed), it would not reduce the significance of the potential impact, because the significance criteria rely on impacts on a single individual, and this risk remains. For example, removing or modifying fewer structures and eliminating or shrinking the footprint of disposal sites would reduce the chances that construction would occur in an area that would impact special-status bird nests. Large bat maternity roosts have been documented at structures that would be retained under this alternative including Copco No. 1 Dam – C12 Gate house, Copco No. 1 Diversion Tunnel, and Iron Gate Diversion tunnel, and retaining these structures would be the same as existing conditions and reduce population-level impacts on bats compared to the Proposed Project (Potential Impact 3.5-14). However, if state, federal, or proposed-listed bird nests or hibernacula or maternity roosts are within the range of the lesser amount of construction, impacts would still be the same vis-à-vis on those birds or bat colonies and would still be potentially significant.

Compared to the existing condition, the substantial construction involved with constructing fish passage facilities would have the potential to significantly impact special-status wildlife species for the reasons described above and in Section 3.5.5 (Potential Impacts 3.5-10, 3.5-11, 3.5-12, 3.5-13, 3.5-14, and 3.5-28). Implementation of Mitigation Measures TER-2 and TER-3 would reduce construction-related impacts, including in-water work, on all special-status amphibian species to less than significant. Implementation of Recommended Terrestrial Measures 3–12 would reduce impacts on special-status birds and mammals to less than significant. Implementation of the TER-2 and TER-3 measures would be enforceable through inclusion in a water quality certification. Therefore, the TER-2 and TER-3 measures are feasible and Potential Impact 3.5-10 would result in no significant impacts on amphibian and reptile with mitigation from construction-related impacts and Potential Impact 3.5-28 impacts would be reduced for the reasons described in Section 3.5.5.3 *Terrestrial Resources Potential Impacts and Mitigation*. It is not clear, however, whether the hydroelectric project owner or operator would implement the Recommended Terrestrial Measures 3–12 (Potential Impacts 3.5-10, 3.5-11, 3.5-12, 3.5-13, 3.5-14, and 3.5-28) through 'good citizen' agreements, as described in the Definite Plan, and it is unclear how these recommended terrestrial measures would be enforced in light of Federal Power Act preemption. Without an enforcement mechanism, these restoration activities cannot be deemed feasible for the purposes of CEQA. Therefore, this impact on special-status birds, and mammals would be significant and unavoidable.

Since Iron Gate Hatchery operations would not change under the Continued Operations with Fish Passage Alternative, there would be no potential impacts on special-status plant and wildlife species related to changes in hatchery operations (Potential Impact 3.5-26).

Short-term impacts of elevated SSCs in the mainstem Klamath River from reservoir drawdown and dam removal would not occur under the Continued Operations with Fish Passage Alternative since the dams would remain in place and no drawdown would occur (Potential Impacts 3.5-16 and 3.5-18).

There would be no impact resulting from long-term habitat loss (or beneficial gain for willow flycatcher) as compared to existing conditions, since the reservoirs would remain and would continue to provide habitat for western pond turtle, many species of birds, including waterfowl and bald eagles, bats, and other special-status wildlife and plants that are supported by aquatic habitat provided by the reservoirs (Potential Impacts 3.5-21 and 3.5-22). However, fish passage would allow for nutrient distribution upstream of Iron Gate Dam, for reasons described for the Proposed Project (Potential Impact 3.5-30). Additional flow releases in the Middle Klamath River (downstream of Iron Gate Dam) would occur to address the conditions associated with fish disease, and impacts from these (2017) court-ordered flows on foothill yellow-legged frog breeding, if present, would be significant and unavoidable for reasons described for the No Project Alternative (Potential Impact 4.2.5-1) in both the short term and the long term. Potential impacts on western pond turtle would be less than significant for reasons described for the No Project Alternative (Potential Impact 4.2.5-1) in both the short term and the long term.

Under the Continued Operations with Fish Passage Alternative, there would be increased minimum flows in the J.C. Boyle Bypass Reach and peaking operations at J.C. Boyle Powerhouse in Oregon would be limited to one day per week. The habitat differences from these actions would be more muted in California, as they are attenuated with distance downstream due to tributary inputs and accretion flows, but, as described in Section 3.2.4, there would be slightly lower maximum water temperatures, and less artificial diel temperature variation during summer and early fall (Potential Impact 3.2-1). Thus, the temperature and flow regime would move towards a more natural condition than that under the existing condition, reducing the stressors to amphibian and reptile species located there. Increases in minimum flows for the Copco No. 2 bypass reach, with a release of 70 cfs or inflow, whichever is less, to the bypass reach would occur; this increase would not affect special-status amphibians or reptiles if present. Thus, there would be no dam-related downstream flow fluctuations below the Copco No 2. or the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir that could otherwise adversely impact amphibian or reptile species located there. Retaining the Lower Klamath Project dams would likely prevent any upward movement of the foothill yellow-legged frog into this reach and as a result no impact on foothill yellow-legged frog is anticipated. A slight decrease in the maximum water temperature in this reach is not anticipated to other wildlife species (e.g., western pond turtle). There would be no impact on special-status wildlife species in California due to the increased minimum flows and limited hydropower peaking flows originated from J. C. Boyle Dam in Oregon or Copco No. 2 Dam operations.

4.4.5.4 Wildlife Corridors and Habitat Connectivity

Under the Continued Operations with Fish Passage Alternative, the reservoirs and dams would continue to present a barrier or hindrance to movement for some terrestrial wildlife species such and amphibians, reptiles, mammals, and riparian birds, as described under Section 3.5.2.6 *Environmental Setting, Wildlife Corridors and Habitat Connectivity*. (Potential Impacts 3.5-19, 3.5-23). With the fishway prescription, salmon and other fish species would be able to access reaches upstream of Iron Gate Dam, and thus would provide nutrient-rich food for terrestrial species located there. Marine-derived nutrients would be subsequently deposited into terrestrial habitats and productivity of the terrestrial ecosystem as a whole could improve from existing conditions, although not to the extent described for the Proposed Project in Potential Impacts 3.5-24 and 3.5-25, because of because of the difference in migration success through fishways and reservoirs compared to through a riverine system. There would be no impact compared with existing conditions.

4.4.6 Flood Hydrology

Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect flood hydrology, and therefore would present no change from the existing condition. Flow increases in the J.C. Boyle and Copco No. 2 bypass reaches are related to minimum instream flows and would not impact peak flows during flood events.

4.4.7 Groundwater

Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect groundwater, and therefore would present no change from the existing condition.

4.4.8 Water Supply/Water Rights

Flow increases in the J.C. Boyle and Copco No. 2 bypass reaches are related to minimum instream flows in the Hydroelectric Reach and would not impact water supply or water rights downstream of Iron Gate Dam. Similarly, there would be no changes to water supply/water rights related to the 2017 flow requirements, which is discussed in detail in Potential Impact 4.2.8-1. Overall, the Continued Operations with Fish Passage Alternative would not affect water supply/water rights as compared with the existing condition.

4.4.9 Air Quality

Under the Continued Operations with Fish Passage Alternative, construction activities to install fish ladders would occur at all four Lower Klamath Project dam complexes. Construction activities would result from the development of structures to support these fish passage options; however, the overall area of ground disturbance would be reduced as less structures would be removed and less debris would be created as compared to the Proposed Project (see also Section 4.4.1 *[Continued Operations with Fish Passage Alternative] Alternative Description*) Under this alternative, fugitive dust emissions would be caused by movement of construction equipment on the soil and internal haul roads and a small amount of cut/fill activities. As construction activities required for implementing fish passage would be less than those necessary for removal of the Lower Klamath Project dam complexes under the Proposed Project, the level of overall construction activities and thus peak daily emissions of air pollutants (i.e., VOCs, CO, NOx, SOs, PM_{10}, $PM_{2.5}$) in the Hydroelectric Reach in California would be less than those described under the Proposed Project (Potential Impact 3.9-1). Further, since the construction activities may occur over a period of four to eight years for all of the fish passage facilities, the estimated maximum daily emissions would be less than the subtotal of activities for each dam (Table 4.4-2). Construction-related emissions would not exceed the Siskiyou County Air Pollution Control District's (SCAPCD) thresholds of significance in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants) for the Continued Operations with Fish Passage Alternative.

Table 4.4-2. Summary of Peak Daily Emissions (pounds per day)[1,2] for Construction Activities for the Continued Operations with Fish Passage Alternative.

Dam	Peak Daily Emissions (pounds per day)[1,2]					
	VOC	CO	NOx	SOx	PM_{10}	$PM_{2.5}$
Iron Gate Subtotal	11	63	59	<1	8	3
Copco No. 1 Subtotal	9	51	37	<1	2	1
Copco No. 2 Subtotal	10	58	50	<1	5	2
J.C. Boyle Subtotal	9	16	50	4	11	6
Maximum Daily Emissions	11	63	59	4	11	6
Significance Criterion	250	2,500	250	250	250	250

1 Data from 2012 KHSA EIS/EIR.
2 Breakdown of peak daily emissions associated with types of construction activities under the Continued Operation with Fish Passage Alternative is provided in Appendix N, Table N-16.

Key:

VOC = volatile organic compounds
CO = carbon monoxide
NOx = nitrogen oxides

SO_x = sulfur oxides
PM_{10} = inhalable particulate matter
$PM_{2.5}$ = fine particulate matter

This alternative would not include operational changes that would affect air emissions in the long term for implementation of fish ladders and there would be no significant impact (Potential Impact 3.9-1).

If trap and haul facilities were to be constructed instead of fish ladders, peak daily emissions due to construction activities would be less than those described above. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Iron Gate Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Iron Gate Dam. Although the exact extent and timing of these ongoing hauling activities is not known, peak daily air quality emissions would be considerably less than those estimated above because it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 60 to 70 miles each way between Iron Gate Dam and J.C. Boyle Reservoir. Therefore, the long-term potential impact on air quality emissions due to trap and haul operations would be less than significant.

4.4.10 Greenhouse Gas Emissions

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to facilitate upstream and downstream fishways, which may include installing fish ladders, trap and haul, or experimental fish cannons, at all four Lower Klamath Project dam complexes. This construction would release greenhouse gasses as described under the Proposed Project (Potential Impact 3.10-1). As construction activities required for fish passage facilities would be less than those necessary for removal of the Lower Klamath Project dam complexes under the Proposed Project, uncontrolled direct total GHG emissions from construction under this alternative also would be below the SCAQMD's 10,000 MTCO2e significance threshold and would result in no significant impact.

The Continued Operations with Fish Passage Alternative would not remove a source of renewable power and thus would have no indirect effect on production of greenhouse gas emissions relative to existing conditions (Potential Impact 3.10-2).

If trap and haul facilities were to be constructed instead of fish ladders, greenhouse gas emissions due to construction activities would be less than those described above. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Iron Gate Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Iron Gate Dam. Although the exact extent and timing of these ongoing hauling activities is not known, greenhouse gas emissions would be considerably less than those estimated above because it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 60 to 70 miles each way between Iron Gate Dam and J.C. Boyle Reservoir. Therefore, the long-term potential impact on greenhouse gas emissions due to trap and haul operations would be less than significant.

4.4.11 Geology, Soils, and Mineral Resources

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders, at all four Lower Klamath Project dam complexes. While these activities would be less than those described for the Proposed Project, there would still be potential for soil disturbance associated with heavy vehicle use, excavation, and grading during the construction of fish passage facilities, which could result in erosion at Iron Gate, Copco No. 2, and J.C. Boyle reservoirs and could exacerbate existing erosion at Copco No. 1 Reservoir (see also Potential Impact 3.11-2). For reasons described for the Proposed Project, implementation of BMPs to prevent erosion during demolition activities would minimize the potential for erosion and sediment delivery into the reservoir areas and there would be no significant impact due to soil disturbance associated with construction activities (Potential Impact 3.11-2).

Increases in minimum flows and decreases in peaking flows due to changes in J.C. Boyle Dam and Copco No. 2 Dam operations, plus the winter-spring surface flushing flows and deep flushing flow requirements at Iron Gate Dam (and emergency dilution flows, if needed) (see also Section 4.2.1.1 *[No Project] Alternative Description – Summary of Available Hydrology Information for the No Project Alternative)*, would result in an overall increase in flows under this alternative compared to existing conditions. While the additional flows would increase the mobility of existing surficial fine sediment deposits and infilled fine sediment from the armor layer, with potential for slight mobilization of the armor layer in some locations, new sediment supply would not occur and overall maintenance of static channel features would represent no change from existing adverse conditions for the Middle Klamath River between Iron Gate Dam and the confluence with the Scott River.

For reasons described for the No Project Alternative, there would be no other significant impacts of this alternative on geology and soils.

4.4.12 Historical Resources and Tribal Cultural Resources

Under the Continued Operations with Fish Passage Alternative, there would be no significant impacts to tribal cultural resources due to potential shifting and/or exposure of resources within the Lower Klamath Project reservoir footprints or located along the Klamath River (Potential Impacts 3.12-2, 3.12-3, 3.12-7), nor increased potential for looting (Potential Impacts 3.12-6, 3.12-8), since reservoir drawdown would not occur. The potential for impacts to tribal cultural resources due to wave erosion in the annual reservoir fluctuation zone would continue, as described under Potential Impacts 3.12-2 and 3.12-8 of the Proposed Project. Potential impacts to submerged historic-period archaeological resources (Potential Impacts 3.12-12 through 3.12-16) within the reservoir footprints and along the Klamath River also would not occur since the dams would not be removed and reservoir drawdown would not occur.

Salmonid habitat would increase due to fish passage installation under this alternative, and 2017 court-ordered flushing and emergency dilution flows would reduce the incidence of fish disease and parasites in the Klamath River, both of which would improve conditions for the Klamath Cultural Riverscape related to fisheries (Potential Impact 3.12-9) relative to existing conditions. This would be a beneficial effect.

Since only modest improvements in water quality would occur under this alternative, the ability of tribes to use the Middle and Lower Klamath River for ceremonial and other purposes would remain limited by existing, adverse conditions (Potential Impact 3.12-10). The Continued Operations with Fish Passage Alternative would continue to result in the same elevated concentrations of algal toxins in the water that commonly exceed public health advisory postings for water contact and inhibit the use of the Middle and Lower Klamath River for tribal purposes as under existing conditions (see also Potential Impact 3.12-10). As described under Potential Impact 4.2.2-7, there would be no change from existing adverse conditions related to algal toxins under this alternative, despite development and implementation of PacifiCorp's Reservoir Management Plan. Further, while nutrient reduction measures in Oregon and California's TMDLs would, over time, be beneficial with respect to decreasing the prevalence of toxin-producing nuisance blue-green algal species such as *Microcystis aeruginosa*, it is anticipated that full attainment of the Oregon and California TMDLs would require decades to achieve. Warmer water temperatures under climate change would further exacerbate seasonal blooms of nuisance algal species in Copco No. 1 and Iron Gate reservoirs and overall there is currently no reasonable proposal to achieve water quality standards with the dams in place. Overall, the Continued Operations with Fish Passage Alternative would result in no change from existing adverse conditions with respect to Cultural Use of Klamath River waters without risk of adverse health effects (Potential Impact 3.12-10) and there would be no significant impact.

Under the Continued Operations with Fish Passage Alternative, construction activities to install fish ladders would occur at all four Lower Klamath Project dam complexes. Construction activities would result from the development of structures to support these fish passage options; however, the overall area of ground disturbance would be reduced as less structures would be removed. While construction-related impacts under this alternative would be less than those described for the Proposed Project, there would still be potential for construction-related impacts due to ground-disturbance, heavy equipment, and blasting such that Potential Impacts 3.12-1, 3.12-4, and 3.12-5 for tribal cultural resources and Potential Impacts 3.12-12, 3.12-15, and 3.12-16 for historic-period archaeological resources, would occur in the manner described for the Proposed Project. Implementation of Mitigation Measure TCR-1 (Tribal Resource Management Plan), including the specific terms one through seven thereunder enumerated, would reduce impacts to tribal cultural resources and historic-period archaeological resources from construction activities. It is not clear, however, whether the hydroelectric project owner or operator would implement these measures through good citizen agreements, as described in the Definite Plan, and it is unclear how these measures would be enforced, outside of the measures required under the National Historic Preservation Act and the Native American Graves Protection and Repatriation Act. Without an enforcement mechanism, these measures cannot be deemed feasible for the purposes of CEQA. Therefore, the aforementioned short-term construction-related impacts under the Continued Operations with Fish Passage Alternative would be significant and unavoidable.

4.4.13 Paleontologic Resources

The Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect paleontologic resources as compared to existing conditions (Section 3.13.2 *[Paleontologic Resources] Environmental Setting*).

4.4.14 Land Use and Planning

The Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect land use and planning and thus there would be no change from existing conditions (Section 3.14.2 *[Land Use and Planning] Environmental Setting*).

4.4.15 Agriculture and Forestry Resources

The Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect agriculture and forestry resources thus there would be no change from existing conditions Section 3.15.2 *[Agricultural and Forestry Resources] Environmental Setting*).

4.4.16 Population and Housing

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install fish ladders at all four Lower Klamath Project dam complexes. The estimated average construction workforce would be less than that of the Proposed Project (see Table 4.4-1 and Table 2.7-8) since the level of construction under this alternative would be less. Further, the process for constructing fish ladder facilities may occur over a period of four to eight years, which is a longer timeline as compared to that described for the Proposed Project, such that fewer construction workers may be present at any given time as compared with the Proposed Project. For construction of trap and haul facilities, the construction workforce would be even less. Although long-term employment to manage a trap and haul system would require more labor as compared to the fishway, the number of workers would be relatively small and overall the Continued Operations with Fish Passage Alternative would not result in a substantial influx of population (Potential Impact 3.16-1), nor would there be a need to displace existing residents or build replacement housing elsewhere (Potential Impact 3.16-2), for either short-term construction-related activities or long-term operational needs, and there would be no significant impacts.

4.4.17 Public Services

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. Construction activities required for fish passage facilities would be less than those necessary for removal of the Lower Klamath Project dam complexes under the Proposed Project and would occur with less intensity since they may occur over a period of four to eight years. However, during periods of construction for this alternative, there would still be the potential for increased response times for emergency fire, police, and medical services due to construction-related traffic (Potential Impact 3.17-1), which may occur over a four-to eight-year period. This would be a significant impact. Implementation of Mitigation Measure HZ-1 (Section 3.21 *Hazards and Hazardous Materials*) would reduce this impact to less than significant for reasons described under the Proposed Project. Overseeing development and implementation of a Hazardous Materials Management Plan, as required under Mitigation Measure HZ-1 falls within the scope of the State Water Board's water quality certification authority. It is not clear, however, whether the hydroelectric project owner or operator would implement measures relating to traffic management (such as Recommended Measure TR-1), emergency response, and construction-related fire management through ‘good citizen’ agreements, as described in the Definite Plan, and it is unclear how these measures would be enforced. Because the State Water Board cannot ensure implementation of these additional measures, it has determined that the construction-related impact on increased response times for emergency, fire, police, and medical services to be significant and unavoidable under this alternative.

Under the Continued Operations with Fish Passage Alternative, the Lower Klamath Project reservoirs would remain in place and there would be no change from the existing condition in terms of the facilities’ availability to serve as a long-term water source for fighting wildfires. Therefore, there would be no impact (Potential Impact 3.17-2).

The Continued Operations with Fish Passage Alternative does not have the potential to affect schools in terms of additional students or longer bus routes, nor would it generate the need for additional classrooms or school services, and as identified under the Proposed Project (Potential Impact 3.17-3), would result in no significant impact.

4.4.18 Utilities and Service Systems

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. Construction activities required for fish passage facilities would be of a type similar to those described for the Proposed Project, but would be less than those necessary for removal of the Lower Klamath Project dam complexes and would occur with less intensity since they may occur over a period of four to eight years. However, during periods of construction for this alternative, there would still be the potential for impacts related to utilities and service systems, as described below.

The Continued Operations with Fish Passage Alternative would include the use of temporary wastewater treatment (i.e., portable chemical toilet facilities that are regularly cleaned, pumped, and have wastes disposed of by the toilet providers), stormwater drainage, and/or solid waste disposal facilities, albeit at a lower level than that described for the Proposed Project (Potential Impacts 3.18-1 through 3.18-4). Since the total area of construction-related activities for this alternative would amount to greater than one acre, the Proposed Project would be required to obtain coverage under the State Water Board Construction General Permit (2009-0009-DWQ as amended by 2010-0014-DWQ and 2012-0006-DWQ) (CGP). Each of the proposed construction areas, including staging, stockpiling, onsite disposal, and access-related areas, must be covered by the CGP. The CGP requires the applicant to address such items as employee wastewater generated during construction and spill containment and clean-up. Thus, meeting CGP requirements for onsite toilet facilities for short-term use by construction crews would not result in a significant impact as there would not be an increased need for permanent wastewater treatment facilities or an anticipated demand for additional wastewater treatment facilities.

Long-term employment to support operations of a trap and haul system would require relatively more labor as compared to that for fish ladders; however, overall the number of long-term workers would be relatively small and would not rise to the level that would affect utilities and service systems. Thus, this alternative would cause no change from existing conditions in the long term.

4.4.19 Aesthetics

Under the Continued Operations with Fish Passage Alternative, construction activities to install upstream and downstream fish ladders would occur at all four Lower Klamath Project dam complexes. This activity would take place within the Limits of Work for the Proposed Project. and would involve construction equipment, as well as use of staging areas and demolition areas. However, since construction of new infrastructure to support fish passage would occur near and potentially directly adjacent to the existing infrastructure (Potential Impact 3.19-5), the construction activities and the facilities themselves would not distract from a natural view relative to existing conditions in the short term or the long term and this alternative would result in a less than significant impact. No construction of new recreational facilities or improvements to existing recreational facilities would occur under this alternative. The level of overall construction is anticipated to be less under Continued Operations with Fish Passage Alternative than that described for the Proposed Project; thus the intensity and duration of the potential aesthetics impacts would also be less than those described for the Proposed Project and there would be no significant impact (Potential Impact 3.19-6). However, for reasons described for the Proposed Project, construction lighting would have significant and unavoidable impacts on nighttime views (Potential Impact 3.19-7). It is not clear whether the hydroelectric project owner or operator would implement measures to reduce nighttime light and glare on surrounding residences during construction. Overseeing development and implementation of measures to reduce impacts to nighttime views does not fall within the scope of the State Water Board's water quality certification authority. Without an enforcement mechanism, such measures cannot be deemed feasible for the purposes of CEQA. Therefore, the impact of this alternative on nighttime views would be significant and unavoidable during the period of construction activities.

The existing Lower Klamath Project dam complexes are already a part of the environmental baseline. Under the Continued Operations with Fish Passage Alternative, there would be no loss of open water vistas (Potential Impact 3.19-1), no significant changes in flows or channel morphology (Potential Impact 3.19-2), no changes in visual water quality due during periods of elevated SSCs (Potential Impact 3.19-3), and no exposure of bare areas of sediment and rock (Potential Impact 3.19-4), since the reservoirs would remain in place. Thus, this alternative would have no significant impact relative to existing conditions for these aspects of aesthetics. As the Continued Operations with Fish Passage Alternative does not include other physical or operational changes that would affect aesthetics in the long term, this determination also applies in the long term (5+ years).

4.4.20 Recreation

Unlike under the Proposed Project, reservoir-based recreation would continue under the Continued Operations with Fish Passage Alternative.

Under the Continued Operations with Fish Passage Alternative, construction activities would occur due to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. While construction activities required for fishway facilities would be less than those required for removal of the Lower Klamath Project dam complexes under the Proposed Project, they would still result in potential restrictions, noise, and dust. However, for reasons described for the Proposed Project, these impacts would be less than significant (Potential Impact 3.20-1). Although these impacts may be spread across a four- to eight-year period, no one site would be affected for that entire length of time and thus there still would be no significant impact compared with existing conditions. Facility construction and any related potential recreational impacts for trap and haul would be less than that described for fish ladders. Under this alternative, there would be no changes to or loss of local or regional reservoir-based recreation activities and facilities compared with existing conditions (Potential Impact 3.20-2 and 3.20-3), and no construction of new or expanded recreational facilities (Potential Impact 3.20-4) due to dam removal.

The Continued Operations with Fish Passage Alternative would increase minimum flows in the J.C. Boyle Bypass Reach and limit peaking operations at J.C. Boyle Powerhouse to one day per week. Since recreational flows in the Hydroelectric Reach would be limited under this alternative, the loss of whitewater boating opportunities in the Hell's Corner Reach[203] would be similar to those described for the Proposed Project (Potential Impact 3.20-5), except that the white water boating would be available one day per week. However, for the remaining six days per week during the late summer and early fall, when other regional alternative rafting opportunities are less available, see discussion in Potential Impact 3.20-5), this alternative would result in the loss of a unique opportunity in the region to raft Class IV+ rapids. This would affect up to 250 people per day during that time, as well as 10 commercial outfitters and would be a significant and unavoidable impact for the Hell's Corner Reach. There would be no significant impact in the Middle and Lower Klamath River since the effect of the altered river flows would be muted in California.

Under the Continued Operations with Fish Passage Alternative, construction of upstream and downstream fish passage at all Lower Klamath Project dams would benefit recreational fishing of anadromous fish throughout the Klamath River in California, including the Hydroelectric Reach, in a similar manner to that discussed under Potential Impact 3.20-6, although to a lesser degree. This alternative would result in continuation of some of the stresses that currently affect Chinook salmon populations. The presence of dams and reservoirs under the Continued Operations with Fish Passage Alternative would continue to cause seasonally poor water quality, and high late summer and early fall water temperatures, allowing some conditions favorable for the transmission of fish disease to persist. Due to implementation of actions contained within PacifiCorp's Reservoir Management Plan, these conditions are likely to improve somewhat over the long term, however not to the degree expected under the Proposed Project. Overall, the Continued Operations with Fish Passage Alternative would have a beneficial effect on fishing for anadromous fish compared with existing conditions.

There would be no potential impacts on Wild and Scenic River resources, designations, or eligibility for listing due to construction of fish passage facilities (Potential Impact 3.20-7). In summary, with the exception of the loss of whitewater boating opportunities in the Hell's Corner Reach relative to existing conditions (which would be a significant and unavoidable impact), improvements in recreational fishing opportunities due to an increase in anadromous fish habitat (which would be a beneficial effect), and minor visual changes due to fish passage improvements (which would result in no significant impacts), scenery, recreation, fisheries, and wildlife conditions would remain consistent

[203] This reach is within the Hydroelectric Reach, extending approximately 16.4 river miles from J.C. Boyle Reservoir to Copco No. 1 Reservoir.

with existing conditions and there would be no short-term (0−5 years) or long-term (5+ years) impacts to recreational resources.

4.4.21 Hazards and Hazardous Materials

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. Construction activities required for fish passage facilities would be within the construction Limits of Work for the Proposed Project and would have similar potential for hazards and hazardous materials-related impacts as described in Section 3.21.5 *[Hazards and Hazardous Materials] Potential Impacts and Mitigation*. However, the level of construction under this alternative would be less than the level of construction necessary for removal of the Lower Klamath Project dam facilities under the Proposed Project and would result in less transport, use, and disposal of general construction waste materials (i.e., transport of waste materials from the removed dam facilities would not occur) and of hazardous materials from decommissioning of generation and transmission facilities (Potential Impacts 3.21-1, 3.21-2, and 3.21-4). For the reasons described under the Proposed Project, implementation of Mitigation Measure HZ-1 would result in no significant impacts.

The existing hazardous materials that have been identified at the Lower Klamath Project dam complexes would not be altered compared with existing conditions (Potential Impact 3.21-4). Therefore, there would be no significant impact.

For the reasons described under the Proposed Project, there would be no significant impacts due to hazards or hazardous materials in relation to schools (Potential Impact 3.21-3), public airports (Potential Impact 3.21-5), or private airstrips (Potential Impact 3.21-6).

Although the level of construction under this alternative would be less than the level of construction necessary for removal of the Lower Klamath Project dam facilities under the Proposed Project, this alternative could still result in short term impacts consisting of an increase in traffic on narrow rural roads from commuting workers, hauling of large equipment, and disposal of wastes. This additional traffic could interfere with emergency response vehicles as well as create a situation requiring an additional need for emergency response due to personal and vehicular accidents, natural and worksite-caused fires, and accidental releases of hazardous materials in the same manner as under the Proposed Project, though to a lesser degree (Potential Impact 3.21-7). This alternative could also result in an increased risk of wildland fires in the short term due to construction site activities (Potential Impact 3.21-8). It is not clear whether the hydroelectric project owner or operator would implement measures relating to traffic management, emergency response, and construction-related fire management through ‘good citizen’ agreements, as described in the Definite Plan, and it is unclear how these measures would be enforced. Without an enforcement mechanism, these measures cannot be deemed feasible for the purposes of CEQA. Therefore, these impacts would be significant and unavoidable.

In the long term, there would be no impact related to the potential for longer response times and limitations on access to Klamath River water for fighting wildland fires under this alternative since the Lower Klamath Project reservoirs would not be removed (Potential Impact 3.21-8). This alternative would be the same as existing conditions. As the Continued Operations with Fish Passage Alternative does not include physical or operational changes that would affect other aspects of hazards and hazardous materials in the long term, there would be no significant long-term impact related to hazards and hazardous materials.

4.4.22 Transportation and Traffic

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. These construction activities would include the type of transportation and traffic impacts described for the Proposed Project (Potential Impacts 3.22.5-1 through 3.22.5-6). Although the level of construction under this alternative would be less than the level of construction necessary for removal of the Lower Klamath Project dam complexes under the Proposed Project, this alternative could still result in an increase in traffic on narrow rural roads from commuting workers, hauling of large equipment, and disposal of wastes, particularly for fishway construction at Iron Gate Dam and Copco No. 1 dams, which would last for 12 months and 9 months, respectively (Table 4.4-1). For reasons described for the Proposed Project (Section 3.22 *[Traffic and Transportation] Potential Impacts and Mitigation*), this would be a significant impact compared with existing conditions. Implementation of measures such as those contained in the Traffic Management Plan and Emergency Management Plan proposed by the KRRC, as well as Recommended Measure TR-1, would be expected to reduce construction-related impacts to less than significant under this alternative. It is not clear, however, whether the hydroelectric project owner or operator would implement these measures through 'good citizen' agreements, as described in the Definite Plan, and it is unclear how these measures would be enforced. Without an enforcement mechanism, these measures cannot be deemed feasible for the purposes of CEQA. Therefore, this alternative would result in significant and unavoidable traffic and transportation impacts.

Facility construction, and thus any related potential transportation and traffic impacts, for trap and haul would be less than that described for fish ladders. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Iron Gate Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Iron Gate Dam. Roads within the traffic and transportation Area of Analysis currently carry substantially fewer vehicles than the planning capacity (Table 3.22-2 and Section 3.22.2.1*Traffic Flow*), such that additional truck trips, assuming both upstream and downstream trap and haul operations, would not substantially change traffic conditions. Although the exact extent and timing of these ongoing hauling activities is not known, it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 60 to 70 miles each way between Iron Gate Dam and J.C. Boyle Reservoir. Therefore, trap and haul traffic would be a less than significant impact.

Significance
No significant impact

4.4.23 Noise

Under the Continued Operations with Fish Passage Alternative, construction activities would occur to install upstream and downstream fish ladders at all four Lower Klamath Project dam complexes. Construction activities would result in potential noise impacts in the same manner as described for the Proposed Project in Section 3.23.5 *[Noise] Potential Impacts and Mitigation*. Although the level of construction required for fish passage facilities would be less than construction required for removal of the Lower Klamath Project dam complexes, any use of dozers, jackhammers, and/or tractors would constitute an exceedance of the maximum allowable noise levels identified in the Siskiyou County General Plan Noise Element (Siskiyou County 1978) and would be a significant impact (Potential Impact 3.23-1). Implementation of a noise and vibration control plan such as that proposed by the KRRC (Appendix B: *Definite Plan – Appendix O5*) would reduce the short-term noise-related impacts from fish passage construction activities at Copco No. 1, Copco No. 2, and Iron Gate dams (Impacts 3.23-1 through 3.23-6). It is not clear, however, whether the hydroelectric project owner or operator would implement noise and vibration control measures through 'good citizen' agreements, as described in the Definite Plan, and it is unclear how these measures would be enforced. Without an enforcement mechanism, the NVCP cannot be deemed feasible for the purposes of CEQA. Further, since any use of dozers, jackhammers, and/or tractors would constitute an exceedance of the maximum allowable County noise levels, noise-related impacts on sensitive receptors at Copco No. 1 and Iron Gate dams would remain significant and unavoidable (Potential Impact 3.23-1).

Due to the natural topography surrounding Copco No. 2 Dam and the distance between the dam and the closest receptor (see Potential Impact 3.23-3), noise from on-site construction activities at the Copco No. 2 Dam would be reduced by more than 65 dB (approximately 35 dB by the distance and an additional 30 dB due to the topography). This amount of noise and vibration reduction would reduce impacts on sensitive receptors such that there would not be a substantial increase and there would be no significant impact at sensitive receptors.

Activities associated with the implementation of seasonal trap and haul operation prescriptions for a new FERC license for the Continued Operations with Fish Passage Alternative could increase traffic noise on local roads. However, the number of trucks and travel frequency would be significantly less than during the construction phase of the project and there would be no significant traffic noise impact to sensitive receptors. If trap and haul is combined with an additional fishway prescription, such that it is used for either upstream or downstream fish passage from below Iron Gate Dam to above J.C. Boyle Dam, truck trips would be less and there also would be no substantial increase in noise and vibration on sensitive receptors and there would be no significant impact. Therefore, noise-related impacts due to traffic noise along haul routes (Potential Impact 3.23-7) would not result in a substantial increase of noise on sensitive receptors and would result in no significant impact.

Moving or elevating structures with flood risk and modification of downstream water intakes, and construction activities related to deepening or replacement of existing groundwater wells, would not occur under this alternative, and would therefore result in no noise change from the existing condition (Potential Impacts 3.23-8, 3.23-9, and 3.23-10, respectively).

4.5 Two Dam Removal Alternative

4.5.1 Introduction

4.5.1.1 Alternative Description

In the Two Dam Removal Alternative, Copco No. 1 and Iron Gate dams and associated facilities would be fully removed, and J.C. Boyle and Copco No. 2 dams and associated facilities would remain. The J.C. Boyle facilities that would remain include (see also Figure 2.3-1):

1. A 2,629-acre-feet reservoir (J.C. Boyle Reservoir);
2. A 68-foot tall earthfill dam (J.C. Boyle Dam), concrete spillway, and three spill gates;
3. A concrete intake structure connecting to a 2.5-mile water conveyance system with an overflow forebay;
4. A 98-megawatt (MW) J.C. Boyle Powerhouse;
5. A switchyard with 2.8 miles of transmission lines; and
6. Ancillary buildings including an office building (known as the Red Barn), maintenance shop, fire protection building, communications building, two occupied residences, and a warehouse.

The Copco No. 2 facilities that would remain include (see also Figure 2.3-3):

1. A 70-acre-feet reservoir (Copco No. 2 Reservoir);
2. A 32-foot tall concrete diversion dam (Copco No. 2 Dam) including a gated spillway, basin apron, end sill, and a remnant cofferdam upstream of the concrete dam below the normal water surface elevation of the reservoir;
3. An approximately 15,000-square foot earthen embankment section with a gunite cutoff wall along the river right sidewall;
4. A diversion water conveyance system consisting of 3,610 feet of concrete-lined, 16-foot diameter conveyance tunnel, 1,330 feet of a 16-foot diameter wooden-stave penstock, an underground surge tank, a 405.5-foot long, 16-foot diameter steel penstock, and a 410.6-foot long, 16-foot diameter steel penstock;
5. A 7,000-square foot, 27-MW Copco No. 2 Powerhouse;
6. A 1,900-square foot control center building;
7. A 4,500-square foot maintenance building;
8. A 650-square foot oil and gas storage building; and
9. The nearby mostly vacant Copco Village, with a total structure area of 32,200 square feet, consisting of a cookhouse, bunkhouse, storage building, bungalow, three modular houses, four old style ranch houses, and a schoolhouse/community center.

This alternative assumes that the J.C. Boyle and Copco No. 2 dams and associated facilities would be relicensed by FERC for continued operations with changes to allow for upstream and downstream fish passage and updated flow requirements. More specifically, the Two Dam Removal Alternative assumes conditions described in the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and*

Iron Gate Alternative[204] for J.C. Boyle Dam and Copco No. 2 Dam. The primary conditions under the Two Dam Removal Alternative are the following:

- *Fishway Prescriptions* – upstream and downstream fish passage at J.C. Boyle Dam and Copco No. 2 Dam consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007) and upheld in a trial-type administrative hearing, and any specific fishway facility design and construction details included in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*[204], including fishway (i.e., fish passage structures installation for both upstream and downstream migrations and barriers to prevent entrainment into turbines);
- *Changes to J.C. Boyle Operations* – At least 40 percent of J.C. Boyle Reservoir inflow to be released downstream through the J.C. Boyle Bypass to increase minimum flows in the Bypass Reach (RM 225.2 to RM 229.8). J.C. Boyle hydroelectric peaking operations and/or recreation flows would not occur under the Two Dam Removal Alternative since Copco No. 1 and Iron Gate dams would not be present to reregulate flows downstream[205]. Power generation would be suspended and all inflow to J.C. Boyle Reservoir would be released down the Bypass Reach under a seasonal high flow event that would occur for seven full days in later winter/spring when inflows to J.C. Boyle first exceed 3,300 cfs (DOI 2007, NMFS 2007, FERC 2007); and
- *Changes to Copco No. 2 Operations* – Increase in minimum flows for the Copco No. 2 Bypass Reach (RM 200.0 to RM 201.5), with a release of 70 cfs or inflow, whichever is less, to the Bypass Reach. Inflow would be computed as a 3-day running average of flows at the J.C. Boyle Powerhouse gage added to the flow from Shovel Creek, as measured by a new gage (FERC 2007).

The following conditions under the Two Dam Removal Alternative are a modification to the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*:

- Flows specified in the NMFS and USFWS 2013 BiOp for the USBR Klamath Irrigation Project, which are currently being considered under reinitiated consultation (see also 3.1.6.1 *Klamath River Flows under the Klamath Irrigation Project's 2013 BiOp*).

As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing and emergency dilution flows are required to be released from Iron Gate Dam as part of re-initiation of consultation on the 2013 BiOp Flows, but they are not modeled as part of existing conditions hydrology. Potential new BiOp flow requirements under this alternative are speculative at this time, and it is not clear whether flushing and emergency dilution flow requirements would continue under the new BiOp during or after dam removal. However, the 2017 flow

[204] The KHSA 2012 EIS/EIR's *Section 2.4.5 Fish Passage at Four Dams Alternative* and *Section 2.4.6 Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative* (Appendix U) include fishway facility design and construction details beyond what are specifically required in the FERC prescriptions and that are based on designs of similar fishway facilities used at other hydroelectric facilities.

[205] Although it would remain in place under this alternative, Copco No. 2 Reservoir does not have adequate capacity to reregulate flows associated with J.C. Boyle Dam peaking operations so that they would be suitable for fish downstream.

requirements are considered to be the most reasonable assumption for conditions until agency formal consultation is completed and a new BiOp is issued. For analysis of potential impacts related to fish disease, the Two Dam Removal Alternative considers conditions with and without 2017 court-ordered flushing and emergency dilution flows.

Additionally, Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project* addresses the potential effects of using fishways other than the volitional ladders described in the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*, and points out where such other fishways would result in different effects than fish ladders. Such fishway installation could include volitional facilities, or trap and haul facilities, or a combination of approaches. Regardless of how fish passage is provided, this alternative assumes fish passage consistent with the general prescriptions (DOI 2007) that cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007).

This alternative does not make any assumptions regarding conditions that could be imposed by the states of Oregon or California through water quality certification authority.

The aforementioned flow-related measures would reduce power generation at J.C. Boyle Dam. Power generation at Copco No. 2 Dam would decrease relative to existing conditions since Copco No. 1 would not be present upstream to regulate flows entering the Copco No. 2 Powerhouse. This alternative assumes that installation of fish passage facilities would follow the schedule described in *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*[206], which would install downstream passage facilities prior to upstream passage facilities and would take place over a 4-month period (June through September of dam removal year 2) for both J.C. Boyle Dam and Copco No. 2 Dam. The level of construction for J.C. Boyle and Copco No. 2 fish passage would be consistent with that estimated for development of the 2012 KHSA EIS/EIR *Fish Passage at Four Dams Alternative,* which includes removal of the existing J.C. Boyle fish ladder structure, construction of a new fishway at or near the same location as the existing fish ladder (Figure 2.3-1), and construction of downstream fish passage for J.C. Boyle Dam, as well as construction of upstream and downstream fish passage for Copco No. 2 Dam.

As neither the Fall Creek nor the Iron Gate hatchery facilities were built to address potential fisheries effects of J.C. Boyle Dam or Copco No. 2 Dam (Boyle 1976), this alternative assumes that hatchery operations would continue for eight years, with reduced production goals consistent with those described for the Proposed Project (see Section 2.7.6 *Hatchery Operations*).

---

[206] Fishway feature design was provided in the 2012 KHSA EIS/EIR *Section 2.4.5 Fish Passage at Four Dams Alternative* and *Section 2.4.6 Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative* (Appendix U) and is used for this EIR to support the construction-related effects analysis. The KRRC would be required to obtain concurrence from USFWS and NMFS regarding fishway design and construction plans for each Lower Klamath Project facility prior to advancing to feasibility-level of design.

Although leaving the J.C. Boyle Dam facilities in place, removing the existing fish ladder and installing a new fish ladder, would be less construction than removing the dam and associated facilities, this difference would not decrease the degree of construction activities or the associated impacts to resources in California since J.C. Boyle is located in Oregon. In California, removal of the Iron Gate and Copco No. 1 facilities would be the same as described for the Proposed Project. California materials import for Copco No. 1 and Iron Gate would be the same as that described in Section 2.7.1 *Dam and Powerhouse Deconstruction* and California waste disposal quantities, truck trips, and haul distances would be the same as presented in Table 2.7-3 (Copco No. 1 Dam) and Table 2.7-7 (Iron Gate Dam). None of the deconstruction activities described in Section 2.7.1.3 *Copco No. 2 Dam and Powerhouse* would occur under this alternative, eliminating the need for offsite transport and disposal of the waste materials and quantities listed in Table 2.7-5 such that overall haul distances for waste disposal would be lower than those described for the Proposed Project. Additional import of construction materials in California would be required for fishway construction at Copco No. 2, which could include approximately 1,000 cubic yards of reinforced concrete (2012 KHSA EIS/EIR, Table 2-26) depending on the type of fish passage facilities that would be constructed. This amount of import would be considerably less than the bulk quantity of concrete that would be removed from Copco No. 2 Dam and Powerhouse under the Proposed Project (Table 2.7-5). Leaving Copco No. 2 Powerhouse and the wooden-stave penstock in place under this alternative would avoid the need for replacing Daggett Road Bridge (Appendix B: *Definite Plan – Section 5.4 Copco No. 2 Dam and Powerhouse*) and any associated materials import and waste disposal, and it would avoid the need to dispose of 700 tons of treated wood (Table 2.7-5). Recreation facilities near J.C. Boyle Reservoir would remain intact, and the Copco No. 2 Reservoir does not have any developed recreation facilities. Recreation facilities at Iron Gate and Copco No. 1 reservoirs would be removed, as described under the Proposed Project (Section 2.7.8.3 *Recreation Facilities Management*).

Overall, under the Two Dam Removal Alternative the level of construction activities in California in the Hydroelectric Reach due to dam deconstruction at Copco No. 1 and Iron Gate facilities, and construction of upstream and downstream fish passage at Copco No. 2 Dam would be slightly less than those described under the Proposed Project, since full removal of the two largest dam facilities (Copco No. 1 and Iron Gate) would still occur. Workforce projections under the Two Dam Removal Alternative are presented in Table 4.5-1. Since construction activities for fish passage would occur at J.C. Boyle Dam and Copco No. 2 Dam concurrent with activities for removal of the Copco No. 1 and Iron Gate dams and associated facilities (i.e., for a 4-month period June through September of dam removal year 2), any construction-related impacts would also occur concurrently and some of these (e.g., water quality) that occur in Oregon could also result in downstream impacts in California.

Table 4.5-1. Estimated Construction Workforce for the Two Dam Removal Alternative.

Dam	Estimated Average Construction Workforce[a]	Duration	Estimated Peak Workforce	Peak Period
J.C. Boyle*	10 to 15 people[a]	4 to 6 months[a]	15-20 people[a]	Jun−Sep dam removal year 2[b]
Copco No. 1	35 people[b]	12 months[b]	55 people[b]	Apr–Nov dam removal year 2[b]
Copco No. 2	10 to 15 people[a]	4 to 6 months[a]	15-20 people[a]	Apr−Sept dam removal year 2[b]
Iron Gate	40 people[b]	10 months[b]	80 people[b]	Jun−Sep dam removal year 2[b]

* J.C. Boyle Dam is included in this table as some of the traffic flow may use roads in California (e.g., I-5 to OR 66)
[a] 2012 KHSA EIS/EIR
[b] Appendix B: *Definite Plan – Section 5*

If instead of fish ladders, trap and haul or some combination of fish passage methods were used, there would be the potential for reduced construction compared to the aforementioned activities for fish ladders. While trap and haul facilities differ by site, common features include a trap holding pool, diffusers or gates to guide fish into the trap, a channel or port for discharge of attraction flows, a lift mechanism for truck-loading fish, a truck loading station, and a discharge platform. Much of the trap and haul facility would be located in-stream, with only the truck loading station and discharge platform potentially requiring upland grading or other earthwork.

As described for the Proposed Project (Section 2.7.2 *Reservoir Drawdown*), power generation at Copco No. 2 Dam could continue to occur during removal of the other Lower Klamath Project dams and associated facilities if Copco No. 2 power generating equipment proves capable of operating under sediment-laden flow conditions. However, high suspended sediment concentrations (SSCs) that would occur during drawdown of the upstream J.C. Boyle and Copco No. 1 reservoirs could damage the turbines in Copco No. 2 Powerhouse such that they would require repair to support future operations. This EIR assumes continued powerhouse operations at Copco No. 2 during dam removal year 2 as described for the Proposed Project (see Section 2.7.2 *Reservoir Drawdown*) as the need to halt power generation is speculative. Water diversions for hydropower generation at Copco No. 2 would continue to affect flows in the 1.5-mile-long Bypass Reach in the Klamath River between the Copco No. 2 Dam and the Copco No. 2 Powerhouse (Figure 2.3-3) under this alternative.

Under the Two Dam Removal Alternative, the long-term use of the land currently underlying Iron Gate and Copco No. 1 reservoirs is more uncertain than under the Proposed Project, because the KHSA (including Section 7.6.4 that addresses land disposition) would not apply. It is possible that the hydroelectric license holder would reach an agreement to transfer the lands in and surrounding the Copco No. 1 and Iron Gate reservoirs for public interest purposes, in a manner similar to under the KHSA. If this were to happen, the potential impacts would be as analyzed under the Proposed Project, except that the land associated with Copco No. 2 facilities would not be made available.

It is also possible that the dams would remain undeveloped and under the Licensed hydroelectric facility operator, in light of continued operations in the area, or that they would be used for additional revenue generation, such as for lease or additional residential, commercial, or industrial development. It is also possible that a combination of these two scenarios would occur.

Because long-term land use under this alternative is currently unknown, this alternative does not assess the potential impacts of long-term use of the lands currently submerged under Iron Gate and Copco No. 1 reservoirs as that would require speculation.

4.5.1.2 Alternative Analysis Approach

The potential impacts of the Two Dam Removal Alternative are analyzed in comparison to existing conditions, with reference to impact analyses conducted for the No Project Alternative or Proposed Project, where appropriate. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the Two Dam Removal Alternative are the same as those described for the Proposed Project (see Section 3.1 *Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures*). The potential impacts for each environmental resource area are analyzed both in the short term and the long term, and unless otherwise indicated, use the same definitions of short term and long term as described for each resource area analyzed for the Proposed Project.

4.5.2 Water Quality

Water quality modeling specifically for the Two Dam Removal Alternative is limited compared to the available modeling for the Proposed Project or the No Project Alternative, but the influence of J.C. Boyle and Copco No. 2 dams and the effects of J.C. Boyle and Copco No. 2 dams remaining in place can be assessed through a combination of modeling scenarios equivalent to the Two Dam Removal Alternative or interpretation of the modeling done for the Proposed Project or other alternatives. Water quality models and modeling scenarios for evaluating the impacts of the Two Dam Removal Alternative are summarized in Appendix D. An analysis of model results from different reaches within the Klamath River highlights how J.C. Boyle and Copco No. 2 dams remaining in place would impact water quality. The influence of J.C. Boyle Dam on water quality can be assessed by the Klamath River Water Quality Model (KRWQM) and the River Basin Model 10 (RBM10), which both include modeling scenarios that have J.C. Boyle Dam remaining in place and Copco No. 1, Copco No. 2, and Iron Gate dams removed. The Klamath TMDL model includes a “TMDL dams-in” scenario (T4BSRN), which approximates the condition where the Lower Klamath Project dams remain in place, as well as the TOD2RN (Oregon reaches) and TCD2RN (California reaches) scenarios (together the “TMDL dams-out” scenario) that assume the removal of the Lower Klamath Project (see Appendix D for more detail). The Klamath TMDL model assumes full TMDL implementation for both “TMDL dams-in” and “TMDL dams-out” scenarios. While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*). Comparison of “TMDL dams-in” and “TMDL dams-out" model results and comparisons of Proposed Project model results at different points in the Hydroelectric Reach (SRH-1D) also documents the influence of J.C. Boyle Dam. Models and modeling scenarios generally did not represent Copco No. 2 Dam due to its small size and short distance downstream of Copco No. 1 Dam. The influence of Copco No. 2 Dam and how its presence or absence would impact water quality in the Klamath River is determined by assessing the size, average water velocity, and hydraulic residence time of Copco No. 2 Reservoir compared to process(es) influencing the water quality parameters (e.g., settling velocity for suspended sediments). Overall, the available water quality modeling results provide sufficient information that the water quality impacts under the Two Dam Removal Alternative can be quantitatively or qualitatively assessed below.

4.5.2.1 Water Temperature

In general, the Two Dam Removal Alternative would have the same or similar potential impacts on water temperature in California as those identified under the Proposed Project. The presence of the J.C. Boyle Reservoir on the Klamath River does not alter water temperatures in downstream reaches because it has a shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days) that does not support thermal stratification (FERC 2007). However, J.C. Boyle Dam operations do influence Klamath River water temperatures by releasing water for peaking power generation and whitewater recreation. These releases cause water temperature variations in the J.C. Boyle Bypass and Peaking reaches, from the Oregon-California state line to Copco No. 1 Reservoir, due to diversion of warmer reservoir discharges around the J.C. Boyle Bypass Reach, cold groundwater spring flows into the J.C. Boyle Bypass Reach, and the mixing of these flows when they rejoin in the J.C. Boyle Peaking Reach of the Klamath River. The combination of these flows produce an observed increase in daily water temperature range above the natural diel water temperature fluctuations in the J.C. Boyle Peaking Reach at the Oregon-California state line.

The Two Dam Removal Alternative would not include peaking power generation or whitewater recreation flows from J.C. Boyle Dam as the downstream dams would not be available to regulate the peaking flows. Elimination of the peaking and recreation flows from J.C. Boyle Dam would likely result in J.C. Boyle Reservoir operating in a run of the river manner and increases in the water temperature range associated with J.C. Boyle operations would no longer occur under both the Two Dam Removal Alternative and the Proposed Project (see also Section 3.2.2.2 *Water Temperature*).

Model results analyzed for the Proposed Project do not explicitly isolate the effects of the four individual Lower Klamath Project reservoirs on water temperature, but the KRWQM includes a scenario in which only Iron Gate and Copco No. 1[207] dams are removed with J.C. Boyle Dam and Copco No. 2 remaining in place ("WIGC" PacifiCorp 2004a; Dunsmoor and Huntington 2006; see also Appendix D). While the KRWQM WIGC scenario does not document the water temperature effect of Copco No. 2 Dam remaining in place, it does show the effect of J.C. Boyle Dam remaining in place. The KRWQM WIGC scenario results indicate that compared with removal of all four Lower Klamath Project reservoirs ("WIGCJCB"), the long-term effects of keeping J.C. Boyle

[207] Copco No. 2 dam was not explicitly included in the model due to its negligible size and hydraulic residence time.

Dam and Copco No. 2 in place under the Two Dam Removal Alternative would be similar to effects on water temperature under the Proposed Project (Figure 4.5-1).

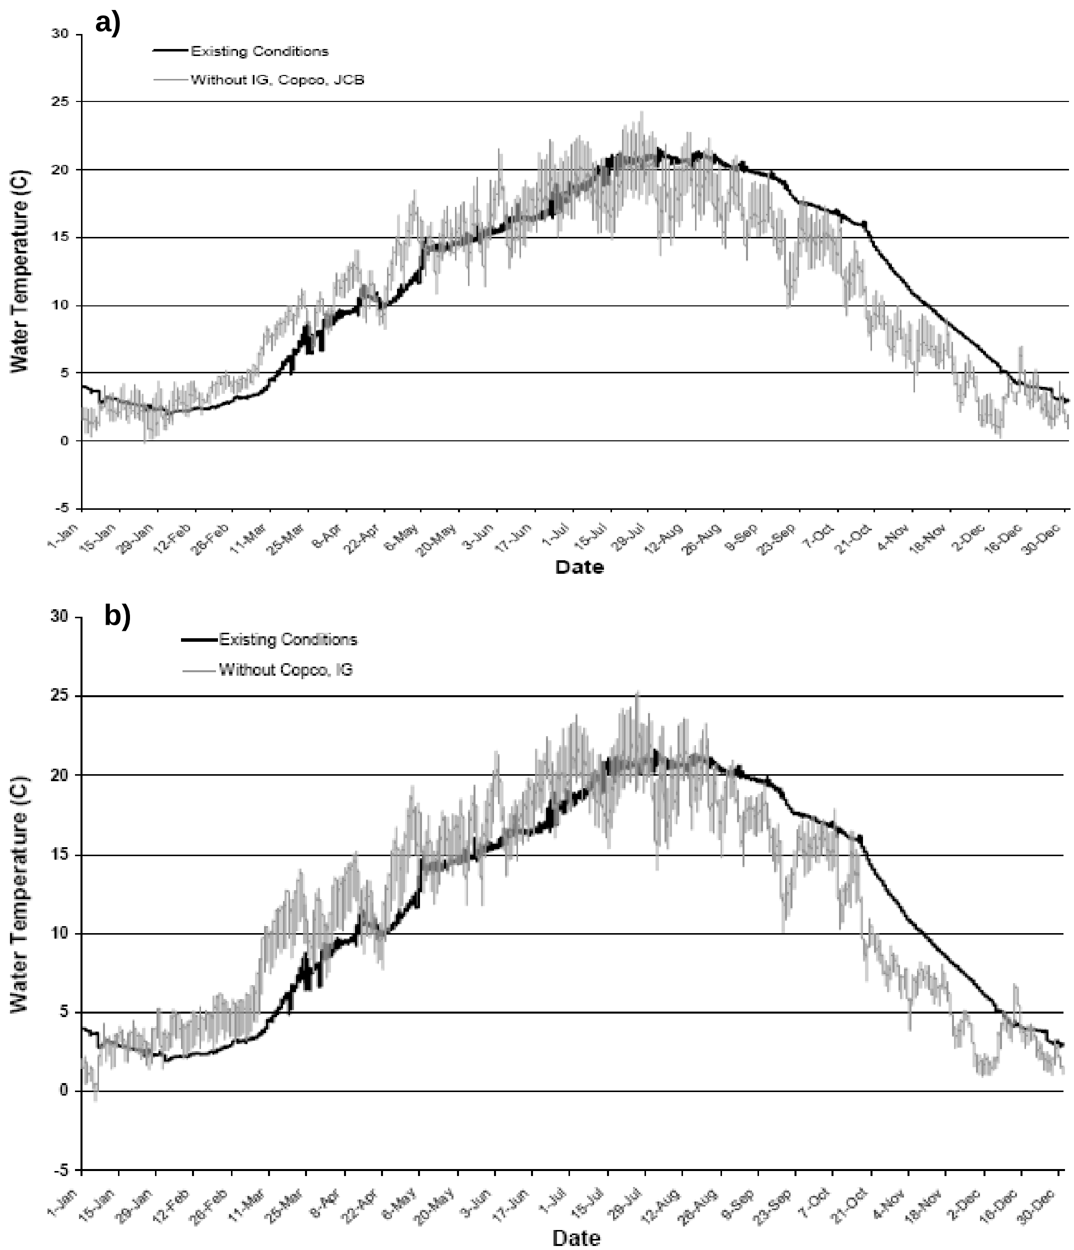

Figure 4.5-1. Simulated Hourly Water Temperature Downstream from Iron Gate Dam Based on Year 2004 for Current Conditions Compared to Hypothetical Conditions: (a) without Iron Gate (IG), Copco No. 1 and 2, and J.C. Boyle (JCB) Dams and (b) without Iron Gate (IG) and Copco No. 1 and 2 Dams. Source: PacifiCorp 2005.

Copco No. 2 Reservoir has a small volume (approximately 70 acre-feet), a short hydraulic residence time (less than a day), no active storage, and it does not thermally stratify, such that the reservoir has a negligible impact on water temperature, unlike the larger Copco No. 1 and Iron Gate reservoirs (see 3.2.2.1 *Overview of Water Quality Processes in the Klamath Basin*; FERC 2007; USBR 2012). Copco No. 2 Reservoir and Dam typically are not represented in modeling of the Klamath River as it is considered to have a negligible influence on water quality, including water temperature, in the Klamath River due to its small size, short hydraulic residence time, and lack of active storage. There is no data indicating Copco No. 2 Reservoir alters water temperatures in downstream reaches. As such, keeping Copco No. 2 Dam and Reservoir in place under the Two Dam Removal Alternative would not be anticipated to alter water temperature.

Relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on water temperature would be the same as or similar to those described for the Proposed Project, except as follows:

- J.C. Boyle Reservoir would not alter water temperature in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir and J.C. Boyle Dam operations for peaking and recreation releases that cause increases in the water temperature range would be eliminated under both the Two Dam Removal Alternative and the Proposed Project. Short-term and long-term alterations in water temperatures in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir under the Two Dam Removal Alternative would result in water temperature effects similar to those of the Proposed Project (i.e., slightly lower maximum water temperatures and less artificial diel temperature variation during summer and early fall, see also Potential Impact 3.2-1) and would be beneficial.
- Short-term and long-term alterations in water temperatures due to conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.2-1) and keeping Copco No. 2 Reservoir in place would be the same as under the Proposed Project as retaining Copco No. 2 Reservoir would not alter water temperature in the Klamath River, and the alterations would be beneficial for the Hydroelectric Reach and the Middle Klamath River to the confluence with the Salmon River. As under the Proposed Project, there would be no significant impact for the Middle Klamath River downstream from the Salmon River, the Lower Klamath River, or the Klamath River Estuary.
- Sediment trapped by J.C. Boyle Dam would not be released under the Two Dam Removal Alternative, but the magnitude of the sediment releases from Copco No. 1 and Iron Gate reservoirs would still be over 90 percent of the sediment releases under the Proposed Project (Table 2.7-11). Copco No. 2 Reservoir would not retain the sediment released from Copco No. 1 due to its short residence time and the sediment characteristics (see Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown* and Section 4.5.2.2 *Suspended Sediments*). Thus, the overall short-term and long-term alterations in seasonal water temperatures in the Klamath River due to potential morphological changes induced by sediment release from Copco No. 1 and Iron Gate reservoirs and subsequent deposition would be similar under the Two Dam Removal Alternative and the Proposed Project (Potential Impact 3.2-2), and there would be no significant impact.

4.5.2.2 Suspended Sediments

As the Two Dam Removal Alternative does not include the removal of J.C. Boyle and Copco No. 2 dams, short-term mobilization of J.C. Boyle reservoir sediment deposits would not occur under this alternative and the associated 1,190,000 cubic yards of deposits estimated to occur in the reservoir in 2020[208] (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-10 and 2.7-11) would not be eroded or delivered to downstream reaches and the Pacific Ocean. The approximately 27 to 51 percent of the sediment trapped behind the J.C. Boyle Dam predicted to move downstream through the California reaches of the Klamath River and out into the Pacific Ocean under the Proposed Project (USBR 2012) would not be transported under the Two Dam Removal Alternative. Copco No. 2 Dam also does not retain appreciable amounts of sediment (USBR 2011b) since Copco No. 1 Dam is 0.25 miles upstream and intercepts and retains all upstream sediment. As such, the variation in the amount of sediment transported under the Two Dam Removal Alternative compared to under the Proposed Project would be due to only the decrease from J.C. Boyle reservoir sediment deposited being retained.

Copco No. 1 and Iron Gate reservoirs contain approximately 92 percent of the total estimated 2020 reservoir deposits (50 and 42 percent, respectively) and approximately 92 to 94 percent of the amount of sediment anticipated to erode from these reservoirs under the Proposed Project (Table 2.7-11) would occur under the Two Dam Removal Alternative. Increases in suspended sediment concentrations (SSCs) in the Hydroelectric Reach upstream of Copco No. 1 Reservoir from removal of J.C. Boyle Reservoir would be eliminated under this alternative as reservoir sediment would not be released from J.C. Boyle Reservoir. While there would be some reduction in SSCs downstream of Copco No. 1 due to no SSCs being released by J.C. Boyle Dam removal, Copco No. 2 Dam is unlikely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*), such that leaving it in place would not result in a difference in short-term mobilization of reservoir sediment deposits or SSCs under the Two Dam Removal Alternative compared to the Proposed Project.

Modeling of SSCs downstream of Copco No. 1 Reservoir from release of only Copco No. 1 Reservoir sediment deposits across the wet, average, and dry water year types indicate SSCs, within the general uncertainty of the model, would peak at approximately 7,000 to 8,000 mg/L between Copco No. 1 Dam and Iron Gate Reservoir within one to two months of reservoir drawdown, then SSCs would decrease to generally less than 1,000 mg/L within approximately one more month (Figure 3.2-15; see Section 3.2.5.2 *Suspended Sediments*). Thus, SSCs in the Hydroelectric Reach between Copco No. 1 and Iron Gate reservoirs would still exceed the significance criteria for suspended sediment (SSCs greater than 100 mg/L over a continuous two-week exposure period) under the Two Dam Removal Alternative due to the overall magnitude of reservoir deposits still anticipated to erode from Copco No. 1 and Iron Gate reservoirs. Downstream of the Hydroelectric Reach, SSCs would also exceed the significance criteria for suspended sediment under the Two Dam Removal Alternative since over 90 percent of the reservoir deposited sediments anticipated to be transported under the

[208] Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable.

Proposed Project would still occur. Thus, the overall short-term impact of decreases in SSCs in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir due to J.C. Boyle Dam remaining in place, no change in SSCs from Copco No. 2 Dam remaining in place, and increases in SSCs due release of sediments currently trapped behind Copco No. 1 and Iron Gate dams under the Two Dam Removal Alternative would be similar to impacts under the Proposed Project in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment. (see Section 3.2.5.2 *Suspended Sediments* for additional details).

Sediments and suspended materials (inorganic and organic) would continue to be intercepted and retained behind J.C. Boyle Dam in the long term under the Two Dam Removal Alternative since that dam would remain in place. While the amount of sediment supplied to the Klamath River on an annual basis from the watershed upstream of J.C. Boyle Dam is a relatively small fraction of the total sediment (Stillwater Sciences 2010) (see also Section 3.11.2.4 *Sediment Load*), the long-term increase in mineral (inorganic) suspended material downstream of J.C. Boyle Dam under this alternative would be less than under the Proposed Project since J.C. Boyle Dam would continue to intercept upstream sediment. The majority of algal-derived (organic) suspended material from upstream sources (Upper Klamath Lake, Klamath Straights Drain, Lost River) is intercepted and retained by the Keno Impoundment/Lake Ewauna, but J.C. Boyle Dam does retain some algal-derived (organic) suspended material (see Appendix C, Section C.2.1 *Upper Klamath Basin* for more detail). Thus, the long-term increases in algal-derived (organic) suspended material downstream of J.C. Boyle Dam under this alternative would be less than under the Proposed Project since the dam would continue to intercept and retain upstream algal-derived suspended material.

Long-term interception and retention of sediments and suspended materials (inorganic and organic) would be minimal behind Copco No. 2 Dam[209] due to its small size and short residence time. Fine sediment and suspended material would be unlikely to accumulate behind Copco No. 2 Dam because the range of flow and water velocities along with the short residence time in Copco No. 2 Reservoir would inhibit appreciable amounts of fine sediment and suspended material from settling within the reservoir. However, some larger sediment (i.e., sand) that can settle out faster may accumulate over time behind Copco No. 2 Dam, but the overall interception and retention would be limited since J.C. Boyle Dam upstream would intercept and retain larger sediment from upstream of that dam. The sediment load in the Hydroelectric Reach from J.C. Boyle Dam to Copco No. 2 Dam is relatively small compared to upstream of J.C. Boyle Dam, and higher winter flows in Copco No. 2 Reservoir under the Two Dam Removal Alternative would be likely to mobilize desposited sand sediments. Thus, the long-term inteception and retention in sediments and suspended materials (inorganic and organic) behind Copco No. 2 Dam under this alternative would be minimal and the overall long-term inteception and retention in sediments and suspended materials would be similar to conditions under the Proposed Project.

Long-term interception and retention of sediments and suspended materials (inorganic and organic) would not occur behind Copco No. 1 and Iron Gate dams since they would be removed under the Two Dam Removal Alternative. Long-term increases in mineral

[209] Copco No. 2 Dam does not intercept or retain appreciable amounts of sediment (USBR 2011b).

(inorganic) and algal-derived (organic) suspended material under this alternative would be less than under the Proposed Project because J.C. Boyle Dam would continue to retain sediments and suspended materials from upstream of that dam. However, the overall long-term impact from changes in the interception of sediments due to retention of J.C. Boyle and Copco No. 2 dams and removal of Copco No. 1 and Iron Gate dams would be similar under both the Two Dam Removal Alternative and the Proposed Project. The long-term increases in mineral (inorganic) and algal-derived (organic) suspended material due to the lack of interception by the dams would be a less than significant impact under the Proposed Project as only a small amount of sediment and suspended material is delivered from upstream of J.C. Boyle Dam. Thus, a decrease in the amount of sediment transported downstream under the Two Dam Alternative due to the retention of J.C. Boyle and Copco No. 2 dams and removal of Copco No. 1 and Iron Gate dams would still be a less than significant impact.

Relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on suspended sediments would be the same as or similar to those described for the Proposed Project, except as follows:

- As discussed in the first two paragraphs of this section, there would be no change in SSCs from the existing conditions in the Hydroelectric Reach between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir since sediment deposits in J.C. Boyle Dam would remain in place. While Copco No. 2 remaining in place would not retain appreciable amount of sediments or alter SSCs during drawdown, the increases in suspended sediment in the Hydroelectric Reach due to release of sediments currently trapped behind Copco No. 1 and Iron Gate Dams would remain a short-term significant and unavoidable impact for the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary (Potential Impact 3.2-3). The magnitude of suspended sediments increases in the Pacific Ocean nearshore environment due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams would be within the range of historical conditions, but the duration (i.e., weeks) of elevated suspended sediments would be greater than historical conditions, thus there would be a short-term significant and unavoidable impact on suspended sediments in the Pacific Ocean nearshore environment (Potential Impact 3.2-3). Suspended sediments would resume modeled background levels by the end of Post-Dam removal year 1, so there would be no significant impact in the long term for the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment (Potential Impact 3.2-3). The short-term significant impact of increased SSCs in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment due to removal of Copco No. 1 and Iron Gate dams cannot be avoided or substantially decreased through reasonably feasible mitigation.
- While there would not be potential construction-related short-term increases in suspended material from removal of J.C. Boyle Dam under the Two Dam Removal Alternative, there would be construction of new fish passage facilities at J.C. Boyle Dam that would potentially result short-term increases in suspended material downstream in California. Although short-term dam deconstruction activities would not occur at Copco No. 2 Dam under the Two Dam Removal Alternative, construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur. As such, the level of overall

construction activities in the Hydroelectric Reach in California would be slightly less than under the Proposed Project. Potential construction-related short-term increases in suspended material from pre-construction, dam removal, and restoration activities at Copco No. 1 and Iron Gate dams would be the same under this alternative as under the Proposed Project since these activities would occur in both scenarios. Under the Two Dam Removal Alternative, short-term increases in suspended material from stormwater runoff due construction activities associated with new fish passage facilities at J.C. Boyle and Copco No. 2 dams, a new day use area near Copco No. 2 Dam, and pre-construction, dam removal, and restoration activities at Copco No. 1 and Iron Gate dams would be potentially significant short-term impacts without mitigation in the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam and in the Middle Klamath River immediately downstream of Iron Gate Dam (Potential Impact 3.2-4). Implementation of mitigation measures WQ-1, TER-1, and HZ-1 would reduce this potential impact under the Two Dam Removal Alternative to no significant impact with mitigation, similar to the Proposed Project.

- As discussed earlier in this section, there would be no long-term change from existing conditions regarding the interception and retention of mineral (inorganic) (Potential Impact 3.2-5) or algal-derived (organic) (Potential Impact 3.2-6) suspended material by J.C. Boyle Dam in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir under the Two Dam Removal Alternative because J.C. Boyle Dam would remain in place and continue to intercept and retain mineral and algal-derived suspended material to the same extent that it currently does. Similar to under the Proposed Project, there would be potential long-term increases in suspended material in the Hydroelectric Reach downstream of Copco No. 1 Reservoir because Copco No. 1, and Iron Gate dams would be removed under this alternative and they would no longer intercept and retain suspended material. Copco No. 2 Dam remaining in place under this alternative would not alter the long-term change in sediments and suspended materials (inorganic and organic) compared to the Proposed Project because the small size and short residence time of Copco No. 2 Reservoir would limit the trapping of sediment and suspended material (inorganic and organic). Overall, keeping J.C. Boyle and Copco No. 2 dams in place and removing of Copco No. 1 and Iron Gate dams would result in a long-term increase in suspended material under the Two Dam Removal Alternative similar to the Proposed Project due to the lack of continued interception and retention of mineral (inorganic) and algal-derived (organic) downstream of Copco No. 1 Dam and there would be no significant impact for the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam, the Middle Klamath River, Lower Klamath River, Klamath River Estuary, and the Pacific Ocean nearshore environment (Potential Impacts 3.2-5 and 3.2-6).

4.5.2.3 Nutrients

Short-term or long-term increases in sediment-associated nutrients due to release of J.C. Boyle reservoir sediment deposits would not occur in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Two Dam Removal Alternative because none of the associated 1,190,000 cubic yards of deposits estimated to occur in the reservoir in 2020[210] (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches. As detailed in Section 4.5.2.2 *Suspended Sediments*, approximately 27 to 51 percent of the sediment trapped behind the J.C. Boyle Dam is predicted to be transported under the Proposed Project (USBR 2012), but this would not occur under the Two Dam Removal Alternative. Thus, nutrients associated with these sediments also would not be transported downstream and there would be no increase in sediment-associated nutrients from existing conditions in the Hydroelectric Reach between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir.

Approximately 92 to 94 percent of the sediment anticipated to erode from Copco No. 1 and Iron Gate reservoirs under the Proposed Project (Table 2.7-11) would occur under the Two Dam Removal Alternative and mobilization of nutrients associated with these reservoir sediment deposits would occur. The majority of sediment-associated nutrients would be transported under both this alternative and the Proposed Project, but sediment-associated nutrients downstream of Copco No. 1 Dam would be slightly less under the Two Dam Removal Alternative than under the Proposed Project because nutrients associated with J.C. Boyle reservoir sediments would not contribute to nutrient concentrations. Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b) under existing conditions and it is not expected to trap appreciable amounts of sediment during drawdown, so keeping Copco No. 2 in place under the Two Dam Removal Alternative would not alter the amount of sediment-associated nutrients transported downstream compared to under the Proposed Project. Thus, the overall pattern and duration of short-term and long-term increases in sediment-associated nutrients due to release of sediments from behind the Copco No. 1 and Iron Gate dams under the Two Dam Removal Alternative would be similar to the Proposed Project in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment, but the magnitude of nutrient concentrations would be slightly less. See Section 3.2.5.3 *Nutrients* for further details.

Since J.C. Boyle Dam would remain in place, continuing interception and retention of sediment-associated nutrients and suspended materials would still occur behind J.C. Boyle Dam in the long term. However, Klamath TMDL modeling[211] and empirical data indicate that J.C. Boyle Dam does not retain high amounts of nutrients such that long-term effects of dam removal on nutrient levels in the Hydroelectric Reach under the Proposed Project would be primarily due to the removal of Copco No. 1 and Iron Gate dams (see generally Section 3.2.2.4 *Nutrients* and Section 3.2.5.3 *Nutrients* for information on the existing conditions for nutrients in the reservoirs). Under existing conditions, Klamath TMDL modeling[211] indicates interception results in Copco No. 1

[210] Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable.

[211] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

retaining approximately 10.0 percent of the annual total nitrogen and approximately 5.1 percent of the annual total phosphorus; and Iron Gate retaining approximately 6.7 percent of the annual total nitrogen and approximately 3.3 percent of the annual total phosphorus (North Coast Regional Board 2010). The relative amounts of nutrient retention in each of the reservoirs without full TMDL implementation may be somewhat higher than the aforementioned estimates because the model mechanism increases the rate of retention as incoming nutrient concentrations increase; however, the model mechanism also indicates that the longer the retention time of water in the reservoir, the higher the nutrient retention. Copco No. 1 and Iron Gate reservoirs have average retention times of 11 days and 15 days, respectively, while J.C. Boyle Reservoir has a lower retention time of only approximately 1 day (Table 3.6-4) and thus allows most sediment-associated nutrients to pass through J.C. Boyle Reservoir and move downstream. Under the Two Dam Removal Alternative, long-term interception and retention of sediments and sediment-associated nutrients behind Copco No. 1 and Iron Gate dams would cease, similar to the Proposed Project, as the facilities would be removed. While Copco No. 2 Dam may retain some larger sediment (i.e., sand or larger), nutrients are not associated with such larger sediments and Copco No. 2 Dam is not anticipated to retain appreciable amount of fine sediment that have sediment-associated nutrients after removal of Copco No. 1 and Iron Gate dams. Thus, Copco No. 2 Dam staying in place under the Two Dam Removal Alternative would not alter long-term transport of sediment-associated nutrients compared to the Proposed Project.

Relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on nutrients would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term or long-term change to the existing condition with regard to sediment-associated nutrients in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir, since sediment deposits in J.C. Boyle Dam would remain in place and no sediment-associated nutrients would be transported due to the release of sediments trapped behind J.C. Boyle Dam. Copco No. 2 Dam does not retain appreciable amounts of sediments or sediment-associated nutrients under existing conditions, so keeping Copco No. 2 in place under the Two Dam Removal Alternative would not alter the amount of sediment-associated nutrients transported downstream compared to under the Proposed Project. However, there would be short-term increases in sediment-associated nutrients due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams as in the Proposed Project (Potential Impact 3.2-7). Potential short-term increases in suspended material from construction of a new fish ladder at J.C. Boyle would be not result in short-term increases in sediment-associated nutrients since potential construction sediments would only have the nutrient content of the soils surrounding J.C. Boyle with substantially less nutrients than reservoir sediment deposits. As described in Section 3.2.5.3 *Nutrients*, this would result in no significant impact in the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam, the Middle Klamath River, the Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment.
- Under the Two Dam Removal Alternative, there would be no long-term change from existing nutrient levels due to interception of nutrients by J.C. Boyle Dam in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Dam would remain in place.

Copco No. 1 and Iron Gate dams would be removed and replaced by a free-flowing river under this alternative like in the Proposed Project, so these dams would no longer intercept and retain incoming nutrients. Copco No. 2 Dam would not retain appreciable amounts of sediments with sediment-associated nutrients, so keeping Copco No. 2 Dam in place would not alter the long-term nutrients levels compared to the Proposed Project. Long-term increases in nutrient levels from the lack of continued interception by the Copco No. 1 and Iron Gate dams and conversion of the reservoir areas to a free-flowing river (Potential Impact 3.2-8) would result in no significant impact under the Two Dam Removal Alternative for the Hydroelectric Reach, Middle and Lower Klamath River, Klamath River Estuary, and the Pacific Ocean nearshore environment, similar to the Proposed Project.

4.5.2.4 Dissolved Oxygen

J.C. Boyle reservoir sediment deposits (approximately 1,190,000 cubic yards in 2020 or approximately eight percent of total sediment volume trapped behind the Lower Klamath Project dams, see also Tables 2.7-7 and 2.7-8) would be not mobilized in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Two Dam Removal Alternative since J.C. Boyle Dam would remain in place (see Section 4.5.2.2 *Suspended Sediments*). Thus, the short-term mobilization associated effects of these sediments on sediment-associated oxygen demand and dissolved oxygen (i.e., high content of organic carbon present in the reservoir sediments allows for the possibility of microbial oxidation of organic matter exposed to the water column from deep within the sediment profile and mobilized during dam removal), would also not occur in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Two Dam Removal Alternative. However, approximately 92 to 94 percent the reservoir sediment deposits anticipated to erode under the Proposed Project would still occur in this alternative due to transport of reservoir sediments from Copco No. 1 and Iron Gate reservoirs (see Section 4.5.2.2 *Suspended Sediments*). Copco No. 2 Dam remaining in place under the Two Dam Removal Alternative would not alter the amount of sediment-associated oxygen demand compared to under the Proposed Project as the dam does not retain appreciable amounts of sediment under existing conditions (USBR 2011b) and it is not expected to trap appreciable amounts of sediment during drawdown. While there would be some reduction in SSCs downstream of Copco No. 1 due to no sediment being released by J.C. Boyle Dam removal, the overall short-term effects of sediment release and SSCs on sediment-associated oxygen demand and dissolved oxygen concentrations in the Hydroelectric Reach from downstream of Copco No. 1 Dam to Iron Gate Dam under the Two Dam Removal Alternative would still be similar to effects for the Hydroelectric Reach under the Proposed Project and impact significance associated with SSCs and SSC associated oxygen demand and dissolved oxygen concentration would be as described for the Proposed Project (see Potential Impact 3.2-9 for additional details for additional details).

Less sediment would be mobilized into the Middle Klamath River under the Two Dam Removal Alternative; therefore, the extent of downstream increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in this reach under the Two Dam Removal Alternative would be somewhat less than the following those of the Proposed Project. Since the range of SSCs under the Proposed Project would be greater than those expected under this alternative (see Section 4.5.2.2 *Suspended Sediments*), the range of dissolved oxygen conditions modeled for the Proposed Project would generally bracket those anticipated under the Two Dam Removal Alternative. Minimum dissolved oxygen values likely would occur slightly upstream compared the Proposed Project, but they would still generally occur near RM 191 to 193.1 (approximately 0 to 2 miles downstream from Iron Gate Dam) since the location of minimum dissolved oxygen concentrations does not change much with variations in SSCs (see Table 3.2-13). Similarly, the farthest distance downstream with dissolved oxygen less than 5 mg/L likely would shift slightly upstream, but the distance would be similar to the Proposed Project (i.e., approximately RM 145 to RM 122 or within 48 to 71 miles downstream of Iron Gate Dam) since it does not change much with variations in SSCs. Minimum dissolved oxygen values would likely show a greater relative increase under the Two Dam Removal Alternative compared the Proposed Project, since the amount of IOD and BOD downstream of Iron Gate Dam is strongly influenced by variations in SSCs and there would be less sediment transported under this alternative.

Despite the potential for a slightly shorter distance of short-term impacts due to decreases in the sediment-associated oxygen demand and a reduction in the magnitude of the decrease in dissolved oxygen in the Middle Klamath River under the Two Dam Removal Alternative, the release of sediments trapped behind Copco No. 1 and Iron Gate Dam would decrease dissolved oxygen concentrations in the Klamath River below the Basin Plan water quality objective for dissolved oxygen (90 percent saturation) in the short term and constitute a significant impact. Additionally, since the location where the minimum and at least 5 mg/L dissolved oxygen concentrations occurred during modeling under the Proposed Project did not change much with variations in SSC, it is conservatively estimated that the distance the significant impact from the short-term increase in sediment-associated oxygen demand and reductions in dissolved oxygen under the Two Dam Removal Alternative occurs would be similar to that modeled under the Proposed Project (Potential Impact 3.2-9), so the short-term impact would remain significant in the Middle Klamath River from Iron Gate Dam to approximately the confluence with the Salmon River (RM 66).

Similarly, it is conservatively estimated that the distance where there would be no significant impact on dissolved oxygen from releases of reservoir deposited sediments under the Two Dam Removal Alternative would be similar to that modeled under the Proposed Project. Modeling under the Proposed Project indicates that downstream of the confluence with the Salmon River on the Middle Klamath River, as well as in the Lower Klamath River and the Klamath River Estuary, there would be no significant impact from the release of sediments trapped behind the Lower Klamath Project dams (see Section 3.2.5.4 *Dissolved Oxygen*). Thus, there also would be no significant impact under the Two Dam Removal Alternative in the Middle Klamath River from downstream of the confluence with the Salmon River, the Lower Klamath River, and the Klamath River Estuary.

In the long term, since J.C. Boyle Dam would remain in place, continuing summertime interception and retention of sediments and suspended materials from upstream sources containing high biological oxygen demand (see also 3.2.2.5 *Dissolved Oxygen*) would still occur in J.C. Boyle Reservoir under the Two Dam Removal Alternative. Accordingly, existing large summertime variations in dissolved oxygen in J.C. Boyle Reservoir, especially at depth, would still occur and could continue to influence dissolved oxygen concentrations in the California portion of the Hydroelectric Reach in the same manner as under existing conditions (see also 3.2.2.5 *Dissolved Oxygen*). Modeling of existing conditions indicates these summertime dissolved oxygen variations in J.C. Boyle Reservoir increase the range of dissolved oxygen concentrations between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir (North Coast Regional Board 2011), but aeration and fast water velocities within the free-flowing reach result in dissolved oxygen concentrations near or slightly greater than saturation upstream of Copco No. 1 Reservoir (FERC 2007; Raymond 2008). The Two Dam Removal Alternative would not include peaking power generation and release of flow for recreation within the J.C. Boyle Peaking Reach, but the dissolved oxygen at the Oregon-California state line would still likely have slightly greater daily variability than natural conditions (see also Potential Impact 3.2-10). While the degree of influence of peaking flows on daily variability in dissolved oxygen concentrations at the Oregon-California state line is not clearly defined by existing information, the daily variability is not currently adversely affecting beneficial uses. However, dissolved oxygen concentrations immediately downstream of J.C. Boyle would potentially fall below 85 percent saturation and 6.5 mg/L during summer similar to existing conditions. Thus, retaining J.C. Boyle Dam with no peaking or recreation flows under the Two Dam Removal Alternative would have only a small influence on dissolved oxygen concentrations downstream of the Oregon-California state line compared to existing conditions and there would be no significant impact.

Within the Hydroelectric Reach downstream of Copco No. 1 Reservoir, the long-term effects of the Two Dam Removal Alternative on dissolved oxygen concentrations would be the same as effects described for the Proposed Project (Potential Impact 3.2-10) as conversion of Copco No. 1 and Iron Gate reservoirs to free-flowing riverine reaches with higher velocities and more turbulent mixing would increase aeration of Klamath River. Additionally, keeping Copco No. 2 Dam and Reservoir in place would not alter dissolved oxygen concentrations in the Klamath River since Copco No. 2 Reservoir has a short residence time (less than a day) and it is not anticipated to retain appreciable amounts of fine sediment or suspended material that would alter dissolved oxygen conditions under the Two Dam Removal Alternative (see Section 4.5.2.2 *Suspended Sediments*). The extreme super-saturated surface water and oxygen-depleted hypolimnion conditions found in existing conditions in April/May to October/November would not occur under the Two Dam Removal Alternative as Copco No. 1 and Iron Gate reservoirs would be removed (see Section 3.2.5.4 *Dissolved Oxygen* for details). While Klamath TMDL modeling scenarios[212] included the removal of Copco No. 2 Dam, modeling results of the conversion of Copco No. 1, Copco No. 2, and Iron Gate reservoirs to free-flowing river reaches scenario are still likely representative of conditions under the Two Dam Removal Alternative because the small size and short residence time of Copco No. 2 Dam would be unlikely to influence dissolved oxygen conditions in the Klamath River. The Klamath TMDL modeling for this scenario indicates seasonal extremes in dissolved oxygen concentrations downstream of Iron Gate Dam would be eliminated (see Section 3.2.5.4 *Dissolved Oxygen* for details). Thus, the long-term effects of dam removal on concentrations of dissolved oxygen in the Middle and Lower Klamath, the Klamath River Estuary, and the Pacific Ocean nearshore environment under the Two Dam Removal Alternative would be the same as those described for the Proposed Project.

[212] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

In summary, relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on increased IOD and BOD and dissolved oxygen would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term increases in IOD and BOD or reductions in dissolved oxygen in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir since sediment deposits in J.C. Boyle Dam would remain in place (Potential Impact 3.2-9). Copco No. 2 Dam remaining in place would not accumulate appreciable sediments during drawdown, and therefore, would not alter short-term IOD, BOD, and dissolved oxygen compared to the Proposed Project, short-term increases in IOD and BOD along with reductions in dissolved oxygen due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams (Potential Impact 3.2-9) would result in a significant and unavoidable impact in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle Klamath River from Iron Gate Dam to approximately the confluence with the Salmon River under the Two Dam Removal Alternative, similar to the Proposed Project. There would be no significant impact in the Middle Klamath River downstream of the confluence with the Salmon River, Lower Klamath River, and the Klamath River Estuary under the Two Dam Removal Alternative, similar to the Proposed Project. The short-term significant impact of increases in IOD and BOD and reductions in dissolved oxygen due to release of sediments in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, and the Klamath River Estuary cannot be avoided or substantially decreased through reasonably feasible mitigation.
- Potential long-term alterations in daily variability of dissolved oxygen concentrations in the Hydroelectric Reach in California due to the elimination of hydropower peaking flows at J.C. Boyle Dam (Potential Impact 3.2-10) would result in no significant impact. However, long-term increases in dissolved oxygen, as well as increased daily variability in dissolved oxygen, due to conversion of the Copco No. 1 and Iron Gate reservoirs to a free-flowing river (Potential Impact 3.2-10) would be the same under the Two Dam Removal Alternative as under the Proposed Project. Copco No. 2 Dam and Reservoir staying in place under the Two Dam Removal Alternative would not alter dissolved oxygen concentrations compared to the Proposed Project due to its short residence time (less than a day) and minimal long-term sediment retention. Thus, under the Two Dam Removal Alternative there would be no significant impact for daily fluctuations in the Hydroelectric Reach between Copco No. 1 and Iron Gate Dam and the Middle Klamath River immediately downstream of Iron Gate Dam, would be beneficial for elimination of summer and fall extremes in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam, and would result in no significant impact in the Lower Klamath River and Klamath River Estuary.

4.5.2.5 pH

In general, the Two Dam Removal Alternative would have the same or similar potential impacts on pH as those identified under the Proposed Project. As J.C. Boyle Reservoir and peaking power generation and whitewater recreation flows downstream of J.C. Boyle Dam do not substantially alter pH in the downstream river under existing conditions, leaving this dam in place and ceasing peaking and recreation flows would be unlikely to impact pH relative to existing conditions in either the short-term or long-term. Under the existing conditions in Copco No. 1 and Iron Gate reservoirs, seasonal and daily pH is characterized by high pH (greater than 9 s.u.) and large (0.5 to 1.5 s.u.) daily fluctuations occurring in reservoir surface waters during periods of intense phytoplankton blooms (see Section 3.2.2.6 *pH*). Klamath River TMDL modeling[213] for the Proposed Project indicates that removal of these two reservoirs, which would occur under the Two Dam Removal Alternative, would eliminate the occurrences of high pH and large daily fluctuations in pH in these reaches, because the free-flowing reaches of the river replacing these reservoirs would not support the intense phytoplankton blooms that are driving the existing pH conditions (see Section 3.2.5.5 *pH*). Due its small size and low retention time, Copco No. 2 Reservoir does not affect pH under existing conditions and keeping it in place under the Two Dam Removal Alternative also would not affect pH within the Hydroelectric Reach or downstream reaches. In the Klamath River downstream from Iron Gate Dam, pH conditions under the Two Dam Removal Alternative would be the same as under the Proposed Project (Potential Impact 3.2-11).

In summary, relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on pH would be the same as or similar to those as described for the Proposed Project (Potential Impact 3.2-11). Thus, there would be no significant impact in the short term or long-term to pH in the Hydroelectric Reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Reservoir does not substantially alter pH in the river downstream from this dam under existing conditions (Potential Impact 3.2-11). While retaining Copco No. 2 Dam would not alter pH conditions in the Klamath River, short-term and long-term decreases in summertime pH and daily pH fluctuations due to a conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.2-11) would be beneficial for the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, and would have no significant impact for the Middle Klamath River, the Lower Klamath River, and the Klamath River Estuary.

4.5.2.6 Chlorophyll-a and Algal Toxins

In general, the Two Dam Removal Alternative would have the same or similar potential impacts on chlorophyll-*a* and algal toxins as those identified under the Proposed Project (see Section 3.2.5.6 *Chlorophyll-a and Algal Toxins*). The shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days at average flows) of J.C. Boyle Reservoir does not promote the low mixing conditions or thermal stratification that create optimal habitat for phytoplankton growth, so the reservoir does not have large phytoplankton blooms (as measured by chlorophyll-a) under existing conditions (see Figure 3.2-5). Under existing conditions, peaking power generation flows occur in the late afternoons and early evenings to meet high power demand, and J.C. Boyle Reservoir refills during the night when power demand is minimal. Daily fluctuations in the reservoir water level under existing operations increases mixing in the reservoir, making the reservoir slightly less suitable habitat for phytoplankton during the season of maximum phytoplankton and cyanobacteria (blue-green-algae) growth in the system. Ceasing peaking power generation flows would reduce daily reservoir water level fluctuations in J.C. Boyle Reservoir because the facility would no longer be operated to draw on reservoir storage to support daily peaks in hydropower production when there is

[213] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

not sufficient river flow for peak production (3,000 cfs), as occurs during the summer and fall low flow period under existing conditions. However, the residence time of J.C. Boyle Reservoir without peaking operations would still be short (i.e., on the order of one to three days), so leaving this dam in place and ceasing peaking flows would be unlikely to create conditions that would support large seasonal phytoplankton blooms or increase chlorophyll-*a* concentrations relative to existing conditions. Concentrations of the algal toxin microcystin are generally low in J.C. Boyle Reservoir (Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*) and in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir since the J.C. Boyle Reservoir does not support large blooms of toxigenic blue-green algae and springs downstream of J.C. Boyle Dam dilute any algal toxins that may be present within that reach. Thus, leaving J.C. Boyle Dam in place and ceasing peaking flows would not promote conditions that would support production of algal toxins.

In Copco No. 1 and Iron Gate reservoirs, existing conditions for chlorophyll-*a* levels in summer and early fall can be two to 10 times greater than those recorded in the mainstem river upstream of Copco No. 1 Reservoir near Shovel Creek. High chlorophyll-*a* readings in the reservoirs as compared to the Klamath River are in part due to the lower mixing conditions and longer residence times of these reservoirs (10.7 days for Copco No. 1 and 14.8 days for Iron Gate at average flows) that promote the growth of phytoplankton and the associated production of chlorophyll-*a* within the reservoirs. Additionally, measurements of microcystin in Copco No. 1 and Iron Gate reservoirs during summer months show high microcystin concentrations, especially during algal blooms when microcystin concentrations measured between 2006 and 2015 exceeded the State Water Board et al. (2010, updated 2016) threshold of 0.8 ug/L and peaked from 64 ug/L in Iron Gate Reservoir to 73,000 ug/L in Copco No. 1 Reservoir (Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). Under the Two Dam Removal Alternative, elimination of Copco No.1 and Iron Gate reservoirs, which currently support growth conditions for toxin-producing nuisance algal species such as *Microcystis aeruginosa,* would result in decreases in high seasonal concentrations of chlorophyll-*a* and periodically high levels of algal toxins generated by suspended blue-green algae, consistent with the Proposed Project (see Section 3.2.5.6 *Chlorophyll-a and Algal Toxins*). The removal of Copco No. 1 and Iron Gate reservoirs also would eliminate the primary habitat for blue-green algae in the Hydroelectric Reach, reducing both the amount of blue-green algae present that could contribute to chlorophyll-*a* and algal toxins within this reach and the amount of blue-green algae that may be exported into the Klamath River downstream of Iron Gate Dam. Due its small size and low residence time (less than a day), Copco No. 2 Reservoir does not have the habitat conditions (i.e., slow water velocity, low mixing conditions, or thermal stratification) that would promote phytoplankton growth and alter chlorophyll-*a* and algal toxins concentrations under existing conditions and keeping it in place under the Two Dam Removal Alternative also would not affect chlorophyll-*a* and algal toxins within the Hydroelectric Reach or downstream reaches.

As phytoplankton and the resulting chlorophyll-*a* and algal toxin levels (e.g., microcystin) are primarily internally generated in Copco No. 1 and Iron Gate reservoirs, removal of these reservoirs under the Two Dam Removal Alternative would also reduce the transport of chlorophyll-a and algal toxins to the Klamath River downstream of Iron Gate Dam in both the short-term and the long-term, consistent with the Proposed Project.

In summary, relative to existing conditions, the potential impacts and impacts of the Two Dam Removal Alternative on chlorophyll-*a* and algal toxins would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term or long-term alterations in chlorophyll-a and algal toxins in the Hydroelectric Reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Reservoir would remain in place, but it does not support conditions promoting large phytoplankton blooms and associated chlorophyll-a and algal toxins under existing conditions (Potential Impact 3.2-12). However, short-term and long-term reduction of chlorophyll-a and algal toxin levels due to a conversion of the reservoir areas to a free-flowing river (Potential Impact 3.2-12) under the Two Dam Removal Alternative would be beneficial for the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, the Middle Klamath River, Lower Klamath River, and Klamath River Estuary, similar to the Proposed Project.

4.5.2.7 Inorganic and Organic Contaminants

Short-term mobilization of J.C. Boyle reservoir sediment deposits would not occur under the Two Dam Removal Alternative and none of the associated 1,190,000 cubic yards of deposits (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches. While Copco No. 2 Dam would remain in place, it does not retain appreciable amounts of sediment (USBR 2011b) and it is unlikely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*), thus the short-term mobilization of reservoir sediment deposits and potential sediment-associated inorganic and organic contaminants in the Copco No. 2 section of the Hydroelectric Reach under the Two Dam Removal Alternative would be similar to under the Proposed Project. Mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs would still occur such that the short-term potential for mobilization of inorganic and organic contaminants in the Hydroelectric Reach from downstream of Copco No. 1 Dam to Iron Gate Dam under the Two Dam Removal Alternative would be similar to impacts for the Hydroelectric Reach under the Proposed Project (Section 3.2.5.7 *Inorganic and Organic Contaminants*).

Mobilization of sediments from J.C. Boyle Reservoir are anticipated to not significantly impact freshwater benthic organism survival under the Proposed Project after consideration of dispersal and dilution, but testing of sediments from J.C. Boyle Reservoir without any dispersal or dilution suggests a higher potential for toxicity to freshwater benthic organisms compared to Copco No. 1 and Iron Gate reservoir sediments (Section 3.2.5.7 *Inorganic and Organic Contaminants*). Thus, the potential for toxicity to freshwater benthic organisms may be relatively slightly less under the Two Dam Removal Alternative than that of the Proposed Project due to no sediment from J.C. Boyle Reservoir being transported downstream. However, the overall impact of the release of sediments trapped behind Lower Klamath Project dams under both the Two Dam Removal Alternative and under the Proposed Project would be expected to be similar. The Proposed Project analysis assumes mixing of sediment deposits from all the reservoirs as they move downstream and exposure of downstream aquatic biota to an “average” sediment composition, rather than a reservoir-specific composition (Section 3.2.5.7 *Inorganic and Organic Contaminants*), so overall water column toxicity due to the concentration of inorganic or organic substances under the Proposed Project is unlikely. As such, there would be a less than significant impact due to the release of sediments trapped behind Lower Klamath Project dams, including J.C. Boyle Dam, under the Proposed Project. While leaving J.C. Boyle Dam in place and not releasing J.C. Boyle reservoir deposited sediments under the Two Dam Removal Alternative would potentially slightly reduce toxicity to benthic freshwater organisms, the overall impact from the release of Copco No. 1 and Iron Gate reservoir deposited sediments and the sediment-associated inorganic and organic contaminants would be a less than significant impact in the short term under the Two Dam Removal Alternative, similar to the Proposed Project.

While the overall extent of fish passage construction activities at J.C. Boyle and Copco No. 2 dams and dam deconstruction activities at Copco No. 1 and Iron Gate dams in the Hydroelectric Reach under the Two Dam Removal Alternative would be slightly less than the extent of dam deconstruction activities for all four dams in the Hydroelectric Reach under the Proposed Project (see also 4.5.1 *[Two Dam Removal Alternative] Introduction – Alternative Analysis Approach*), short-term increases in inorganic and organic contaminants from hazardous materials associated with construction and restoration activities under the Two Dam Removal Alternative would be similar to those described for the Proposed Project and they would be potentially significant impacts without mitigation in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam. Implementation of mitigation measures WQ-1, TER-1, and HZ-1 would reduce impacts to less than significant.

In the long term, existing inorganic and organic contaminant data characterizing J.C. Boyle Reservoir sediment deposits indicate that a relatively small number of chemicals (i.e., mercury, DDTs, and possibly dioxin-like chemicals) are present at levels that have the potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) to freshwater aquatic species remaining in this reservoir under the Two Dam Removal Alternative. Elutriate sediment sample bioassay results from J.C. Boyle Reservoir indicate that no further dilution would be required to prevent water column toxicity to freshwater fish. Relative to existing condition, there would be no change. Copco No. 2 Reservoir remaining in place would also be similar to existing conditions since it neither contains appreciable sediment deposits nor is it expected to accumulate appreciable amounts of sediment with associated inorganic or organic contaminants (i.e., fine sediments) in the long term (see Section 4.5.2.2 *Suspended Sediment*). However, long-term retention of inorganic and organic contaminants contained within existing sediment deposits behind Copco No. 1 and Iron Gate dams and their potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) would not occur since they would be removed under the Two Dam Removal Alternative, which would be beneficial.

In summary, relative to existing conditions the potential impacts and impacts of the Two Dam Removal Alternative on inorganic and organic contaminants would be the same as or similar to those described for the Proposed Project, except as noted below:

- J.C. Boyle Reservoir sediment deposits and its sediment-associated inorganic and organic contaminants would not be released downstream, but the short-term and long-term human exposure to inorganic and organic contaminants due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams (Potential Impact 3.2-13) would result in a potentially significant impact for the Hydroelectric Reach, Middle Klamath River, Lower Klamath River, and Klamath River Estuary.

Implementation of, mitigation measures WQ-2 and WQ-3 would result in no significant impact.

- While J.C. Boyle Reservoir sediment deposits and its sediment-associated inorganic and organic contaminants would not be released downstream and Copco No. 2 would remain in place, the short-term and long-term freshwater aquatic species' exposure to inorganic and organic contaminants due to release of sediments currently trapped behind the Copco No. 1 and Iron Gate dams (Potential Impact 3.2-14) would result in no significant impact for the Hydroelectric Reach, Middle Klamath River, Lower Klamath River, Klamath River Estuary, and Pacific Ocean nearshore environment based on sediment screening and/or laboratory toxicity results after consideration of dilution conditions during drawdown.
- Short-term increases in inorganic and organic contaminants from hazardous materials associated with construction and restoration activities (Potential Impact 3.2-15) in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam would be potentially significant without mitigation. Implementation of Mitigation Measure WQ-1 would result in no significant impact.
- Short-term impacts to aquatic biota from herbicide application during restoration of the reservoir footprint area (Potential Impact 3.2-16) would be potentially significant without mitigation. Implementation of Mitigation Measure WQ-4 would result in no significant impact.
- Long-term freshwater aquatic species' exposure to inorganic and organic contaminants contained within J.C. Boyle Reservoir sediment deposits would continue to have the potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) to some freshwater aquatic species in the reservoir (Potential Impact 4.2.2-8), which would be no impact (no change from existing adverse conditions).

4.5.2.8 General Water Quality

Iron Gate Hatchery operations would continue, and Fall Creek Hatchery would reopen, for eight years under the Two Dam Removal Alternative. The potential short-term and long-term impacts of these operations on the Klamath River, Bogus Creek, and Fall Creek water quality would be the same as described for the Proposed Project (Potential Impact 3.2-17).

4.5.3 Aquatic Resources

4.5.3.1 Suspended Sediment

As discussed in Section 4.5.2.2 *Suspended Sediments*, while there would be some reduction in SSCs downstream of Copco No. 1 due to no SSCs being released by Copco No. 2 and J.C. Boyle Dam removal, the reduction of SSCs under the Two Dam Removal Alternative would not alter the overall impact of dam removal on SSCs compared to the Proposed Project in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment. Thus, the potential impacts of suspended sediment on aquatic resources in California would be the same under the Two Dam Removal Alternative as those described under the Proposed Project (see also Section 3.3.5.1 *Suspended Sediment*).

4.5.3.2 Bed Elevation and Grain Size Distribution

Because the volume of stored sediment in Copco No. 2 and J.C. Boyle reservoirs is relatively small compared with the volume of stored sediment in Copco No. 1 and Iron Gate reservoirs, the potential for alterations in bed elevation and grain size distribution and the associated effects on aquatic resources in California would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (see also Section 3.3.5.2 *Bed Elevation and Grain Size Distribution*). Thus, downstream impacts to aquatic species due to bed elevation and grain size distribution would be very similar to those described for the Proposed Project.

4.5.3.3 Water Quality

For the reasons discussed below, potential impacts of water quality on aquatic resources in California would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (see also Section 3.3.5.3 *Water Quality*). As Copco No. 1 and Iron Gate reservoirs are the largest of the four Lower Klamath Project reservoirs, they have the greatest impact on water quality (FERC 2007), and their removal would result in water quality conditions similar to those of the Proposed Project. Because of their relatively small size and short residence time, continuing to store water within Copco No. 2 and J.C. Boyle reservoirs would generally not result in the same poor water temperature conditions that occur downstream of the larger Lower Klamath Project reservoirs (Iron Gate and Copco No. 1 reservoirs) under existing conditions. Section 4.5.2 discusses the impacts of the Two Dam Removal Alternative with an emphasis on similarities and differences with the potential impacts of the Proposed Project.

The Two Dam Removal Alternative includes no peaking power generation or release of flow for recreation at J.C. Boyle Dam. As described in Section 3.2.2.2 *Water Temperature*, daily peaking operations at J.C. Boyle Powerhouse (RM 225.2) result in an increase in the daily water temperature range in the Bypass Reach because warmer reservoir discharges are diverted around this reach and cold groundwater springs enter the river and dominate remaining flows. The temperature effects of altering the flow regime under the Two Dam Removal Alternative (while keeping J.C. Boyle Dam in place) would be a reduction in diel (24-hour) temperature variation and overall warmer water temperatures in the Bypass Reach during summer and early fall compared with existing conditions. In the Peaking Reach, water temperature effects would be the same as under the Proposed Project (i.e., slightly lower maximum water temperatures and less artificial diel [24-hour] temperature variation during summer and early fall) since no peaking flows would occur and the effect of J.C. Boyle thermal mass on water temperatures does not extend this far downstream (see also Section 4.5.2.1 *Water Temperature*).

In the Hydroelectric Reach from the upstream end of Copco No. 1 Reservoir to Iron Gate Dam, removing Iron Gate, Copco No. 1, and Copco No. 2 reservoirs and converting the reservoir areas to a free-flowing river under this alternative would result in the same effects on water temperatures in the Middle Klamath River immediately downstream from Iron Gate Dam as described for the Proposed Project (i.e., long-term increases in spring water temperatures and decreases in late summer/fall water temperatures) (see Section 3.3.5.3 *Water Quality*).

4.5.3.4 Fish Disease and Parasites

For the reasons discussed below, potential impacts of fish disease and parasites on aquatic resources in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.5 *Fish Disease and Parasites*). The main factors contributing to risk of juvenile salmonid infection by *C. shasta* and *P. minibicornis* include availability of habitat (pools, eddies, and sediment) for the polychaete intermediate host; microhabitat characteristics (static flows and low velocities); congregations of spawned adult salmon with high spore; polychaete proximity to spawning areas; planktonic food sources from Lower Klamath Project reservoirs; and water temperatures greater than 59°F (Bartholomew and Foott 2010). The current reach with highest infectivity (nidus) for *C. shasta* and *P. minibicornis* is located in the Klamath River downstream of Iron Gate Dam, where returning adult spawners congregate. For adult salmon, *Ichthyophthirius multifis* (Ich) and *Flavobacterium columnare* (columnaris) have occasionally resulted in substantial mortality, particularly when habitat conditions include exceptionally low flows, high water temperatures, and high densities of fish (such as adult Chinook salmon migrating upstream in the fall and holding at high densities in pools). This section addresses differences between these disease factors anticipated under the Two Dam Removal Alternative in comparison with the Proposed Project, and implications for effects on juvenile and adult salmonid life stages.

The availability of habitat for the polychaete worm intermediate host is driven by sediment transport and hydrologic dynamics that as described in sections above would be nearly the same as the Proposed Project. The relatively low volume of sediment in Copco No. 2 and J.C. Boyle reservoirs would not appreciably affect habitat for the polychaete host relative to existing conditions, and the hydrology affecting microhabitat characteristics would be the same as that described for the Proposed Project. The reduction in congregations of spawned adults with proximity to polychaetes would be similar to the Proposed Project, since anadromous salmonids would have upstream migratory access past Iron Gate Dam, including provision of fish passage at Copco No. 2 and J.B. Boyle Dam, and would be as widely distributed. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing and emergency dilution flows are required to be released from Iron Gate Dam as part of re-initiation of consultation on the 2013 BiOp Flows, but they are not modeled as part of existing conditions hydrology. Under the Two Dam Removal Alternative, it is anticipated that the nidus would no longer form downstream of Iron Gate Dam, and the risk of a new nidus forming upstream is low, even in the absence of the 2017 flow requirements (see also Section 3.3.5.5 *Fish Disease and Parasites*). Although the conditions leading to a reach that would exhibit the highest infectivity (nidus) for *C. shasta* and *P. minibicornis* downstream of Iron Gate Dam would be ameliorated once Copco No. 1 and Iron Gate dams are removed, some disease factors would continue under the Two Dam Removal Alternative, including eight years of additional Iron Gate Hatchery operations potentially resulting in continued (through post-dam removal year 10) congregations of mostly adult fall-run Chinook salmon in the reach from Iron Gate Dam to Seiad Valley (see also Section 3.3.5.6 *Fish Hatcheries*). Under the Two Dam Removal Alternative, if a nidus were to remain in the vicinity of Iron Gate Hatchery, or theoretically were to form within newly accessible upstream habitat such as the reach immediately downstream of Copco No. 2 or J.C. Boyle dam where future fish passage facility entrances would be located, flushing and emergency dilution flows as required by the 2017 court order may be required from a new upstream location to achieve the same ecological benefits (i.e., disruption of nidus).

Under the Two Dam Removal Alternative, planktonic (e.g., floating organisms such as algae) food sources would be reduced relative to existing conditions with elimination of reservoir habitats, similar to conditions under the Proposed Project. However, because Copco No. 2 and J.C. Boyle reservoirs would remain it would continue to provide a source of planktonic food for the polychaete host of *C. shasta* and *P. minibicornis*. Therefore, while planktonic food sources would be reduced under the Two Dam Removal Alternative relative to existing conditions, slightly more reservoir (and thus planktonic food source) would be removed under the Proposed Project.

Conditions resulting in water temperatures greater than 59°F downstream of Iron Gate Dam under the Two Dam Removal Alternative would be the same as those identified under the Proposed Project. As described in Section 4.5.2.1 *Water Temperature*, the presence of the Copco No. 2 and J.C. Boyle reservoirs on the Klamath River do not alter water temperatures in further downstream reaches J.C. Boyle Reservoir has a shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days) that does not support thermal stratification (FERC 2007), and Copco No. 2 Reservoir has a small volume (approximately 70 acre-feet originally), a short hydraulic residence time (less than a day), no active storage, and it does not thermally stratify, such that the reservoir has a negligible impact on water temperature.

Under the Two Dam Removal Alternative, the conditions that can support Ich and columnaris outbreaks among adult salmonids (i.e., exceptionally low flows, high water temperatures, and high densities of fish), would be similar to those identified under the Proposed Project, especially within the Lower Klamath River where Ich and columnaris have caused substantial mortality under existing conditions. Downstream of the confluence with the Salmon River neither the Proposed Project or the Two Dam Removal Alternative would have a pronounced effect on instream flows, water temperatures, or congregations of fish, due to the contributions of several large tributaries (notably the Trinity River). Overall, impacts to aquatic species due to fish disease and parasites would improve relative to existing conditions under the Two Dam Removal Alternative and they would be very similar to those described for the Proposed Project.

4.5.3.5 Fish Hatcheries

The potential impacts of fish hatcheries on aquatic resources in the California portions of the Klamath River would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.6 *Fish Hatcheries*). As this alternative includes volitional fish passage at Copco No. 2 and J.C. Boyle dams consistent with mandatory conditions issued for relicensing of the Klamath Hydroelectric Project, thereby eliminating Copco No. 2 and J.C. Boyle dams as fish barriers, this alternative assumes that hatchery operations would continue for eight years under the Two Dam Removal Alternative and then the hatcheries would be removed. During the eight years following removal of Copco No. 1 and Iron Gate dams, the hatcheries would operate with reduced production goals consistent with those described for the Proposed Project (see Section 2.7.6 *Hatchery Operations*).

4.5.3.6 Algal Toxins

Potential impacts of algal toxins on aquatic resources in the California portions of the Klamath River would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.7 *Algal Toxins*). Removal of the larger Copco No. 1 and Iron Gate reservoirs would decrease or eliminate support for excessive growth of phytoplankton, including seasonal blue-green algae blooms and associated algal toxins (e.g., microcystin), by eliminating large areas of quiescent habitat where these phytoplankton species currently thrive. While Copco No. 2 and J.C. Boyle reservoirs would remain, because of their small sizes (Table 2.3-1) and short hydraulic residence times (Table 3.6-4), they would not support substantial blooms and thus the expected decrease in algal toxins anticipated under the Two Dam Removal Alternative would be the same as described for the Proposed Project. Additionally, potential for bioaccumulation of algal toxins in freshwater mollusk and fish tissue under the Two Dam Removal Alternative would be expected to decrease in the mainstem Klamath River from the Hydroelectric Reach to the Klamath River Estuary, as described for the Proposed Project.

4.5.3.7 Aquatic Habitat

For the reasons discussed below, potential impacts of aquatic habitat on aquatic resources in California portions of the Klamath River would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.8 *Aquatic Habitat*). Improvements in aquatic habitat conditions resulting from increased minimum flows and eliminated peaking operations in the Bypass Reach downstream of J.C. Boyle Dam based on federal mandatory conditions in the PacifiCorp hydroelectric relicensing process would occur under the Two Dam Removal Alternative as described for the Proposed Project. As described in sections above, changes in sediment dynamics would also be similar to those described under the Proposed Project. Access to additional aquatic habitat upstream of Iron Gate Dam would be the same under the Two Dam Removal Alternative as described for the Proposed Project, since fish passage would be provided at Copco No. 2 and J.C. Boyle dams (see also Section 4.5.3.8 *Fish Passage*). The primary difference under the Two Dam Removal Alternative is that aquatic habitat within Copco No. 2 and J.C. Boyle reservoirs would remain lentic rather than reverting to the riverine conditions described for the Proposed Project. Based on the estimate by Cunanan (2009) of 3.5 miles of riverine habitat currently inundated by J.C. Boyle Reservoir, and an estimated 0.3 miles inundated by Copco No. 2, there would be approximately 3.8 fewer miles of additional riverine habitat that would become available under this alternative compared to the Proposed Project. However, Copco No. 2 and J.C. Boyle reservoir inundation is a small proportion (approximately 16 percent) of the 22 miles of Lower Klamath Project reservoir habitat that would be restored to riverine habitat under the Proposed Project (the original estimate of 22 miles did not take into account the relatively minor inundation at Copco No. 2 Reservoir). In addition, J.C. Boyle Dam would continue to provide reservoir habitat to support aquatic resources (including shortnose and Lost River suckers). Under the Two Dam Removal Alternative, the two larger lower reservoirs would be removed as described for the Proposed Project, restoring approximately 18.5 miles of mainstem river that previously exhibited high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009).

4.5.3.8 Fish Passage

Copco No. 2 Dam is not currently equipped with fish passage facilities (DOI 2007). The current upstream fishway at J.C. Boyle Dam is obsolete and does not meet NMFS (2011) design criteria (U.S. Department of Interior, DOI 2007). Under the Two Dam Removal Alternative, fish would have access beyond the location of Copco No. 1 and Iron Gate dams, as described for the Proposed Project (Section 3.3.5.8 *Aquatic Habitat*). However, whereas under the Proposed Project fish would have volitional unimpeded access past Copco No. 2 and J.C. Boyle dams, under the Two Dam Removal Alternative fish migrating upstream and downstream past Copco No. 2 and J.C. Boyle dams would access upstream habitat via fishways. DOI (2007) included a prescription for a NMFS-criteria volitional year-round fish ladder at Copco No. 2 and J.C. Boyle dams to provide for the safe, timely, and effective upstream passage of Chinook and coho salmon, steelhead trout, Pacific lamprey, and redband trout. In addition, DOI (2007) prescribed a new year-round NMFS criteria fish screen and a bypass facility at Copco No. 2 and J.C. Boyle dams (and modifications to spillways) to provide for the safe, timely, and effective downstream passage of Chinook and coho salmon, steelhead trout, Pacific lamprey, redband trout, and listed sucker species. Under the Two Dam Removal Alternative, fishways would be consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007), and specific fishway facility design and construction details included in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*[215], including fishway (i.e., fish ladder and screens) installation for both upstream and downstream migrations and barriers to prevent juvenile salmonid entrainment into turbines. Use of trap and haul would involve design assumptions described in the Section 4.4 *Continued Operations with Fish Passage Alternative,* but the assumptions would only be applied to Copco No. 2 and J.C. Boyle dams. In this EIR, it is assumed that for application at these two dams (Copco No. 2 and J.C. Boyle dams), if alternative passage facilities were designed and constructed, they would necessarily meet agency criteria and thus would have an equivalent level of mortality as volitional fishways.

In their preliminary fishway prescriptions for the Lower Klamath Project dams, NMFS (2006) recommended dam removal to FERC under FPA S10(a) and (j) as the environmentally preferred alternative to provide the least mortality and injury to migrating fish. The associated NMFS fishway prescription (DOI 2007) is a mandatory conditioning authority that was submitted during the hydropower relicensing process at the time, in case FERC chose to reject NMFS' strong recommendation to removal all of the Lower Klamath Project mainstem dams. While unimpeded volitional fish passage is assumed to have higher survival and lower injury than fishways, no data or analyses are available to accurately compare the effectiveness of unimpeded fish passage under the Proposed Project with volitional fishways under the Two Dam Removal Alternative. NMFS does not provide an expected level of mortality or injury in association with fishways constructed to their criteria, and performance would depend on many site-specific factors that would be considered in the design phase of new fishways. Based on the measured effectiveness of fishways constructed to NMFS criteria at other dams (DWR 2013), this EIR assumes at least 98 percent survival (or less than 2 percent mortality) of upstream and downstream migrating aquatic species at each facility in recognition that while survival could be high at properly constructed facilities, it is unlikely to be as high as survival would be with dams removed (i.e., 100 percent). Therefore, the assumed cumulative upstream mortality for fish migrating past both Copco No. 2 Dam and J.C. Boyle Dam would be around 4 percent, and the same for downstream mortality.

Regardless of how fish passage is provided, this alternative assumes fish passage consistent with the general prescriptions (DOI 2007) that cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007). This EIR also assumes that effects of passage through volitional fishways would be equivalent for other migratory species, which appears to be a reasonable assumption based on available data (DWR 2013) for fishways designed and constructed to modern agency criteria as required by DOI (2007).

Based on the similarities between the Two Dam Removal Alternative and the Proposed Project for several of the key ecological attributes discussed above, the potential impacts of the Two Dam Removal Alternative would be the same as those described under the Proposed Project for several potential impacts (Potential Impact 3.3-2, 3.3-3, 3.3-5, 3.3-6, 3.3-12, 3.3-15, 3.3-16, 3.3-18, 3.3-20, 3.3-21, 3.3-22, 3.3-23, and 3.3-24). The potential impacts of the Two Dam Removal Alternative that could result in different effects than those already discussed under the Proposed Project are discussed below.

Potential Impact 3.3-1 Effects on coho salmon critical habitat quality and quantity due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on coho salmon critical habitat in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-1), with a few subtle differences. For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins* impacts on critical habitat from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities. Habitat in the J.C. Boyle Bypass and Peaking Reaches would be improved through elimination of peaking operations and higher baseflows. Therefore, although upstream of current designated critical habitat, the Two Dam Removal Alternative would expand the geographic extent of habitat available to coho salmon in a similar manner to the Proposed Project.

The short-term impacts on coho salmon critical habitat from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-1), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. Based on the substantial short-term decrease in quality of the features of critical habitat and PCEs supporting SONCC coho salmon, there would be a significant impact to coho salmon critical habitat under the Two Dam Removal Alternative in the short term.

However, as described for the Proposed Project, the Two Dam Removal Alternative includes aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on coho salmon PCEs of critical habitat. In addition, mitigation measures AQR-1 and AQR-2 (described in Section 3.3.5.9), would be implemented to increase certainty of the effectiveness of the aquatic resource measures AR-1 and AR-2 and reduce the short-term significant adverse impacts of the Two Dam Removal Alternative on coho salmon critical habitat. Consistent with the Proposed Project, based on the wide distribution of coho salmon critical habitat within tributaries, aquatic resource measures, and mitigation measures designed to offset short-term impacts to PCEs of critical habitat, there would not be a substantial decrease in the quality of a substantial proportion of habitat for coho salmon critical habitat in the short term. Therefore, the Two Dam Removal Alternative would have no significant impact on coho salmon critical habitat in the short term.

For the reasons described in Section 4.5.3.7 *Aquatic Habitat*, in the long term the Two Dam Removal Alternative would increase the amount of habitat available to coho salmon upstream of currently designated critical habitat and improve water quality and bedload characteristics in the mainstem Klamath River within current critical habitat in the same manner as the Proposed Project. Overall, these changes would be a substantial increase in the quality and quantity of coho salmon critical habitat in the long term as compared to existing conditions. Therefore, the Two Dam Removal Alternative would be beneficial for coho salmon critical habitat in the long term.

Significance

No significant impact with mitigation to coho salmon critical habitat in the short term

Beneficial for coho salmon critical habitat in the long term

Potential Impact 3.3-4 Effects on Chinook and coho salmon Essential Fish Habitat (EFH) quality and quantity due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Chinook and coho salmon EFH in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-4), with a few subtle differences. For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on EFH from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

The short-term impacts on Chinook and coho salmon EFH from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-4), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed*

Elevation and Grain Size Distribution. Based on the substantial short-term decrease in quality of EFH for Chinook and coho salmon, there would be a significant impact to Chinook and coho salmon EFH under the Two Dam Removal Alternative in the short term.

However, as described for the Proposed Project, the Two Dam Removal Alternative includes aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on Chinook and coho salmon EFH. In addition, mitigation measures AQR-1 and AQR-2 (described in Section 3.3.5.9), would be implemented to increase certainty of the effectiveness of the aquatic resource measures AR-1 and AR-2 and reduce the short-term significant adverse impacts of the Two Dam Removal Alternative on Chinook and coho salmon EFH. Consistent with the Proposed Project, based on the wide distribution and use of tributaries by both juvenile and adult Chinook and coho salmon, aquatic resource measures (AR-1 and AR-2), and mitigation measures (AQR-1 and AQR-2), designed to offset short-term impacts to Chinook and coho salmon EFH, there would not be a substantial decrease in the quality of a large proportion of Chinook and coho salmon EFH in the short term. Therefore, the Two Dam Removal Alternative would have no significant impact, with mitigation, on Chinook and coho salmon EFH in the short term.

For the reasons described above in Section 4.5.3.7 *Aquatic Habitat*, in the long term the Two Dam Removal Alternative would increase habitat for Chinook and coho salmon (upstream of currently designated EFH) by providing access to habitats upstream of Iron Gate Dam in the same manner as the Proposed Project. Overall, these changes would be a substantial increase in the quality and quantity of Chinook and coho salmon EFH in the long term. Therefore, the Two Dam Removal Alternative would be beneficial for Chinook and coho salmon EFH in the long term.

Significance

No significant impact with mitigation to Chinook and coho salmon EFH in the short term

Beneficial for Chinook and coho salmon EFH in the long term

Potential Impact 3.3-7 Effects on the fall-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on fall-run Chinook salmon in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-7), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on fall-run Chinook salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Based on the 440 miles of fall-run Chinook salmon habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.8 miles that would remain inundated by Copco No. 2 and J.C. Boyle reservoirs rather than reverting to riverine habitat under the Two Dam Removal Alternative is not substantial (< 1 percent of newly accessible habitat). Juvenile Chinook salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities. Therefore, the estimated increases in fall-run Chinook salmon abundance predicted to occur under the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-7), would be less under the Two Dam Removal Alternative due to mortality in fish passage facilities and migration through reservoir habitat.

The short-term impacts on fall-run Chinook salmon from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-7), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. As described for the Proposed Project (Potential Impact 3.3-7), because there would be no substantial short-term decrease in fall-run Chinook salmon abundance of a year class, and no substantial decrease in habitat quality or quantity, there would not be a significant impact to fall-run Chinook salmon under the Two Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on fall-run Chinook salmon In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Two Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including fall-run Chinook salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Two Dam Removal Alternative on fall-run Chinook salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, in the long term the Two Dam Removal Alternative would increase habitat availability, restore a more natural flow regime and seasonal water temperature variation, improve water quality, and reduce the likelihood of fish disease and algal toxins, all of which would be beneficial for fall-run Chinook salmon in the same manner as the Proposed Project. Overall, the multiple benefits of the Two Dam Removal Alternative would be beneficial for fall-run Chinook salmon in the long term.

Significance

No significant impact for fall-run Chinook salmon populations in the short term

Beneficial for fall-run Chinook salmon populations in the long term

Potential Impact 3.3-8 Effects on the spring-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on spring-run Chinook salmon in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-8), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on spring-run Chinook salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Based on the 440 miles of spring-run Chinook salmon habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.8 miles that would remain inundated by Copco No. 2 and J.C. Boyle reservoirs rather than revert to riverine habitat under the Two Dam Removal Alternative is unsubstantial (< 1 percent of newly accessible habitat). Juvenile Chinook salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

The short-term impacts on spring-run Chinook salmon from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-8), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. As described for the Proposed Project (Potential Impact 3.3-8), because there would not be a substantial short-term decrease in spring-run Chinook salmon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to spring-run Chinook salmon under the Two Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on fall-run Chinook salmon In the short term, aquatic resource measure AR-2 (Juvenile Outmigration) would occur under the Two Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including spring-run Chinook salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measure AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Two Dam Removal Alternative on spring-run Chinook salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3 *Algal Toxins*, in the long term the Two Dam Removal Alternative would increase habitat availability, restore a more natural flow regime and seasonal water temperature variation, improve water quality, and reduce the likelihood of fish disease and algal toxins, all of which would be beneficial for spring-run Chinook salmon in the same manner as the Proposed Project. Overall, the multiple benefits of the Two Dam Removal Alternative would be beneficial for spring-run Chinook salmon in the long term.

Significance

No significant impact for spring-run Chinook salmon populations in the short term

Beneficial for spring-run Chinook salmon populations in the long term

Potential Impact 3.3-9 Effects on coho salmon populations due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on coho salmon in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-9), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on coho salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion (approximately 80 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Juvenile coho salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

The short-term impacts on coho salmon from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-9), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in coho salmon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to coho salmon under the Two Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on coho salmon In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Two

Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including coho salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Two Dam Removal Alternative on coho salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, in the long term the Two Dam Removal Alternative would increase the amount of habitat available to coho salmon and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of coho salmon populations in the long term. Therefore, the Two Dam Removal Alternative would be beneficial for coho salmon in the long term.

Significance

No significant impact for coho salmon populations in the short term

Beneficial for coho salmon populations in the long term

Potential Impact 3.3-10 Effects on the steelhead population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on steelhead in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-10), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on steelhead from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion (approximately 440 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Juvenile steelhead would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

The short-term impacts on steelhead from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-10), for the reasons described in

Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in steelhead abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to steelhead under the Two Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on steelhead In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Two Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including steelhead. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Two Dam Removal Alternative on steelhead by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6. *Algal Toxins*, in the long term the Two Dam Removal Alternative would increase the amount of habitat available to steelhead and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of steelhead populations in the long term. Therefore, the Two Dam Removal Alternative would be beneficial for steelhead in the long term.

Significance

No significant impact for steelhead populations in the short term

Beneficial for steelhead populations in the long term

Potential Impact 3.3-11 Effects on the Pacific lamprey population due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Pacific lamprey in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-11), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on Pacific lamprey from sediment releases would be similar to the Proposed Project, as well as water quality, and algal toxins. The same habitat expansion (approximately 80 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under Copco No. 2 Reservoir (0.3 miles) and J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir and unlikely to be used by Pacific Lamprey. Based on the 80 miles of Pacific lamprey habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.8 miles that would remain inundated by Copco No. 2 and J.C. Boyle reservoirs rather than revert to riverine habitat under the Two Dam Removal Alternative is unsubstantial (< 5 percent of newly accessible habitat). Juvenile lamprey would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

The short-term impacts on Pacific lamprey from sediment releases would be the same under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-11), for the reasons described in Section 4.5.3.1 *Suspended Sediment* and Section 4.5.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in Pacific lamprey abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to Pacific lamprey under the Two Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on Pacific lamprey In the short term, aquatic resource measure AR-1 (Mainstem Spawning) would occur under the Two Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on Pacific lamprey. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measure AQR-1, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Two Dam Removal Alternative on Pacific lamprey by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6. *Algal Toxins*, in the long term the Two Dam Removal Alternative would increase the amount of habitat available to Pacific lamprey and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of Pacific lamprey populations in the long term. Therefore, the Two Dam Removal Alternative would be beneficial for Pacific lamprey in the long term.

Significance

No significant impact for Pacific lamprey in the short term

Beneficial for Pacific lamprey in the long term

Potential Impact 3.3-12 Effects on the green sturgeon population due to short-term sediment releases and long-term changes in habitat quality due to dam removal.
Southern DPS Green Sturgeon may enter the Klamath River Estuary to forage during the summer months. They would not be present when the most severe effects of dam removal are occurring and are not expected to be affected by the Two Dam Removal Alternative. The remainder of this section focuses on the effects of the Two Dam Removal Alternative on the Northern Green Sturgeon DPS. Northern Green Sturgeon

do not occur upstream of Ishi Pishi Falls and would not be affected by Two Dam Removal Alternative impacts that do not extend downstream past these falls. Potential impacts on green sturgeon in California would be the same under the Two Dam Removal Alternative as those described for the Proposed Project in the short- and long-term (Potential Impact 3.3-12). Because there would not be a substantial short-term decrease in green sturgeon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the green sturgeon population under the Two Dam Removal Alternative in the short term.

For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6. *Algal Toxins*, in the long term the Two Dam Removal Alternative would result in improvements in flow regime, water quality, temperature variation, and algal toxins which could affect Northern Green Sturgeon in the same manner as the Proposed Project. Because there would not be a substantial long-term decrease in green sturgeon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the green sturgeon population under the Two Dam Removal Alternative in the long term.

Significance

No significant impact for green sturgeon in the short or long term

Potential Impact 3.3-13 Effects on Lost River and shortnose sucker populations due to short- and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Lost River and shortnose suckers in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-13), with a few notable differences. For reasons described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on Lost River and shortnose suckers in Upper Klamath Lake, interactions with anadromous fish, and from conversion of Lower Klamath Project reservoir habitat to riverine habitat would be similar to the Proposed Project. Lost River and shortnose suckers currently occur within all Lower Klamath Project reservoirs, except Copco No. 2 due to its small size (Desjardins and Markle 1999). Therefore, while under the Proposed Project all Lower Klamath Project reservoir habitat currently supporting Lost River and shortnose suckers would be removed (2,347 acres), under the Two Dam Removal Alternative habitat would remain in J.C. Boyle Reservoir (420 acres). Most of the reservoir habitat (82 percent), and the preponderance of the Lost River and shortnose sucker populations in the Hydroelectric Reach is within Iron Gate and Copco No. 1 reservoirs.

Overall, the short-term impact of the Two Dam Removal Alternative would be very similar to the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-13), with the exception of those Lost River and shortnose sucker individuals that are able to remain within J.C. Boyle Reservoir habitat. All individual suckers occurring within Iron Gate and Copco No. 1 reservoirs would likely be lost within dam removal year 2; however, these individuals are not considered to substantially contribute to the achievement of conservation goals or recovery, since little or no reproduction occurs downstream from Keno Dam (Buettner et al. 2006), and there is no potential for interaction with upstream populations (Hamilton et al. 2011). Based on the best available estimates of Lost River and shortnose sucker abundance in the Lower Klamath Project excluding J.C. Boyle and Copco No. 2 reservoirs, there are likely fewer than 1,000 adult suckers of both species (USFWS 2012, Desjardins and Markle 1999), with a combined suitable sucker area of less than 2,500 acres. The populations in Upper Klamath Lake are estimated at 50,000 to 100,000 Lost River sucker (USFWS 2013b), and up to 25,000 shortnose suckers (USFWS 2013c), within around 79,000 acres of suitable habitat in Upper Klamath Lake and connected water bodies. Therefore, a loss of the suckers in Lower Klamath Project reservoirs (excluding J.C. Boyle and Copco No. 2 reservoirs) represents around less than 1.5 percent of the total sucker population, and a loss of less than 3.5 percent of the total suitable sucker habitat. Based on no predicted substantial (< 1.5 percent) short-term decrease in Lost River and shortnose suckers' abundance of a year class, or substantial decrease in habitat quality or quantity (<1.5 percent), the Two Dam Removal Alternative would not cause a significant impact to the Lost River and shortnose sucker populations in the short term.

For the reasons described above in Section 4.5.3.7 *Aquatic Habitat*, in the long term reservoir removal associated with dam removal under the Two Dam Removal Alternative would eliminate habitat availability and affect Lost River and shortnose suckers in Iron Gate and Copco No. 1 reservoirs. All individual suckers occurring within these reservoirs would likely be lost within the short term and would not be replaced in the long term. However, as described above, these individuals are not considered to substantially contribute to the achievement of conservation goals or recovery of the populations (Hamilton et al. 2011). Because there would not be a substantial long-term decrease in Lost River and shortnose suckers abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the Lost River and shortnose sucker populations under the Two Dam Removal Alternative in the long term.

In addition, and as described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-13), although this EIR finds no significant impact on Lost River and shortnose suckers in the short term or long term, aquatic resource measure AR-6 (Suckers) would occur under the Two Dam Removal Alternative, which would further reduce the potential for effects of reservoir removal.

Significance

No significant impact for Lost River and shortnose sucker populations in the short term

No significant impact for Lost River and shortnose sucker populations in the long term

Potential Impact 3.3-14 Effects on the redband trout population due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on redband trout in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-14), with a few notable differences. As described in Section 4.5.3.1 *Suspended Sediment* through Section 4.5.3.6 *Algal Toxins*, impacts on redband trout from water quality would be similar to the Proposed Project, as well as algal toxins. Redband trout would also be affected by the reintroduction of anadromous fish, including the potential for competition, predation, and exposure to disease in the same manner as described for the Proposed Project (Potential Impact 3.3-14), since these result from restored habitat access of anadromous salmonids that would not differ between the Proposed Project and the Two Dam Removal Alternative.

Suspended and bedload sediment effects would differ from those described for the Proposed Project. Redband trout are distributed upstream of Iron Gate Dam, and therefore under the Proposed Project the only impacts these individuals would experience from sediment releases would be downstream of J.C. Boyle or downstream of Copco No.2). Therefore, despite the relatively small volume of sediment stored in J.C. Boyle Reservoir (and even less in Copco No. 2), impacts of sediment release on redband trout that would occur under the Proposed Project would be substantially less under the Two Dam Removal Alternative.

As described in Section 4.5.3.7 *Aquatic Habitat*, conversion of Lower Klamath Project reservoir habitat to riverine habitat would be similar to the Proposed Project, with the exception of Copco No. 2 and J.C. Boyle reservoirs. Under the Two Dam Removal Alternative redband trout would benefit from changes in hydropower operations, and from the conversation of 17.7 miles of reservoir habitat to riverine habitat, in the same manner as for the Proposed Project. However, 3.8 miles of mainstem and tributary habitat would continue to be inundated by Copco No. 2 and J.C. Boyle reservoirs. It is anticipated that under the Two Dam Removal Alternative this habitat would continue to support an adfluvial redband trout population. As described in Section 4.5.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at Copco No. 2 and J.C. Boyle dams is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles at each facility, or 4 percent cumulative mortality for migrants that use both facilities.

Because there would not be a substantial short-term decrease in redband trout abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the redband trout population under the Two Dam Removal Alternative in the short term. Based on a long-term substantial increase in redband trout habitat quality and quantity, the Two Dam Removal Alternative would be beneficial for redband trout in the long term.

Significance

No significant impact for redband trout in the short term

Beneficial for redband trout in the long term

Potential Impact 3.3-17 Effects on species interactions between introduced resident fish species and native aquatic species due to short- and long-term changes in habitat quality and quantity due to dam removal.

Introduced fish species threaten the diversity and abundance of native fish species through competition for resources, predation, interbreeding with native populations, and causing potential physical changes to the invaded habitat (Moyle 2002). Potential impacts on species interactions between introduced resident fish species and native aquatic species ("species interactions") in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14), with a few notable differences. As described for the Proposed Project, implementation of the Two Dam Removal Alternative would eliminate reservoir habitat associated with Iron Gate and Copco No. 1 reservoirs, and thus the abundance of introduced resident species would decline substantially (Buchanan et al. 2011a), providing a benefit to native aquatic species. However, the Two Dam Removal Alternative would retain the habitat supporting non-native fish species associated primarily with J.C. Boyle Reservoir. As described in Section 3.3.2.1 *Aquatic Species* *[non-native fish species]*, non-native fish species would continue to occur in J.C. Boyle Reservoir, including yellow perch and bass species (Copco No. 2 is too small to provide substantial habitat for non-native species). Juvenile salmonids and lamprey would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018). However, in restoration efforts elsewhere in the Pacific Northwest, anadromous juveniles successfully pass through reservoirs under similarly difficult circumstances (NMFS 2006a). In addition, the majority of the non-native species are within Iron Gate and Copco No. 1 reservoirs, which support popular recreational fisheries for yellow perch and bass. Therefore, species interactions under the Two Dam Removal Alternative would be substantially improved relative to existing conditions, albeit to a lesser degree than under the Proposed Project. This effect would be beneficial for native aquatic species in the short and long term.

Significance
Beneficial for the effects of introduced resident fish species on aquatic species in the short term and long term

Potential Impact 3.3-19 Effects on freshwater mollusks populations due to short-term sediment releases and long-term changes in habitat quality due to dam removal.
Potential impacts on freshwater mollusks in California would be similar under the Two Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-19), with a few subtle differences. As described in Section 4.5.3.1 *Suspended Sediment*, impacts on freshwater mollusks from sediment releases would be similar to the Proposed Project. Based on the distribution of freshwater mollusks primarily downstream of Iron Gate dam (summarized in Section 3.3.5.9, Potential Impact 3.3-14), the impacts of the Two Dam Removal Alternative would be the same as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14) with one exception. The Proposed Project would have the most substantial impact on the floater mussels (*Anodonta spp*.) which occur in the mainstem Klamath River in the Hydroelectric Reach, within Lower Klamath Project reservoirs, in a reach (<15 miles) directly downstream of Iron Gate Dam, and within the Upper Shasta River. *Anodonta spp*. have been found in high abundance within J.C. Boyle Reservoir as recently as summer 2018 (Troy Brandt, River Design Group, pers. comm., November 2018). Therefore, under the Two Dam Removal Alternative the *Anodonta spp.* would remain unaffected within a portion of their range in J.C. Boyle Reservoir and Upper Shasta River. Therefore, while the impacts to other species of freshwater mollusks would be the same under the Proposed Project (not significant), impacts to the *Anodonta spp*. would be less substantial under the Two Dam Removal Alternative than under the Proposed Project. However, impacts the *Anodonta spp.* would still occur under the Two Dam Removal Alternative in the mainstem Klamath River (primarily downstream of Iron Gate Dam) as described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14), and based on predicted substantial short-term decrease in *Anodonta spp.* abundance of a year class, there would be a significant impact to the *Anodonta spp.* population under the Two Dam Removal Alternative in the short term.

However, the Two Dam Removal Alternative includes aquatic resource measure AR-7 (Freshwater Mussels) to reduce the short-term effects of sediment transport during dam removal on *Anodonta spp.*, as described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14). Under the Proposed Project this salvage and relocation plan would consider sites for translocation downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco No. 1 Reservoir (RM 209.0). These areas would have less impact from increased SSCs but would not be completely protected from short-term effects. The areas downstream of the Trinity River confluence do not currently support *Anodonta spp*. and are unlikely to in the future (Davis et al. 2013). However, under the Two Dam Removal Alternative *Anodonta spp*. could be salvaged from the reach downstream of Iron Gate Dam and relocated to J.C. Boyle Reservoir, which does support suitable *Anodonta spp*. habitat. Therefore, with aquatic resource measure AR-7, there would likely not be a substantial reduction in the abundance of *Anodonta spp.* species in the short term, and impacts would be not significant with for *Anodonta spp.* in the short term.

Significance

No significant impact for *M. falcata, G. angulate, or Anodonta spp.* in the short or long term

No significant impact for freshwater clams in the short or long term

4.5.4 Phytoplankton and Periphyton

4.5.4.1 Phytoplankton

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Two Dam Removal Alternative (see Section 4.5.2.2 *Suspended Sediments*), thus there would be no short-term increase in sediment-associated nutrients downstream of J.C Boyle Dam (see Section 4.5.2.3 *Nutrients*). There would be no change in the short term sediment-associated nutrients in the Hydroelectric Reach or downstream under the Two Dam Removal Alternative compared to under the Proposed Project due to keeping Copco No. 2 Dam in place, since that dam with its small size and short residence time is not expected to intercept or retain appreciable amounts of sediment or the associated nutrients during drawdown. While there would be a short-term increase in sediment-associated nutrients from release of Copco No. 1 and Iron Gate reservoir deposited sediments and associated nutrients in the Hydroelectric Reach, as well as in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary during reservoir drawdown (see Section 4.5.2.3 *Nutrients*), minimal deposition of fine suspended sediments, including the associated nutrients, would occur in the river channel and the estuary (Stillwater Sciences 2008; USBR 2012). Thus, the short-term increase in nutrients would be limited to the time period when sediment deposits are being transported through the Klamath River. The drawdown of Copco No. 1 and Iron Gate reservoirs and release of these nutrients also would occur during winter months when the rates of phytoplankton growth and reproduction along with the rates of nutrient transformations by microbes (e.g., nitrification and denitrification) are relatively low, so the ability of phytoplankton to use sediment-associated nutrients mobilized during reservoir drawdown would be low (see Potential Impact 3.4-1). Sediment released during reservoir drawdown under the Two Dam Removal Alternative also would increase suspended sediment concentrations and water turbidity (see also Potential Impact 3.2-3), limiting light availability for phytoplankton photosynthesis and further reducing the potential for additional phytoplankton growth and reproduction. Under the Two Dam Removal Alternative, the sediment-associated nutrients would be less than under the

Proposed Project since no J.C. Boyle sediment-associated nutrients would be released, but the overall impact would be the same in both the Two Dam Removal Alternative and the Proposed Project. The sediment-associated nutrients would not be likely to stimulate phytoplankton growth or reproduction that would lead to an increase spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton, so there would be no significant impact.

With respect to potential long-term impacts, J.C. Boyle Reservoir does not support low mixing conditions or thermal stratification that create optimal habitat for phytoplankton growth or reproduction under existing conditions due to its shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days at average flows) and it would not do so under the Two Dam Removal Alternative. Peaking power generation flows are released in the late afternoons and early evenings to meet high power demand, and J.C. Boyle Reservoir refills during the night when power demand is minimal. Daily fluctuations in the reservoir water level under existing operations increases mixing in the reservoir, making the reservoir slightly less suitable habitat for phytoplankton during the season of maximum phytoplankton and cyanobacteria (blue-green-algae) growth in the system. Ceasing peaking power generation flows would reduce daily reservoir water level fluctuations in J.C. Boyle Reservoir because the facility would no longer be operated to draw on reservoir storage to support daily peaks in hydropower production when there is not sufficient river flow for peak production (3,000 cfs), as occurs during the summer and fall low flow period under existing conditions. However, the residence time of J.C. Boyle Reservoir without peaking operations would still be short (i.e., on the order of one to three days), so leaving this dam in place and ceasing peaking flows would not change long-term phytoplankton growth or reproduction and thus it would not change the spatial extent, temporal duration, or concentration of nuisance and/or noxious phytoplankton blooms, including blue-green algae, to the degree that new or further impairment of designated beneficial uses would occur.

Similarly, Copco No. 2 Reservoir has no active storage, a negligible hydraulic residence time (i.e., less than one day) (USBR 2012), and does not thermally stratify, such that the reservoir under existing conditions does not support conditions for the growth of phytoplankton in the epilimnion, unlike the larger Copco No. 1 and Iron Gate reservoirs (see 3.2.2.1 *Overview of Water Quality Processes in the Klamath Basin*). Under the Two Dam Removal Alternative, Copco No. 2 Reservoir remaining in place would not affect the spatial extent, temporal duration, and concentration of nuisance and/or noxious phytoplankton species within the Hydroelectric Reach or downstream reaches since it would continue to not support suitable habitat for phytoplankton growth, reproduction, or blooms.

Copco No. 1 and Iron Gate reservoirs currently support growth conditions for toxin-producing nuisance phytoplankton species such as *Microcystis aeruginosa*, with these two reservoirs serving as the primary habitat for blue-green algae in the Hydroelectric Reach. Thus, the removal of Copco No. 1 and Iron Gate reservoirs under the Two Dam Removal Alternative would eliminate the main habitat for toxin-producing nuisance phytoplankton and reduce the long-term spatial extent, temporal duration, and concentration of nuisance and/or noxious phytoplankton species relative to existing conditions, consistent with the Proposed Project. The elimination of Copco No. 1 and Iron Gate reservoirs would be beneficial in the Hydroelectric Reach downstream of Copco No. 1 Reservoir.

Because seasonal phytoplankton blooms are primarily internally generated in Copco No. 1 and Iron Gate reservoirs, removal of these reservoirs under the Two Dam Removal Alternative would also decrease or eliminate the long-term downstream transport of nuisance and/or noxious phytoplankton species and their associated toxins from Copco No. 1 and Iron Gate reservoirs into the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment.

In summary, relative to existing conditions, the potential impacts and impacts of the Two Dam Removal Alternative on phytoplankton would be the same as or similar to those described for the Proposed Project, as follows:

- There would be no short-term change in phytoplankton growth and reproduction from existing conditions in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir due to mobilization of sediment-associated nutrients from J.C. Boyle Reservoir because this reservoir and its sediment deposits would remain in place (Potential Impact 3.4-1).
- While there would be short-term increases in sediment-associated nutrients downstream of Copco No. 1 Dam due to the release of sediments currently trapped behind the Copco No. 1 and Iron Gate dams, Copco No. 2 remaining in place would not alter the short-term sediment-associated nutrients conditions compared to the Proposed Project and the short-term increases in sediment-associated nutrients would not increase the spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton species, including blue-green algae, in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, and the Klamath River Estuary such that there would be new or further impairment of designated beneficial uses; thus there would be no significant impact in the short term (Potential Impact 3.4-1).
- There would be no significant impact in the long term from J.C. Boyle Dam remaining in place and ceasing peaking power generation flows on the spatial extent, temporal duration, transport, and/or concentration of nuisance and/or noxious phytoplankton species and concentrations of algal toxins because J.C. Boyle Reservoir would not support habitat that would promote phytoplankton blooms under the Two Dam Removal Alternative similar to under existing conditions (Potential Impact 3.4-2).
- Copco No. 2 remaining in place would not alter the phytoplankton conditions in the Hydroelectric Reach since it does not support habitat conditions for the growth or reproduction of phytoplankton, including blue-green algae. However, the long-term reduction in the spatial extent, temporal duration, transport, and/or concentration of nuisance and/or noxious phytoplankton species and concentrations of algal toxins due to elimination of Copco No. 1 and Iron Gate reservoir habitats would be beneficial for the Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary (Potential Impact 3.4-2). There would be no significant impact for the Pacific Ocean nearshore environment (Potential Impact 3.4-2).

4.5.4.2 Periphyton

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Two Dam Removal Alternative, thus there would be no short-term increase in sediment-associated nutrients downstream of J.C Boyle Dam. There would be no change in the short term sediment-associated nutrients in the Hydroelectric Reach or downstream under the Two Dam Removal Alternative compared to under the Proposed Project due to keeping Copco No. 2 Dam in place, since it is not expected to intercept or retain appreciable amounts of sediment or the associated nutrients during drawdown (see Section 4.5.2.2 *Suspended Sediments* and Section 4.5.2.3 *Nutrients*). While there would be a short-term increase in sediment-associated nutrients between Copco No. 1 Reservoir and Iron Gate Dam in the Hydroelectric Reach, as well as in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary during reservoir drawdown, minimal deposition of fine suspended sediments, including the associated nutrients, would occur in the river channel and the estuary (Stillwater Sciences 2008; USBR 2012). Thus, the short-term increase in nutrients would be limited to the time period when sediment deposits are being transported through the Klamath River. The drawdown of Copco No. 1 and Iron Gate reservoirs and release of these nutrients would occur during winter months when the rates of periphyton growth and reproduction along with the rates of nutrient transformations by microbes (e.g., nitrification and denitrification) are relatively low due to less light availability for photosynthesis and lower water temperatures. As a result, the ability of periphyton to use sediment-associated nutrients would be limited and there would not be an increase in periphyton growth or reproduction during this period, even though additional nutrients would be available due to the release of sediments trapped behind the Lower Klamath Project dams. Light limitation from high concentrations of suspended sediments in the water (Potential Impact 3.2-3) would also reduce any potential for nuisance levels of periphyton growth during reservoir drawdown. Additionally, high river flows during the winter drawdown period and late spring storm events would result in greater sediment movement and scouring, which would greatly limit, if not eliminate, the area of the streambed that periphyton can establish to grow during this period. Thus, the Two Dam Removal Alternative would not be likely to stimulate an increase in periphyton growth or reproduction and result in an increase in the spatial extent, temporal duration, or biomass of nuisance periphyton species that causes a new or further impairment of designated beneficial uses, similar to the Proposed Project.

Under the Two Dam Removal Alternative, J.C. Boyle Reservoir would remain in place and peaking power generation and release of recreation flows would cease from J.C. Boyle Dam, so there would be less artificial diel temperature variation during summer and early fall in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir, similar to the Proposed Project (see also Potential Impact 3.2-1). While J.C. Boyle retains relatively little nutrients under existing conditions (see Appendix C, Section C.3.1.1 *Hydroelectric Reach*), nutrient conditions in this reach would be the same under the Two Dam Removal Alternative as under existing conditions since there would be no change in nutrient interception or retention with J.C. Boyle Dam remaining in place. The less diel temperature variations and slight decrease in the maximum water temperature in this reach is not anticipated to affect periphyton colonization. Additionally, the generally high gradient and velocity in the J.C. Boyle Peaking Reach does not currently support excessive periphyton mats and it is not anticipated this reach would support excessive periphyton mats under lower flows once peaking and recreation flows cease. In the short term and long term, increases in periphyton biomass from elimination of peaking and recreation flows along with the change in water temperature in this reach are expected to be limited under the Two Dam Removal Alternative and any potential increase in periphyton would not result in new or further impairment of designated beneficial uses. Nutrient reduction measures in California's Lower Lost River TMDLs and Klamath River TMDLs could, in the long term, further minimize colonization of periphyton mats in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir. However, the measures necessary to achieve significant reductions are, at this point, unknown.

Further downstream in the Hydroelectric Reach, periphyton growth in low-gradient channel margin areas in the footprints of Copco No. 1 and Iron Gate reservoirs could increase on a seasonal basis following dam removal because removal of those two reservoirs would provide additional low-gradient habitat suitable for periphyton assemblages. Periphyton growth would not be likely to be supported in the approximately 0.3 miles of Copco No. 2 Reservoir due to relatively deep water (i.e., up to 28 feet [USBR 2012]), so retaining Copco No. 2 Dam under the Two Dam Removal Alternative and the reduction in suitable periphyton habitat would slightly reduce the extent of periphyton growth compared to the Proposed Project. Dam removal construction and restoration activities in dam removal year 2 and additional sediment transport and scour during winter post-dam removal year 1 may inhibit some periphyton growth in the Hydroelectric Reach in the Copco No. 1 and Iron Gate reservoir footprints, but, overall, periphyton would be expected to begin colonizing the newly created suitable habitat within the short term and would continue in the long term. While retaining Copco No. 2 Reservoir would reduce the available periphyton habitat compared to the Proposed Project, the growth of periphyton within the newly created low-gradient channel margin areas in the Copco No. 1 and Iron Gate reservoirs' footprint conservatively would be a significant impact similar to the Proposed Project (Potential Impact 3.4-4) due to potential increases in nuisance periphyton within the footprints of those two reservoirs. The response of periphyton in the river is subject to many competing processes that could either accelerate or hinder periphyton growth and potential increases in nuisance periphyton (i.e., *Cladophora* sp.) extent, duration, and biomass. In the long term, improvements (i.e., reductions in biomass) are expected from several processes such as scour, long term nutrient reductions stemming from TMDL actions, and in-stream retention processes, whereas improvements could be diminished by processes such as reduced nutrient retention from the reservoirs or climate change. While the growth of nuisance periphyton along channel margin areas is not expected to contribute algal toxins that would impair water quality, the degree to which designated beneficial uses would be impaired due to an increase in nuisance periphyton species (i.e., *Cladophora* sp.) in the newly formed low-gradient channel margin areas of the Hydroelectric Reach is not fully understood. The implications of potential changes in periphyton biomass and community composition on dissolved oxygen and the spread of fish disease are described in Section 3.2.5.4 *Dissolved Oxygen* and Section 3.3.5.5 *Fish Disease and Parasites*, respectively.

Periphyton are a natural component of river ecology and they are an important element of aquatic food webs. The establishment and growth of periphyton, including nuisance periphyton species, along the margins of the newly created low gradient river channel is a natural process. While processes that influence periphyton establishment and growth have been identified (e.g., light availability, nutrient availability, water temperature, seasonal flow variations, sediment transport), variations in these processes within the Hydroelectric Reach of the Klamath River after dam removal would not completely prevent the potential for growth of nuisance periphyton species along the margins of the newly created low gradient river channels. In the reservoir areas of the Hydroelectric Reach that would become the newly created low gradient habitat, there is no periphyton since it is not suitable habitat. No mitigation measure would completely eliminate the potential for establishment and growth of periphyton or specifically nuisance periphyton within these areas. As such, there are no mitigation measures that can be proposed to significantly avoid or minimize this impact and reduce the impact to less than significant.

In summary, relative to existing conditions, the potential impacts of the Two Dam Removal Alternative on periphyton would be the same as or similar to those described for the Proposed Project, as follows:

- There would be no significant impact in the short term from changes in periphyton growth compared to existing conditions due to mobilization of sediment-associated nutrients from J.C. Boyle Reservoir (Potential Impact 3.4-3) because this reservoir and its sediment deposits would remain in place.
- Copco No. 2 Dam remaining in place would not alter the short-term sediment-associated nutrients during drawdown and periphyton usage of sediment-associated nutrients mobilized from Copco No. 1 and Iron Gate reservoirs would be limited due to lower light levels reducing photosynthesis for periphyton growth and higher flows scouring periphyton from the streambed during winter and early spring. Thus, there would not be an increase in the spatial extent, temporal duration, or biomass of nuisance periphyton species in the Hydroelectric Reach downstream of Copco No. 1, the Middle and Lower Klamath River, or the Klamath River Estuary that would result in a new or further impairment of designated beneficial uses (Potential Impact 3.4-3), and there would be no significant impact.
- There would be no short-term or long-term increase in nuisance periphyton growth that results in new or further impairment of designated beneficial uses in the Hydroelectric Reach from J.C. Boyle Dam to Copco No. 1 Reservoir, including the Oregon-California state line, due to increased nutrients or ceasing of peaking flows at J.C. Boyle (Potential Impact 3.4-4), so there would be no significant impact.
- While Copco No. 2 Dam remaining in place would reduce the available periphyton habitat compared to the Proposed Project, there could be a short-term and/or long-term increase in nuisance periphyton growth that would result in new or further impairment of designated beneficial uses in the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam due to an increase in nutrients and available low-gradient channel margin habitat from conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.4-4) and if this increase were to occur, it would be a significant and unavoidable impact.
- There would be no long-term increase in biomass of nuisance periphyton that would result in new or further impairment of designated beneficial uses in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary due to increased nutrient availability from upstream dam removal under the Two Dam Removal Alternative similar to the Proposed Project (Potential Impact 3.4-5), so there would be no significant impact.

4.5.5 Terrestrial Resources

Although short-term dam deconstruction activities would not occur for Copco No. 2 Dam under the Two Dam Removal Alternative, deconstruction of Copco No. 1 and Iron Gate dams and associated facilities, and construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur, and thus the level of overall construction activities in the Hydroelectric Reach in California would be only slightly less than those described under the Proposed Project. Therefore, in general the Two Dam Removal Alternative would have slightly less short-term potential impacts on vegetation communities, culturally significant species, special status species, wildlife corridors and habitat connectivity, as those described for the Proposed Project (see Section 3.5.5 *[Terrestrial Resources] Potential Impacts and Mitigation]*. The mitigation measures and recommended terrestrial measures would be the same as those identified for the Proposed Project. Long-term potential impacts and any short-term potential impacts that would be different under the Two Dam Removal Alternative than the Proposed Project are discussed below.

In the long term, since Copco No. 2 Dam and Reservoir would remain under the Two Dam Removal Alternative, the reduction of existing wet habitat that currently supports the following wetland vegetation communities would not occur and there would be no significant impact compared with existing conditions:

- Palustrine Scrub-shrub Wetland and Palustrine Forested Wetland on the southern slope of Copco No. 2 Dam.
- Small, local patches of Palustrine Emergent Wetland supported by water leaks from the Copco No. 2 penstock.

While retaining the existing wet habitat at Copco No. 2 Reservoir would reduce potential long-term impacts to these wetland and riparian vegetation communities described under the Proposed Project and thus may be relatively beneficial, the proposed acreage (150 acres) for restored riparian and wetland vegetation under the Proposed Project is well above the total acreage that would potentially be impacted (68 acres), such that the policy of no net loss compared with existing conditions would be achieved regardless of whether the Copco No. 2 Dam remains under the Two Dam Removal Alternative.

Leaving Copco No. 2 Dam in place under the Two Dam Removal Alternative would avoid potential long-term impacts to the rock talus habitat present just downstream of the dam, and there would be no significant impact on Forest Service or BLM special-status terrestrial invertebrates Oregon shoulderband, Trinity shoulderband, Siskiyou shoulderband, and Tehama chaparral compared with existing conditions. However, since suitable habitat is present in numerous locations throughout the Primary Area of Analysis for terrestrial resources (Appendix G), any impact on this specific area would not be expected to affect any federal species of special concern at a population level, if present (Potential Impact 3.5-10), regardless of whether the Copco No. 2 Reservoir remains under the Two Dam Removal Alternative.

While Copco No. 1 and Iron Gate dams and facilities would be fully removed under this alternative, the Copco No. 2 Dam and facilities and the J.C. Boyle Dam and facilities would remain in place, which would slightly reduce construction activities relative to the Proposed Project. Short-term construction-related noise would still be generated in California due to removal of the Copco No. 1 and Iron Gate dams and associated facilities and installation of fish passage at the Copco No. 2 Dam. Retaining Copco No. 2 structures under this alternative would not reduce noise-related impacts on special-status bats or birds to a less than significant level. Although this alternative would remove structures that also support known bat roosts, including maternity roosts (e.g., Copco No. 1 Dam – C-12 Gatehouse, Copco No. 1 Powerhouse, and Copco No 1. Diversion Tunnel), some of the structures that would be retained (i.e., Copco No. 2 Powerhouse and vacant house #21601) are known to support maternity colonies (see Section 3.5.5.3 *Special-status Species and Rare Natural Communities*). Thus, relative to the Proposed Project, the Two Dam Removal Alternative would reduce the potential for long-term population-level impacts due to the removal of large maternity colonies day roosts and large maternity colonies that may be present (Potential Impact 3.5-15). While there would be no significant impact to maternity roosts associated with the Copco No. 2 structures compared with existing conditions, there would still be a significant impact compared to existing conditions for this alternative due to the removal of maternity roosts associated with the Copco No. 1 structures.

Retaining Copco No. 2 facilities (reservoir, dam, penstocks, buildings) under the Two Dam Removal Alternative would result in no change from existing conditions with respect to wildlife corridors and habitat connectivity associated with these structures. Effects on wildlife corridors and habitat connectivity would be marginally less beneficial in terms of providing enhanced migration opportunities as those described for the Proposed Project because Copco No. 2 facilities would remain and may continue to impede wildlife migration. The greatest length of parallel steel penstocks that would remain at Copco No. 2 Dam under this alternative is approximately 410 feet and the length of wooden-stave penstock that would remain is approximately 1,330 feet. The Copco No. 2 powerhouse and intake structure do not present a migration barrier under existing conditions such that retaining these features would not represent a change from existing conditions. While retaining Copco No. 2 Dam and Reservoir under the Two Dam Removal Alternative would continue to impede upstream movement of amphibians and reptiles, as described for the Proposed Project, removing Copco No. 1 and Iron Gate dams and reservoirs would benefit some terrestrial species by eliminating barriers to migration (Potential Impacts 3.5-24, 3.5-30, 3.5-31) and overall the effect of the Two Dam Removal Alternative on wildlife corridors and habitat connectivity would be beneficial.

In summary, relative to existing conditions, the potential long-term impacts of the Two Dam Removal Alternative on terrestrial resources would be different from those described for the Proposed Project, as follows:

- Long-term reduction of existing wet habitat that supports the aforementioned wetland vegetation communities on the southern slope of Copco No. 2 Dam and associated with the Copco No. 2 penstock (Potential Impact 3.5-2) would not occur and there would be no significant impact.
- Long-term disturbance of potentially suitable rock talus habitat for the terrestrial invertebrates Oregon shoulderband, Trinity shoulderband, Siskiyou shoulderband, and Tehama chaparral located just downstream of Copco No. 2 Dam (Potential Impact 3.5-9) would not occur and there would be no significant impact.
- Long-term impacts to small day roosts and large maternity colonies in or near the Copco No. 2 Powerhouse and other Copco No. 2 facility structures (Potential Impact 3.5-15) would not occur and there would be no significant impact.

4.5.6 Flood Hydrology

The Two Dam Removal Alternative would have the same potential impacts on flood hydrology as those described for the Proposed Project (Potential Impacts 3.6-1 through 3.6-6). This is because Copco No. 2 Reservoir has no active storage, J.C. Boyle Reservoir has a relatively small storage capacity (2,267 acre-feet total storage; 1,724 acre-feet active storage; see Table 3.6-4) and does not attenuate flood flows in the Area of Analysis, and PacifiCorp does not operate either reservoir for flood control. Therefore, leaving Copco No. 2 and J.C. Boyle reservoirs in place would not affect flood hydrology compared to the Proposed Project and there would be no significant impacts for Potential Impacts 3.6-1, 3.6-2, and 3.6-4 through 3.6-6. There would be significant and unavoidable impacts related to exposing structures to a substantial risk of damage due to flooding downstream of the location of Iron Gate Dam (Potential Impact 3.6-3).

4.5.7 Groundwater

The Two Dam Removal Alternative would have the same potential impacts on groundwater as those identified under the Proposed Project (Potential Impacts 3.7-1 and 3.7-2). This is because Copco No. 2 Reservoir has no active storage and J.C. Boyle is more than 20 river miles upstream of the Area of Analysis, such that leaving these reservoirs in place would not affect groundwater levels or wells immediately adjacent (potentially extending up to a mile from the reservoirs under certain conditions) to Copco No. 1 and Iron Gate reservoirs compared to the Proposed Project. Removal of Copco No. 1 and Iron Gate reservoirs under the Two Dam Removal Alternative would result in the same effects on groundwater as described for the Proposed Project (Section 3.7.5 *[Groundwater] Potential Impacts and Mitigation*) for the reasons described in Potential Impacts 3.7-1 and 3.7-2, and there would be no significant impacts.

4.5.8 Water Supply/Water Rights

The Two Dam Removal Alternative would have the same potential impacts on water supply/water rights as those identified under the Proposed Project (Potential Impacts 3.8-1 through 3.8-5). This is because Copco No. 2 Reservoir has no active storage, J.C. Boyle Reservoir has a relatively small storage capacity (2,267 acre-feet total storage; 1,724 acre-feet active storage; see Table 3.6-4), and neither reservoir is operated by PacifiCorp as a water supply source, such that leaving these reservoirs in place would not affect water supply/water rights compared to the Proposed Project. Thus, Potential Impacts 3.8-1, 3.8-2, and 3.8-5 under the Proposed Project would be the same under the Two Dam Removal Alternative, and there would be no significant impacts.

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Two Dam Removal Alternative and none of the associated 1,190,000 cubic yards of deposits (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches, although little to no sediment deposition would be expected in the reach between J.C. Boyle Dam and Copco No. 1 Reservoir (USBR 2012). Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). However, mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs would still occur under this alternative such that release of stored sediment during reservoir drawdown could still impact water intake pumps downstream from Iron Gate Dam (Potential Impact 3.8-3). This would be a significant impact. Implementation of Mitigation Measure WSWR-1 would be required to result in no significant impact.

The City of Yreka's municipal water supply pipeline would still need to be relocated following drawdown of Iron Gate Reservoir, and there would still be potential for disruption to the City's water supply, as described under the Proposed Project. This would be a significant impact. Implementation of Mitigation Measure WSWR-2 would reduce this potential impact to less than significant.

4.5.9 Air Quality

For the reasons discussed below, potential air quality impacts due to construction activities under the Two Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.9-1 through 3.9-5). Construction activities at J.C. Boyle Dam, regardless of whether these would be for dam removal or fish ladder construction, would occur in Oregon. However, as with the Proposed Project, due to the potential for the emissions generated from construction activity in Oregon to have air quality impacts in Siskiyou County, California, the emissions from construction activity in Oregon are conservatively included in the estimate of total emissions due to construction activity under this alternative.

In California, while short-term dam deconstruction activities would not occur at Copco No. 2 Dam under the Two Dam Removal Alternative, construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur, and thus the level of overall construction activities and thus daily emissions of air pollutants (i.e., VOCs, CO, NOx, SOs, PM_{10}, $PM_{2.5}$) in the Hydroelectric Reach in California would be slightly less than those described under the Proposed Project. However, this alternative would still result in air quality levels that exceed the Siskiyou County Air Pollution Control District emissions thresholds for NOx and PM_{10} (Table 4.5-2). If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle and Copco No. 2 dams would be further reduced, however this degree of difference would not be sufficient to result in emissions below the Siskiyou County Air Pollution Control District emissions thresholds for NOx and PM_{10} (Table 4.5-2) and this alternative would result in a significant and unavoidable impact.

Table 4.5-2. Total Uncontrolled Daily Emissions from the Two Dam Removal Alternative.[1]

Project Activity	Daily Emissions (pounds per day)[2]					
	VOC	CO	NOx	SOx	PM_{10}	$PM_{2.5}$
Dam and Powerhouse Deconstruction	117	552	620	7	399	225
Restoration Activities	18	60	165	20	3	3
Recreation Facilities	8	45	54	0	13	6
Yreka Water Supply Pipeline Relocation	3	16	18	0	10	3
Total	146	673	**857**	27	**425**	237
Significance Criterion[2]	250	2,500	250	250	250	250

[1] Data from 2012 KHSA EIS/EIR.
[2] Values shown in grey highlight exceed the Siskiyou County Air Pollution Control District's (SCAPCD) thresholds of significance in Rule 6.1 (Construction Permit Standards for Criteria Air Pollutants).

Key:
- VOC = volatile organic compounds
- CO = carbon monoxide
- NOx = nitrogen oxides
- SOx = sulfur oxides
- PM_{10} = inhalable particulate matter
- $PM_{2.5}$ = fine particulate matter

This alternative would not include operational changes that would affect air emissions in the long term for implementation of fish ladders and there would be no significant impact (Potential Impact 3.9-1).

If trap and haul facilities were to be constructed instead of fish ladders, peak daily emissions due to construction activities would be less than those described above. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Copco No. 2 Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Copco No. 2 Dam. Although the exact extent and timing of these ongoing hauling activities is not known, peak daily air quality emissions would be considerably less than those estimated above because it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 30 for 40 miles each way between Copco No. 2 Dam and J.C. Boyle Reservoir. Therefore, the long-term potential impact on air quality emissions due to trap and haul operations would be less than significant.

4.5.10 Greenhouse Gas Emissions

For the reasons described below, greenhouse gas (GHG) impacts under the Two Dam Removal Alternative would be the slightly less than those described for the Proposed Project (Section 3.10.5 *[Greenhouse Gas Emissions] Potential Impacts and Mitigation*). Construction activities at J.C. Boyle Dam, regardless of whether these would be for dam removal or fish ladder construction (or trap and haul or some combination of fish passage methods) would occur in Oregon. However, as with the Proposed Project, due to the cumulative nature of GHG emissions, the emissions from construction activity in Oregon are conservatively included in the estimate of total emissions due to construction activity under this alternative. In California, construction activities at Copco No. 1 and Iron Gate dams would still occur and this, combined with construction activities at Copco No. 2 Dam (including fishway construction) and at J.C. Boyle Dam in Oregon, means that the detailed discussion of impacts to GHGs provided in the Proposed Project (Potential Impact 3.10-1) also applies to this alternative. Leaving Copco No. 2 and J.C. Boyle dams in place would not change the potential for a conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing the emissions of GHGs (Potential Impact 3.10-2). Overall, the Two Dam Removal Alternative would result in no significant impacts due to GHG emissions.

If trap and haul facilities were to be constructed instead of fish ladders, greenhouse gas emissions due to construction activities would be less than those described above. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Copco No. 2 Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Copco No. 2 Dam. Although the exact extent and timing of these ongoing hauling activities is not known, greenhouse gas emissions would be considerably less than those estimated above because it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 30 to 40 miles each way between Copco No. 2 Dam and J.C. Boyle Reservoir. Therefore, the long-term potential impact on greenhouse gas emissions due to trap and haul operations would be less than significant.

4.5.11 Geology, Soils, and Mineral Resources

For the reasons discussed below, the Two Dam Removal Alternative would have similar effects on geology, soils, and mineral resources in California as would the Proposed Project (Section 3.11 *Geology, Soils, and Mineral Resources*), with minor differences discussed at the end of this section. Relative to the Proposed Project, leaving J.C. Boyle and Copco No. 2 dams and associated facilities in place would reduce overall construction activities related to dam removal. However, as discussed in Section 4.6.1.1 *Alternative Description*, the Two Dam Removal Alternative also includes construction of a new fish ladder at J.C. Boyle Dam (and removal of the existing one within a similar footprint to the existing ladder) and construction of a fish ladder at Copco No. 2 Dam. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle and Copco No. 2 dams would be further reduced relative to the Proposed Project. While there would potentially be less construction activities resulting in short-term soil disturbance under this alternative than under the Proposed Project, the relative decrease in construction activities under the Two Dam Removal Alternative would not change the potential for impacts compared to existing conditions due to geologic hazards, short-term soil disturbance, hillslope instability, earthen dam embankment instability, or loss of mineral resources and impacts would be the same as those described for the Proposed Project.

In California, any of these potential impacts, under either the Proposed Project or the Two Dam Removal Alternative, would be due to removal and reservoir drawdown activities at Copco No. 1 and Iron Gate dams and associated facilities in California. Thus, there would be no significant impacts due to potential for changes to geologic hazards, short-term soil disturbance, earthen dam embankment instability, and mineral resource availability under the Three Dam Removal Alternative for the reasons described for the Proposed Project (Potential Impacts 3.11-1, 3.11-2, 3.11-4 and 3.11-8).

As with the Proposed Project, implementation of Mitigation Measure GEO-1 would be necessary to reduce the potential impacts resulting from slope failure in reservoir rim areas at Copco No. 1 Reservoir (see Potential Impact 3.11-3). With implementation of Mitigation Measure GEO-1, there would be no significant impacts due to the potential for hillslope instability at Copco No. 1 Reservoir during drawdown and the year following drawdown.

Under the Two Dam Removal Alternative, J.C. Boyle Dam would remain in place and the associated 1,190,000 cubic yards of reservoir sediment deposits (eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would not be eroded or delivered to downstream reaches. The latter would reduce associated short-term erosion and sediment delivery impacts (i.e., sedimentation and bank erosion downstream of Iron Gate Reservoir) that would occur under the Proposed Project, given the relatively smaller volume of sediments in J.C. Boyle Reservoir compared with Copco No. 1 and Iron Gate reservoirs. However, the effect would be relatively small since mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs would still occur. Further, Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*). Therefore, potential short-term erosion and sediment delivery impacts under the Two Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.11-5 through 3.11-7) and there would be no significant impacts, with the exception of the Middle Klamath River between Iron Gate Dam and Cottonwood Creek where there would be a significant and unavoidable impact (see Potential Impact 3.11-5). In the long term, J.C. Boyle Reservoir would continue accumulating sediment at approximately the rate that it does under existing conditions, which is generally low (see Table 3.11-6).

4.5.12 Historical Resources and Tribal Cultural Resources

Under the Two Dam Removal Alternative, leaving the J.C. Boyle Dam and associated facilities in place would reduce construction activities related to dam removal relative to the Proposed Project; however, it would not decrease the degree of construction activities or the associated impacts to historical and tribal cultural resources in California since J.C. Boyle is located in Oregon. Unlike under the Proposed Project, reservoir drawdown associated with the removal of J.C. Boyle Dam would not occur under the Two Dam Removal Alternative. However, as discussed in Potential Impact 3.12-3, drawdown releases from J.C. Boyle Dam under the Proposed Project would not cause flooding of the river between the dam and Copco No. 1 Reservoir and would not result in short-term erosion or flood disturbance to the numerous prehistoric archaeological riverside sites with habitation debris, house pits and rock features and cemeteries; as well as ethnographic places and other features of the cultural landscape that have been identified as TCRs along this reach of the Klamath River (PacifiCorp 2004, Daniels 2006). Therefore, leaving J.C. Boyle Dam in place under the Two Dam Removal Alternative would have no bearing on the potential for impacts to known or unknown historical and/or tribal cultural resources within this reach and, like the Proposed Project, there would be no significant impact. The potential for flood disturbance further downstream along the Klamath River would not be different under this alternative from that described for the Proposed Project (Potential Impact 3.12-3) since the two largest reservoirs, Copco No. 1 and Iron Gate would still be removed.

Copco No. 1 and Iron Gate dams would be removed under this alternative and potential impacts to the built environment and historic-period archaeological resources (Potential Impacts 3.12-11 through 3.12-16) and tribal cultural resources (Potential Impacts 3.12-1 through 3.12-8) would be the same as those described for the Proposed Project and would be significant and unavoidable. However, under the Two Dam Removal Alternative, the Copco No. 2 facility, which contributes to the Klamath Hydroelectric Historic District [214], would not be removed and direct impacts to the historical significance of its structures and hydroelectric facilities (e.g., wooden-stave penstock) would not occur (Potential Impact 3.12-11). Installation of upstream and downstream fish passage at Copco No. 2 dam, including all associated construction activities, may impact Copco No. 2 Dam and its associated facilities, and combined with the removal of Copco No. 1 and Iron Gate facilities, the Two Dam Alternative could possibly affect the overall integrity of the Klamath Hydroelectric Historic District. This would be a significant

[214] The Klamath Hydroelectric Historic District is presumed eligible for inclusion on the National Register and the California Register due to its role in early development of electricity and economy of the southern Oregon and northern California regions (see also Section 3.12.2.3 *Known Tribal and Historical Resources in the Vicinity of the Proposed Project*).

and unavoidable impact for the reasons described under the Proposed Project (Potential Impact 3.12-11).

Leaving Copco No. 2 Dam in place under the Two Dam Removal would reduce impacts to known, or as yet unknown, tribal cultural resources located within the footprint of Copco No. 2 reservoir and its associated hydroelectric facilities. However, installation of upstream and downstream fish passage at Copco No. 2 dam and a new day use area near Copco No. 2 Dam, including all associated construction activities, may impact known, or as yet unknown, tribal cultural resources to a similar degree as that described for the Proposed Project. For this reason, and because Copco No. 1 and Iron Gate dams would be removed under this alternative as described for the Proposed Project, potential impacts to tribal cultural resources (Potential Impacts 3.12-1 through 3.12-8) would be the same as those described for the Proposed Project. Implementation of Mitigation Measures TCR-1 through TCR-8 would reduce impacts to tribal cultural resources, but for the reasons described under the Proposed Project, the impacts would remain significant and unavoidable.

There would be approximately 18.2 miles of additional riverine habitat that would become available for salmonids under this alternative (not including 3.5 miles of riverine habitat that would remain inundated by J.C. Boyle Reservoir, and an estimated 0.3 miles of riverine habitat that would remain inundated by Copco No. 2). The additional habitat, combined with a reduced incidence of fish disease and parasites in the Klamath River under this alternative (see Section 4.5.3.4 *Fish Disease and Parasites*), would improve conditions for the Klamath Cultural Riverscape related to fisheries (Potential Impact 3.12-9) relative to existing conditions. This would be a beneficial effect. Reductions in blue-green algae concentrations under this alternative (see Section 4.5.2.6 *Chlorophyll-a and Algal Toxins*) would support Cultural Use of Klamath River waters without risk of adverse health effects, which would improve tribal members' access to the river above levels occurring under existing conditions (Potential Impact 3.12-10) and would be a beneficial effect.

4.5.13 Paleontologic Resources

For the reasons described under the Proposed Project (Section 3.13.5 *[Paleontologic Resources] Potential Impacts and Mitigation*), there could be instances of bank erosion and slope failures in the Middle Klamath River due to changes in river discharge should Copco No. 1 and Iron Date dams be removed (Potential Impact 3.13-1). However, the magnitude of this bank erosion would not be substantial compared to the existing condition and there would be a low likelihood that downcutting or erosion of the Hornbrook Formation located downstream of Iron Gate Dam would occur to a greater degree than existing conditions. Because of their small size (2,267 acre-feet total storage for J.C. Boyle and 70 acre-feet total storage for Copco No. 2; see Table 3.6-4) and because they are not operated by PacifiCorp as a flood control reservoir, retaining J.C. Boyle and Copco No. 2 reservoirs under this alternative would not affect the likelihood of downcutting or erosion relative to existing conditions or the Proposed Project, and given the formation's Low Paleontologic Potential (Potential Impact 3.13-1), there would be no significant impact to paleontologic resources under the Two Dam Removal Alternative.

4.5.14 Land Use and Planning

Under the Two Dam Removal Alternative, the short-term impacts on land use and planning in California would be the same as those described for the Proposed Project in Section 3.14.5 *[Land use and Planning] Potential Impacts and Mitigation*, with the exception of the transfer of Parcel B lands. Because long-term land use under this alternative is currently unknown, this alternative does not assess the potential impacts of long-term use of the lands currently submerged under Iron Gate and Copco No. 1 reservoirs as that would require speculation. The dam removal actions at Copco No. 1 and Iron Gate dams would occur in the same manner under both the Two Dam Removal Alternative and the Proposed Project. Maintaining J.C. Boyle Dam 20 miles upstream in Oregon would not have an impact on California land use or planning. Additionally, the relatively small footprint of the Copco No. 2 Dam and associated facilities would not have a significant impact on land use and planning compared to the Proposed Project.

4.5.15 Agriculture and Forestry Resources

For the reasons discussed below, the potential for impacts on agriculture and forestry resources in California under the Two Dam Removal Alternative would be the same as that for the Proposed Project. Retaining J.C. Boyle Dam would not change or result in the conversion of any California land use relating to agriculture or forestry. In addition, the issues relating to agricultural water in the Lower Klamath Project area would be the same regardless of whether J.C. Boyle Dam remains in place or is removed. The relatively small footprint of the Copco No. 2 Dam and associated facilities does not affect agriculture and forestry resources, such that leaving this reservoir in place would not affect agriculture and forestry resources compared to the Proposed Project. Therefore, under the Two Dam Removal Alternative, potential impacts on agriculture and forestry resources would be the same as those of the Proposed Project and there would be no significant impacts (Potential Impacts 3.15-1 through 3.15-3).

4.5.16 Population and Housing

In California, although short-term dam deconstruction activities would not occur at Copco No. 2 Dam under the Two Dam Removal Alternative, construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur and thus the level of overall construction activities and associated population and housing impacts would be slightly less than those described under the Proposed Project (Potential Impacts 3.16-1 and 3.16-2). If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle and Copco No. 2 dams would be further reduced relative to the Proposed Project. For reasons described for the Proposed Project, the Two Dam Removal Alternative would not result in a substantial influx of population (Potential Impact 3.16-1), nor would there be a need to displace existing residents or build replacement housing elsewhere (Potential Impact 3.16-2), and there would be no significant population and housing impacts.

4.5.17 Public Services

In California, although short-term dam deconstruction activities would not occur at Copco No. 2 Dam under the Two Dam Removal Alternative, construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur and thus the level of overall construction activities and associated impacts to utilities and service systems would be slightly less than those analyzed under the Proposed Project. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle and Copco No. 2 dams would be further reduced relative to the Proposed Project. For reasons described for the Proposed Project, removal of the two largest California dams under this alternative would still result in significant impacts due to short-term increased response times for emergency fire, police, and medical services (Potential Impact 3.17-1). Mitigation Measure HZ-1 would reduce impacts. In addition, the KRRC is developing a Traffic Management Plan to identify mitigation and other protective measures that would be implemented to reduce impacts to public services. It would also be appropriate for the final Traffic Management Plan to include Recommended Measure TR-1. Overseeing development and implementation of the Traffic Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that this plan will be finalized and implemented, at this time the plan is not finalized, and the State Water Board cannot require its implementation. Accordingly, while the State Water Board anticipates that implementation of Mitigation Measure HZ-1 would reduce impacts to public services, because it cannot require implementation of Recommended Measure TR-1, it is analyzing the impacts under this alternative as significant and unavoidable.

With respect to the elimination of a long-term water source for wildfire services (Potential Impact 3.17-2), under this alternative J.C. Boyle Reservoir and Copco No. 2 Reservoir would remain in place and would serve as relatively accessible sources of water for helicopter fire suppression crews compared to the mainstem Klamath River. However, because J.C. Boyle Reservoir is approximately 20 river miles upstream of Copco No. 1 Reservoir and has a relatively small surface area (approximately 350 acres versus 942 acres [Iron Gate Reservoir] and 972 acres [Copco No. 1 Reservoir], see also Table 2.3-1), response and travel times between water fills related to this reservoir would still be increased over existing conditions. Within the California portion of the Hydroelectric Reach, Copco No. 2 Reservoir would remain as a local source of water for fire suppression relative to existing conditions. Copco No. 2 Reservoir has not been identified by CalFire as a water source for wildfire suppression during the past three years (2015−2018), although this may be because the much larger Copco No. 1 and Iron Gate reservoirs are directly adjacent and presently serve as adequate sources. Under the Two Dam Removal Alternative, Copco No. 2 Reservoir would provide a small surface area, potentially less than 10 acres depending on its upstream extent once Copco No. 1 Dam is removed. The considerably smaller surface area means that Copco No. 2 Reservoir could accommodate fewer helicopters at one time as compared with Copco No. 1 and Iron Gate reservoirs under existing conditions, which would increase response times. The State Water Board anticipates that implementation of alternative water sources for both ground and helicopter crews that are developed through the FERC process would provide a level of protection for reducing the public's risk of loss from wildfires, thereby reducing impacts to less than significant. The KRRC is developing a Fire Management Plan to identify mitigation and other protective measures that would be implemented to reduce impacts to public services. It would be appropriate for the final Fire Management Plan to include Recommended Measure PS-1. Overseeing development and implementation of the final Fire Management Plan does not fall within the scope of the State Water Board's water quality certification authority. While the State Water Board expects that this plan will be finalized and implemented, at this time the plan is not finalized, and the State Water Board cannot require its implementation. Accordingly, while the State Water Board anticipates that implementation of Recommended Measure PS-1 would reduce impacts to public services, because it cannot require implementation of Recommended Measure PS-1, it is analyzing the impacts under this alternative as significant and unavoidable.

Because removal of Copco No.1, Copco No. 2, and Iron Gate dams and associated facilities would occur under the Two Dam Removal Alternative in the same manner and to the same extent as under the Proposed Project, potential impacts on school services and facilities (Potential Impact 3.17-3) under this alternative would be the same as described for the Proposed Project and would be less than significant.

4.5.18 Utilities and Service Systems

Construction-related activity in California under the Two Dam Removal Alternative would require the need for onsite wastewater disposal, stormwater drainage, and/or solid waste disposal facilities at levels similar to that described for the Proposed Project (Potential Impacts 3.18-1 through 3.18-4) and would result in no significant impacts. Although short-term dam deconstruction activities would not occur at Copco No. 2 Dam and the need for offsite transport and disposal of the waste materials and quantities listed in Table 2.7-5 would be eliminated, there is sufficient permitted capacity to accommodate the solid waste disposal needs of the Lower Klamath Project regardless of whether the Copco No. 2 Dam and associated facilities are removed (Potential Impact 3.18-4). Under this alternative, construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would be likely to require additional materials import, depending on the type of fish passage facilities and day use area that are constructed. However, the overall level of construction-related activity in California would be only slightly less than that described under the Proposed Project, regardless of the type of fishway used, such that the degree of difference would not be sufficient to significantly change the assessment of dam removal activities on the potential for impacts to utilities and service systems. There would be no significant impacts on utilities and service systems related to this degree of construction for the Two Dam Removal Alternative, and construction is the only part of the proposed activities that merits analysis for potential impacts on utilities and service systems.

4.5.19 Aesthetics

For the reasons described in Section 3.19.5 *[Aesthetics] Potential Impacts and Mitigation*, under the Two Dam Removal Alternative, short-term and long-term impacts on aesthetic resources in California, including a loss of open water and lake vistas in favor of more natural river, canyon, and valley vistas (Potential Impact 3.19-1) and changes in river flows, channel morphology, and visual water quality (Potential Impacts 3.19-2 and 3.19-3) would be the same as those of the Proposed Project, since the two largest Lower Klamath Project reservoirs (Copco No. 1 and Iron Gate) would be removed. Although Copco No. 2 Reservoir would not be removed, its small size (70 acre-feet) and lack of access does not provide a substantial open water vista under existing conditions and thus leaving it in place would not materially affect the value of scenic vistas as described under the Proposed Project (Potential Impact 3.19-1) and there would be no significant impacts. In addition, for the reasons described under the Proposed Project, visual changes resulting from drawdown of Copco No. 1 and Iron Gate reservoirs would still be significant and unavoidable in the short term and would have no significant impact in the long term (Potential Impact 3.19-4) under the Two Dam Removal Alternative.

Under the Two Dam Removal Alternative, the Copco No. 2 facilities would not be removed and installation of new upstream and downstream fish passage at Copco No. 2 Dam, including all associated construction activities, would occur. However, due to the small size of the Copco No. 2 facilities, their inaccessibility to the public, and the fact that they are already inconsistent with the area VRM classification, this would not change the significance determination.

Visual changes due to removal of Copco No. 1 and Iron Gate dams and facilities (Potential Impact 3.19-5), construction activities (Potential Impact 3.19-6) including fishway construction at Copco No. 2 Dam, would be the same as those of the Proposed Project since the manner of dam deconstruction for these two relatively large facilities would be the same under the Two Dam Removal Alternative; impacts would be less than significant. Similarly, impacts to nighttime views from construction lighting would be significant and unavoidable as under the Proposed Project (Potential Impact 3.19-7).

4.5.20 Recreation

Under the Two Dam Removal Alternative, short-term dam deconstruction activities would not occur at Copco No. 2 Dam, and construction of upstream and downstream fish passage facilities and a new day use area near Copco No. 2 Dam would occur, such that the level of overall construction activities and short-term impacts to recreational opportunities in California would be slightly less than those described under the Proposed Project (Potential Impact 3.20-1). For the reasons described in Potential Impact 3.20-1, there would be no significant impact on recreation from implementation of the Two Dam Removal Alternative.

Recreational facilities associated with Copco No. 1 and Iron Gate reservoirs would still be subject to closure and reservoir-related recreation use would still transfer to other regional recreational facilities and/or would be replaced with river-related recreation under this alternative. All portions of the existing recreational facilities at J.C. Boyle Reservoir (Pioneer Park, Topsy Campground, Spring Island River Access) would remain in place under this alternative, offering more regional boating and fishing recreational opportunities relative to the Proposed Project. Elimination of peaking operations under this alternative may increase the appeal of J.C. Boyle Reservoir recreational sites due to elimination of regular reservoir water level fluctuations, but otherwise there would be no change from existing conditions for J.C. Boyle Reservoir recreational opportunities. Although Copco No. 2 Reservoir would not be removed, its small size (70 acre-feet) does not support reservoir-based recreation under existing conditions and thus leaving it in place would not affect reservoir-based recreation opportunities compared to existing conditions and there would be no significant impacts (Potential Impacts 3.20-2 and 3.20-3).

Because long-term land use under this alternative is currently unknown, this alternative does not assess the potential impacts of long-term use of the lands currently submerged under Iron Gate and Copco No. 1 reservoirs as that would require speculation. Therefore, any adverse effects from the construction of new or expansion of existing recreational facilities (Potential Impact 3.20-4) is unknown and not analyzed for this alternative.

While the Two Dam Removal Alternative would not remove J.C. Boyle Reservoir, it also would increase minimum flows in the Bypass Reach, and would not include peaking power generation or release of flows for recreation at J.C. Boyle Dam. Since there would be no recreational flows in the Hydroelectric Reach under this alternative, and flows in the Hydroelectric Reach would be similar to those under the Proposed Project, the loss of whitewater boating opportunities in the Hell's Corner Reach (within the upper portion of the Hydroelectric Reach) would be the same as the Proposed Project (Potential Impact 3.20-5) and would be significant and unavoidable. Farther downstream in the Hydroelectric Reach, Copco No. 2 Dam would remain in place under this alternative, and a new day use area would be constructed near Copco No. 2 Dam that would serve as a whitewater boater take-out point for boaters putting in downstream of J.C. Boyle Dam (FERC 2007). Thus, the Two Dam Removal Alternative would not adversely impact potential new whitewater boating opportunities in the Copco No. 1 and Iron Gate reservoir footprints described for the Proposed Project.

Just downstream of Copco No. 2 Dam in the Copco No. 2 Bypass Reach, effects of the Two Dam Removal Alternative would be different than those described for the Proposed Project. Model results analyzed for the Proposed Project (Potential Impact 3.20-5) indicate that there would be a substantial increase in whitewater boating opportunities during the July through September time period under the 2013 BiOp Flows, which would be a long-term beneficial effect under the Proposed Project. Under the Two Dam Removal Alternative, water diversions for hydropower generation at Copco No. 2 Dam would continue to affect flows in the a 1.5-mile-long Bypass Reach in the Klamath River between the Copco No. 2 Dam and the Copco No. 2 Powerhouse (Figure 2.3-3), such that the long-term benefit to whitewater boating opportunities that would occur under the Proposed Project would not occur under this alternative. Relative to existing conditions, there would be a significant and unavoidable impact to whitewater boating opportunities in the Hell's Corner reach (within the upper portion of the Hydroelectric Reach), a less than significant impact in the Hydroelectric Reach in the Copco No. 1 and Iron Gate reservoir footprints, and no impact in the Copco No. 2 Bypass Reach (where conditions currently do not support whitewater boating), under the Two Dam Removal Alternative. For the reasons described for the Proposed Project (Potential Impact 3.20-5), there would be no significant impact to whitewater boating opportunities in the Middle and Lower Klamath River under this alternative.

Under the Two Dam Removal Alternative, removal of Copco No. 1 and Iron Gate dams and construction of upstream and downstream fish passage at Copco No. 2 and J.C. Boyle dams would beneficially affect recreational fishing of anadromous fish (Chinook and coho salmon, steelhead trout, Pacific lamprey, and redband trout) throughout the Hydroelectric Reach in California, as described for the Proposed Project (Potential Impact 3.20-6). The primary difference under the Two Dam Removal Alternative is that approximately 3.5 miles of aquatic habitat within J.C. Boyle Reservoir and 0.3 miles of aquatic habitat within Copco No. 2 Reservoir would remain lentic rather than reverting to the riverine conditions described for the Proposed Project. However, the combined inundation length for Copco No. 2 and J.C. Boyle reservoirs is a small proportion (approximately 16 percent) of the 22 miles of Lower Klamath Project reservoir habitat that would be restored to riverine habitat under the Proposed Project (see also Section 4.5.3.7 *[Two Dam Removal Alternative] Aquatic Habitat*) and so the effect of the Two Dam Removal Alternative on California recreational fishing would remain beneficial compared with existing conditions.

The Two Dam Removal Alternative would result in the same impacts to other (non-whitewater boating) river-based recreational facilities in the Middle Klamath River and Lower Klamath River as the Proposed Project (Potential Impact 3.20-6). Water quality improvements would be beneficial for the Hydroelectric Reach, the Middle Klamath River downstream of Humbug Creek (RM 174.3), and the Lower Klamath River. With respect to potential flooding impacts to existing river-based recreational facilities, maintaining J.C. Boyle Reservoir and Copco No. 2 Reservoir would not affect flood hydrology, relative to Proposed Project or to existing conditions, in the Hydroelectric Reach or farther downstream Middle Klamath River and Lower Klamath River (see also Section 4.6.6 *Flood Hydrology*). As under the Proposed Project, there would be little to no change to the 100-year floodplain extent in the Klamath River and Lower Klamath River, with the exception of the reach along the Middle Klamath River from Iron Gate Dam (RM 193.1) to the confluence with Humbug Creek (RM 174.0), where the 100-year floodplain extent would change slightly due to removal of the California Lower Klamath Project dams. However, the slightly increased potential for flooding in this reach would not represent a change or loss of a rare or unique river-based recreational facility affecting a large area or substantial number of people and therefore impacts to recreation under the Two Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impact 3.20-6) and would be less than significant.

As under the Proposed Project, there would be long-term beneficial effects on the scenic quality, recreation, fisheries and wildlife of the California Klamath River wild and scenic river segment and to the resource values of the eligible and suitable wild and scenic river segment (Potential Impact 3.20-7), though some of the impacts (such as to scenic resources) would be less beneficial under the Two Dam Removal Alternative. However, beneficial effects on water quality, natural flow regimes and anadromous fisheries would still occur.

4.5.21 Hazards and Hazardous Materials

The Two Dam Removal Alternative would have similar potential impacts on hazards and hazardous materials as those described for the Proposed Project (see Section 3.22.5 *[Hazards and Hazardous Materials] Potential Impacts and Mitigation*). Short-term dam deconstruction activities would not occur at Copco No. 2 Dam under the Two Dam Removal Alternative, eliminating the need for offsite transport and disposal of potentially hazardous materials at Copco No. 2 Dam and Powerhouse, including the creosote-treated wooden-stave (redwood) penstock, coatings containing heavy metals in the powerhouse, on the exterior surfaces of the steel penstocks, air vents, and other painted materials, a fueling facility containing above-ground gasoline (1,000 gallon) and diesel (500 gallon) tanks, and underground septic systems used for seven residences near the powerhouse (see also Section 2.7.1.3 *Copco No. 2 Dam and Powerhouse).* While this alternative would reduce potential impacts in California due to reduced offsite transport and disposal of these hazardous materials relative to the Proposed Project, the aforementioned Copco No. 2 features that have coatings containing heavy metals, gasoline and diesel tanks, and underground septic systems could be damaged or exposed during or following construction activities and would require preservation to reduce the risk of environmental contamination. Further, construction of upstream and downstream fish passage facilities at Copco No. 2 Dam would result in an overall level of construction-related activity in California that would be only slightly less than that described under the Proposed Project, where the degree of difference would not be sufficient to significantly change the assessment of dam removal activities on the potential for hazard-related impacts due to transport or use of hazardous materials during construction activities as compared with those discussed under the Proposed Project. Lastly, maintaining J.C. Boyle Dam in Oregon would not change the hazards and hazardous materials analysis for California because the transport, use, and disposal of general construction waste materials (e.g., concrete, rebar, building waste, power lines) associated with J.C. Boyle Dam removal, as well as construction-related activities that could result in the accidental release of hazardous materials to the environment, would occur in Oregon. Overall, potential construction-related impacts under the Two Dam Removal Alternative would be slightly less than or the same as those of the Proposed Project (Potential Impacts 3.21-1, 3.21-2, and 3.21-4) and would be significant. Implementation of Mitigation Measure HZ-1 would be required to result in no significant impacts. For the reasons described for the Proposed Project, the potential short-term impact of this alternative on the implementation of adopted emergency response plans would be significant and unavoidable (Potential Impact 3.21-7).

With respect to removal of the Lower Klamath Project reservoirs as a readily available source of water for helicopter fire suppression crews fighting local fires, Copco No. 2 Reservoir has not been identified by CalFire as a water source for wildfires during the past three years (2015−2018), while Copco No. 1 and Iron Gate reservoirs have served in this capacity (see also Potential Impact 3.21-8). The two largest Lower Klamath Project reservoirs (Copco No. 1 and Iron Gate) would still be removed under this alternative, which would substantially increase the public's risk of loss, injury or death associated with wildfires as described for the Proposed Project (Potential Impact 3.21-8). J.C. Boyle Reservoir and Copco No. 2 Reservoir would remain in place and would continue to serve as accessible water surfaces for helicopter fire suppression crews compared to the mainstem Klamath River. However, because J.C. Boyle Reservoir is approximately 20 river miles upstream of Copco No. 1 Reservoir and has a relatively small surface area (approximately 350 acres versus 942 acres [Iron Gate Reservoir] and 972 acres [Copco No. 1 Reservoir], see also Table 2.3-1), response and travel times between water fills would still be increased over existing conditions and the Proposed Project for helicopter crews to fly to J.C. Boyle Reservoir for water pick up. Within the California portion of the Hydroelectric Reach, Copco No. 2 Reservoir would remain as a local source of water for fire suppression relative to existing conditions. However, this reservoir would have an even smaller surface area, potentially less than 10 acres (depending on its upstream extent) once Copco No. 1 Dam is removed. A smaller surface area means that it could theoretically accommodate fewer helicopters at one time, as compared with Copco No. 1 and Iron Gate reservoirs under existing conditions, which would increase response times. Overall, relative to existing conditions, removal of the two largest reservoirs (Copco No. 1 and Iron Gate) under the Two Dam Removal Alternative would result in a substantial increased public risk of loss, injury, or death involving wildland fires due to increased response and travel times relative to existing conditions and would be a significant impact.

4.5.22 Transportation and Traffic

For the reasons described in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation Measures*, removal of the two largest of the Lower Klamath Project dams and associated facilities (Copco No. 1 and Iron Gate) would still occur under the Two Dam Removal Alternative and would result in short-term potential impacts on transportation and traffic. In California, short-term dam deconstruction activities would not occur at Copco No. 2 Dam under this alternative, reducing the need for offsite waste transport and the number of associated truck trips relative to the Proposed Project. However, construction of upstream and downstream fish passage facilities at Copco No. 2 Dam would occur, potentially increasing the need for material import and associated California truck trips for this facility such that overall construction levels under this alternative would be slightly less than those described for the Proposed Project. In Oregon, construction of upstream and downstream fish passage at J.C. Boyle Dam would generate a short-term increase in construction-related vehicle trips, which would be similar to, albeit likely somewhat less than, transportation and traffic impacts described for dam deconstruction under the Proposed Project. Note that J.C. Boyle Dam-associated vehicle trips are included in the analysis of the Proposed Project as some of the construction-related traffic flow may use roads in California (e.g., I-5 to OR 66) and this also would be likely to occur under the Two Dam Removal Alternative.

As described in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation*, the Proposed Project would result in significant and unavoidable short-term impacts to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation, unless and until KRRC reaches enforceable ‘good citizen’ agreements that are finalized and implemented through the FERC process and that include proposed items for the final Traffic Management Plan and Emergency Response Plan (Appendix B: *Definite Plan − Appendices O1 through O4*), as well as the additional components included in Recommended Measure TR-1 (Potential Impacts 3.22-1 through 3.22-5). Because the level of overall construction activities and impacts to transportation and traffic in California would be only slightly less than those described under the Proposed Project, the Two Dam Removal would also result in significant and unavoidable short-term impacts to the aforementioned traffic- and transportation-related activities and would require similarly enforceable ‘good citizen’ agreements to reduce impacts to less than significant, as described for the Proposed Project.

As described for the Proposed Project, the Lower Klamath Project dams are not located within two miles of an airport nor would their removal result in a change in air traffic patterns that would result in a substantial safety risks, regardless of whether J.C. Boyle Dam and Copco No. 2 Dam remain place, and there would be no significant impact (Potential Impact 3.22-6).

As described previously, fish passage under the Two Dam Removal Alternative would either be provided by volitional fishways, or trap and haul, or some combination. Facility construction, and thus any related potential transportation and traffic impacts, for trap and haul would be less than that described for fish ladders. Long term trap and haul operations would consist of trapping adult upstream migrants downstream of Copco No. 2 Dam and releasing them in J.C. Boyle Reservoir as an ongoing activity. Similarly, downstream migrating smolts would be trapped at J.C. Boyle Reservoir, and released downstream of Copco No. 2 Dam. Roads within the traffic and transportation Area of Analysis currently carry substantially fewer vehicles than the planning capacity (Table 3.22-2 and Section 3.22.2.1*Traffic Flow*), such that additional truck trips, assuming both upstream and downstream trap and haul operations, would not substantially change traffic conditions. Although the exact extent and timing of these ongoing hauling activities is not known, it is unlikely that more than ten truck trips per day would be necessary, including a conservative assumption of round trip (i.e., upstream and downstream) hauling for 30 to 40 miles each way between Copco No. 2 Dam and J.C. Boyle Reservoir. Therefore, trap and haul traffic would be a less than significant impact.

Significance
No significant impact

4.5.23 Noise

For the reasons described in Section 3.23.5 *[Noise] Potential Impacts and Mitigation Measures*, removal of Copco No. 1 and Iron Gate dams would result in noise and vibration that would affect sensitive receptors and exceed Siskiyou County General Plan standards under this alternative. The Two Dam Removal Alternative would have slightly less short-term potential impacts on noise than those described for the Proposed Project since short-term dam deconstruction activities would not occur at Copco No. 2 Dam. However, construction of upstream and downstream fish passage facilities would occur and would likely generate short-term increases in daytime and nighttime noise levels affecting nearby residents such that overall there would be significant and unavoidable adverse environmental impacts resulting from: construction equipment exceeding maximum allowable noise levels (Potential Impact 3.23-1); noise disturbance to residents from construction-generated noise at Copco No. 1 and Iron Gate dams (Potential Impacts 3.23-2 and 3.23-4), reservoir restoration at Copco No.1 and Iron Gate dams (Potential Impact 3.23-5); and vibration disturbance from blasting activities at Copco No. 1 and Iron Gate dams (Potential Impact 3.23-6). Other noise and vibration generation from the Two Dam Removal Alternative would not have a significant adverse impact (Section 3.23-5 *[Noise] Potential Impacts and Mitigation*).

As described previously, fish passage under the Two Dam Removal Alternative would either be provided by volitional fishways, or trap and haul, or some combination. If trap and haul were to be used there could be potential long-term noise-related impacts due to regular truck traffic during seasonal trap and haul operations, as described below.

Potential Impact 4.5-1 Trap and haul-related noise.
Activities associated with the implementation of seasonal trap and haul operation prescriptions for Copco No. 2 Dam and associated facilities could result in daytime and nighttime noise levels affecting nearby residents. Trap and haul operations for J.C. Boyle would occur in Oregon and thus would not result in noise-related impacts in California. As described under the analysis of traffic flow effects for the Continued Operations with Fish Passage Alternative (Section 4.4), vehicle trips associated with trap and haul operations would take place following dam deconstruction and fishway construction. There would be no overlap between these trips and peak construction-related traffic. The closest noise-sensitive receptor to Copco No. 2 Dam is the Janice Avenue rural residential area, located approximately 3,700 feet to the east of the dam (Figure 3.23-4). The line of sight from the receptor to Copco No. 2 Dam is blocked by a hill. Due to the natural topography surrounding the dam and the distance between the dam and the receptor, noise from ongoing, seasonal trap and haul activities at the Copco No. 2 Dam would be reduced to less than significant levels at sensitive receptors.

Significance
No significant impact

4.6 Three Dam Removal Alternative

4.6.1 Introduction

4.6.1.1 Alternative Description

In the Three Dam Removal Alternative, the Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities would be fully removed, and J.C. Boyle dam and associated facilities would remain. The J.C. Boyle Dam facilities that would remain include (see also Figure 2.3-1):

1. A 2,629-acre-feet reservoir (J.C. Boyle Reservoir);
2. A 68-foot tall earthfill dam (J.C. Boyle Dam), concrete spillway, and three spill gates;
3. A concrete intake structure connecting to a 2.5-mile water conveyance system with an overflow forebay;
4. A 98-megawatt (MW) J.C. Boyle Powerhouse;
5. A switchyard with 2.8 miles of transmission lines; and
6. Ancillary buildings including an office building (known as the Red Barn), maintenance shop, fire protection building, communications building, two occupied residences, and a warehouse.

This alternative assumes that the J.C. Boyle Dam facilities would be relicensed by FERC for continued operations with changes to allow for upstream and downstream fish passage and updated flow requirements. More specifically, the Three Dam Removal Alternative assumes conditions described in the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*[215] for J.C. Boyle Dam. The primary conditions assumed for the Three Dam Removal Alternative are the following:

- *Fishway Prescriptions* – volitional year-round upstream and downstream fish passage at J.C. Boyle Dam consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007) and upheld in a trial-type administrative hearing, and specific fishway facility design and construction details included in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*[215], including fishway (i.e., fish ladder and screens) installation for both upstream and downstream migrations and barriers to prevent entrainment into turbines; and
- *Changes to J.C. Boyle Operations* – At least 40 percent of J.C. Boyle Reservoir inflow to be released downstream through the J.C. Boyle Bypass to increase minimum flows in the Bypass Reach (RM 225.2 to RM 229.8). J.C. Boyle hydroelectric peaking operations and/or recreation flows would not occur under the Three Dam Removal Alternative since Copco No. 1 and Iron Gate dams would not be present to reregulate flows downstream. Power generation would be suspended and all inflow to J.C. Boyle Reservoir would be released down the Bypass Reach under the seasonal high flow event that would occur for seven full

[215] The KHSA 2012 EIS/EIR's *Section 2.4.5 Fish Passage at Four Dams Alternative* and *Section 2.4.6 Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative* (included in Appendix U of this EIR) include fishway facility design and construction details beyond what are specifically required in the FERC prescriptions and that are based on designs of similar fishway facilities used at other hydroelectric facilities.

days in later winter/spring when inflows to J.C. Boyle first exceed 3,300 cfs (DOI 2007; NMFS 2007; FERC 2007).

The following conditions under the Three Dam Removal Alternative are modifications to the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*:

- Removal of Copco No. 2 facilities as described under the Proposed Project; and
- Flows specified in the NMFS and USFWS 2013 BiOp for the USBR Klamath Irrigation Project, which are currently being considered under reinitiated consultation (see also 3.1.6.1 *Klamath River Flows under the Klamath Irrigation Project's 2013 BiOp*).

As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing and emergency dilution flows are required to be released from Iron Gate Dam as part of re-initiation of consultation on the 2013 BiOp Flows, but they are not modeled as part of existing conditions hydrology. Potential new BiOp flow requirements under this alternative are speculative at this time, and it is not clear whether flushing and emergency dilution flow requirements would continue under the new BiOp during or after dam removal. However, the 2017 flow requirements are considered to be the most reasonable assumption for conditions until agency formal consultation is completed and a new BiOp is issued. For analysis of potential impacts related to fish disease, the Three Dam Removal Alternative considers conditions with and without 2017 court-ordered flushing flows.

Additionally, this section addresses the potential effects of using fishways other than the volitional ladders described in the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*, and points out where such other fishways would result in different effects than fish ladders. Such fishway installation could include trap and haul facilities or a combination of these two approaches. Regardless of how fish passage is provided, this alternative assumes fish passage consistent with the general prescriptions (DOI 2007) that cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007).

This alternative does not make any assumptions regarding conditions that could be imposed by the states of Oregon or California through water quality certification authority.

The aforementioned flow-related measures would reduce power generation at J.C. Boyle Dam. This alternative assumes that installation of fish passage facilities would follow the schedule described in *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*[216], which would install downstream passage facilities prior to

[216] Fishway feature design was provided in the 2012 KHSA EIS/EIR *Section 2.4.5 Fish Passage at Four Dams Alternative* and *Section 2.4.6 Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative* (Appendix U) and is used for this EIR to support the construction-related effects analysis. The KRRC would be required to obtain concurrence from USFWS and NMFS regarding fishway design and construction plans for each Lower Klamath Project facility prior to advancing to feasibility-level of design.

upstream passage facilities and would take place over a 4-month period (June through September of dam removal year 2) for J.C. Boyle Dam. The level of construction for fish passage at J.C. Boyle Dam would be consistent with that estimated for development of the 2012 KHSA EIS/EIR *Fish Passage at J.C. Boyle and Copco 2, Remove Copco 1 and Iron Gate Alternative*[216], which includes removal of the existing J.C. Boyle fish ladder structure, construction of a new fishway at or near the same location as the existing fish ladder (Figure 2.3-1), and construction of downstream fish passage.

As neither the Fall Creek nor the Iron Gate hatchery facilities were built to address potential fisheries effects of J.C. Boyle Dam (Boyle 1976), this alternative assumes that hatchery operations would continue for eight years under the Three Dam Removal Alternative, with reduced production goals consistent with those described for the Proposed Project (see Section 2.7.6 *Hatchery Operations*).

Although leaving J.C. Boyle Dam in place, removing the existing fish ladder and installing a new fish ladder, would be less construction than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts to resources in California since J.C. Boyle is located in Oregon. California materials import for Copco No. 1, Copco No. 2, and Iron Gate facilities deconstruction would be the same as that described in Section 2.7.1 *Dam and Powerhouse Deconstruction,* and California waste disposal quantities, truck trips, and haul distances would be the same as presented in Table 2.7-3 (Copco No. 1 Dam), Table 2.7-5 (Copco No. 2 Dam), and Table 2.7-7 (Iron Gate Dam). Further, this alternative assumes that construction activities to meet FERC prescriptions for fish passage would occur at the J.C. Boyle Dam concurrent with activities for removal of the other Lower Klamath Project dams and associated facilities, such that any construction-related impacts would also occur concurrently and some of these (e.g., water quality) could result in downstream impacts in California. As described previously, fish passage under the Three Dam Removal Alternative would be provided by volitional fishways, trap and haul, or some combination. Overall, regardless of the method of fish passage, the level of construction activities in the Hydroelectric Reach in California under the Three Dam Removal Alternative would not be materially different than that described for the Proposed Project. California workforce projections under the Three Dam Removal Alternative also would be the same as those presented for the Proposed Project (Table 2.7-18).

If instead of a fish ladder, trap and haul or some combination of fish passage methods were used, there would be the potential for reduced construction compared to the aforementioned activities for a fish ladder. While trap and haul facilities differ by site, common features include a trap holding pool, diffusers or gates to guide fish into the trap, a channel or port for discharge of attraction flows, a lift mechanism for truck-loading fish, a truck loading station, and a discharge platform. Much of the trap and haul facility would be located in-stream, with only the truck loading station and discharge platform potentially requiring upland grading or other earthwork.

Because long-term land use under this alternative is currently unknown, this alternative does not assess the potential impacts of long-term use of the lands currently submerged under Iron Gate and Copco No. 1 reservoirs as that would require speculation.

4.6.1.2 Alternative Analysis Approach

The potential impacts of the Three Dam Removal Alternative are analyzed in comparison to existing conditions, with reference to impact analyses conducted for the No Project Alternative or the Proposed Project, where appropriate. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the Three Dam Removal Alternative are the same as those described for the Proposed Project (see Section 3.1 *Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures*). The potential impacts and impacts for each environmental resource area are analyzed both in the short term and the long term, and unless otherwise indicated, use the same definitions of short term and long term as described for each resource area analyzed for the Proposed Project. Unless otherwise indicated, the mitigation measures described in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures* are similarly applicable. This section describes changes to mitigation measures in light of differing project impacts associated with this alternative.

4.6.2 Water Quality

Water quality modeling results applicable to the Three Dam Removal Alternative are not as extensive as results applicable to the Proposed Project or the No Project Alternative. The effects of Three Dam Removal Alternative can be assessed through a combination of modeling scenarios undertaken for the Proposed Project and other alternatives. Appendix D of this EIR summarizes the models used to evaluate potential water quality impacts, including identification of which model scenarios are directly applicable to the Three Dam Removal Alternative. The Klamath River Water Quality Model (KRWQM) developed by PacifiCorp and the River Basin Model 10 (RBM10) developed as part of the Klamath Dam Removal Secretarial Determination studies both include modeling scenarios that have J.C. Boyle remaining in place and Copco No. 1, Copco No. 2, and Iron Gate dams removed. An evaluation of model results from different reaches within the Klamath River also can be used to assess how J.C. Boyle remaining in place would impact water quality. The Klamath TMDL model includes a “TMDL dams-in” scenario (T4BSRN), which approximates the condition where the Lower Klamath Project dams remain in place, as well as the TOD2RN (Oregon reaches) and TCD2RN (California reaches) scenarios (together the “TMDL dams-out” scenario) that assume the removal of the Lower Klamath Project (see Appendix D for more detail). The Klamath TMDL model assumes full TMDL implementation for both “TMDL dams-in” and “TMDL dams-out” scenarios. While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*). For example, comparisons of the modeling scenarios “TMDL dams-in” Oregon reaches (TOD2RN) and “TMDL dams-out” (T4BSRN) for the reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir document how the presence of J.C. Boyle Dam influences conditions in that portion of the Hydroelectric Reach. Similarly, comparison of the SRH-1 sediment modeling results downstream of J.C. Boyle Dam with the SRH-1 results downstream of Iron Gate Dam, and SRH-2D sediment modeling results showing the suspended sediment concentrations from removal of only Copco No. 1 Dam, provides significant insight into the similarities and differences between suspended sediment concentrations due to the release of reservoir deposited sediments under the Three Dam Removal Alternative and under the Proposed Project. Overall, the available water quality modeling results provide sufficient information that the water quality impacts under the Three Dam Removal Alternative can be quantitatively or qualitatively assessed, as described below.

4.6.2.1 Water Temperature

In general, the Three Dam Removal Alternative would have the same or similar potential impacts on water temperature in California as those identified under the Proposed Project. The presence of the J.C. Boyle Reservoir on the Klamath River does not alter water temperatures in further downstream reaches because it has a shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days) that does not support thermal stratification (FERC 2007). However, J.C. Boyle Dam operations do influence Klamath River water temperatures by releasing flow for peaking power generation and whitewater recreation. These releases cause water temperature variations in the J.C. Boyle Bypass and Peaking reaches, including from the Oregon-California state line to Copco No. 1 Reservoir, due to diversion of warmer reservoir discharges around the J.C. Boyle Bypass Reach, cold groundwater spring flows into the J.C. Boyle Bypass Reach, and the mixing of these flows when they rejoin in the J.C. Boyle Peaking Reach of the Klamath River. The combination of these flows produce an observed increase in daily water temperature range above the natural diel (24-hour) water temperature fluctuations in the J.C. Boyle Peaking Reach at the Oregon-California state line.

The Three Dam Removal Alternative would not include peaking power generation or whitewater recreation flows from J.C. Boyle Dam since the downstream dams would not be available to reregulate the peaking and recreation flows. Elimination of the peaking and recreation flows from J.C. Boyle Dam would likely result in J.C. Boyle operating in a run of the river manner and increases in the water temperature range associated with J.C. Boyle operations would no longer occur under both the Three Dam Removal Alternative and the Proposed Project (see also Section 3.2.2.2 *Water Temperature*).

Model results analyzed for the Proposed Project do not explicitly isolate the effects of the four individual Lower Klamath Project reservoirs on water temperatures, but the KRWQM includes a scenario in which only Iron Gate and Copco No. 1 dams are removed[217] with J.C. Boyle and Copco No. 2 remaining in place ("WIGC" PacifiCorp 2004a; Dunsmoor and Huntington 2006; see also Appendix D of this EIR). KRWQM WIGC results indicate that compared with removal of J.C. Boyle, Copco No. 1 and Iron Gate reservoirs ("WIGCJCB"), the long-term effects of removing Iron Gate, Copco No. 1, and Copco No. 2 reservoirs and converting the reservoir areas to a free-flowing river under the Three Dam Removal Alternative would be similar to effects on water temperature under the Proposed Project as illustrated in Figure 4.6-1.

[217] Copco No. 2 dam was not explicitly included in the model due to its negligible size and hydraulic residence time.

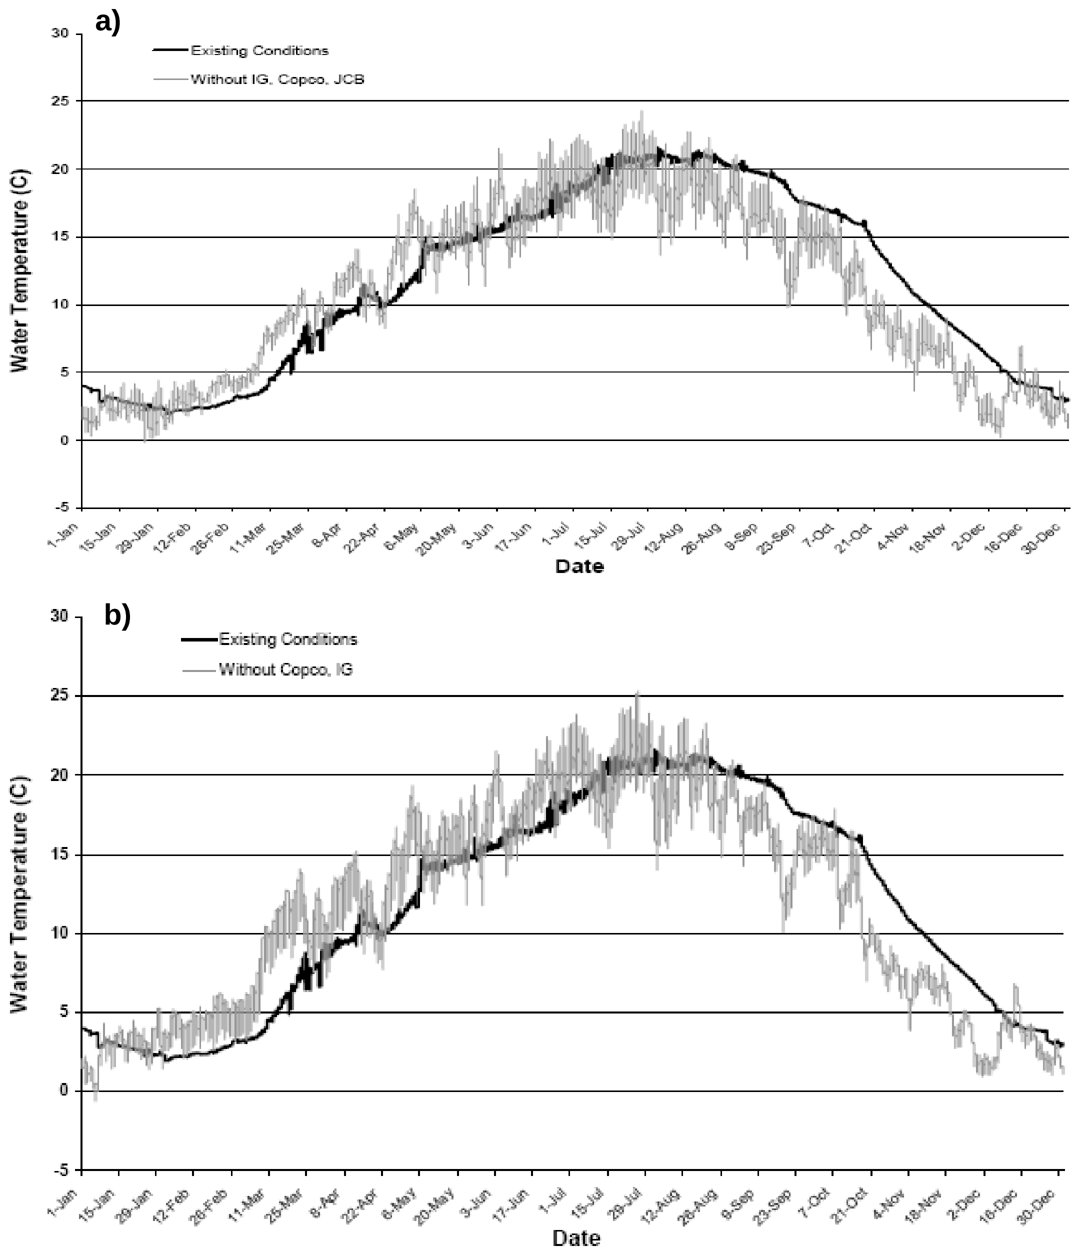

Figure 4.6-1. Simulated Hourly Water Temperature Downstream from Iron Gate Dam Based on Year 2004 for Current Conditions Compared to Hypothetical Conditions: (a) without Iron Gate (IG), Copco No. 1 and 2, and J.C. Boyle (JCB) Dams and (b) without Iron Gate (IG) and Copco No. 1 and 2 Dams. Source: PacifiCorp 2005.

Relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on water temperature would be the same as or similar to those described for the Proposed Project, except as follows:

- J.C. Boyle Reservoir would not alter water temperature in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir. J.C. Boyle Dam operations for peaking and recreation releases under existing conditions that cause increases in the water temperature range would be eliminated under both the Three Dam Removal Alternative and the Proposed Project. Short-term and long-term alterations in water temperatures in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir under the Three Dam Removal Alternative would result in water temperature effects similar to those of the Proposed Project (i.e., slightly lower maximum water temperatures and less artificial diel (24-hour) temperature variation during summer and early fall, see also Potential Impact 3.2-1) and would be beneficial.
- Short-term and long-term alterations in water temperatures due to conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.2-1) would be the same as under the Proposed Project, and would be beneficial for the Hydroelectric Reach and the Middle Klamath River to the confluence with the Salmon River. As under the Proposed Project, there would be no significant impact for the Middle Klamath River downstream from the Salmon River, the Lower Klamath River, and the Klamath River Estuary.
- Sediment trapped by J.C. Boyle Dam would not be released under the Three Dam Removal Alternative, but the magnitude of the sediment releases from Copco No. 1 and Iron Gate reservoirs[219] would still be over 90 percent of the sediment releases under the Proposed Project (Table 2.7-11). Thus, the overall short-term and long-term alterations in seasonal water temperatures in the Klamath River Estuary due to potential morphological changes induced by sediment release from Copco No. 1 and Iron Gate reservoirs and subsequent deposition in the Klamath River Estuary would be similar under the Three Dam Removal Alternative and the Proposed Project (Potential Impact 3.2-2), and there would be no significant impact.

4.6.2.2 Suspended Sediments

As the Three Dam Removal Alternative does not include the removal of J.C. Boyle Dam, short-term mobilization of J.C. Boyle reservoir sediment deposits would not occur under this alternative and none of the associated 1,190,000 cubic yards of deposits estimated to occur in the reservoir in 2020[218] (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-10 and 2.7-11) would be eroded or delivered to downstream reaches and the Pacific Ocean. The approximately 27 to 51 percent of the sediment trapped behind the J.C. Boyle Dam predicted to move downstream through the California reaches of the Klamath River and out into the Pacific Ocean under the Proposed Project (USBR 2012) would not be transported under the Three Dam Removal Alternative.

[218] Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable.

However, Copco No. 1 and Iron Gate reservoirs contain approximately 92 percent of the total estimated 2020 reservoir deposits (50 and 42 percent, respectively) such that approximately 92 to 94 percent of sediment anticipated to erode from these reservoirs[219] under the Proposed Project (Table 2.7-10 and Table 2.7-11) would still occur under the Three Dam Removal Alternative. Increases in suspended sediment concentrations (SSCs) in the Hydroelectric Reach upstream of Copco No. 1 Reservoir from removal of J.C. Boyle Reservoir would be eliminated under this alternative since reservoir deposited sediment would not be released from J.C. Boyle Reservoir. While there would be some reduction in SSCs downstream of Copco No. 1 due to no SSCs being released by J.C. Boyle Dam removal, the reduction of SSCs under the Three Dam Removal Alternative would not alter the overall impact of dam removal on SSCs compared to the Proposed Project in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment. Modeling of SSCs downstream of Copco No. 1 Reservoir from release of only Copco No. 1 Reservoir sediment deposits across the wet, average, and dry water year types indicate SSCs, within the general uncertainty of the model, would peak at approximately 7,000 to 8,000 mg/L between Copco No. 1 Dam and Iron Gate Reservoir within one to two months of reservoir drawdown, then SSCs would decrease to generally less than 1,000 mg/L within approximately one more month (Figure 3.2-15; see Section 3.2.5.2 *Suspended Sediments*). Thus, SSCs in the Hydroelectric Reach between Copco No. 1 and Iron Gate reservoirs would still exceed the significance criteria for suspended sediment (SSCs greater than 100 mg/L over a continuous two-week exposure period) under the Three Dam Removal Alternative due to the overall magnitude of reservoir deposits still anticipated to erode from Copco No. 1 and Iron Gate reservoirs. Downstream of the Hydroelectric Reach, SSCs would also exceed the significance criteria for suspended sediment under the Three Dam Removal Alternative since over 90 percent of the reservoir deposited sediments anticipated to be transported under the Proposed Project would still occur. Thus, the overall short-term impact of increases in SSCs due release of sediments currently trapped behind Copco No. 1 and Iron Gate dams under the Three Dam Removal Alternative would be similar to impacts under the Proposed Project (see Section 3.2.5.2 *Suspended Sediments* for additional details).

Sediments and suspended materials (inorganic and organic) would continue to be intercepted and retained behind J.C. Boyle Dam in the long term under the Three Dam Removal Alternative since that dam would remain in place. While the amount of sediment supplied to the Klamath River on an annual basis from the watershed upstream of J.C. Boyle is a relatively small fraction of the total sediment (Stillwater Sciences 2010) (see also Section 3.11.2.4 *Sediment Load*), the long-term increase in mineral (inorganic) suspended material downstream of J.C. Boyle Dam under this alternative would be less than under the Proposed Project since J.C. Boyle Dam would continue to intercept upstream sediment. The majority of algal-derived (organic) suspended material from upstream sources (Upper Klamath Lake, Klamath Straights Drain, Lost River) is intercepted and retained by the Keno Impoundment/Lake Ewauna, but J.C. Boyle Dam does retain some algal-derived (organic) suspended material (see Appendix C, Section C.2.1 *Upper Klamath Basin* for more detail). Thus, the long-term

[219] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown of Copco No. 2 Dam begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

increases in algal-derived (organic) suspended material downstream of J.C. Boyle Dam under this alternative would be less than under the Proposed Project.

Long-term interception and retention of sediments and suspended materials (inorganic and organic) would not occur behind Copco No. 1, Copco No. 2[220], and Iron Gate dams since they would be removed under the Three Dam Removal Alternative. Long-term increases in mineral (inorganic) and algal-derived (organic) suspended material under this alternative would be less than under the Proposed Project because J.C. Boyle Dam would continue to retain sediments and suspended materials from upstream of that dam. However, the overall long-term impact from changes in the interception of sediments due to retention of J.C. Boyle Dam and removal of Copco No. 1, Copco No. 2, and Iron Gate dams would be similar under both the Three Dam Removal Alternative and the Proposed Project. The long-term increases in mineral (inorganic) and algal-derived (organic) suspended material due to the lack of interception by the dams would be a less than significant impact under the Proposed Project since only a small amount of sediment and suspended material is delivered from upstream of J.C. Boyle Dam. Thus, a decrease in the amount of sediment transported downstream under the Three Dam Alternative due to the retention of J.C. Boyle Dam and removal of Copco No. 1, Copco No. 2, and Iron Gate dams would still be a less than significant impact.

Relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on suspended sediments would be the same as or similar to those described for the Proposed Project, except as follows:

- As discussed in the first two paragraphs of this section, there would be no change in SSCs from the existing conditions in the Hydroelectric Reach between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir since sediment deposits in J.C. Boyle Dam would remain in place. However, the increases in suspended sediment in the Hydroelectric Reach due to release of sediments currently trapped behind Copco No. 1 and Iron Gate Dams would remain a short-term significant and unavoidable impact for the Hydroelectric Reach, the Middle and Lower Klamath River, and the Klamath River Estuary (Potential Impact 3.2-3). The magnitude of suspended sediments increases in the Pacific Ocean nearshore environment due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams would be within the range of historical conditions, but the duration (i.e., weeks) of elevated suspended sediments still would be greater than historical conditions, thus there would be a short-term significant and unavoidable impact on suspended sediments in the Pacific Ocean nearshore environment (Potential Impact 3.2-3). Suspended sediments would resume modeled background levels by the end of Post-Dam removal year 1, so there would be no significant impact in the long term for the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment (Potential Impact 3.2-3). The short-term significant impact of increases SSCs due to dam removal in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment cannot be avoided or substantially decreased through reasonably feasible mitigation.

[220] Copco No. 2 Dam does not intercept or retain appreciable amounts of sediment (USBR 2011b).

- While there would not be potential construction-related short-term increases in suspended material from removal of J.C. Boyle Dam under the Three Dam Removal Alternative, there would be construction of new fish passage facilities at J.C. Boyle Dam that would potentially result short-term increases in suspended material downstream in California. Potential construction-related short-term increases in suspended material from pre-construction, dam removal, and restoration activities at Copco No. 1, Copco No. 2, and Iron Gate dams would be the same under the Three Dam Removal Alternative as under the Proposed Project since these activities would occur in both scenarios. Under the Three Dam Removal Alternative, short-term increases in suspended material from stormwater runoff due construction activities associated with new fish passage facilities at J.C. Boyle Dam and pre-construction, dam removal, and restoration activities at Copco No. 1, Copco No. 2, and Iron Gate dams would be potentially significant impacts without mitigation in the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam and in the Middle Klamath River immediately downstream of Iron Gate Dam (Potential Impact 3.2-4). Implementation of mitigation measures WQ-1, TER-1, and HZ-1 would reduce this potential impact under the Three Dam Removal Alternative to no significant impact, similar to the Proposed Project.
- As discussed earlier in this section, there would be no long-term change from existing conditions regarding the interception and retention of mineral (inorganic) (Potential Impact 3.2-5) or algal-derived (organic) (Potential Impact 3.2-6) suspended material by J.C. Boyle Dam in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir under the Three Dam Removal Alternative because J.C. Boyle Dam would remain in place and continue to intercept and retain mineral and algal-derived suspended material to the same extent that it currently does. However, similar to under the Proposed Project, there would be potential long-term increases in suspended material in the Hydroelectric Reach downstream of Copco No. 1 Reservoir because Copco No. 1, Copco No. 2, and Iron Gate dams would be removed under this alternative and they would no longer intercept and retain suspended material. While there would be no long-term change in the suspended material in the Hydroelectric Reach from the Oregon-California state line to Copco No. 1 Reservoir under the Three Dam Removal Alternative, the removal of Copco No. 1, Copco No. 2, and Iron Gate dams would result in this alternative having an overall similar long-term increase in suspended material due to lack of interception or retention by dams downstream of Copco No. 1 Dam as the Proposed Project. There would be no significant impact under the Three Dam Removal Alternative from long-term increases in suspended material due to the lack of continued interception and retention of mineral (inorganic) and algal-derived (organic) for the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam, the Middle Klamath River, Lower Klamath River, Klamath River Estuary, and the Pacific Ocean nearshore environment, similar to under the Proposed Project (Potential Impact 3.2-5 and 3.2-6).

4.6.2.3 Nutrients

Short-term or long-term increases in sediment-associated nutrients due to release of J.C. Boyle reservoir sediment deposits would not occur in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Three Dam Removal Alternative because none of the associated 1,190,000 cubic yards of deposits estimated to occur in the reservoir in 2020[221] (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches. As detailed in Section 4.6.2.2 *Suspended Sediments*, approximately 27 to 51 percent of the sediment trapped behind the J.C. Boyle Dam is predicted to be transported under the Proposed Project (USBR 2012), but this would not occur under the Three Dam Removal Alternative. Thus, nutrients associated with these sediments also would not be transported downstream and there would be no increase in sediment-associated nutrients from existing conditions in the Hydroelectric Reach between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir associated with the Three Dam Removal Alternative.

However, approximately 92 to 94 percent of the sediment anticipated to erode from Copco No. 1 and Iron Gate reservoirs[222] under the Proposed Project (Table 2.7-11) would occur under the Three Dam Removal Alternative and mobilization of nutrients associated with these reservoir sediment deposits would occur. The majority of sediment-associated nutrients would be transported under both this alternative and the Proposed Project, but sediment-associated nutrients downstream of Copco No. 1 Dam would be slightly less under the Three Dam Removal Alternative than under the Proposed Project because nutrients associated with J.C. Boyle reservoir sediments would not contribute to nutrient concentrations. Thus, overall pattern and duration of short-term and long-term increases in sediment-associated nutrients due to release of sediments from behind the Copco No. 1 and Iron Gate dams under the Three Dam Removal Alternative would be similar to the Proposed Project in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment, but the magnitude of nutrient concentrations would be slightly less. See Section 3.2.5.3 *Nutrients* for further details.

Since J.C. Boyle dam would remain in place, continuing interception and retention of sediment-associated nutrients and suspended materials would still occur behind J.C. Boyle Dam in the long term. However, TMDL modeling[223] and empirical data indicate that J.C. Boyle Dam does not retain high amounts of nutrients such that long-term effects of dam removal on nutrient levels in the Hydroelectric Reach under the Proposed Project would be primarily due to the removal of Copco No. 1 and Iron Gate dams (see also Section 3.2.2.4 *Nutrients* and Section 3.2.5.3 *Nutrients* for information on the existing conditions for nutrients in the reservoirs). More specifically, the "TMDL dams-in"

[221] Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable.

[222] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown of Copco No. 2 Dam begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

[223] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

Oregon reaches (TOD2RN) scenario indicates that Copco No. 1 retains approximately 10.0 percent of the annual total nitrogen and approximately 5.1 percent of the annual total phosphorus; and Iron Gate retains approximately 6.7 percent of the annual total nitrogen and approximately 3.3 percent of the annual total phosphorus (North Coast Regional Board 2010). The relative amounts of nutrient retention in each of the reservoirs without full TMDL implementation may be somewhat higher than the aforementioned estimates because the model mechanism increases the rate of retention as incoming nutrient concentrations increase; however, the model mechanism also indicates that the longer the retention time of water in the reservoir, the higher the nutrient retention. Copco No. 1 and Iron Gate reservoirs have average retention times of 11 days and 15 days, respectively, while J.C. Boyle Reservoir has a lower retention time of only approximately 1 day (Table 3.6-4) and thus allows most sediment-associated nutrients to pass through the reservoir and move downstream. Overall, under the Three Dam Removal Alternative, long-term interception and retention of sediments and suspended materials behind Copco No. 1 and Iron Gate dams would cease, since the facilities would be removed, and nutrient removal for the Hydroelectric Reach would be similar to that described for the Proposed Project.

Relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on nutrients would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term or long-term change to the existing condition with regard to sediment-associated nutrients in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir, since sediment deposits in J.C. Boyle Dam would remain in place and no sediment-associated nutrients would be transported due to the release of sediments trapped behind J.C. Boyle Dam. However, there would be short-term increases in sediment-associated nutrients due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams[224] as in the Proposed Project (Potential Impact 3.2-7). Potential short-term increases in suspended material from construction of a new fish ladder at J.C. Boyle would be not result in short-term increases in sediment-associated nutrients since potential construction sediments would only have the nutrient content of the soils surrounding J.C. Boyle with substantially less nutrients than reservoir sediment deposits. As described in Section 3.2.5.3 Nutrients, this would result in no significant impact in the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam, the Middle Klamath River, the Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment
- Under the Three Dam Removal Alternative, there would be no long-term change from existing nutrient levels due to interception of nutrients by J.C. Boyle Dam in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Dam would remain in place. However, Copco No. 1, Copco No. 2, and Iron Gate dams would be removed and replaced by a free-flowing river under this alternative, so these dams would no longer intercept and retain incoming nutrients. As under the Proposed Project, long-term increases in nutrient levels from the lack of continued interception by the

[224] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown of Copco No. 2 Dam begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

Copco No. 1, Copco No. 2, and Iron Gate dams and conversion of the reservoir areas to a free-flowing river (Potential Impact 3.2-8) would result in no significant impact for the Hydroelectric Reach, Middle and Lower Klamath River, Klamath River Estuary, and the Pacific Ocean nearshore environment.

4.6.2.4 Dissolved Oxygen

J.C. Boyle Reservoir sediment deposits (approximately 1,190,000 cubic yards in 2020[225] or approximately eight percent of total sediment volume trapped behind the Lower Klamath Project dams, see also Tables 2.7-7 and 2.7-8) would be not mobilized in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Three Dam Removal Alternative since J.C. Boyle Dam would remain in place (see Section 4.6.2.2 *Suspended Sediments*). Thus, the short-term mobilization associated effects of these sediments on sediment-associated oxygen demand and dissolved oxygen (i.e., high content of organic carbon present in the reservoir sediments allows for the possibility of microbial oxidation of organic matter exposed to the water column from deep within the sediment profile and mobilized during dam removal), would also not occur in the Hydroelectric Reach from the Oregon-California state line to the upstream end of Copco No. 1 Reservoir under the Three Dam Removal Alternative. However, mobilization of approximately 92 to 94 percent the reservoir sediment deposits anticipated to erode under the Proposed Project due to transport of reservoir sediments from Copco No. 1 and Iron Gate reservoirs[224] would still occur in this alternative (see Section 4.6.2.2 *Suspended Sediments*). While there would be some reduction in SSCs downstream of Copco No. 1 due to no sediment being released by J.C. Boyle Dam removal, the overall short-term effects of sediment release and SSCs on sediment-associated oxygen demand and dissolved oxygen concentrations in the Hydroelectric Reach from downstream of Copco No. 1 Dam to Iron Gate Dam under the Three Dam Removal Alternative would still be similar to effects for the Hydroelectric Reach under the Proposed Project in that impact significance associated with SSCs, sediment-associated oxygen demand, and dissolved oxygen concentrations would be the same as the Proposed Project (see Potential Impact 3.2-9 for additional details).

Less sediment would be mobilized into the Middle Klamath River under the Three Dam Removal Alternative, so the extent of downstream increases in oxygen demand (Immediate Oxygen Demand [IOD] and Biological Oxygen Demand [BOD]) and reductions in dissolved oxygen in this reach under the Three Dam Removal Alternative would be somewhat less than those of the Proposed Project. Minimum dissolved oxygen values likely would occur slightly upstream compared the Proposed Project, but they would still generally occur near RM 191 to 193.1 (approximately 0 to 2 miles downstream from Iron Gate Dam) since the location of minimum dissolved oxygen concentrations does not change much with variations in SSCs (see Table 3.2-13). Similarly, the farthest distance downstream with dissolved oxygen less than 5 mg/L likely

[225] Between 2020 and 2021 (i.e., dam removal year 2 when drawdown would primarily occur), the sediment volume present behind the dams would increase by approximately 81,300 cubic yards in Copco No. 1 Reservoir and approximately 100,000 cubic yards in Iron Gate Reservoir based on estimates of annual sedimentation rates for each reservoir (USBR 2012). The increase in sediment volume between 2020 and 2021 would be an order of magnitude less than the uncertainty of the 2020 total sediment volume estimates, so model results using the 2020 sediment volumes would still be applicable.

would shift slightly upstream, but the distance would be similar to the Proposed Project (i.e., approximately RM 145 to 122 or within 48 to 71 miles downstream of Iron Gate Dam) since it does not change much with variations in SSCs. Minimum dissolved oxygen values would likely show a greater relative increase under the Two Dam Removal Alternative compared the Proposed Project, since the amount of IOD and BOD downstream of Iron Gate Dam is strongly influenced by variations in SSCs and there would be less sediment transported under this alternative.

Despite the potential for a slightly shorter distance of short-term impacts due to decreases in the sediment-associated oxygen demand and a reduction in the magnitude of the decrease in dissolved oxygen in the Middle Klamath River under the Three Dam Removal Alternative, the release of sediments trapped behind Copco No. 1 and Iron Gate Dam would decrease dissolved oxygen concentrations in the Klamath River below the Basin Plan water quality objective for dissolved oxygen (90 percent saturation) in the short term and constitute a significant impact. Additionally, since the location where the minimum and at least 5 mg/L dissolved oxygen concentrations occurred during modeling under the Proposed Project did not change much with variations in SSC, it is conservatively estimated that the distance that the significant impact from short-term increase in sediment-associated oxygen demand and reductions in dissolved oxygen under the Three Dam Removal Alternative occurs would be similar to that modeled under the Proposed Project (Potential Impact 3.2-9), so the short-term impact would remain significant in the Middle Klamath River from Iron Gate Dam to approximately the confluence with the Salmon River (RM 66).

Similarly, it is conservatively estimated that the distance where there would be no significant impact on dissolved oxygen from releases of reservoir deposited sediments under the Three Dam Removal Alternative would be similar to that modeled under the Proposed Project. Modeling under the Proposed Project indicates that downstream of the confluence with the Salmon River on the Middle Klamath River, as well as in the Lower Klamath River and the Klamath River Estuary, there would be no significant impact from the release of sediments trapped behind the Lower Klamath Project dams (see Section 3.2.5.4 *Dissolved Oxygen*). Thus, there also would be no significant impact under the Three Dam Removal Alternative downstream of the confluence with the Salmon River on the Middle Klamath River, as well as in the Lower Klamath River and the Klamath River Estuary.

In the long term, since J.C. Boyle Dam would remain in place, continuing summertime interception and retention of sediments and suspended materials from upstream sources containing high biological oxygen demand (see also 3.2.2.5 *Dissolved Oxygen*) would still occur in J.C. Boyle Reservoir under the Three Dam Removal Alternative. Accordingly, existing large summertime variations in dissolved oxygen in J.C. Boyle Reservoir, especially at depth, would still occur and could continue to influence dissolved oxygen concentrations in the California portion of the Hydroelectric Reach in the same manner as under existing conditions (see also 3.2.2.5 *Dissolved Oxygen*). Modeling of existing conditions indicates these summertime dissolved oxygen variations in J.C. Boyle increase the range of dissolved oxygen concentrations between the Oregon-California state line and the upstream end of Copco No. 1 Reservoir (North Coast Regional Board 2011), but aeration and fast water velocities within the free-flowing reach result in dissolved oxygen concentrations near or slightly greater than saturation upstream of Copco No. 1 Reservoir (FERC 2007; Raymond 2008). The Three Dam Removal Alternative would not include peaking power generation and release of flow for recreation at J.C. Boyle Dam, but the dissolved oxygen at the Oregon-California state line would still likely have slightly greater daily variability than natural conditions (see also Potential Impact 3.2-10). While the degree of influence of peaking flows on daily variability in dissolved oxygen concentrations at the Oregon-California state line is not clearly defined by existing information, the daily variability is not currently adversely affecting beneficial uses. However, dissolved oxygen concentrations immediately downstream of J.C. Boyle would potentially fall below 85 percent saturation and 6.5 mg/L during summer similar to existing conditions. Thus, retaining J.C. Boyle with no peaking or recreation flows under the Three Dam Removal Alternative would have only a small influence on dissolved oxygen concentrations downstream of the Oregon-California state line compared to existing conditions and there would be no significant impact.

Within the Hydroelectric Reach downstream of Copco No. 1 Reservoir, the long-term effects of the Three Dam Removal Alternative on dissolved oxygen concentrations would be the same as effects described for the Proposed Project (Potential Impact 3.2-10) as conversion of Copco No. 1, Copco No. 2, and Iron Gate reservoirs to free-flowing riverine reaches with higher velocities and more turbulent mixing would increase aeration of Klamath River. Additionally, the extreme super-saturated surface water and oxygen-depleted hypolimnion conditions found in existing conditions in April/May to October/November would not occur under the Three Dam Removal Alternative as Copco No. 1 and Iron Gate reservoirs would be removed (see Section 3.2.5.4 *Dissolved Oxygen* for details). The long-term effects of dam removal on concentrations of dissolved oxygen in the Middle and Lower Klamath, the Klamath River Estuary, and the Pacific Ocean nearshore environment under the Three Dam Removal Alternative would also be the same as those described for the Proposed Project, where even assuming full TMDL compliance, modeling results[226] indicate that the conversion of Copco No. 1 and Iron Gate reservoirs to free-flowing river reaches would eliminate seasonal extremes in dissolved oxygen concentrations downstream of Iron Gate Dam (see Section 3.2.5.4 *Dissolved Oxygen* for details).

In summary, relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on increased IOD and BOD and dissolved oxygen would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term increases in IOD and BOD or reductions in dissolved oxygen in the Hydroelectric Reach between Oregon-California state line and the upstream end of Copco No. 1 Reservoir since sediment deposits in J.C. Boyle Dam would remain in place (Potential Impact 3.2-9). However, there would be no change from the Proposed Project downstream of Copco No. 1 Dam because short-term increases in IOD and BOD and reductions in dissolved oxygen due to release of sediments currently trapped behind Copco No. 1 and Iron Gate dams[220] (Potential Impact 3.2-9) would result in a significant and unavoidable impact in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle Klamath River from Iron Gate Dam to the confluence with the Salmon River (RM 66) under the Three Dam Removal Alternative. There would be no significant impact in the Middle Klamath River downstream from the Salmon River

[226] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

confluence, Lower Klamath River, and the Klamath River Estuary under the Three Dam Removal Alternative, similar to the Proposed Project. The short-term significant impact of increases in IOD and BOD and reductions in dissolved oxygen due to release of sediments in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, and the Klamath River Estuary cannot be avoided or substantially decreased through reasonably feasible mitigation.

- Potential long-term alterations in daily variability of dissolved oxygen concentrations in the Hydroelectric Reach in California due to the elimination of hydropower peaking flows at J.C. Boyle Dam (Potential Impact 3.2-10) would result in no significant impact. However, long-term increases in dissolved oxygen, as well as increased daily variability in dissolved oxygen, due to conversion of the Copco No. 1 and Iron Gate reservoirs to a free-flowing river (Potential Impact 3.2-10) would be the same under the Three Dam Removal Alternative as under the Proposed Project. Thus, there would be no significant impact for daily fluctuations in the Hydroelectric Reach between Copco No. 1 and Iron Gate Dam and the Middle Klamath River immediately downstream of Iron Gate Dam, would be beneficial for elimination of summer and fall extremes in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam, and would result in no significant impact in the Lower Klamath River and Klamath River Estuary.

4.6.2.5 pH

In general, the Three Dam Removal Alternative would have the same or similar potential impacts on pH as those identified under the Proposed Project. Because J.C. Boyle Reservoir peaking power generation and whitewater recreation flows downstream of J.C. Boyle Dam do not substantially alter pH in the downstream river under existing conditions, leaving this dam in place and ceasing peaking and recreation flows would be unlikely to affect pH relative to existing conditions in either the short-term or long-term. Under the existing condition in Copco No. 1 and Iron Gate reservoirs, seasonal and daily pH is characterized by high pH (greater than 9 s.u.) and large (0.5 to 1.5 s.u.) daily fluctuations occurring in reservoir surface waters during periods of intense phytoplankton blooms (see Section 3.2.2.6 *pH*). Klamath River TMDL modeling[227] for the Proposed Project indicates that removal of these two reservoirs, which would occur under the Three Dam Removal Alternative, would eliminate the occurrences of high pH and large daily fluctuations in pH in these reaches, because the free-flowing reaches of the river replacing these reservoirs would not support the intense phytoplankton blooms that are driving the existing pH conditions (see Section 3.2.5.5 *pH*). The most significant action to achieve California TMDL compliance is the removal of Copco No. 1, Copco No. 2 and Iron Gate dams as their removal provides lasting long-term benefits to water quality in California. Similar to the Proposed Project, the Three Dam Removal Alternative leads to improved pH conditions and contributes to TMDL compliance on a shorter timeline scale than expected under existing conditions. Due its small size and low retention time, Copco No. 2 Reservoir does not affect pH under existing conditions and its removal under the Three Dam Removal Alternative also would not affect pH within the

[227] While the mechanisms for implementation and the timing required to achieve future TMDL compliance are currently speculative, the Klamath TMDL model results are still informative with respect to the analysis of potential water quality impacts under this alternative for reasons described for the Proposed Project (see Section 3.2.4 *[Water Quality] Impact Analysis Approach*).

Hydroelectric Reach or downstream reaches. In the Klamath River downstream from Iron Gate Dam, pH conditions under the Three Dam Removal Alternative would be the same as under the Proposed Project (Potential Impact 3.2-11).

In summary, relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on pH would be the same as or similar to those as described for the Proposed Project (Potential Impact 3.2-11). Thus, there would be no significant impact in the short term or long-term to pH in the Hydroelectric Reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Reservoir does not substantially alter pH in the river downstream from this dam under existing conditions (Potential Impact 3.2-11). Short-term and long-term decreases in summertime pH and daily pH fluctuations due to a conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.2-11) would be beneficial for the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, and would have no significant impact for the Middle Klamath River, the Lower Klamath River, and the Klamath River Estuary.

4.6.2.6 Chlorophyll-a and algal toxins

In general, the Three Dam Removal Alternative would have the same or similar potential impacts on chlorophyll-*a* and algal toxins as those identified under the Proposed Project (see Section 3.2.5.6 *Chlorophyll-a and Algal Toxins*). The shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days at average flows) of J.C. Boyle Reservoir does not promote the low mixing conditions or thermal stratification that create optimal habitat for phytoplankton growth, so the reservoir does not have large phytoplankton blooms (as measured by chlorophyll-*a*) under existing conditions (see Figure 3.2-5). Under existing conditions, peaking power generation flows occur in the late afternoons and early evenings to meet high power demand, and J.C. Boyle Reservoir refills during the night when power demand is minimal. Daily fluctuations in the reservoir water level under existing operations increases mixing in the reservoir, making the reservoir slightly less suitable habitat for phytoplankton during the season of maximum phytoplankton and cyanobacteria (blue-green-algae) growth in the system. Ceasing peaking power generation flows would reduce daily reservoir water level fluctuations in J.C. Boyle Reservoir because the facility would no longer be operated to draw on reservoir storage to support daily peaks in hydropower production when there is not sufficient river flow for peak production (3,000 cfs), as occurs during the summer and fall low flow period under existing conditions. However, the residence time of J.C. Boyle Reservoir without peaking operations would still be short (i.e., on the order of one to three days), so leaving this dam in place and ceasing peaking flows would be unlikely to create conditions that would support large seasonal phytoplankton blooms or increase chlorophyll-*a* concentrations relative to existing conditions. Concentrations of the algal toxin microcystin are generally low in J.C. Boyle Reservoir (Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*) and in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir since the J.C. Boyle Reservoir does not support large blooms of toxigenic blue-green algae and springs downstream of J.C. Boyle Dam dilute any algal toxins that may be present within that reach. Thus, leaving J.C. Boyle Dam in place and ceasing peaking flows associated with the Three Dam Removal Alternative would not promote conditions that would support production of algal toxins.

In Copco No. 1 and Iron Gate reservoirs, existing conditions for chlorophyll-*a* levels in summer and early fall can be two to 10 times greater than those recorded in the mainstem river upstream of Copco No. 1 Reservoir near Shovel Creek. High chlorophyll-*a* readings in the reservoirs as compared to the Klamath River are in part due to the lower mixing conditions and longer residence times of these reservoirs (10.7 days for Copco No. 1 and 14.8 days for Iron Gate at average flows) that promote the growth of phytoplankton and the associated production of chlorophyll-*a* within the reservoirs. Additionally, measurements of microcystin in Copco No. 1 and Iron Gate during summer months show high microcystin concentrations, especially during algal blooms when microcystin concentrations measured between 2006 and 2015 exceeded the State Water Board et al. (2010, updated 2016) 0.8 ug/L and peaked from 64 ug/L in Iron Gate Reservoir to 73,000 ug/L in Copco No. 1 Reservoir (Section 3.2.2.7 *Chlorophyll-a and Algal Toxins*). Under the Three Dam Removal Alternative, elimination of Copco No.1 and Iron Gate reservoirs, which currently support growth conditions for toxin-producing nuisance algal species such as *Microcystis aeruginosa,* would result in decreases in high seasonal concentrations of chlorophyll-*a* and periodically high levels of algal toxins generated by suspended blue-green algae, consistent with the Proposed Project (see Section 3.2.5.6 *Chlorophyll-a and Algal Toxins*). The removal of Copco No. 1 and Iron Gate reservoirs also would eliminate the primary habitat for blue-green algae in the Hydroelectric Reach, reducing both the amount of blue-green algae present that could contribute to chlorophyll-*a* and algal toxins within this reach and the amount of blue-green algae that may be exported into the Klamath River downstream of Iron Gate Dam. Due its small size and low residence time (less than a day), Copco No. 2 Reservoir does not promote phytoplankton growth that would alter chlorophyll-*a* and algal toxins concentrations under existing conditions and its removal under the Three Dam Removal Alternative also would not affect chlorophyll-*a* and algal toxins within the Hydroelectric Reach or downstream reaches.

Because phytoplankton and the resulting chlorophyll-*a* and algal toxin levels (e.g., microcystin) are primarily internally generated in Copco No. 1 and Iron Gate reservoirs, removal of these reservoirs under the Three Dam Removal Alternative would also reduce the transport of chlorophyll-a and algal toxins to the Klamath River downstream of Iron Gate Dam in both the short-term and the long-term, consistent with the Proposed Project.

In summary, relative to existing conditions, the potential impacts and impacts of the Three Dam Removal Alternative on chlorophyll-*a* and algal toxins would be the same as or similar to those described for the Proposed Project, except as follows:

- There would be no short-term or long-term alterations in chlorophyll-a and algal toxins in the Hydroelectric Reach between J.C. Boyle Dam and the upstream end of Copco No. 1 Reservoir since J.C. Boyle Reservoir would remain in place, but it does not support conditions promoting large phytoplankton blooms and associated chlorophyll-a and algal toxins under existing conditions (Potential Impact 3.2-12). However, short-term and long-term reduction of chlorophyll-a and algal toxin levels due to a conversion of the reservoir areas to a free-flowing river (Potential Impact 3.2-12) under the Three Dam Removal Alternative would be beneficial for the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, the Middle Klamath River, Lower Klamath River, and Klamath River Estuary, similar to the Proposed Project.

4.6.2.7 Inorganic and Organic Contaminants

Short-term mobilization of J.C. Boyle reservoir sediment deposits would not occur under the Three Dam Removal Alternative and none of the associated 1,190,000 cubic yards of deposits (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches. However, mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs[228] would still occur such that the short-term potential for mobilization of inorganic and organic contaminants in the Hydroelectric Reach from downstream of Copco No. 1 Dam to Iron Gate Dam under the Three Dam Removal Alternative would be similar to effects for the Hydroelectric Reach under the Proposed Project (Section 3.2.5.7 *Inorganic and Organic Contaminants*).

Though toxicity testing of sediments from J.C. Boyle Resources suggested potential for toxicity to freshwater benthic organisms (when compared to Copco No 1 and Iron Gate reservoir sediments), dilution and dispersals of sediments as expected in the Proposed Project were anticipated to not result in a significant impact to benthic organism survival (Section 3.2.5.7 *Inorganic and Organic Contaminants*). The Three Dam Removal Alternative does not involve the release of J.C. Boyle reservoir sediment deposits thus the potential for toxicity to freshwater benthic organisms may be relatively slightly less under the Three Dam Removal Alternative than that of the Proposed Project due to no sediment from J.C. Boyle Reservoir being transported downstream. However, the overall impact of the release of sediments trapped behind Lower Klamath Project dams, including J.C. Boyle Dam, under the Three Dam Removal Alternative and under the Proposed Project are expected to be similar. The Proposed Project analysis assumes mixing of sediment deposits from all three reservoirs as they move downstream and exposure of downstream aquatic biota to an "average" sediment composition, rather than a reservoir-specific composition (Section 3.2.5.7 *Inorganic and Organic Contaminants*), so overall water column toxicity due to the concentration of inorganic or organic substances under the Proposed Project is unlikely. As such, there would be a less than significant impact due to the release of sediments trapped behind Lower Klamath Project dams, including J.C. Boyle Dam, under the Proposed Project. While leaving J.C. Boyle Dam in place and not releasing J.C. Boyle reservoir deposited sediments would potentially slightly reduce toxicity to benthic freshwater organisms, the overall impact from the release of Copco No. 1 and Iron Gate reservoir deposited sediments and the sediment-associated inorganic and organic contaminants would be a less than significant impact in the short term under the Three Dam Removal Alternative, similar to the Proposed Project.

Although leaving J.C. Boyle Dam in place, removing the existing fish ladder and installing a new fish ladder, would be less construction than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts to resources in California since J.C. Boyle is located in Oregon. Thus, short-term increases in inorganic and organic contaminants from hazardous materials associated with construction and restoration activities under the Three Dam Removal Alternative would also be the same as or similar to those described for the Proposed Project.

[228] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

In the long term, existing inorganic and organic contaminant data characterizing J.C. Boyle Reservoir sediment deposits indicate that a relatively small number of chemicals (i.e., mercury, DDTs, and possibly dioxin-like chemicals) are present at levels that have the potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) to freshwater aquatic species remaining in this reservoir under the Three Dam Removal Alternative. Elutriate sediment sample bioassay results from J.C. Boyle Reservoir indicate that no further dilution would be required to prevent water column toxicity to freshwater fish. Relative to existing condition, there would be no change. Conversely, long-term retention of inorganic and organic contaminants contained within existing sediment deposits behind Copco No. 1 and Iron Gate dams and their potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) would not occur since they would be removed under the Three Dam Removal Alternative, which would be beneficial.

In summary, relative to existing conditions the potential impacts of the Three Dam Removal Alternative on inorganic and organic contaminants would be the same as or similar to those described for the Proposed Project, except as noted below:

- J.C. Boyle Reservoir sediment deposits and its sediment-associated inorganic and organic contaminants would not be released downstream, but the short-term and long-term human exposure to inorganic and organic contaminants due to release of sediments currently trapped behind the Lower Klamath Project dams (Potential Impact 3.2-13) would result in a potentially significant impact for the Hydroelectric Reach, Middle Klamath River, Lower Klamath River, and Klamath River Estuary. Implementation of mitigation measures WQ-2 and WQ-3 would result in no significant impact.
- While J.C. Boyle Reservoir sediment deposits and its sediment-associated inorganic and organic contaminants would not be released downstream, the short-term and long-term freshwater aquatic species' exposure to inorganic and organic contaminants due to release of sediments currently trapped behind the Copco No. 1 and Iron Gate dams (Potential Impact 3.2-14) would result in no significant impact for the Hydroelectric Reach, Middle Klamath River, Lower Klamath River, Klamath River Estuary, and Pacific Ocean nearshore environment based on sediment screening and/or laboratory toxicity results after consideration of dilution conditions under the Proposed Project.
- Short-term increases in inorganic and organic contaminants from hazardous materials associated with construction and restoration activities (Potential Impact 3.2-15) in the Hydroelectric Reach and the Middle Klamath River immediately downstream of Iron Gate Dam would be potentially significant without mitigation. Implementation of mitigation measures WQ-1, TER-1, and HZ-1 would result in no significant impact.
- Short-term impacts to aquatic biota from herbicide application during restoration of the reservoir footprint area (Potential Impact 3.2-16) would be potentially significant without mitigation. Implementation of Mitigation Measure WQ-4 would result in no significant impact.
- Long-term freshwater aquatic species' exposure to inorganic and organic contaminants contained within J.C. Boyle Reservoir sediment deposits would continue to have the potential to cause minor or limited adverse effects (i.e., toxicity or bioaccumulation) to some freshwater aquatic species in the reservoir

(Potential Impact 4.2.2-8), which would be no significant impact (no change from existing adverse conditions).

4.6.2.8 General Water Quality

Iron Gate Hatchery operations would continue, and Fall Creek Hatchery would reopen, for eight years under the Three Dam Removal Alternative. The potential short-term and long-term impacts of these operations on the Klamath River, Bogus Creek, and Fall Creek water quality would be the same as described for the Proposed Project (Potential Impact 3.2-17).

4.6.3 Aquatic Resources

4.6.3.1 Suspended Sediment

As discussed in Section 4.6.2.2 *Suspended Sediments*, while there would be some reduction in SSCs downstream of Copco No. 1 due to no SSCs being released by J.C. Boyle Dam removal, the reduction of SSCs under the Three Dam Removal Alternative would not alter the overall impact of dam removal on SSCs compared to the Proposed Project in the Hydroelectric Reach, the Middle and Lower Klamath River, the Klamath River Estuary, or the nearshore marine environment. Thus, the potential impacts of suspended sediment on aquatic resources in California would be the same under the Three Dam Removal Alternative as those described under the Proposed Project (see also Section 3.3.5.1 *Suspended Sediment*).

4.6.3.2 Bed Elevation and Grain Size Distribution

Because the volume of stored sediment in J.C. Boyle Reservoir is relatively small compared with the volume of stored sediment in Copco No. 1 and Iron Gate reservoirs, the potential for alterations in bed elevation and grain size distribution and the associated effects on aquatic resources in California would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (see also Section 3.3.5.2 *Bed Elevation and Grain Size Distribution*). Thus, downstream impacts to aquatic species due to bed elevation and grain size distribution would be very similar to those described for the Proposed Project.

4.6.3.3 Water Quality

California would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (see also Section 3.3.5.3 *Water Quality*). As Copco No. 1 and Iron Gate reservoirs are the largest of the four Lower Klamath Project reservoirs, they have the greatest impact on water quality (FERC 2007), and their removal would result in water quality conditions similar to those of the Proposed Project. Because of its small size and short residence time, continuing to store water within J.C. Boyle Reservoir would generally not result in the same poor water temperature conditions that occur downstream of the larger Lower Klamath Project reservoirs under existing conditions. Section 4.6.2 discusses the impacts of the Three Dam Removal Alternative with an emphasis on similarities and differences with the potential impacts of the Proposed Project.

The Three Dam Removal Alternative includes no peaking power generation or release of flow for recreation at J.C. Boyle Dam. As described in Section 3.2.2.2 *Water Temperature*, daily peaking operations at J.C. Boyle Powerhouse (RM 225.2) result in an increase in the daily water temperature range in the Bypass Reach because warmer reservoir discharges are diverted around this reach and cold groundwater springs enter the river and dominate remaining flows. The temperature effects of altering the flow regime under the Three Dam Removal Alternative (while keeping J.C. Boyle Dam in place) would be a reduction in diel (24-hour) temperature variation and overall warmer water temperatures in the Bypass Reach during summer and early fall. In the Peaking Reach, water temperature effects would be the same as under the Proposed Project (i.e., slightly lower maximum water temperatures and less artificial diel [24-hour] temperature variation during summer and early fall) since no peaking flows would occur and the effect of J.C. Boyle thermal mass on water temperatures does not extend this far downstream (see also Section 4.6.2.1 *Water Temperature*).

In the Hydroelectric Reach from the upstream end of Copco No. 1 Reservoir to Iron Gate Dam, removing Iron Gate, Copco No. 1, and Copco No. 2 reservoirs and converting the reservoir areas to a free-flowing river under this alternative would result in the same effects on water temperatures in the Middle Klamath River immediately downstream from Iron Gate Dam as described for the Proposed Project (i.e., long-term increases in spring water temperatures and decreases in late summer/fall water temperatures) (see Section 3.3.5.3 *Water Quality*).

4.6.3.4 Fish Disease and Parasites

For the reasons discussed below, potential impacts of fish disease and parasites on aquatic resources in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.5 *Fish Disease and Parasites*). The main factors contributing to risk of juvenile salmonid infection by *C. shasta* and *P. minibicornis* include availability of habitat (pools, eddies, and sediment) for the polychaete intermediate host; microhabitat characteristics (static flows and low velocities); congregations of spawned adult salmon with high spore; polychaete proximity to spawning areas; planktonic food sources from Lower Klamath Project reservoirs; and water temperatures greater than 59°F (Bartholomew and Foott 2010). The current reach with highest infectivity (nidus) for *C. shasta* and *P. minibicornis* is located in the Klamath River downstream of Iron Gate Dam, where returning adult spawners congregate. For adult salmon, Ich and columnaris have occasionally resulted in substantial mortality, particularly when habitat conditions include exceptionally low flows, high water temperatures, and high densities of fish (such as adult Chinook salmon migrating upstream in the fall and holding at high densities in pools). This section addresses differences between these disease factors anticipated under the Three Dam Removal Alternative in comparison with the Proposed Project, and implications for effects on juvenile and adult salmonid life stages.

The availability of habitat for the polychaete worm intermediate host is driven by sediment transport and hydrologic dynamics that as described in sections above would be nearly the same as the Proposed Project. The relatively low volume of sediment in J.C. Boyle Reservoir would not appreciably affect habitat for the polychaete host relative to the Proposed Project, and thus the hydrology affecting microhabitat characteristics would be the same as that described for the Proposed Project. The reduction in congregations of spawned adults with proximity to polychaetes would be similar to the

Proposed Project, since anadromous salmonids would have upstream migratory access past Iron Gate Dam, including provision of improved fish passage at J.B. Boyle Dam, and would be as widely distributed. As described in Section 3.1.6 *Summary of Available Hydrology Information for the Proposed Project*, 2017 court-ordered flushing and emergency dilution flows are required to be released from Iron Gate Dam prior to reconsultation on the 2013 BiOp Flows, but they are not modeled as part of existing conditions hydrology. Under the Three Dam Removal Alternative, it is anticipated that the nidus would no longer form downstream of Iron Gate Dam, and the risk of a new nidus forming upstream is low, even in the absence of the 2017 flow requirements (see also Section 3.3.5.5 *Fish Disease and Parasites*). Although the conditions leading to a reach that would exhibit the highest infectivity (nidus) for *C. shasta* and *P. minibicornis* downstream of Iron Gate Dam would be ameliorated once Copco No. 1, Copco No. 2, and Iron Gate dams are removed, some disease factors would continue under the Three Dam Removal Alternative, including eight years of additional Iron Gate Hatchery operations potentially resulting in continued (through post-dam removal year 10) congregations of mostly adult fall-run Chinook salmon in the reach from Iron Gate Dam to Seiad Valley (see also Section 3.3.5.6 *Fish Hatcheries*). Under the Three Dam Removal Alternative, if a nidus were to remain in the vicinity of Iron Gate Hatchery, or theoretically were to form within newly accessible upstream habitat such as the reach immediately downstream of J.C. Boyle Dam where a future fish passage facility entrance would be located, flushing and emergency dilution flows as required by the 2017 court order may be required from a new upstream location to achieve the same ecological benefits (i.e., disruption of nidus).

Under the Three Dam Removal Alternative, planktonic (e.g., floating organisms such as algae) food sources would be reduced relative to existing conditions with elimination of reservoir habitats, similar to conditions under the Proposed Project. However, because J.C. Boyle Reservoir would remain it would continue to provide a source of planktonic food for the polychaete host of *C. shasta* and *P. minibicornis*. Therefore, while planktonic food sources would be reduced under the Three Dam Removal Alternative relative to existing conditions, slightly more reservoir (and thus planktonic food source) would be removed under the Proposed Project.

Conditions resulting in water temperatures greater than 59°F downstream of Iron Gate Dam under the Three Dam Removal Alternative would be the same as those identified under the Proposed Project. As described in Section 4.6.2.1 *Water Temperature*, the presence of the J.C. Boyle Reservoir on the Klamath River does not alter water temperatures in further downstream reaches because it has a shallow depth (8.3 feet average depth) and short hydraulic residence time (1.1 days) that does not support thermal stratification (FERC 2007).

Under the Three Dam Removal Alternative, the conditions that can support Ich and columnaris outbreaks among adult salmonids (i.e., exceptionally low flows, high water temperatures, and high densities of fish), would be similar to those identified under the Proposed Project, especially within the Lower Klamath River where Ich and columnaris have caused substantial mortality under existing conditions. Downstream of the confluence with the Salmon River neither the Proposed Project or the Three Dam Removal Alternative would have a pronounced effect on instream flows, water temperatures, or congregations of fish, due to the contributions of several large tributaries (notably the Trinity River). Overall, impacts to aquatic species due to fish disease and parasites would improve relative to existing conditions under the Three

Dam Removal Alternative and they would be very similar to those described for the Proposed Project.

4.6.3.5 Fish Hatcheries

The potential impacts of fish hatcheries on aquatic resources in the California portions of the Klamath River would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.6 *Fish Hatcheries*). As neither the Fall Creek nor the Iron Gate hatchery facilities were built to address potential fisheries effects of J.C. Boyle Dam, and this alternative includes volitional fish passage at J.C. Boyle consistent with mandatory conditions issued for relicensing of the Klamath Hydroelectric Project, thereby eliminating J.C. Boyle Dam as a fish barrier, this alternative assumes that hatchery operations would continue for eight years under the Three Dam Removal Alternative and then the hatcheries would be removed. During the eight years following removal of Copco No. 1, Copco No. 2, and Iron Gate dams, the hatcheries would operate with reduced production goals consistent with those described for the Proposed Project (see Section 2.7.6 *Hatchery Operations*).

4.6.3.6 Algal Toxins

Potential impacts of algal toxins on aquatic resources in the California portions of the Klamath River would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.7 *Algal Toxins*). Removal of the larger Copco No. 1 and Iron Gate reservoirs would decrease or eliminate support for excessive growth of phytoplankton, including seasonal blue-green algae blooms and associated algal toxins (e.g., microcystin), by eliminating large areas of quiescent habitat where these phytoplankton species currently thrive. While J.C. Boyle Reservoir would remain, because of its small size (2,267 acre-feet, Table 2.3-1) and short hydraulic residence time (approximately 1 day, Table 3.6-4), it would not support substantial blooms and thus the expected decrease in algal toxins anticipated under the Proposed Project would be the same under the Three Dam Removal Alternative. Additionally, potential for bioaccumulation of algal toxins in freshwater mollusk and fish tissue under the Three Dam Removal Alternative would be expected to decrease in the mainstem Klamath River from Hydroelectric Reach to the Klamath River Estuary as described for the Proposed Project.

4.6.3.7 Aquatic Habitat

For the reasons discussed below, potential impacts of aquatic habitat on aquatic resources in California portions of the Klamath River would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.8 *Aquatic Habitat*). Improvements in aquatic habitat conditions resulting from increased minimum flows and ending peaking operations downstream of J.C. Boyle Dam based on federal mandatory conditions in the PacifiCorp hydroelectric relicensing process would occur under the Three Dam Removal Alternative as described for the Proposed Project. As described in sections above, changes sediment dynamics would also be similar to those described under the Proposed Project. Access to additional aquatic habitat upstream of Iron Gate Dam would be the same under the Three Dam Removal Alternative as described for the Proposed Project, since fish passage would be provided at J.C. Boyle Dam (see also Section 4.6.3.8 *Fish Passage*). The primary difference under the Three Dam Removal Alternative is that aquatic habitat within J.C. Boyle

Reservoir would remain lentic rather than reverting to the riverine conditions described for the Proposed Project. Based on the estimates of Cunanan (2009), there would be approximately 3.5 fewer miles of additional riverine habitat (currently inundated by J.C. Boyle Reservoir) that would become available under this alternative compared to the Proposed Project. However, J.C. Boyle Reservoir inundation is a small proportion (approximately 16 percent) of the 22 miles of Lower Klamath Project reservoir habitat that would be restored to riverine habitat under the Proposed Project. In addition, J.C. Boyle would continue to provide reservoir habitat to support aquatic resources (including shortnose and Lost River suckers), discussed in Potential Impact 3.3-13. Under the Three Dam Removal Alternative, the three lower reservoirs would be removed as described for the Proposed Project, restoring approximately 18.5 miles of mainstem river that previously exhibited high sinuosity and complex channels that historically provided excellent salmonid spawning and rearing habitats (Hetrick et al. 2009).

4.6.3.8 Fish Passage

The current upstream fishway at J.C. Boyle Dam is obsolete and does not meet NMFS (2011) design criteria (U.S. Department of Interior, DOI 2007). Under the Three Dam Removal Alternative, fish would have access beyond the location of Copco No. 1, Copco No. 2, and Iron Gate dams, as described for the Proposed Project (Section 3.3.5.8 *Aquatic Habitat*). However, whereas under the Proposed Project fish would have volitional unimpeded access past J.C. Boyle Dam, under the Three Dam Removal Alternative fish migrating upstream and downstream past J.C. Boyle Dam would access upstream habitat via fishways. DOI (2007) included a prescription for a NMFS-criteria volitional year-round fish ladder at J.C. Boyle Dam to provide for the safe, timely, and effective upstream passage of Chinook and coho salmon, steelhead trout, Pacific lamprey, and redband trout. In addition, DOI (2007) prescribed a new year-round NMFS criteria fish screen and a bypass facility at J.C. Boyle Dam (and modifications to spillway) to provide for the safe, timely, and effective downstream passage of Chinook and coho salmon, steelhead trout, Pacific lamprey, redband trout, and listed sucker species. Under the Three Dam Removal Alternative, fishways would be consistent with the prescriptions from the DOI and U.S. Department of Commerce imposed during the FERC relicensing process (FERC 2007), and specific fishway facility design and construction details included in the KHSA 2012 EIS/EIR *Fish Passage at Four Dams Alternative*[215], including fishway (i.e., fish ladder and screens) installation for both upstream and downstream migrations and barriers to prevent juvenile salmonid entrainment into turbines. Trap and haul would involve design assumptions described in the Section 4.4. *Continued Operations with Fish Passage Alternative,* but the assumptions would only be applied to J.C. Boyle Dam. In this EIR, it is assumed that for application at one dam (J.C. Boyle Dam), if alternative passage facilities were designed and constructed, they would necessarily meet agency criteria and thus would have an equivalent level of mortality as volitional fishways.

In their preliminary fishway prescriptions for the Lower Klamath Project dams, NMFS (2006) recommended dam removal to FERC under FPA S10(a)and(j) as the environmentally preferred alternative to provide the least mortality and injury to migrating fish. The associated NMFS fishway prescription (DOI 2007) is a mandatory conditioning authority that was submitted during the hydropower relicensing process at the time, in case FERC chose to reject NMFS' strong recommendation to removal all of the Lower Klamath Project mainstem dams. While unimpeded volitional fish passage is assumed to have higher survival and lower injury than fishways, no data or analyses are available to accurately compare the effectiveness of unimpeded fish passage under the Proposed Project with volitional fishways under the Three Dam Removal Alternative. NMFS does not provide an expected level of mortality or injury in association with fishways constructed to their criteria, and performance would depend on many site-specific factors that would be considered in the design phase of new fishways. Based on the measured effectiveness of fishways constructed to NMFS criteria at other dams (DWR 2013), this EIR assumes at least 98 percent survival (or less than 2 percent mortality) of upstream and downstream migrating aquatic species in recognition that while survival could be high at properly constructed facilities, it is unlikely to be as high as survival would be with dams removed (i.e., 100 percent). Regardless of how fish passage is provided, this alternative assumes fish passage consistent with the general prescriptions (DOI 2007) that cover anadromous (fall- and spring-run Chinook salmon, coho salmon, steelhead, and Pacific lamprey) and resident (rainbow and redband trout, shortnose and Lost River suckers) fish passage, and includes implementing operation and maintenance plans and prescribing attraction flows for upstream migrants (DOI 2007). This EIR also assumes that effects of passage through volitional fishways would be equivalent for other migratory species, which appears to be a reasonable assumption based on available data (DWR 2013) for fishways designed and constructed to modern agency criteria as required by DOI (2007).

Based on the similarities between the Three Dam Removal Alternative and the Proposed Project for several of the key ecological attributes discussed above, the potential impacts of the Three Dam Removal Alternative would be the same as those described under the Proposed Project for several potential impacts (Potential Impacts 3.3-2, 3.3-3, 3.3-5, 3.3-6, 3.3-12, 3.3-15, 3.3-16, 3.3-18, 3.3-20, 3.3-21, 3.3-22, 3.3-23, and 3.3-24). The potential impacts of the Three Dam Removal Alternative that could result in different effects than those already discussed under the Proposed Project are discussed below.

Potential Impact 3.3-1 Effects on coho salmon critical habitat quality and quantity due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on coho salmon critical habitat in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-1), with a few subtle differences. For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on critical habitat from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles. Habitat in the J.C. Boyle Bypass and Peaking Reaches would be improved through elimination of peaking operations and higher baseflows. Therefore, although upstream of current designated critical habitat, the Three Dam Removal Alternative would expand the geographic extent of habitat available to coho salmon in a similar manner to the Proposed Project.

The short-term impacts on coho salmon critical habitat from sediment releases would be the same under the Three Dam Removal Alternative as those described for the

Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-1), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. Based on the substantial short-term decrease in quality of the features of critical habitat and PCEs supporting SONCC coho salmon, there would be a significant impact to coho salmon critical habitat under the Three Dam Removal Alternative in the short term.

However, as described for the Proposed Project, the Three Dam Removal Alternative includes aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on coho salmon PCEs of critical habitat. In addition, mitigation measures AQR-1 and AQR-2 (described in Section 3.3.5.9 *Aquatic Resource Impacts*), would be implemented to increase certainty of the effectiveness of the aquatic resource measures AR-1 and AR-2 and reduce the short-term significant adverse impacts of the Three Dam Removal Alternative on coho salmon critical habitat. Consistent with the Proposed Project, based on the wide distribution of coho salmon critical habitat within tributaries, aquatic resource measures, and mitigation measures designed to offset short-term impacts to PCEs of critical habitat, there would not be a substantial decrease in the quality of a substantial proportion of habitat for coho salmon critical habitat in the short term. Therefore, the Three Dam Removal Alternative would have no significant impact on coho salmon critical habitat in the short term.

For the reasons described in Section 4.6.3.7 *Aquatic Habitat*, in the long term the Three Dam Removal Alternative would increase the amount of habitat available to coho salmon upstream of currently designated critical habitat and improve water quality and bedload characteristics in the mainstem Klamath River within current critical habitat in the same manner as the Proposed Project. Overall, these changes would be a substantial increase in the quality and quantity of coho salmon critical habitat in the long term as compared to existing conditions. Therefore, the Three Dam Removal Alternative would be beneficial for coho salmon critical habitat in the long term.

Significance

No significant impact with mitigation to coho salmon critical habitat in the short term

Beneficial for coho salmon critical habitat in the long term

Potential Impact 3.3-4 Effects on Chinook and coho salmon Essential Fish Habitat (EFH) quality and quantity due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Chinook and coho salmon EFH in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-4), with a few subtle differences. For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on EFH from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles.

The short-term impacts on Chinook and coho salmon EFH from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-4), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. Based on the substantial short-term decrease in quality of EFH for Chinook and coho salmon, there would be a significant impact to Chinook and coho salmon EFH under the Three Dam Removal Alternative in the short term.

However, as described for the Proposed Project, the Three Dam Removal Alternative includes aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on Chinook and coho salmon EFH. In addition, mitigation measures AQR-1 and AQR-2 (described in Section 3.3.5.9), would be implemented to increase certainty of the effectiveness of the aquatic resource measures AR-1 and AR-2 and reduce the short-term significant adverse impacts of the Three Dam Removal Alternative on Chinook and coho salmon EFH. Consistent with the Proposed Project, based on the wide distribution and use of tributaries by both juvenile and adult Chinook and coho salmon, aquatic resource measures (AR-1 and AR-2), and mitigation measures (AQR-1 and AQR-2), designed to offset short-term impacts to Chinook and coho salmon EFH, there would not be a substantial decrease in the quality of a large proportion of Chinook and coho salmon EFH in the short term. Therefore, the Three Dam Removal Alternative would have no significant impact, with mitigation, on Chinook and coho salmon EFH in the short term.

For the reasons described above in Section 4.6.3.7 *Aquatic Habitat*, in the long term the Three Dam Removal Alternative would increase habitat for Chinook and coho salmon (upstream of currently designated EFH) by providing access to habitats upstream of Iron Gate Dam in the same manner as the Proposed Project. Overall, these changes would be a substantial increase in the quality and quantity of Chinook and coho salmon EFH in the long term. Therefore, the Three Dam Removal Alternative would be beneficial for Chinook and coho salmon EFH in the long term.

Significance

No significant impact with mitigation to Chinook and coho salmon EFH in the short term

Beneficial for Chinook and coho salmon EFH in the long term

Potential Impact 3.3-7 Effects on the fall-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on fall-run Chinook salmon in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-7), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on fall-run Chinook salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Based on the 440 miles of fall-run Chinook salmon habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.5 miles that would remain inundated by J.C. Boyle Reservoir rather than reverting to riverine habitat under the Three Dam Removal Alternative is not substantial (< 1 percent of newly accessible habitat). Juvenile Chinook salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles. Therefore, due to loss in fish passage facilities and migration through reservoir habitat, the estimated increases in fall-run Chinook salmon abundance predicted to occur under the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-7), would be less under the Three Dam Removal Alternative.

The short-term impacts on fall-run Chinook salmon from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-7), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. As described for the Proposed Project (Potential Impact 3.3-7), because there would be no substantial short-term decrease in fall-run Chinook salmon abundance of a year class, and no substantial decrease in habitat quality or quantity, there would not be a significant impact to fall-run Chinook salmon under the Three Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on fall-run Chinook salmon In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Three Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including fall-run Chinook salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Three Dam Removal Alternative on fall-run Chinook salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would increase habitat availability, restore a more natural flow regime and seasonal water temperature variation, improve water quality, and reduce the likelihood of fish disease and algal toxins, all of which would be beneficial for fall-run Chinook salmon in the same manner as the Proposed Project. Overall, the multiple benefits of the Three Dam Removal Alternative would be beneficial for fall-run Chinook salmon in the long term.

Significance

No significant impact for fall-run Chinook salmon populations in the short term

Beneficial for fall-run Chinook salmon populations in the long term

Potential Impact 3.3-8 Effects on the spring-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on spring-run Chinook salmon in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-8), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on spring-run Chinook salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion expected under the Proposed Project would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Based on the 440 miles of spring-run Chinook salmon habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.5 miles that would remain inundated by J.C. Boyle Reservoir rather than revert to riverine habitat under the Three Dam Removal Alternative is unsubstantial (< 1 percent of newly accessible habitat). Juvenile Chinook salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles.

The short-term impacts on spring-run Chinook salmon from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-8), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. As described for the Proposed Project (Potential Impact 3.3-8), because there would not be a substantial short-term decrease in spring-run Chinook salmon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to spring-run Chinook salmon under the Three Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on fall-run Chinook salmon In the short term, aquatic resource measure AR-2 (Juvenile Outmigration) would occur under the Three Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including spring-run Chinook salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measure AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Three Dam Removal Alternative on spring-run Chinook salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would increase habitat availability, restore a more natural flow regime and seasonal water temperature variation, improve water quality, and reduce the likelihood of fish disease and algal toxins, all of which would be beneficial for spring-run Chinook salmon in the same manner as the Proposed Project. Overall, the multiple benefits of the Three Dam Removal Alternative would be beneficial for spring-run Chinook salmon in the long term.

Significance

No significant impact for spring-run Chinook salmon populations in the short term

Beneficial for spring-run Chinook salmon populations in the long term

Potential Impact 3.3-9 Effects on coho salmon populations due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on coho salmon in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-9), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on coho salmon from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion (approximately 80 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Juvenile coho salmon would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles. Habitat in the J.C. Boyle Bypass and Peaking Reaches would be improved through elimination of peaking operations and higher baseflows. Therefore, the Three Dam Removal Alternative would expand the geographic extent of habitat available to coho salmon in a similar manner to the Proposed Project; albeit with higher migration mortality in fishways and reservoirs.

The short-term impacts on coho salmon from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-9), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in coho salmon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to coho salmon under the Three Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on coho salmon In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Three Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including coho salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Three Dam Removal Alternative on coho salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would increase the amount of habitat available to coho salmon and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of coho salmon populations in the long term. Therefore, the Three Dam Removal Alternative would be beneficial for coho salmon in the long term.

Significance

No significant impact for coho salmon populations in the short term

Beneficial for coho salmon populations in the long term

Potential Impact 3.3-10 Effects on the steelhead population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

Potential impacts on steelhead in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-10), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on steelhead from sediment releases would be similar to the Proposed Project, as well as water quality, fish disease and parasites, fish hatcheries, and algal toxins. The same habitat expansion (approximately 440 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would be accessible but would continue to be inundated by J.C. Boyle Reservoir. Juvenile steelhead would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles.

The short-term impacts on steelhead from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-10), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in steelhead abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to steelhead under the Three Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on steelhead In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the Three Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including steelhead. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Three Dam Removal Alternative on steelhead by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would increase the amount of habitat available to steelhead and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of steelhead populations in the long term. Therefore, the Three Dam Removal Alternative would be beneficial for steelhead in the long term.

Significance

No significant impact for steelhead populations in the short term

Beneficial for steelhead populations in the long term

Potential Impact 3.3-11 Effects on the Pacific lamprey population due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Pacific lamprey in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-11), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on Pacific lamprey from sediment releases would be similar to the Proposed Project, as well as water quality, and algal toxins. The same habitat expansion (approximately 80 miles) expected under the Proposed Project (as described in Section 3.3.5.8 *Aquatic Habitat*) would occur, with the exception of habitat under J.C. Boyle Reservoir (approximately 3.3 miles; Cunanan 2009) and the downstream portion of Spencer Creek (approximately 0.2 miles; Cunanan 2009), which would continue to be inundated by J.C. Boyle Reservoir and unlikely to be used by Pacific Lamprey. Based on the 80 miles of Pacific lamprey habitat estimated upstream of Iron Gate Dam (Section 3.3.5.8 *Aquatic Habitat*), the 3.5 miles that would remain inundated by J.C. Boyle Reservoir rather than revert to riverine habitat under the Three Dam Removal Alternative is unsubstantial (< 5 percent of newly accessible habitat). Juvenile lamprey would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018).

As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles.

The short-term impacts on Pacific lamprey from sediment releases would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-11), for the reasons described in Section 4.6.3.1 *Suspended Sediment* and Section 4.6.3.2 *Bed Elevation and Grain Size Distribution*. Because there would not be a substantial short-term decrease in Pacific lamprey abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to Pacific lamprey under the Three Dam Removal Alternative in the short term.

In addition, and as described for the Proposed Project, although this EIR finds no significant impact on Pacific lamprey In the short term, aquatic resource measure AR-1 (Mainstem Spawning) would occur under the Three Dam Removal Alternative, which would further reduce the potential for short-term effects of SSCs on Pacific lamprey. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measure AQR-1, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4, would even further reduce the potential for short-term effects of the Three Dam Removal Alternative on Pacific lamprey by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would increase the amount of habitat available to Pacific lamprey and improve water quality and bedload characteristics in the mainstem Klamath River in the same manner as the Proposed Project. Overall, these changes could result in a substantial increase the abundance of Pacific lamprey populations in the long term. Therefore, the Three Dam Removal Alternative would be beneficial for Pacific lamprey in the long term.

Significance

No significant impact for Pacific lamprey in the short term

Beneficial for Pacific lamprey in the long term

Potential Impact 3.3-12 Effects on the green sturgeon population due to short-term sediment releases and long-term changes in habitat quality due to dam removal.
Southern DPS Green Sturgeon may enter the Klamath River Estuary to forage during the summer months. They would not be present when the most severe effects of dam removal are occurring and are not expected to be affected by the Three Dam Removal

Alternative. The remainder of this section focuses on the effects of the Three Dam Removal Alternative on the Northern Green Sturgeon DPS. Northern Green Sturgeon do not occur upstream of Ishi Pishi Falls and would not be affected by Three Dam Removal Alternative impacts that do not extend downstream past these falls. Potential impacts on green sturgeon in California would be the same under the Three Dam Removal Alternative as those described for the Proposed Project in the short term (Potential Impact 3.3-12).

For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, in the long term the Three Dam Removal Alternative would result in the same improvements in flow regime, water quality, temperature variation, and algal toxins as described for the Proposed Project (Potential Impact 3.3-12). Because there would not be a substantial short- or long-term decrease in green sturgeon abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the green sturgeon population under the Three Dam Removal Alternative in the short or long term.

Significance

No significant impact for green sturgeon in the short or long term

Potential Impact 3.3-13 Effects on Lost River and shortnose sucker populations due to short- and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on Lost River and shortnose suckers in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-13), with a few notable differences. For reasons described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6. *Algal Toxins*, impacts on Lost River and shortnose suckers in Upper Klamath Lake, interactions with anadromous fish, and from conversion of Lower Klamath Project reservoir habitat to riverine habitat would be similar to the Proposed Project. Lost River and shortnose suckers currently occur within all Lower Klamath Project reservoirs, including J.C. Boyle Reservoir (Desjardins and Markle 1999). Therefore, while under the Proposed Project all Lower Klamath Project reservoir habitat (2,347 acres) currently supporting Lost River and shortnose suckers would be removed, under the Three Dam Removal Alternative habitat would remain in J.C. Boyle Reservoir (420 acres). Most of the reservoir habitat (82 percent), and the preponderance of the Lost River and shortnose sucker populations in the Hydroelectric Reach is within Iron Gate and Copco reservoirs.

Overall, the short-term impact of the Three Dam Removal Alternative would be very similar to the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-13), with the exception of those Lost River and shortnose sucker individuals that are able to remain within J.C. Boyle Reservoir habitat. All individual suckers occurring within the lower three Lower Klamath Project reservoirs would likely be lost within dam removal year 2; however, these individuals are not considered to substantially contribute to the achievement of conservation goals or recovery, since little or no reproduction occurs downstream from Keno Dam (Buettner et al. 2006), and there is no potential for interaction with upstream populations (Hamilton et al. 2011). Based on the best available estimates of Lost River and shortnose sucker abundance in the Lower Klamath Project excluding J.C. Boyle Reservoir, there are likely fewer than 1,000 adult suckers of both species (USFWS 2012, Desjardins and Markle 1999), with a combined suitable sucker area of less than 2,500 acres. The populations in Upper Klamath Lake are estimated at 50,000 to 100,000 Lost River sucker (USFWS 2013b), and up to 25,000 shortnose suckers (USFWS 2013c), within around 79,000 acres of suitable habitat in Upper Klamath Lake and connected water bodies. Therefore, a loss of the suckers in Lower Klamath Project reservoirs (excluding J.C. Boyle Reservoir) represents around less than 1.5 percent of the total sucker population, and a loss of less than 3.5 percent of the total suitable sucker habitat. Based on no predicted substantial (< 1.5 percent) short-term decrease in Lost River and shortnose suckers' abundance of a year class, or substantial decrease in habitat quality or quantity (<1.5 percent), the Three Dam Removal Alternative would not cause a significant impact to the Lost River and shortnose sucker populations in the short term.

For the reasons described above in Section 4.6.3.7 *Aquatic Habitat*, in the long term reservoir removal associated with dam removal under the Three Dam Removal Alternative would eliminate habitat availability and affect Lost River and shortnose suckers in Iron Gate and Copco reservoirs. All individual suckers occurring within these reservoirs would likely be lost within the short term and would not be replaced in the long term. However, as described above, these individuals are not considered to substantially contribute to the achievement of conservation goals or recovery of the populations (Hamilton et al. 2011). Because there would not be a substantial long-term decrease in Lost River and shortnose suckers abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the Lost River and shortnose sucker populations under the Three Dam Removal Alternative in the long term.

In addition, and as described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*, Potential Impact 3.3-13), although this EIR finds no significant impact on Lost River and shortnose suckers in the short term or long term, aquatic resource measure AR-6 (Suckers) would occur under the Three Dam Removal Alternative, which would further reduce the potential for effects of reservoir removal.

<u>Significance</u>

No significant impact for Lost River and shortnose sucker populations in the short term

No significant impact for Lost River and shortnose sucker populations in the long term

Potential Impact 3.3-14 Effects on the redband trout population due to short-term sediment releases and long-term changes in habitat quality and quantity due to dam removal.

Potential impacts on redband trout in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impact 3.3-14), with a few notable differences. As described in Section 4.6.3.1 *Suspended Sediment* through Section 4.6.3.6 *Algal Toxins*, impacts on redband trout from water quality would be similar to the Proposed Project, as well as algal toxins. Redband trout would also be affected by the reintroduction of anadromous fish, including the potential for competition, predation, and exposure to disease in the same manner as described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14), since these result from restored habitat access of anadromous salmonids that would not differ between the Proposed Project and the Three Dam Removal Alternative.

Suspended and bedload sediment effects would differ from those described for the Proposed Project. Redband trout are distributed upstream of Iron Gate and Copco reservoirs, and therefore under the Proposed Project the impacts these individuals would experience from sediment releases would be downstream of J.C. Boyle and downstream of Copco No. 1 and Copco No. 2. Therefore, for those individuals upstream of Copco No. 1, despite the relatively small volume of sediment stored in J.C. Boyle Reservoir, impacts of sediment release on redband trout that would occur under the Three Dam Removal Alternative would be substantially less under the Proposed Project. For those individuals downstream of Copco No. 2 the impacts of sediment release would be indistinguishable from the Proposed Project, due to the relatively large contribution from sediment stored in Copco No. 1 Reservoir.

As described in Section 4.6.3.7 *Aquatic Habitat*, conversion of Lower Klamath Project reservoir habitat to riverine habitat would be similar to the Proposed Project, with the exception of J.C. Boyle Reservoir. Under the Three Dam Removal Alternative redband trout would benefit from changes in hydropower operations, and from the conversation of 17.7 miles of reservoir habitat to riverine habitat, in the same manner as for the Proposed Project. However, 3.5 miles of mainstem and tributary habitat would continue to be inundated by J.C. Boyle Reservoir. It is anticipated that under the Three Dam Removal Alternative this habitat would continue to support an adfluvial redband trout population. As described in Section 4.6.3.8 *Fish Passage*, mortality within fishways (i.e., volitional facilities, trap and haul) at J.C. Boyle Dam is predicted to be less than 2 percent for upstream and downstream migrating adults and juveniles.

Because there would not be a substantial short-term decrease in redband trout abundance of a year class or a substantial decrease in habitat quality or quantity, there would not be a significant impact to the redband trout population under the Three Dam Removal Alternative in the short term. Based on a long-term substantial increase in redband trout habitat quality and quantity, the Three Dam Removal Alternative would be beneficial for redband trout in the long term.

Significance

No significant impact for redband trout in the short term

Beneficial for redband trout in the long term

Potential Impact 3.3-17 Effects on species interactions between introduced resident fish species and native aquatic species due to short- and long-term changes in habitat quality and quantity due to dam removal.

Introduced fish species threaten the diversity and abundance of native fish species through competition for resources, predation, interbreeding with native populations, and causing potential physical changes to the invaded habitat (Moyle 2002). Potential impacts on species interactions between introduced resident fish species and native aquatic species ("species interactions") in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14), with a few notable differences. As described for the Proposed Project, implementation of the Three Dam Removal Alternative would eliminate reservoir habitat associated with three Lower Klamath Project reservoirs, and thus the abundance of introduced resident species would decline substantially (Buchanan et al. 2011a), providing a benefit to native aquatic species. However, the Three Dam Removal Alternative would retain the habitat supporting non-native fish species associated with

J.C. Boyle Reservoir. As described in Section 3.3.2.1 *Aquatic Species [non-native fish species]*, non-native fish species would continue to occur in J.C. Boyle Reservoir, including yellow perch and bass species. Juvenile salmonids and lamprey would be subject to some level of predation by introduced resident species including largemouth bass, catfish, and yellow perch in J.C. Boyle Reservoir, resulting in mortality rates that would depend largely on their size (larger migrants would do better) (NMFS 2006a). Mortality rates in reservoirs can be substantial (>50 percent; Stillwater Sciences 2018). However, in restoration efforts elsewhere in the Pacific Northwest, anadromous juveniles successfully pass through reservoirs under similarly difficult circumstances (NMFS 2006a). In addition, the majority of the non-native species are within Iron Gate and Copco No. 1 reservoirs, which support popular recreational fisheries for yellow perch and bass. Therefore, species interactions under the Three Dam Removal Alternative would be substantially improved relative to existing conditions, albeit to a lesser degree than under the Proposed Project. This effect would be beneficial for native aquatic species in the short and long term.

<u>Significance</u>
Beneficial for the effects of introduced resident fish species on aquatic species in the short term and long term

Potential Impact 3.3-19 Effects on freshwater mollusks populations due to short-term sediment releases and long-term changes in habitat quality due to dam removal.
Potential impacts on freshwater mollusks in California would be similar under the Three Dam Removal Alternative as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-19), with a few subtle differences. As described in Section 4.6.3.1 *Suspended Sediment*, impacts on freshwater mollusks from sediment releases would be similar to the Proposed Project. Based on the distribution of freshwater mollusks primarily downstream of Iron Gate dam (summarized in Section 3.3.5.9, Potential Impact 3.3-14), the impacts of the Three Dam Removal Alternative would be the same as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14) with one exception. The Proposed Project would have the most substantial impact on the floater mussels (*Anodata spp*.) which occur in the mainstem Klamath River in the Hydroelectric Reach, within Lower Klamath Project reservoirs, in a reach (<15 miles) directly downstream of Iron Gate Dam, and within the Upper Shasta River. *Anodata spp*. have been found in high abundance within J.C. Boyle Reservoir as recently as summer 2018 (Troy Brandt, River Design Group, pers. comm., November 2018). Therefore, under the Three Dam Removal Alternative the *Anodata spp.* would remain unaffected within a portion of their range in J.C. Boyle Reservoir and Upper Shasta River. Therefore, while the impacts to other species of freshwater mollusks would be the same under the Proposed Project (not significant), impacts to the *Anodata spp*. would be less substantial under the Three Dam Removal Alternative than under the Proposed Project. However, impacts the Anodata spp. would still occur under the Three Dam Removal Alternative in the mainstem Klamath River (primarily downstream of Iron Gate Dam) as described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14), and based on predicted substantial short-term decrease in *Anodonta spp.* abundance of a year class, there would be a significant impact to the *Anodonta spp.* population under the Proposed Project in the short term.

However, the Three Dam Removal Alternative includes aquatic resource measure AR-7 (Freshwater Mussels) to reduce the short-term effects of sediment transport during dam removal on *Anodonta spp.*, as described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-14). Under the Proposed Project this salvage and relocation plan would consider sites for translocation downstream from the Trinity River confluence (RM 43.4), and between J.C. Boyle Dam (RM 230.6) and Copco Reservoir (RM 209.0). These areas would have less impact from increased SSCs but would not be completely protected from short-term effects. The areas downstream of the Trinity River confluence do not currently support *Anodonta spp*. and are unlikely to in the future (Davis et al. 2013). However, under the Three Dam Removal Alternative *Anodonta spp*. could be salvaged from the reach downstream of Iron Gate Dam and relocated to J.C. Boyle Reservoir, which does support suitable *Anodonta spp*. habitat. Therefore, with aquatic resource measure AR-7, there would likely not be a substantial reduction in the abundance of *Anodonta spp.* species in the short term, and impacts would be not significant with for *Anodonta spp.* in the short term.

Significance

No significant impact for *M. falcata, G. angulate, or Anodonta spp.* in the short or long term

No significant impact for freshwater clams in the short or long term

4.6.4 Phytoplankton and Periphyton

4.6.4.1 Phytoplankton

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Three Dam Removal Alternative (see Section 4.6.2.2 *Suspended Sediments*), thus there would be no short-term increase in sediment-associated nutrients downstream of J.C Boyle Dam (see Section 4.6.2.3 *Nutrients*). While there would be a short-term increase in sediment-associated nutrients between Copco No. 1 Reservoir and Iron Gate Dam in the Hydroelectric Reach, as well as in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary during reservoir drawdown (see Section 4.6.2.3 *Nutrients*), minimal deposition of fine suspended sediments, including the associated nutrients, would occur in the river channel and the estuary (Stillwater Sciences 2008; USBR 2012). Thus, the short-term increase in nutrients would be limited to the time period when sediment deposits are being transported through the Klamath River. The drawdown of Copco No. 1 and Iron Gate reservoirs and release of these nutrients also would occur during winter months when the rates of phytoplankton growth and reproduction along with the rates of nutrient transformations by microbes (e.g., nitrification and denitrification) are relatively low, so the ability of phytoplankton to use sediment-associated nutrients mobilized during reservoir drawdown would be low (see Potential Impact 3.4-1). Sediment released during reservoir drawdown under the Three Dam Removal Alternative also would increase suspended sediment concentrations and water turbidity (see also Potential Impact 3.2-3), limiting light availability for phytoplankton photosynthesis and further reducing the potential for additional phytoplankton growth and reproduction. Under the Three Dam Removal Alternative, the sediment-associated nutrients would be less than under the Proposed Project since no J.C. Boyle sediment-associated nutrients would be released, but the overall impact would be the same in both the Three Dam Removal Alternative and the Proposed Project. The sediment-associated nutrients would not be likely to stimulate phytoplankton growth or reproduction that would lead to an increase spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton, so there would be no significant impact.

With respect to potential long-term impacts, J.C. Boyle Reservoir does not support low mixing conditions or thermal stratification that create optimal habitat for phytoplankton growth or reproduction under existing conditions due to its shallow depth (8.3 feet average depth) and short hydraulic residence time (approximately 1 day at average flows, Table 3.6-4) and it would not do so under the Three Dam Removal Alternative. Peaking power generation flows are released in the late afternoons and early evenings to meet high power demand, and J.C. Boyle Reservoir refills during the night when power demand is minimal. Daily fluctuations in the reservoir water level under existing operations increases mixing in the reservoir, making the reservoir slightly less suitable habitat for phytoplankton during the season of maximum phytoplankton and cyanobacteria (blue-green-algae) growth in the system. Ceasing peaking power generation flows would reduce daily reservoir water level fluctuations in J.C. Boyle Reservoir because the facility would no longer be operated to draw on reservoir storage to support daily peaks in hydropower production when there is not sufficient river flow for peak production (3,000 cfs), as occurs during the summer and fall low flow period under existing conditions. However, the residence time of J.C. Boyle Reservoir without peaking operations would still be short (i.e., on the order of one to three days), so leaving this dam in place and ceasing peaking flows would not change long-term phytoplankton growth or reproduction and thus it would not change the spatial extent, temporal duration, or concentration of nuisance and/or noxious phytoplankton blooms, including blue-green algae, to the degree that new or further impairment of designated beneficial uses would occur.

Copco No. 1 and Iron Gate reservoirs currently support growth conditions for toxin-producing nuisance phytoplankton species such as *Microcystis aeruginosa*, with these two reservoirs serving as the primary habitat for blue-green algae in the Hydroelectric Reach. Thus, the removal of Copco No. 1 and Iron Gate reservoirs under the Three Dam Removal Alternative would eliminate the main habitat toxin-producing nuisance phytoplankton and reduce the long-term spatial extent, temporal duration, and concentration of nuisance and/or noxious phytoplankton species relative to existing conditions, consistent with the Proposed Project. The elimination of Copco No. 1 and Iron Gate reservoirs would be beneficial in the Hydroelectric Reach downstream of Copco No. 1 Reservoir. Due its small size and low residence time (less than a day), Copco No. 2 Reservoir does not promote phytoplankton growth under existing conditions and its removal under the Three Dam Removal Alternative also would not affect the spatial extent, temporal duration, and concentration of nuisance and/or noxious phytoplankton species within the Hydroelectric Reach or downstream reaches.

Because seasonal phytoplankton blooms are primarily internally generated in Copco No. 1 and Iron Gate reservoirs, removal of these reservoirs under the Three Dam Removal Alternative would also decrease or eliminate the long-term downstream transport of nuisance and/or noxious phytoplankton species and their associated toxins from Copco No. 1 and Iron Gate reservoirs into the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment. The decrease or elimination of long-term downstream transport of phytoplankton cells from Copco No. 1 and Iron Gate reservoirs would also reduce the seasonal (i.e., summer and fall) downstream transport of nutrients contained in those phytoplankton cells that potentially promote seasonal increases in phytoplankton and/or periphyton growth in the Middle and Lower Klamath River, the Klamath River Estuary, and the Pacific Ocean nearshore environment.

In summary, relative to existing conditions, the potential impacts and impacts of the Three Dam Removal Alternative on phytoplankton would be the same as or similar to those described for the Proposed Project, as follows:

- There would be no short-term change in phytoplankton growth and reproduction from existing conditions in the Hydroelectric Reach from J.C. Boyle Dam to the upstream end of Copco No. 1 Reservoir due to mobilization of sediment-associated nutrients from J.C. Boyle Reservoir because this reservoir and its sediment deposits would remain in place (Potential Impact 3.4-1).
- While there would be short-term increases in sediment-associated nutrients downstream of Copco No. 1 Dam due to the release of sediments currently trapped behind the Copco No. 1 and Iron Gate dams, there would not be an increase in the spatial extent, temporal duration, toxicity, or concentration of nuisance and/or noxious phytoplankton species, including blue-green algae, in the Hydroelectric Reach downstream of Copco No. 1 Dam, the Middle and Lower Klamath River, and the Klamath River Estuary that results in new or further impairment of designated beneficial uses; therefore, there would be no significant impact in the short term (Potential Impact 3.4-1).
- There would be no significant impact in the long term from J.C. Boyle Dam remaining in place and ceasing peaking power generation flows on the spatial extent, temporal duration, transport, and/or concentration of nuisance and/or noxious phytoplankton species and concentrations of algal toxins because J.C. Boyle Reservoir would not support habitat that would promote phytoplankton blooms under the Three Dam Removal Alternative, similar to under existing conditions (Potential Impact 3.4-2).
- Long-term reduction in the spatial extent, temporal duration, transport, and/or concentration of nuisance and/or noxious phytoplankton species and concentrations of algal toxins due to elimination of Copco No. 1 and Iron Gate reservoir habitats would be beneficial for the Hydroelectric Reach, Middle and Lower Klamath River, and Klamath River Estuary (Potential Impact 3.4-2). There would be no significant impact for the Pacific Ocean nearshore environment (Potential Impact 3.4-2).

4.6.4.2 Periphyton

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Three Dam Removal Alternative, thus there would be no short-term increase in sediment-associated nutrients downstream of J.C Boyle Dam. While there would be a short-term increase in sediment-associated nutrients between Copco No. 1 Reservoir and Iron Gate Dam in the Hydroelectric Reach, as well as in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary during reservoir drawdown, minimal deposition of fine suspended sediments, including the associated nutrients, would occur in the river channel and the estuary (Stillwater Sciences 2008; USBR 2012). Thus, the short-term increase in nutrients would be limited to the time period when sediment deposits are being transported through the Klamath River. The drawdown of Copco No. 1 and Iron Gate reservoirs and release of these nutrients would occur during winter months when the rates of periphyton growth and reproduction along with the rates of nutrient transformations by microbes (e.g., nitrification and denitrification) are relatively low due to less light availability for photosynthesis and lower water temperatures. As a result, the ability of periphyton to use sediment-associated nutrients would be limited and there would not be an increase in periphyton growth or reproduction during this period, even though additional nutrients would be available due to the release of sediments trapped behind the Lower Klamath Project dams. Light limitation from high concentrations of suspended sediments in the water (Potential Impact 3.2-3) would also reduce any potential for nuisance levels of periphyton growth during reservoir drawdown. Additionally, high river flows during the winter drawdown period and late spring storm events would result in greater sediment movement and scouring, which would greatly limit, if not eliminate, the area of the streambed that periphyton can establish to grow during this period. Thus, the Three Dam Removal Alternative would not be likely to stimulate an increase in periphyton growth or reproduction and result in an increase in the spatial extent, temporal duration, or biomass of nuisance periphyton species that causes a new or further impairment of designated beneficial uses, similar to the Proposed Project.

Under the Three Dam Removal Alternative, J.C. Boyle Reservoir would remain in place and peaking power generation and release of recreation flows would cease from J.C. Boyle Dam, so there would be less artificial diel (24-hour) temperature variation during summer and early fall in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir similar to the Proposed Project (see also Potential Impact 3.2-1). J.C. Boyle retains relatively little nutrients under existing conditions (see Appendix C, Section C.3.1.1 *Hydroelectric Reach*), and therefore nutrient conditions in this reach would be the same under the Three Dam Removal Alternative as under existing conditions since there would be no change in nutrient interception or retention with J.C. Boyle Dam remaining in place. The less diel (24-hour) temperature variations and slight decrease in the maximum water temperature in this reach is not anticipated to affect periphyton colonization. Additionally, the generally high gradient and velocity in the J.C. Boyle Peaking Reach does not currently support excessive periphyton mats and it is not anticipated this reach would support excessive periphyton mats under lower flows once peaking and recreation flows cease. In the short term and long term, increases in periphyton biomass from elimination of peaking and recreation flows along with the change in water temperature in this reach are expected to be limited under the Three Dam Removal Alternative and any potential increase in periphyton would not result in new or further impairment of designated beneficial uses.

Further downstream in the Hydroelectric Reach, periphyton growth in low-gradient channel margin areas in the footprints of Copco No. 1 and Iron Gate reservoirs could increase on a seasonal basis following dam removal because removal of the reservoirs would provide additional low-gradient habitat suitable for periphyton assemblages. Dam removal construction and restoration activities in dam removal year 2 and additional sediment transport and scour during winter post-dam removal year 1 may inhibit some periphyton growth in the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam, but, overall, periphyton would be expected to begin colonizing the newly created suitable habitat within the short term and would continue in the long term. Similar to the Proposed Project (Potential Impact 3.4-4), conservatively this would be a significant impact with respect to periphyton growth. The response of periphyton in the river is subject to many competing processes that could either accelerate or hinder periphyton growth and potential increases in nuisance periphyton (i.e., *Cladophora* sp.) extent, duration, and biomass. In the long term, improvements (i.e., reductions in biomass) are expected from several processes such as scour and in-stream retention processes, whereas improvements could be diminished by processes such as reduced nutrient retention from the reservoirs or climate change. While the growth of nuisance periphyton along channel margin areas is not expected to contribute algal toxins that would impair water quality, the degree to which designated beneficial uses would be impaired due to an increase in nuisance periphyton species (i.e., *Cladophora* sp.) in the newly formed low-gradient channel margin areas of the Hydroelectric Reach between Copco No. 1 Reservoir and Iron Gate Dam is not fully understood. The implications of potential changes in periphyton biomass and community composition on dissolved oxygen and the spread of fish disease under the Three Dam Removal Alternative would be similar to those described in Section 3.2.5.4 *Dissolved Oxygen* and Section 4.6.3.4 *Fish Disease and Parasites*, respectively, for the reach between Copco No. 1 Reservoir and Iron Gate Dam.

In summary, relative to existing conditions, the potential impacts of the Three Dam Removal Alternative on periphyton would be the same as or similar to those described for the Proposed Project, as follows:

- There would be no significant impact in the short term from changes in periphyton growth compared to existing conditions due to mobilization of sediment-associated nutrients from J.C. Boyle Reservoir (Potential Impact 3.4-3) because this reservoir and its sediment deposits would remain in place.
- Mobilization of sediment-associated nutrients from Copco No. 1 and Iron Gate reservoirs would occur under the Three Dam Removal Alternative, but usage of these nutrients would be limited due to lower light levels reducing photosynthesis for periphyton growth and higher flows scouring periphyton from the streambed during winter and early spring. Thus, there would not be an increase in the spatial extent, temporal duration, or biomass of nuisance periphyton species in the Hydroelectric Reach downstream of Copco No. 1, the Middle and Lower Klamath River, or the Klamath River Estuary that would result in a new or further impairment of designated beneficial uses (Potential Impact 3.4-3), and there would be no significant impact.
- There would be no short-term or long-term increase in nuisance periphyton growth that results in new or further impairment of designated beneficial uses in the Hydroelectric Reach from J.C. Boyle Dam to Copco No. 1 Reservoir, including the Oregon-California state line, due to increased nutrients or ceasing of peaking flows at J.C. Boyle (Potential Impact 3.4-4), so there would be no significant impact.
- There could be a short-term and/or long-term increase in nuisance periphyton growth that would result in new or further impairment of designated beneficial uses in the Hydroelectric Reach from Copco No. 1 Reservoir to Iron Gate Dam due to an increase in nutrients and available low-gradient channel margin habitat from conversion of the Copco No. 1 and Iron Gate reservoir areas to a free-flowing river (Potential Impact 3.4-4) and if this increase were to occur, it would be a significant and unavoidable impact.
- There would be no long-term increase in biomass of nuisance periphyton that would result in new or further impairment of designated beneficial uses in the Middle Klamath River, Lower Klamath River, and Klamath River Estuary due to increased nutrient availability from upstream dam removal under the Three Dam Removal Alternative similar to the Proposed Project (Potential Impact 3.4-5), so there would be no significant impact.

4.6.5 Terrestrial Resources

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes construction of a new fish ladder at J.C. Boyle Dam (and removal of the existing one within a similar footprint to the existing ladder). While there would potentially be less construction activities resulting in noise or habitat removal under this alternative than under the Proposed Project, the relative decrease in construction activities under the Three Dam Removal Alternative would not change the level of impacts to terrestrial resources in California since J.C. Boyle is located in Oregon. Thus, potential impacts on sensitive habitats (wetlands and riparian habitat), rare natural communities, culturally significant species, special-status species, wildlife corridors and habitat connectivity within the Primary Area of Analysis for terrestrial resources would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impacts 3.5-1 through 3.5-31).

4.6.6 Flood Hydrology

For the reasons discussed below, potential impacts on flood hydrology resources in California would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impacts 3.6-1 through 3.6-6). J.C. Boyle Reservoir has a relatively small storage capacity (2,267 acre-feet total storage; 1,724 acre-feet active storage; see Table 3.6-4) and is not operated by PacifiCorp as a flood control reservoir. Thus, leaving J.C. Boyle Dam in place under the Three Dam Removal Alternative would not affect the FEMA 100-year floodplain nor risks related to flooding during reservoir drawdown downstream from the Oregon-California state line relative to the Proposed Project. Ceasing peaking power generation or release of flow for recreation at J.C. Boyle Dam would reduce daily reservoir level variability, as well as flow variability in the J.C. Boyle Peaking Reach from the Oregon-California state line to Copco No. 1 Reservoir, relative to existing conditions. However, because the reservoir active storage is relatively small, these changes would not affect flood hydrology. Therefore, the flood hydrology impacts of the Three Dam Removal Alternative would be the same as those described for the Proposed Project and there would be no significant impacts for Potential Impacts 3.6-1, 3.6-2, and 3.6-4 through 3.6-6. There would be significant and unavoidable impacts related to exposing structure to a substantial risk of damage due to flooding downstream of the location of Iron Gate Dam (Potential Impact 3.6-3).

4.6.7 Groundwater

would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impacts 3.7-1 and 3.7-2). The Klamath River within the Hydroelectric reach is a gaining reach (i.e., regional groundwater discharges to the river). Groundwater contributions from the Lower Klamath Project reservoirs to surrounding aquifers likely only extends to the immediate vicinity of the reservoirs (i.e., less than approximately 2 miles) (USBR 2012). J.C. Boyle Reservoir is located more than 20 river miles upstream of the other Lower Klamath Project reservoirs, and thus leaving it in place under the Three Dam Removal Alternative would not influence groundwater wells located in the vicinity of Copco No. 1 and Iron Gate reservoirs. Removal of Copco No. 1 and Iron Gate reservoirs under the Three Dam Removal Alternative would result in the same effects on groundwater as described for the

Proposed Project (Section 3.7 *Groundwater*). For the reasons described in Potential Impacts 3.7-1 and 3.7-2, and there would be no significant impacts.

4.6.8 Water Supply/Water Rights

For the reasons discussed below, the water supply and water rights impacts of the Three Dam Removal Alternative would be the same as those analyzed under the Proposed Project (Potential Impacts 3.8-1 through 3.8-5). As discussed in Section 3.8 *Water Supply/Water Rights*, under existing conditions none of the Lower Klamath Project facilities are water supply facilities. Thus, the same set of influences that currently dictate water availability in California would continue to do so regardless of whether J.C. Boyle Dam is removed (as under the Proposed Project) or remains (as under the Three Dam Removal Alternative).

The Lower Klamath Project reservoir that would remain under the Three Dam Removal Alternative, J.C. Boyle, has a relatively small storage capacity (2,267 acre-feet total storage; 1,724 acre-feet active storage; see Table 3.6-4) and, like other Lower Klamath Project facilities, is not a water supply facility for consumptive use in Oregon or California. Ceasing peaking power generation and recreation flow releases at J.C. Boyle Dam would reduce daily reservoir level variability, as well as flow variability downstream from J.C. Boyle Dam, relative to existing conditions. Minimum flows in California under the Three Dam Removal Alternative would be the same as those analyzed under the Proposed Project because minimum instream flows would still be mandated by BiOp requirements. As under the Proposed Project, reducing riverine flow fluctuation in the Hydroelectric Reach and removing the California reservoirs would not reduce the amount of water available or impact diversion facilities for the three diversions identified from the Oregon-California state line to Copco No. 1 Reservoir. Thus, Potential Impacts 3.8-1, 3.8-2, and 3.8-5 under the Proposed Project would be the same under the Three Dam Removal Alternative, and there would be no significant impacts.

Short-term mobilization of J.C. Boyle Reservoir sediment deposits would not occur under the Three Dam Removal Alternative and none of the associated 1,190,000 cubic yards of deposits (i.e., eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches, although little to no sediment deposition would be expected in the reach between J.C. Boyle and Copco No. 1 (USBR 2012). However, mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs[229] would still occur such that release of stored sediment during reservoir drawdown could still impact water intake pumps downstream from Iron Gate Dam (Potential Impact 3.8-3). Implementation of Mitigation Measure WSWR-1 would be required to result in no significant impact.

The City of Yreka's municipal water supply pipeline would still need to be relocated following drawdown of Iron Gate Reservoir, and there would still be potential for disruption to the City's water supply. Implementation of Mitigation Measure WSWR-2 would reduce this potential impact to less than significant.

[229] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1 Reservoir that would subsequently be released downstream once drawdown begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

4.6.9 Air Quality

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. Although this would be less construction than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts to air quality in California. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. Like the Proposed Project, due to the potential for the emissions generated from construction activity in Oregon to have air quality impacts in Siskiyou County, California, the emissions from construction activity in Oregon are conservatively included in the estimate of total emissions due to construction activity under this alternative. In California, construction activities at Copco No. 1, Copco No. 2, and Iron Gate dams would occur under the Three Dam Removal Alternative in the same manner as under the Proposed Project. Thus, overall the detailed discussion of impacts to air quality provided in the Proposed Project also applies to this alternative (see also Appendix N). Note that the magnitude of estimated emissions due to J.C. Boyle Dam and Powerhouse deconstruction is relatively low compared with the other three dam complexes, such that reducing this estimate for a lesser degree of construction under the Three Dam Removal Alternative would not change the expectation that emissions would exceed the Siskiyou County Air Pollution Control District emissions thresholds (see Table 3.9-5). Thus, potential air quality impacts due to construction activities under the Three Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.9-1 through 3.9-5). Like the Proposed Project, construction activities occurring under the Three Dam Removal Alternative would exceed the Siskiyou County Air Pollution Control District emissions thresholds for NO_x, PM_{10}, and $PM_{2.5}$ and would result in a significant and unavoidable impact.

4.6.10 Greenhouse Gas Emissions

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. Although this would be less construction than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts due to GHG emissions in California. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. As with the Proposed Project, due to the cumulative nature of GHG emissions, the emissions from construction activity in Oregon are conservatively included in the estimate of total emissions due to construction activity under this alternative. In California, construction activities at Copco No. 1, Copco No. 2, and Iron Gate dams would still occur and this, combined with lesser degree of construction activities in Oregon, means that the detailed discussion of impacts to greenhouse gases provided in the Proposed Project (Potential Impact 3.10-1) also applies to this alternative, albeit with slightly lower overall GHG emissions. Leaving J.C. Boyle Dam in place and lowering overall construction-related emissions relative to the Proposed Project would not change the potential for a conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing the emissions of greenhouse gases (Potential Impact 3.10-2). Overall, Three Dam Removal Alternative would result in no significant impacts due to greenhouse gas emissions.

4.6.11 Geology, Soils, and Mineral Resources

For the reasons discussed below, the Three Dam Removal Alternative would have similar effects on geology, soils, and mineral resources in California as would the Proposed Project (Section 3.11 *Geology, Soils, and Mineral Resources*), with minor differences discussed at the end of this section. Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes construction of a new fish ladder at J.C. Boyle Dam (and removal of the existing one within a similar footprint to the existing ladder). If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. While there would potentially be less construction activities resulting in short-term soil disturbance under this alternative than under the Proposed Project, the relative decrease in construction activities under the Three Dam Removal Alternative would not change the potential for impacts due to geologic hazards, short-term soil disturbance, hillslope instability, earthen dam embankment instability, or loss of mineral resources in California since J.C. Boyle is located in Oregon.

In California, potential impacts under the Three Dam Removal Alternative would be due to removal and reservoir drawdown activities at Copco No. 1, Copco No. 2, and Iron Gate dams and associated facilities in California. Thus, there would be no significant impacts due to potential for changes to geologic hazards, short-term soil disturbance, earthen dam embankment instability, and mineral resource availability under the Three Dam Removal Alternative for the reasons described for the Proposed Project (Potential Impacts 3.11-1, 3.11-2, 3.11-4 and 3.11-8).

For the reasons described for the Proposed Project, Implementation of Mitigation Measure GEO-1 would be necessary to reduce the potential impacts resulting from slope failure in reservoir rim areas at Copco No. 1 Reservoir (see Potential Impact 3.11-3). With implementation of Mitigation Measure GEO-1, there would be no significant impacts due to the potential for hillslope instability at Copco No. 1 Reservoir during drawdown and the year following drawdown.

Under the Three Dam Removal Alternative, J.C. Boyle Dam would remain in place and none of the associated 1,190,000 cubic yards of reservoir sediment deposits (eight percent of total volume for the Lower Klamath Project reservoirs, see also Tables 2.7-7 and 2.7-8) would be eroded or delivered to downstream reaches. The latter would reduce associated short-term erosion and sediment delivery impacts (i.e., sedimentation and bank erosion downstream of Iron Gate Reservoir) that would occur under the Proposed Project, given the relatively smaller volume of sediments in J.C. Boyle Reservoir compared with Copco No. 1 and Iron Gate reservoirs. However, the effect would be relatively small since mobilization of reservoir sediment deposits in the much larger Copco No. 1 and Iron Gate reservoirs[230] would still occur. Therefore, potential

[230] Copco No. 2 Dam does not retain appreciable amounts of sediment (USBR 2011b), nor is it likely to accumulate large sediment deposits during drawdown of the upstream Copco No. 1

short-term erosion and sediment delivery impacts under the Three Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.11-5 through 3.11-7) and there would be no significant impacts, with the exception of the Middle Klamath River between Iron Gate Dam and Cottonwood Creek where there would be a significant and unavoidable impact (see Potential Impact 3.11-5). In the long term, J.C. Boyle Reservoir would continue accumulating sediment at approximately the rate that it does under existing conditions, which is generally low (see Table 3.11-6).

4.6.12 Historical Resources and Tribal Cultural Resources

Leaving the J.C. Boyle Dam and associated facilities in place would reduce construction activities related to dam removal relative to the Proposed Project; however, it would not decrease the degree of construction activities or the associated impacts to historical and tribal cultural resources in California since J.C. Boyle is located in Oregon. Unlike under the Proposed Project, reservoir drawdown associated with the removal of J.C. Boyle Dam would not occur under the Three Dam Removal Alternative. However, as discussed in Potential Impact 3.12-3, drawdown releases from J.C. Boyle Dam under the Proposed Project would not cause flooding of the river between the dam and Copco No. 1 Reservoir and would not result in short-term erosion or flood disturbance to the numerous prehistoric archaeological riverside sites with habitation debris, house pits and rock features and cemeteries; as well as ethnographic places and other features of the cultural landscape that have been identified as TCRs along this reach of the Klamath River (PacifiCorp 2004, Daniels 2006). Therefore, leaving J.C. Boyle Dam in place under the Three Dam Removal Alternative would have no bearing on the potential for impacts to known or unknown historical and/or tribal cultural resources within this reach and, like the Proposed Project, there would be no significant impact. The potential for flood disturbance further downstream along the Klamath River would not be different under this alternative from that described for the Proposed Project (Potential Impact 3.12-3) since Copco No. 1, Copco No. 2, and Iron Gate dams would still be removed.

As Copco No. 1, Copco No. 2, and Iron Gate dams would be removed under this alternative as described for the Proposed Project, other potential impacts to tribal cultural resources (Potential Impacts 3.12-1, 3.12-2, 3.12-4 through 3.12-8) and the built environment and historic-period archaeological resources (Potential Impacts 3.12-11 through 3.12-16) and would be the same as those described for the Proposed Project. Implementation of Mitigation Measures TCR-1 through TCR-8 would be required to reduce impacts to tribal cultural resources, but the impacts would remain significant and unavoidable.

There would be approximately 18.5 miles of additional riverine habitat that would become available for salmonids under this alternative (not including 3.5 miles of riverine habitat that would remain inundated by J.C. Boyle Reservoir). The additional habitat, combined with a reduced incidence of fish disease and parasites in the Klamath River under this alternative (see Section 4.6.3.4 *Fish Disease and Parasites*), would improve conditions for the Klamath Cultural Riverscape related to fisheries (Potential Impact 3.12-9) relative to existing conditions. This would be a beneficial effect. Reductions in blue-green algae concentrations under this alternative (see Section 4.6.2.6 *Chlorophyll-a*

Reservoir that would subsequently be released downstream once drawdown begins (see also Section 2.7.3 *Reservoir Sediment Deposits and Erosion During Drawdown*).

and Algal Toxins) would support Cultural Use of Klamath River waters without risk of adverse health effects, which would improve tribal members' access to the river above levels occurring under existing conditions (Potential Impact 3.12-10) and would be a beneficial effect.

4.6.13 Paleontologic Resources

For the reasons described under Proposed Project, there could be instances of bank erosion and slope failures in the Middle Klamath River due to changes in river discharge should the Copco No. 1, Copco No. 2, and Iron Gate dams be removed (Potential Impact 3.13-1). However, the magnitude of this bank erosion would not be substantial compared to existing conditions and there would be a low likelihood that downcutting or erosion of the Hornbrook Formation located downstream of Iron Gate Dam would occur to a greater degree than existing conditions. Because of its small size (2,267 acre-feet total storage; see Table 3.6-4) and because it is not operated by PacifiCorp as a flood control reservoir, retaining J.C. Boyle Reservoir under this alternative would not affect the likelihood of downcutting or erosion relative to existing conditions or the Proposed Project. For these reasons, and given the formation's Low Paleontologic Potential (Potential Impact 3.13-1), there would be no significant impact to paleontologic resources under the Three Dam Removal Alternative.

4.6.14 Land Use and Planning

Under the Three Dam Removal Alternative, the impacts on land use and planning in California would be the same as those described for the Proposed Project in Section 3.14.5 *[Land use and Planning] Potential Impacts and Mitigation*. Because long-term land use under this alternative is currently unknown, this alternative does not assess the potential impacts of long-term use of the lands currently submerged under Iron Gate and Copco No. 1 reservoirs as that would require speculation. The California dam removal actions would occur in the same manner under both the Three Dam Removal Alternative and under the Proposed Project. Maintaining or removing J.C. Boyle Dam 20 miles upstream in Oregon would not have an impact on California land use or planning.

4.6.15 Agriculture and Forestry Resources

The potential for impacts on agriculture and forestry resources in California under the Three Dam Removal Alternative would be the same as described for the Proposed Project because retaining J.C. Boyle Dam would not change or result in the conversion of any California land use relating to agriculture or forestry. In addition, the issues relating to agricultural water in the Lower Klamath Project area would be the same regardless of whether J.C. Boyle Dam remains in place or is removed. Therefore, under the Three Dam Removal Alternative, potential impacts on agriculture and forestry resources would be the same as those of the Proposed Project and there would be no significant impacts (Potential Impacts 3.15-1 through 3.15-3).

4.6.16 Population and Housing

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. Although there would be less construction for fish passage than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated California impacts to population and housing that are described for the Proposed Project (Potential Impacts 3.16-1 and 3.16-2). Like the Proposed Project, the Three Dam Removal Alternative would not result in a substantial influx of population (Potential Impact 3.16-1), nor would there be a need to displace existing residents or build replacement housing elsewhere (Potential Impact 3.16-2), and there would be no significant population and housing impacts.

4.6.17 Public Services

Overall, under the Three Dam Removal Alternative, potential impacts on public services in California would be the same as those described for the Proposed Project. The California dam removal actions would occur in the same manner under both the Three Dam Removal Alternative and under the Proposed Project. Thus, for reasons described in Section 3.17.5 *[Public Services] Potential Impacts and Mitigation*, impacts and associated mitigation measures from increased public service response times for emergency fire, police, and medical services due to construction and demolition activities, elimination of a long-term water source for wildfire services substantially increasing the response time for suppressing wildfires, and potential effects on schools services and facilities would be the same under the Three Dam Removal Alternative as those described for the Proposed Project (Potential Impacts 3.5-1 through 3.5-3).

4.6.18 Utilities and Service Systems

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. Although there would be less construction for fish passage than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts to public services in California since J.C. Boyle is in Oregon. Thus, potential construction-related impacts to utilities and service systems would be the same as described for the Proposed Project (Potential Impacts 3.18-1 through 3.18-4). There would be no significant impacts on utilities and service systems related to this degree of construction for the Proposed Project, and construction is the only part of the proposed activities that merits analysis for potential impacts on utilities and service systems. Construction-related activity in California would still require the need for onsite wastewater treatment, stormwater drainage, and/or solid waste disposal facilities at the same level as the Proposed Project (Potential Impacts 3.18-1 through 3.18-4) and would result in no significant impacts.

4.6.19 Aesthetics

Under the Three Dam Removal Alternative, the aesthetic impacts would be the same as described for the Proposed Project (Section 3.19). The California dam removal actions would occur in the same manner under both the Three Dam Removal Alternative and the Proposed Project. Although the level of overall construction activities due to dam deconstruction in California and construction of upstream and downstream fish passage in Oregon under the Three Dam Removal Alternative would be less than that of the Proposed Project, construction-related activities at J.C. Boyle Dam, which is located 20 miles upstream of the Oregon-California state line, would not affect California aesthetics.

For the reasons described in Section 3.19.5 *[Aesthetics] Potential Impacts and Mitigation*, under the Three Dam Removal Alternative, short-term and long-term impacts on aesthetic resources in California, including a loss of open water and lake vistas in favor of more natural river, canyon, and valley vistas (Potential Impact 3.19-1) and changes in river flows, channel morphology, and visual water quality (Potential Impacts 3.19-2 and 3.19-3) would be the same as those of the Proposed Project, since Copco No. 1, Copco No. 2, and Iron Gate reservoirs would be removed, and there would be no significant impacts. Visual changes resulting from drawdown of Copco No.1, Copco No. 2 and Iron Gate reservoirs would be significant and unavoidable in the short term and would have no significant impact in the long term (Potential Impact 3.19-4). Visual changes due to removal of the California dams and facilities and improvements to or construction of new infrastructure (Potential Impact 3.19-5), and construction activities (Potential Impact 3.19-6) would also be the same as those of the Proposed Project since the manner of dam deconstruction would be the same under the Three Dam Removal Alternative. Impacts from construction lighting would still be significant and unavoidable as under the Proposed Project (Potential Impact 3.19-7).

4.6.20 Recreation

Under the Three Dam Removal Alternative, short-term construction-related activities would occur at Copco No. 1, Copco No. 2 and Iron Gate dams and associated facilities and would be lower than those described for the Proposed Project (Potential Impact 3.20-1). For the reasons described in Potential Impact 3.20-1, there would be no significant impact on recreation from the Three Dam Removal Alternative. Recreational facilities associated with Copco No. 1 and Iron Gate reservoirs would still be subject to closure and reservoir-related recreation would still increase the use of other regional recreational facilities and/or would be replaced with river-related recreation; however as with the Proposed Project there would be no significant impacts (Potential Impacts 3.20-2 and 3.20-3). Under the Three Dam Removal Alternative, all portions of the existing recreational facilities at J.C. Boyle Reservoir (Pioneer Park, Topsy Campground, Spring Island River Access) would remain in place under this alternative, offering more regional boating and fishing recreational opportunities relative to the Proposed Project. Elimination of peaking operations and higher baseflows under this alternative may increase the appeal of J.C. Boyle Reservoir recreational sites due to elimination of regular reservoir water level fluctuations and increased low flows in the Hydroelectric Reach.

While the Three Dam Removal Alternative would not remove J.C. Boyle Reservoir, it also would increase minimum flows in the Bypass Reach and would not include peaking power generation or release of flows for recreation at J.C. Boyle Dam. Since there would be no recreational flows in the Hydroelectric Reach under this alternative, and flows in the Hydroelectric Reach would be similar to those under the Proposed Project, the loss of whitewater boating opportunities in the Hell's Corner Reach (within the upper portion of the Hydroelectric Reach) would be the same as the Proposed Project

(Potential Impact 3.20-5) and would be significant and unavoidable. There would be no significant impact in the Middle and Lower Klamath River.

Under the Three Dam Removal Alternative, removal of Copco No. 1, Copco No. 2 and Iron Gate dams and construction of upstream and downstream fish passage at J.C. Boyle Dam would beneficially affect recreational fishing of anadromous fish (Chinook and coho salmon, steelhead trout, Pacific lamprey, and redband trout) throughout the Hydroelectric Reach in California, as described for the Proposed Project (Potential Impact 3.20-6). The primary difference under the Three Dam Removal Alternative is that approximately 3.5 miles of aquatic habitat within J.C. Boyle Reservoir would remain lentic rather than reverting to the riverine conditions described for the Proposed Project; however, this would occur in Oregon and so would not affect California recreational fishing.

The Three Dam Removal Alternative would result in the same impacts to river-based recreational facilities in the Middle Klamath River and Lower Klamath River as the Proposed Project (Potential Impact 3.20-6). Water quality improvements would be beneficial for the Hydroelectric Reach, the Middle Klamath River downstream of Humbug Creek (RM 174.3), and the Lower Klamath River. With respect to potential flooding impacts to existing river-based recreational facilities, maintaining J.C. Boyle Reservoir would not affect flood hydrology, relative to Proposed Project or to existing conditions, in the Hydroelectric Reach or further downstream Middle Klamath River and Lower Klamath River (see also Section 4.6.6 *Flood Hydrology*). As under the Proposed Project, there would be little to no change to the 100-year floodplain extent in the Klamath River and Lower Klamath River, with the exception of the reach along the Middle Klamath River from Iron Gate Dam (RM 193.1) to the confluence with Humbug Creek (RM 174.0), where the 100-year floodplain extent would change slightly due to removal of the California Lower Klamath Project dams. However, the slightly increased potential for flooding in this reach would not represent a change or loss of a rare or unique river-based recreational facility affecting a large area or substantial number of people and therefore impacts to recreation under the Three Dam Removal Alternative would be the same as those described for the Proposed Project (Potential Impact 3.20-6) and would be less than significant.

4.6.21 Hazards and Hazardous Materials

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. Although there would be less construction for fish passage than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts due to hazards and hazardous materials since J.C. Boyle is in Oregon. Construction activities in Oregon under this alternative would not change the hazards and hazardous materials analysis for California because the transport, use, and disposal of general construction waste materials (e.g., concrete, rebar, building waste, power lines) associated with J.C. Boyle Dam removal and fish passage construction, as well as construction-related activities that could result in the accidental release of hazardous materials to the environment, would occur in Oregon. Potential construction-related impacts would be the same as those of the Proposed Project (Potential Impacts 3.21-1, 3.21-2, 3.21-4, and 3.21-7) and would be significant. Implementation of Mitigation Measure HZ-1 would result in no significant impacts for these construction-related impacts. With respect to removal of the Lower Klamath Project reservoirs as a readily available source of water for helicopter fire suppression crews fighting local fires, the two largest reservoirs (Copco No. 1 and Iron Gate) would still be removed under this alternative, which would substantially increase the public's risk of loss, injury or death associated with wildfires as described for the Proposed Project (Potential Impact 3.21-8). J.C. Boyle Reservoir would remain in place and would continue to serve as a relatively accessible water surface for helicopter fire suppression crews compared to the mainstem Klamath River. However, because J.C. Boyle Reservoir is approximately 20 river miles upstream of Copco No. 1 Reservoir and has a relatively small surface area (approximately 350 acres versus 942 acres [Iron Gate Reservoir] and 972 acres [Copco No. 1 Reservoir], see also Table 2.3-1), response and travel times between water fills would still be increased over existing conditions and the Proposed Project for helicopter crews to fly to J.C. Boyle Reservoir for water pick up. Thus, the Three Dam Removal Alternative would result in a substantial increased public risk of loss, injury, or death involving wildland fires due to increased response and travel times relative to existing conditions and would be a significant impact.

4.6.22 Transportation and Traffic

Relative to the Proposed Project, leaving the J.C. Boyle Dam and associated facilities in place would reduce overall construction activities related to dam removal. However, the Three Dam Removal Alternative also includes removing the existing fish ladder and installing a new fish ladder. If instead of fish ladders, trap and haul or some combination of fish passage methods were used, the level of construction activities at J.C. Boyle would be further reduced relative to the Proposed Project. Although there would be less construction for fish passage than removing the dam and associated facilities, this difference would not meaningfully decrease the degree of construction activities or the associated impacts to traffic and transportation since J.C. Boyle is in Oregon. Note that J.C. Boyle Dam-associated vehicle trips are included in the analysis of the Proposed Project as some of the construction-related traffic flow may use roads in California (e.g., I-5 to OR 66). As described in Section 3.22.5 *[Transportation and Traffic] Potential Impacts and Mitigation*, the Proposed Project would result in significant and unavoidable short-term impacts to traffic flow, road safety, road conditions, emergency access, public transit, and non-motorized transportation, unless and until KRRC reaches enforceable 'good citizen' agreements that are finalized and implemented through the FERC process and that include proposed items for the final TMP and Emergency Response Plan (Appendix B: *Definite Plan − Appendices O1 through O4*), as well as the additional components included in Recommended Measure TR-1 (Potential Impacts 3.22-1 through 3.22-5). As described for the Proposed Project, the Lower Klamath Project dams are not located within two miles of an airport nor would their removal result in a change in air traffic patterns that would result in a substantial safety risks, regardless of whether J.C. Boyle Dam remains place, and there would be no significant impact (Potential Impact 3.22-6).

4.6.23 Noise

The level of overall construction activities due to dam deconstruction in California and construction of upstream and downstream fish passage in Oregon under the Three Dam Removal Alternative would be the same as those described for the Proposed Project. Whether J.C. Boyle Dam remains or is removed would not affect noise impacts within the Proposed Project Area of Analysis due to J.C. Boyle Dam's location in Oregon, approximately 20 miles upstream of the Oregon-California state line. For the reasons described in Section 3.23.5 *[Noise] Potential Impacts and Mitigation Measures*, removal of Copco No. 1, Copco No. 2, and Iron Gate dams would result in noise and vibration that will affect sensitive receptors and exceed Siskiyou County General Plan standards under this alternative. Significant and unavoidable adverse environmental impacts would result from: construction equipment exceeding maximum allowable noise levels (Potential Impact 3.23-1); noise disturbance to residents from construction-generated noise at Copco No. 1 and Iron Gate dams (Potential Impacts 3.23-2 and 3.23-4), reservoir restoration at Copco No.1 and Iron Gate dams (Potential Impact 3.23-5); and vibration disturbance from blasting activities at Copco No. 1, Copco No. 2, and Iron Gate dams (Potential Impact 3.23-6). Other noise and vibration generation from the Three Dam Removal Alternative would not have a significant adverse impact (Section 3.23-5 *[Noise] Potential Impacts and Mitigation*).

4.7 No Hatchery Alternative

4.7.1 Introduction

4.7.1.1 Alternative Description

The No Hatchery Alternative is the same as the Proposed Project except that operations at the Iron Gate Hatchery would cease at the time of dam removal and would not continue for eight years following dam removal, and the Fall Creek Hatchery would not reopen with upgraded facilities. Under this alternative, all hatchery production of salmonids would be discontinued after hatchery releases occur in the fall of dam removal year 1 and the production goals for the Proposed Project as identified in Section 2.7.6 *Hatchery Operations* would not occur.

Post-dam removal adult fall-run Chinook salmon could continue to return to the former location of the hatchery through post-dam removal year 2 (age 4 returning adults), and post-dam removal adult coho salmon could continue to return potentially through post-dam removal year 1 (age 3 adults) (Table 4.7-1).

Table 4.7-1. Natural (N) and Hatchery (H) smolts and adult returns in Klamath River under the No Hatchery Alternative.

Species		Dam Removal Year		Post-dam Removal Year			
		1[a]	2[b]	1	2	3	4
Chinook salmon	Produced	N and final H smolts (age 0 in spring and age 1 in fall)	N smolts	N smolts from new habitat	N smolts	N smolts	N smolts
	Returning	N and H adults (age 3–4) downstream of Iron Gate Dam	N and H adults access new habitat	N and H adults	N and last H adults (age 4, progeny of post-dam removal year 1 outmigration)	N adults (age 3) from new habitat	N adults
Coho salmon	Produced	N and final H smolts (age 1)	N smolts	N smolts	N smolts from new habitat	N smolts	N smolts
	Returning	N and H adults (age 3) downstream of Iron Gate Dam	N and H adults access new habitat	N and last H adults (age 3, progeny of post-dam removal year 1 outmigration)	N adults	N adults (age 3) from new habitat	N adults

[a] Final year of hatchery releases occurs in dam removal year 1. Early drawdown of Copco No. 1 begins in dam removal year 1.
[b] Drawdown of all reservoirs occurs and dams are removed in dam removal year 2 (see Table 2.8-1).
H hatchery releases or progeny
N progeny of natural spawning (natural-origin)

Under the No Hatchery Alternative, construction activities would include all those identified under the Proposed Project, except that Iron Gate Hatchery facilities would be completely removed, instead of partially removed and redeveloped as under the Proposed Project (Section 2.7.1.4 *Iron Gate Dam and Powerhouse*). The fish trapping and holding facilities at the toe of Iron Gate Dam and the cold-water supply for the hatchery would be removed, consistent with the Proposed Project, but they would not be relocated. In order to make a conservative assumption about the greatest potential impact, this alternative assumes that all Iron Gate Hatchery facilities would be demolished, rather than re-purposed or decommissioned in place. Additional deconstruction activities at Iron Gate Hatchery under this alternative would therefore include removal of all weirs, traps, additional holding pools, raceways, tanks, buildings, and other infrastructure (see also Figure 2.3-4 and Section 2.7.1.4 *Iron Gate Dam and Powerhouse*). Iron Gate Hatchery facilities would be removed as part of dam deconstruction activities starting January 1 of dam removal year 2. Under the No Hatchery Alternative, water diversion from Bogus Creek to operate the Iron Gate Hatchery would not be needed, so the diversion for the hatchery water supply would not be constructed near the confluence of Bogus Creek and the Klamath River (Section 2.7.6 *Hatchery Operations*).

Under the No Hatchery Alternative, the Fall Creek Hatchery would not reopen with upgraded facilities (e.g., renovated raceways, upgraded plumbing) for raising coho salmon and Chinook salmon. Construction of the settling pond would not be needed on Parcel B lands downstream of the Fall Creek Hatchery. Water diversion from the PacifiCorp Fall Creek powerhouse return canal downstream of the City of Yreka's diversion facility at Fall Creek Dam A would not be needed. As Fall Creek Hatchery is part of PacifiCorp's Klamath Hydroelectric Project No. 2082, the existing Fall Creek Hatchery facilities are subject to the terms of any new FERC action for Project No. 2082. Accordingly, this alternative analysis assumes the status quo, i.e., that the Fall Creek Hatchery facilities would not be demolished or re-purposed.

4.7.1.2 Alternative Analysis Approach

The potential impacts of the No Hatchery Alternative are analyzed in comparison to existing conditions, with reference to impact analyses conducted for the Proposed Project, where appropriate. Unless otherwise indicated, the significance criteria, area of analysis, environmental setting, and impact analysis approach, including consideration of existing local policies, for all environmental resource areas under the No Hatchery Alternative are the same as those described for the Proposed Project (see Section 3.1 *Introduction* and individual resource area subsections in Section 3 *Environmental Setting, Potential Impacts, and Mitigation Measures*). The potential impacts for each environmental resource area are analyzed both in the short term and the long term, and unless otherwise indicated, use the same definitions of short term and long term as described for each resource area analyzed for the Proposed Project.

4.7.2 Water Quality

With the exception of potential water quality effects related to hatchery operations, the No Hatchery Alternative would have the same potential short-term and long-term impacts on water temperature, suspended sediments, nutrients, dissolved oxygen, pH, chlorophyll-*a*, algal toxins, and inorganic and organic contaminants relative to existing conditions as those described for the Proposed Project (Potential Impacts 3.2-1 through

3.2-18). Potential short-term impacts on water quality would be the same as those described for the Proposed Project because full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and related short-term impacts to water quality as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades that are included under the Proposed Project.

Under this alternative, there would be no discharges from Iron Gate Hatchery to the Middle Klamath River. While these hatchery discharges would be eliminated under this alternative, hatchery discharges under existing conditions have a less than significant impact on water quality, including water temperature, suspended material, nutrients, biochemical oxygen demand, and inorganic and organic contaminants (i.e., water treatment chemicals) based on an evaluation of the water quality impacts of California Department of Fish and Wildlife hatcheries, including Iron Gate Hatchery (ICF 2010) (for more detail see Potential Impact 3.2-17). There would be no changes to water quality in Fall Creek or the Klamath River under this alternative relative to existing conditions since Fall Creek Hatchery production has been zero since 2003 and it would remain zero under this alternative. Potential impacts to water quality in Fall Creek and the Klamath River under the Proposed Project (see Potential Impact 3.2-17) would not occur under this alternative since the Fall Creek Hatchery would not be reopened, fish production and associated water quality changes would not occur, and there would be no upgrades to Fall Creek Hatchery facilities to accommodate the fish production specified under the Proposed Project.

Overall, eliminating the Iron Gate Hatchery effluent discharges would reduce potential less-than-significant variations in water quality due to hatchery discharges compared to existing conditions or the lower fish production conditions under the Proposed Project, thus there would be no significant impact on water quality due to ceasing Iron Gate Hatchery operations under the No Hatchery Alternative. Additionally, there would be no change in water quality under this alternative compared to existing conditions due to Fall Creek Hatchery fish production continuing to be zero and potential impacts to water quality due to increases in fish production at Fall Creek Hatchery under the Proposed Project would be eliminated, thus there would be no significant impact on water quality due to Fall Creek Hatchery remaining closed under the No Hatchery Alternative.

4.7.3 Aquatic Resources

Potential impacts to most aquatic ecological attributes (e.g., suspended sediment, bedload, water quality, algal toxins, aquatic habitat, and instream flows) under the No Hatchery Alternative would be the same as impacts under the Proposed Project, described in Section 3.3.5 *[Aquatic Resources] Potential Impacts and Mitigation,* except that impacts to aquatic ecological attributes related to incidence of fish disease and resource competition would be different under the No Hatchery Alternative, as compared with those of the Proposed Project.

The current infectious nidus (i.e., the river reach exhibiting the highest infectivity) for salmonid smolts for *C. shasta* and *P. minibicornis* appears to be the result of the synergistic effect of high spore input from heavily infected spawned adult salmon that congregate downstream from Iron Gate Dam and Iron Gate Hatchery, and the proximity of congregating salmonids to dense populations of polychaetes (Bartholomew et al. 2007). Juveniles released from Iron Gate Hatchery may also contribute to the infectious nidus, as hatchery released juvenile fish that become infected and experience mortality further downstream in the Klamath River may become another source of myxospores threatening aquatic resources in the Middle and Lower Klamath River (Som et al. 2016c).

Discontinuing hatchery operations would eliminate the congregation of returning hatchery adults to the reach immediately downstream of Iron Gate Dam beginning in post-dam removal year 3 (Table 4.6-1), because dam removal would increase the likelihood that adults would disperse further upstream beginning in post-dam removal year 1 (note that the effect of dam removal on fish disease and parasites is described in more detail in Section 3.3.5 *[Aquatic Resources] Potential Impacts and Mitigation*).

In addition, beginning in dam removal year 2, hatchery juveniles would no longer be released during the natural smolt outmigration period. The Chinook salmon released to the Klamath River annually also likely result in deleterious effects on natural-origin populations, including competitive pressure between hatchery-derived and natural-origin fish in the limited habitat areas (e.g., thermal refugia) used by rearing juveniles in the Klamath River (NMFS 2010a). Iron Gate Hatchery releases Chinook salmon from the middle of May to the end of June, a period when discharge from Iron Gate Dam is in steep decline and water temperatures are rapidly rising, which may create competition between hatchery and natural-origin fish (Chinook salmon, coho salmon, and steelhead) for food and limited resources, especially limited space and resources in thermal refugia (NMFS 2010a). Negative hatchery effects due to competition, leading to displacement and lower growth, are well documented (Flagg et al. 2000, McMichael et al. 1997). In the Clackamas River, Oregon, hatchery steelhead released in the upper basin resulted in an exceedance of system carrying capacity, resulting in negative outcomes for natural-origin fish (Kostow et al. 2003 and Kostow and Zhou 2006), up to a 50 percent decline in the number of recruits per spawner, and a 22 percent decline in the maximum number of natural-origin recruits. These trends appear to have reversed after releases of hatchery fish were discontinued in 2000. Such density-dependent negative effects of hatchery-released fish can extend even into the marine environment, especially during periods of poor ocean conditions (Beamish et al. 1997a, Sweeting et al. 2003). Therefore, it is anticipated that the No Hatchery Alternative would result in reduced impacts to juvenile salmonids from resource competition.

Reservoir drawdown associated with dam removal under the No Hatchery Alternative could directly impact aquatic species. In addition, the removal of the Lower Klamath Project dams and reservoirs could alter the availability and quality of habitat in the Klamath River, resulting in direct and indirect effects on aquatic species. With a few exceptions, potential impacts under this alternative would be the same as those described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-1 through Potential Impact 3.3-24) since discontinuing hatchery operations in dam removal year 2 is the only difference between this alternative and the Proposed Project. While the Proposed Project includes continued operation of Iron Gate Hatchery for eight years using flows diverted from Bogus Creek (Section 3.3.5.9, Potential Impact 3.3-23) and the reopening of Fall Creek Hatchery for eight years using flows diverted from Fall Creek (Section 3.3.5.9, Potential Impact 3.3-24), the No Hatchery Alternative does not include continued hatchery operations, and thus there would be no flow diversions from Bogus Creek or Fall Creek and no change relative to existing conditions.

The No Hatchery Alternative includes aquatic resource measures described for the Proposed Project in Section 3.3.5.9, including AR-1 (Mainstem Spawning), AR-2 (Juvenile Outmigration), AR-6 (Suckers), and AR-7 (Freshwater Mussels). Similarly, mitigation measures AQR-1 (Mainstem Spawning) and AQR-2 (Juvenile Outmigration) (described in Section 3.3.5.9, Potential Impact 3.3-1) are included. However, Aquatic Resource Measure AR-4 (Iron Gate Hatchery Management) and Mitigation Measure AQR-3 (Bogus Creek Flow Diversions) would not be included, since both pertain to the Iron Gate Hatchery, which would not be operational under this alternative. Potential impacts to fish species currently propagated at Iron Gate Hatchery (i.e., fall-run Chinook salmon and coho salmon) that would differ from impacts described under the Proposed Project are discussed below.

Potential Impact 3.3-7 Effects on the fall-run Chinook salmon population due to short-term sediment releases and long-term changes habitat quality, habitat quantity, and hatchery operations due to dam removal.
In the short term, reservoir drawdown under the No Hatchery Alternative would result in elevated suspended sediment concentrations (SSCs) and altered sand and finer bedload sediment transport and deposition and would adversely impact fall-run Chinook salmon primarily in the Middle Klamath River downstream of Iron Gate Dam, as described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*). Also consistent with the Proposed Project, the effect of SSCs from the No Hatchery Alternative on the fall-run Chinook salmon population, under all scenarios, would not be expected to substantially reduce the population in the short term.

Under the No Hatchery Alternative, hatchery Chinook salmon smolts (age 0 released in spring) and yearlings (age 1 released in fall) would no longer be released into the Klamath River as occurs under existing conditions. From 1978 through 2016, returns of fall-run Chinook salmon adults to the Iron Gate Hatchery have ranged from 2,558 (in 1980) to 72,474 (in 2001), with an average of 16,559 fish (CDFW 2016b). During the same period, natural-origin returns in the Klamath River (not including Trinity River) ranged from 6,957 to 91,757 fall-run Chinook salmon, with an average of 31,379 fish (CDFW 2016a). While natural-origin returns typically outnumber hatchery returns, the proportion of the Chinook salmon escapement comprised of Iron Gate Hatchery returns has historically been substantial (~35 percent of age 3 adults; KRTT 2011, 2012, 2015). Eliminating the hatchery goal of releasing around 6 million Chinook salmon smolts and yearlings annually would likely result in a reduction in adult hatchery returns to the Klamath River. Most adult returns are age 3 (around 75 percent), with some age 4 (around 23 percent), and a few age 5 (<2 percent) fish (KRTT 2011, 2012, 2015). As a result, progeny of hatchery releases would likely return as adults, continuing mostly through post-dam removal year 1 (i.e., 4-year old returns, see Table 4.7-1). The first adult returns from the progeny of natural-origin fish fall-run Chinook salmon using newly accessible habitat upstream of Iron Gate Dam would be expected during post-dam removal year 3 (i.e., 3-year old returns); it is anticipated that initial returns would be low in abundance as the newly accessible habitat is gradually seeded. Based on historical data (CDFW 2016b), the reduction in returns could average around 16,000 fish beginning in post-dam removal year 3, as the population responds to the benefits of dam removal. Based on the current proportion of hatchery adults in the run, this could represent a short-term reduction in abundance of around 35 percent of age 3 adults on average until production from newly accessible habitat increases adult escapement (anticipated to begin in dam removal year 3, Table 4.6-1). However, depending on the year, the reduction could be as high as 50 percent (the proportion of hatchery return adult spawners in 1993 for example), or as low as 19 percent (the proportion in 1995) (KRTT 2015). The impact of a reduction in the number of hatchery returning fish is not equivalent to a reduction in the natural-origin population, from a population perspective. These adults are progeny of hatchery releases, and they typically return to the hatchery without contributing to the long-term sustainability of the fall-run Chinook salmon population. As discussed in detail in Section 3.3.2.3 *Habitat Attributed Expected to be Affected by the Proposed Project [Fish Hatcheries]*, hatchery returning adults can have substantial detrimental effects on native populations. As such, a reduction in hatchery returns under this alternative would be a benefit for fall-run Chinook salmon over the long term.

Under the No Hatchery Alternative, dam removal would increase habitat access for fall-run Chinook salmon, as described for the Proposed Project. As described in Section 3.3.5.9 *Aquatic Resource Impacts*, quantitative modeling of fall-run Chinook salmon populations suggests that the Proposed Project has a higher likelihood of resulting in increased Chinook salmon abundance than other management scenarios (e.g., continuation of existing conditions) (Oosterhout 2005, Huntington 2006, Dunsmoor and Huntington 2006, Hendrix 2011, Lindley and Davis 2011). Of the available models, the Hendrix (2011) life-cycle model (Evaluation of Dam Removal and Restoration of Anadromy [EDRRA]) approach is considered the most intensive and robust conducted to date. Since the model predictions are based on increased habitat access, the same gains would be expected for the No Hatchery Alternative as for the Proposed Project.

The rate at which recolonization and full post-dam removal fish production occurs would be partially dependent on the number of fish (natural-origin and hatchery strays) available and their ability to persist and adapt to the new habitat conditions. Although eight years of additional hatchery production under the Proposed Project is anticipated to achieve the production levels predicted by the EDRRA model sooner than without continued hatchery production, immediate closure of Iron Gate Hatchery and no production at Fall Creek Hatchery would eliminate most interbreeding of hatchery and natural-origin salmon by post-dam removal year 3, and would likely increase the rate at which Chinook salmon develop traits adapted to their new habitats upstream of Iron Gate Dam (Goodman et al. 2011). This could increase survival of natural-origin Chinook salmon at a faster rate than with continued hatchery operations under the Proposed Project. Goodman et al. (2011) note that this effect would depend, in part, on the degree to which local Chinook salmon stocks have been integrated into the hatchery brood stock and the degree to which the current mixed hatchery and natural-origin spawning population has maintained genetic potential for life history diversity to adapt to conditions upstream of Iron Gate Dam.

As described above in Section 4.7.3 *Aquatic Resources*, mortality from disease has the potential be reduced under this alternative more quickly than under the Proposed Project, since the release of Chinook and coho salmon would cease in dam removal year 2, rather than after eight additional years of hatchery releases.

The cessation of juvenile fish releases from Iron Gate Hatchery may also significantly decrease the amount of competition for food resources and habitat space between hatchery-reared and natural-origin smolts and yearlings in the Klamath River. This would result in higher growth rates for natural-origin fish (McMichael et al. 1997), and thus larger size at ocean entry beginning in dam removal year 2. Smolt size is correlated with increased marine survival for Chinook salmon (Scheuerell et al. 2009, Feldhaus et al.

2016), which in conjunction with reduced competition with hatchery smolts in the marine environment (Sweeting et al. 2003), would likely result in increased adult returns as soon as post-dam removal year 2 (i.e., 3-year-old adult returns).

Summary
In the short term, elevated SSCs and altered sand and finer bedload sediment transport and deposition and would adversely affect fall-run Chinook salmon primarily in the Middle Klamath River downstream of Iron Gate Dam, as described for the Proposed Project (Potential Impact 3.3-7), but would not be expected to substantially reduce the population. However, the elimination of hatchery produced fall-run Chinook salmon would likely result in a reduction (averaging 35 percent, potentially ranging from 19 to 50 percent based on existing conditions) in adult returns beginning in post-dam removal year 3 and continuing for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal predicted by the EDRRA model for adult fall-run Chinook salmon are realized. In comparison with the Proposed Project, the natural-origin Chinook salmon population may adapt more quickly to restored habitat and benefit sooner from decreased competition and disease interactions, potentially reducing the period of short-term impacts. Overall, based on data from 1985 through 2014 (KRRT 2015), natural-origin returns of adult fall-run Chinook salmon have always outnumbered hatchery adult returns in the Klamath River Basin, and hatchery returns have never been estimated to be greater than 50 percent of the escapement in any year and are typically around 35 percent. Furthermore, hatchery returning adults are considered detrimental to the sustainability of natural spawning populations. Therefore, no substantial (> 50 percent) reduction in fall-run Chinook salmon abundance of a year-class is predicted to occur in the short term and this alternative would result in a less than significant impact.

In the long term, removal of the Lower Klamath Project dams under the No Hatchery Alternative would increase habitat availability, restore a more natural flow regime and seasonal variation in water temperature, improve water quality, and reduce the likelihood of fish disease and algal toxins, all of which would be beneficial for fall-run Chinook salmon. As described for the Proposed Project, if fish passage is not provided a Keno Impoundment/Lake Ewuana, restored habitat access to the Hydroelectric Reach and the multiple benefits of the Proposed Project would be beneficial for fall-run Chinook salmon in the long term. If fish passage were provided (per DOI [2007] fish passage prescriptions), an even greater magnitude of restored habitat access to the Upper Klamath River Basin and the multiple benefits of the No Hatchery Alternative would be beneficial for fall-run Chinook salmon in the long term.

Significance
No significant impact for fall-run Chinook salmon in the short term

Beneficial for fall-run Chinook salmon in the long term

Potential Impact 3.3-8 Effects on the spring-run Chinook salmon population due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.
In the short term, reservoir drawdown under the No Hatchery Alternative would increase SSCs and bedload sediment transport and deposition and impact spring-run Chinook salmon, as described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*). However, based on the distribution of spring-run Chinook salmon in the lower

Klamath River Basin (e.g., within the Salmon and Trinity rivers), the overall effect of suspended sediment from the Proposed Project on the spring-run Chinook salmon population is not anticipated to differ substantially from existing conditions. Also consistent with the Proposed Project, no reduction in the abundance of a year class is predicted in the short term.

Under the No Hatchery Alternative, coho and fall-run Chinook salmon yearlings and smolts would no longer be released into the Klamath River. There are currently no releases of spring-run Chinook salmon from hatcheries into the Klamath River. Therefore, the closure of the Iron Gate Hatchery is not anticipated to result in a decline in adult returns for spring-run Chinook salmon. However, as described above in Section 4.7.3 *Aquatic Resources*, outmigrant spring-run Chinook smolt mortality due to disease would be reduced under this alternative more quickly than under the Proposed Project, since the release of fall-run Chinook and coho salmon would cease in dam removal year 2, rather than after eight additional years of hatchery releases following dam removal. The cessation of juvenile fish releases from Iron Gate Hatchery in conjunction with dam removal may also significantly decrease the amount of competition for food resources and habitat space between hatchery-reared and natural-origin smolts in the Klamath River. This would result in higher growth rates for natural-origin fish (McMichael et al. 1997) and thus larger size at ocean entry beginning in dam removal year 2. Smolt size is correlated with increased marine survival for Chinook salmon (Scheuerell et al. 2009, Feldhaus et al. 2016), which in conjunction with reduced competition with hatchery smolts in the marine environment (Sweeting et al. 2003) is anticipated to result in increased adult returns as soon as post-dam removal year 2 (i.e., 3-year-old adult returns). Therefore, ending hatchery operations under this alternative may result in a more rapid increase in the spring-run Chinook salmon adult population as a result of dam removal than under the Proposed Project.

Summary

In the short term, elevated SSCs and bedload sediment transport and deposition would adversely impact spring-run Chinook salmon, but based on the distribution of spring-run Chinook salmon in the lower Klamath River Basin (e.g., within the Salmon and Trinity rivers) the overall effect on the population is not anticipated to differ substantially from existing conditions and no reduction in the abundance of a year class is predicted.

Under the No Hatchery Alternative, the elimination of hatchery produced salmonids would not affect spring-run Chinook salmon adult returns in the short term. As described for the Proposed Project, this alternative includes aquatic resource measure AR-2 (Juvenile Outmigration) to reduce the short-term effects of SSCs on spring-run Chinook salmon smolts. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measure AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4 (Section 3.3.5.9 *Aquatic Resource Impacts*), would even further reduce the potential for short-term effects of the No Hatchery Alternative on spring-run Chinook salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measure. With implementation of resource measures, there would still be short-term impacts on spring-run Chinook salmon, including some potential direct mortality, but there would not be a substantial reduction in the abundance of a year class. The impact of the No Hatchery Alternative would be less than significant for spring-run Chinook salmon in the short term.

In the long term, removal of the Lower Klamath Project dams under the No Hatchery Alternative would improve habitat availability, flow regime, water quality, seasonal water temperature variation, and would reduce or eliminate algal toxins, all of which would benefit spring-run Chinook salmon. Dam removal would restore connectivity to hundreds of miles of historical habitat in the Upper Klamath Basin and would create additional habitat within the Hydroelectric Reach. The No Hatchery Alternative would be beneficial for spring-run Chinook salmon in the long term.

Significance

No significant impact for spring-run Chinook salmon in the short term

Beneficial for spring-run Chinook salmon in the long term

Potential Impact 3.3-9 Effects on coho salmon populations due to short-term sediment releases and long-term changes in habitat quality, habitat quantity, and hatchery operations due to dam removal.

In the short term, reservoir drawdown under the No Hatchery Alternative would increase SSCs and bedload sediment transport and deposition and impact coho salmon, as described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts; Potential Impact 3.3-9*). In general, the wide distribution and use of tributaries by both juvenile and adult coho salmon would likely protect the population from the worst short-term impacts of this alternative. However, direct mortality is anticipated for redds from the Upper Klamath River Population Unit (at most 13 redds based on historic data, see Appendix E). As described for the Proposed Project (Section 3.3.5.9 *Aquatic Resource Impacts*; Potential Impact 3.3-9), no mortality is anticipated for the other population units.

Under the No Hatchery Alternative, hatchery coho salmon smolts (age 1 released in fall) would no longer be released into the Klamath River. Iron Gate Hatchery has a goal to produce 75,000 coho salmon smolts on an annual basis, although that goal has only been met in three of the last seven years (2011–2017). Overall, coho salmon yearling smolt goals are achieved on average (K. Pomeroy, CDFW, pers. comm., 2018). Based on current production levels, ceasing operations would likely result in a reduction of up to 75,000 coho salmon smolts per year beginning in dam removal year 2 (Table 4.7-1). Based on the current low abundance of coho salmon in the upper Klamath River population unit, a conservation focus for the coho salmon program has been deemed necessary to protect the remaining genetic resources of that population unit (CDFW 2014). Coho salmon adult returns to Iron Gate Hatchery have significantly and steadily declined from a high of 2,466 adults in the 2001/2002 return year to 38 adults in the 2015/2016 return year, with an annual average of 866 (CDFW 2016b). Assuming coho smolts would be released for the last time in dam removal year 1 (Table 4.7-1), adults of hatchery progeny would continue to return through post-dam removal year 1 (as age 3 adults). Based on the average coho salmon smolt-to-adult survival ratio of 0.99 percent estimated for current coho salmon Iron Gate Hatchery operations (CDFW 2014), a reduction in the release of 75,000 coho salmon smolts following closure of Iron Gate Hatchery could result in a decline of around 743 adult returns on average annually starting in post-dam removal year 2 (Table 4.7-1). These adults would return to the Iron Gate Hatchery, but also stray into tributaries (primarily Bogus Creek) and spawn naturally. Between 2004 and 2011 an average of 46 coho salmon hatchery adults per year strayed into Bogus Creek (CDFW 2014).

Under existing conditions, CDFW (2014) estimates that greater than 30 percent on average of the total adult returns to the Upper Klamath River are of hatchery origin, including greater than 70 percent of returns to the hatchery, around 34 percent of returns to Bogus Creek, and around 16 percent of returns to tributaries such as the Shasta and Scott rivers. The natural abundance of coho salmon adults in the Upper Klamath Population Unit is less than 200 fish, and in some years the majority of natural-origin spawning is from adults of hatchery origin (CDFW 2014).

Assuming that hatchery production ceases in dam removal year 1, the total reduction in coho salmon returns in post-dam removal year 2 (i.e., after hatchery returns have ended and prior to realization of dam removal habitat benefits) would vary depending on population unit, and it could be substantial (> 50 percent) in the Upper Klamath River Population Unit depending on strength of the natural-origin returning spawners. Reductions are anticipated to be less than substantial (< 20 percent reduction) for the other population units. While the impact could be substantial for the upper Klamath River coho salmon population unit In the short term, the overall short-term impact on coho salmon populations in the Klamath River Basin would not be substantial. In addition, the impact of a reduction in the number of hatchery returning fish is not equivalent to a reduction in the natural spawning population, from a population perspective. These adults are progeny of hatchery releases, and typically return to the hatchery without contributing to the long-term sustainability of the coho salmon population. As discussed in detail in Section 3.3.2.3 *Habitat Attributed Expected to be Affected by the Proposed Project [Fish Hatcheries]*, hatchery returning adults can have substantial detrimental effects on native populations; as addressed by CDFWs plan to operate the hatchery for coho salmon conservation (CDFW 2014).

In addition, and as described in Section 3.3.2.3 *Habitat Attributes Expected to be Affected by the Proposed Project* and summarized in CDFW (2014), there are adverse hatchery-related effects on the coho salmon population, including straying of Iron Gate Hatchery fish into important tributaries with the potential to reduce the reproductive success of the natural population (Mclean et al. 2003, Chilcote 2003, Araki et al. 2007) and negatively affect the diversity of the interior Klamath populations via outbreeding depression[231] (Reisenbichler and Rubin 1999). As described above in Section 4.7.3 *Aquatic Resources*, outmigrant smolt mortality from disease would be reduced under the No Hatchery Alternative more quickly than under the Proposed Project, since the release of Chinook and coho salmon would cease in dam removal year 2, rather than after eight additional years of hatchery releases. The cessation of juvenile fish releases from Iron Gate Hatchery may also significantly decrease the amount of competition for food resources and habitat space between hatchery-reared and natural-origin spawned smolts in the Klamath River. This would result in higher growth rates for natural-origin spawned fish (McMichael et al. 1997), and thus larger size at ocean entry beginning in dam removal year 2. Smolt size is correlated with increased marine survival for coho salmon (Holtby et al. 1990), which in conjunction with reduced competition with hatchery smolts in the marine environment (Sweeting et al. 2003) would likely result in increased adult returns as soon as post-dam removal year 2 (i.e., 3-year-old adult returns). Therefore, ending hatchery operations as part of dam removal may result in a more rapid increase in the adult coho salmon population as compared with the Proposed Project.

[231] Outbreeding depression is progeny that are less adapted to the environment than parents.

As described for the Proposed Project (Section 3.3.5.9, Potential Impact 3.3-9), under the No Hatchery Alternative, dam removal and the associated habitat improvements would likely result in an increase in coho salmon abundance. The first adults that could potentially access the newly available habitat upstream of Iron Gate Dam would occur in dam removal year 2, and they would produce progeny benefiting from improved river function in post-dam removal year 1. Therefore, the first adult returns that could reflect the improved habitat conditions would occur in post-dam removal year 4 (i.e., as age 3 adults).

Summary

In the short term, reservoir drawdown under the No Hatchery Alternative would increase SSCs and bedload sediment transport and deposition and adversely impact coho salmon, as described for the Proposed Project. In general, the wide distribution and use of tributaries by both juvenile and adult coho salmon would likely protect the population from the worst short-term impacts of this alternative. However, direct mortality is anticipated for redds from the Upper Klamath River Population Unit (at most 13 redds based on historic data, see Appendix E). No mortality is anticipated for the other population units.

The elimination of hatchery produced coho salmon would likely result in a reduction in adult returns for a period of one to five years before the benefits of dam removal are realized. Compared with the Proposed Project, the natural coho salmon population would benefit sooner from decreased competition and disease interactions once hatchery releases are eliminated, which would potentially reduce the period of short-term impacts under the No Hatchery Alternative. However, in post-dam removal years 2 and 3 (at a minimum), there would be a 10 to 30 percent reduction in adult returns (depending on population unit), since this would be after hatchery returns have ended, and prior to the first adults capable of realizing the benefits of dam removal (Table 4.6-1). In addition, closure of the coho salmon hatchery program at Iron Gate Hatchery in dam removal year 1 would result in cessation of the genetic management plan's goal of improving diversity and fitness of Klamath River coho salmon (CDFW 2014). Overall, because there would not be a predicted substantial short-term decrease in coho salmon abundance of a year class, nor would there be a substantial decrease in habitat quality or quantity, there would not be a significant impact to coho salmon under the No Hatchery alternative in the short term.

In addition, and as described for the Proposed Project, although there would be no significant impact on coho salmon In the short term, aquatic resource measures AR-1 (Mainstem Spawning) and AR-2 (Juvenile Outmigration) would occur under the No Hatchery Alternative, which would further reduce the potential for short-term effects of SSCs on salmonid juveniles, smolts, and eggs, including coho salmon. In addition, although CEQA Guidelines Section 15126.4(a)(3) states that mitigation measures are not required for effects which are not found to be significant, mitigation measures AQR-1 and AQR-2, which would be implemented as a result of significant adverse impacts described for Potential Impact 3.3-1 and Potential Impact 3.3-4 (Section 3.3.5.9 *Aquatic Resource Impacts*), would even further reduce the potential for short-term effects of the No Hatchery Alternative on coho salmon by increasing certainty regarding the effectiveness of the proposed aquatic resource measures.

In the long term, removal of the Lower Klamath Project dams under the No Hatchery Alternative would improve habitat availability, flow regime, water quality, seasonal temperature variation, and reduce fish disease incidence and algal toxins, all of which would benefit coho salmon. Dam removal would restore connectivity to habitat on the mainstem Klamath River up to and including Spencer Creek and would create additional habitat within the Hydroelectric Reach. Dam removal would also cause water temperatures to become warmer earlier in the spring and early summer, cooler earlier in the late summer and fall, and have diurnal variations more in sync with historical migration and spawning periods (Hamilton et al. 2011). These changes would result in water temperatures that are more favorable for salmonids in the mainstem.

In the long term, increased adult returns resulting from newly accessible habitat upstream of Iron Gate Dam would offset reductions in adult returns due to cessation of hatchery operations. It is anticipated that as a result of the No Hatchery Alternative, the coho salmon population would experience an increase in abundance, productivity, population spatial structure, and genetic diversity. In general, free flowing river conditions under the No Hatchery Alternative would likely increase adult migration efficiency, decrease outmigrant delay, and increase adult escapement (Buchanan et al. 2011b). The increases associated with dam removal would result in overall increases in the abundance and viability of the coho salmon from all Klamath River population units in the long term.

Significance

No significant impact for coho salmon populations in the short term

Beneficial for coho salmon from all Klamath River population units in the long term

4.7.4 Phytoplankton and Periphyton

The No Hatchery Alternative would have the same potential short-term and long-term impacts on phytoplankton and periphyton as those described for the Proposed Project (Potential Impacts 3.4-1 through 3.4-5). The primary changes to the existing phytoplankton and periphyton conditions under both the Proposed Project and the No Hatchery Alternative are from dam removal and the shift in dynamics from a reservoir system to a riverine system in the Hydroelectric Reach. The difference between the No Hatchery Alternative and either existing conditions or the Proposed Project results from ending operations at Iron Gate Hatchery and not restarting operations at Fall Creek Hatchery. Under the No Hatchery Alternative, discharges from Iron Gate Hatchery, including nutrient discharges, under existing conditions and the Proposed Project would cease. While Iron Gate Hatchery nutrient releases would decrease under the No Hatchery Alternative, the hatchery nutrient discharges are less-than-significant based on an analysis of the water quality impacts of California Department of Fish and Wildlife hatcheries, including Iron Gate Hatchery (ICF 2010) and decreases in hatchery nutrient releases would not necessarily result in a beneficial effect on phytoplankton or periphyton conditions downstream of the hatchery discharge. Thus, phytoplankton and periphyton conditions under the No Hatchery Alternative with no nutrient releases from Iron Gate Hatchery discharges would be similar to existing conditions or the Proposed Project. Potential impacts to dissolved oxygen and water temperature in Fall Creek under the Proposed Project (see Potential Impact 3.2-17) would be eliminated under this alternative since the fish production at Fall Creek Hatchery would not restart and the hatchery discharges would not occur.

Overall, ceasing production and removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would result in no significant difference in phytoplankton and periphyton growth relative to existing conditions or the Proposed Project, thus there would be no significant impact on phytoplankton and periphyton under the No Hatchery Alternative.

4.7.5 Terrestrial Resources

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts to terrestrial resources as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Further, not operating the hatcheries under this alternative would have no bearing on the anticipated long-term changes in terrestrial habitat that would result from removal of the Lower Klamath Project dams, reservoirs, and associated facilities. Therefore, the No Hatchery Alternative would have the same short-term and long-term potential impacts on vegetation communities, culturally significant species, special-status species, wildlife corridors, and habitat connectivity as those described for the Proposed Project (Potential Impacts 3.5-1 through 3.5-24 and 3.5-28 through 3.5-30).

While the Proposed Project includes continued operation of Iron Gate Hatchery for eight years using flows diverted from Bogus Creek (Potential Impact 3.5-26) and the reopening of Fall Creek Hatchery for eight years using flows diverted from Fall Creek (Potential Impact 3.5-27), the No Hatchery Alternative does not include continued hatchery operations, and thus there would be no flow diversions from Bogus Creek or Fall Creek and no impact (no change from existing conditions). Potential impacts on wildlife due to the loss of salmon currently propagated at Iron Gate Hatchery (i.e., fall-run Chinook salmon and coho salmon), which would differ from impacts described under the Proposed Project, is discussed below.

Potential Impact 3.5-25 Effects on wildlife from increased habitat for salmonids and changes in hatchery production.
Full removal of the Iron Gate Hatchery, which currently releases fall-run Chinook and coho salmon smolts and contributes to returning adults, may reduce prey availability for special-status wildlife in the short term. Special-status wildlife such as bald eagle, Barrow’s goldeneye, common loon, and western pond turtle may forage on out-migrating natural and hatchery-produced salmonids and/or on returning adult carcasses.

Under the No Hatchery Alternative, there would be a reduction of outmigrating yearlings and smolts compared to existing conditions. No data are available to accurately estimate the number of naturally produced smolts in the watershed in comparison with hatchery production, but based on adult returns (Section 3.3.2 *[Aquatic Resources] Environmental Setting*), hatchery-origin out-migrating yearlings and smolts currently comprise approximately 35 percent of all fall-run Chinook salmon smolts outmigrating in the mainstem Klamath River (Section 4.7.2, Potential Impact 3.3-7), and around 30 percent on average of the total coho salmon smolt production (Section 4.7.2, Potential Impact 3.3-9). Thus, under this alternative, beginning in dam removal year 2 hatchery juveniles would not be released during the natural spring smolt outmigration period and prey availability for raptors and mammals during this period would be reduced by over 30 percent. Yearling and smolt production would begin to increase again following dam removal (i.e., post-dam removal year 1) since both (previously released) hatchery and natural-origin adults would have access to new habitat for spawning. Production would occur in post-dam removal year 1 (see also Section 3.3.5.6 *Fish Hatcheries*), and on average would be expected to increase the availability of outmigrating salmonids as prey for wildlife each year following dam removal.

With respect to adult returns, the elimination of hatchery produced fall-run Chinook salmon would likely result in a reduction (averaging 35 percent, potentially ranging from 19 to 50 percent based on existing conditions) in adult returns in the fall beginning in post-dam removal year 3 and continuing for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal are realized (see Section 4.7.3 *Aquatic Resources*, Potential Impact 3.3-7). The elimination of hatchery produced coho salmon would likely result in a reduction in adult returns for a period of one to five years before the benefits of dam removal are realized (see Section 4.7.3 *Aquatic Resources*, Potential Impact 3.3-9).

Although a variety of wildlife prey directly forage on outmigrating smolts or adult returns originating from Iron Gate Hatchery, bald eagles would be the most likely state-listed special-status species to do so in the Klamath Basin; other state species of special concern that forage on fish include the western pond turtle, Barrow's goldeneye, and common loon. Bald eagles are opportunistic foragers and hunt mainly for fish and waterfowl, but will also feed on small mammals and other small vertebrates and carrion (see also Potential Impact 3.5-21). Similarly, the diet of other state species of special concern includes prey items other than fish. For example, western pond turtles forage on aquatic plants, benthic macroinvertebrates, frogs, and crayfish(see also Potential Impact 3.5-20); Barrow's goldeneye primarily eat aquatic invertebrates and fish eggs (Cornell Lab of Ornithology 2017a); and the common loon also feeds on crustaceans, snails, and aquatic insect larvae (Cornell Lab of Ornithology 2017b).

While the anticipated peak reduction in availability of hatchery-origin outmigrating smolts would occur during spring of dam removal year 2, there would also be an enhanced opportunity for these species to consume stranded or dead fish during and following reservoir drawdown (winter through spring of dam removal year 2) (Potential Impact 3.5-21). Further, these species would continue to forage on natural-origin outmigrating salmonids elsewhere in the basin (e.g., Scott, Shasta, Salmon, Trinity rivers) and would utilize alternate food sources as described above. Overall, the anticipated peak reduction in outmigrating smolts in dam removal year 2 under this alternative would not significantly affect the ability of these special-status species to perform essential feeding behaviors. Similarly, although adult returns would be reduced on average by 35 percent for fall-run Chinook beginning in post-dam removal year 3 and continuing for one to five years, bald eagles that regularly forage in the Middle and Lower Klamath River, and/or the Klamath River Estuary, would still have access to alternate food sources such as small mammals and birds such that this alternative would not significantly affect the ability of this species to perform essential feeding behaviors three to five years following dam removal. Thus, there would be no significant impact in the short term.

In the long term, dam removal would result in increased adult returns for fall-run Chinook and coho salmon due to restored connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and creation of additional spawning and rearing habitat within the Hydroelectric Reach, as well as improved habitat quality (i.e., more natural flow regime and seasonal variation in water temperature, improved water quality, reduced likelihood of fish disease and algal toxins). These long-term effects would be beneficial for fall-run Chinook salmon and would offset short-term reductions in adult returns due to cessation of hatchery operations under this alternative. In the long term, the increased abundance and productivity of these adult, juvenile, and out-migrating salmon species would result in an increased prey base and would be beneficial for bald eagles, Barrow's goldeneye, and western pond turtles. Similar conditions would occur for other fish-eating wildlife, including a variety of birds (osprey, merganser, cormorant, egret, heron) and mammals (otters, bears), such that overall there would be no short-term or long-term significant impacts on wildlife due to the loss of hatchery production under this alternative.

Significance

No significant impact in the short term or long term

4.7.6 Flood Hydrology

Removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not affect river flood stages or flood flow conditions relative to the Proposed Project. Therefore, the flood hydrology impacts of the No Hatchery Alternative would be the same as those described for the Proposed Project (Section 3.6.5 *[Flood Hydrology] Potential Impacts and Mitigation*) and there would be no significant impacts relative to existing conditions for Potential Impacts 3.6-1, 3.6-2, and 3.6-4 through 3.6-6. For reasons described in the Proposed Project, there would be significant and unavoidable impacts relative to existing conditions from exposing structures to a substantial risk of damage due to flooding in the reach between Iron Gate Dam (RM 193) and Humbug Creek (RM 174) (Potential Impact 3.6-3).

4.7.7 Groundwater

Removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not affect groundwater levels or wells immediately adjacent (potentially extending up to a mile from the reservoirs under certain conditions) to Copco No. 1 and Iron Gate reservoirs relative to the Proposed Project. Therefore, the groundwater impacts of the No Hatchery Alternative would be the same as those described for the Proposed Project (Potential Impacts 3.7-1 and 3.7-2) and there would be no significant impacts relative to existing conditions.

4.7.8 Water Supply/Water Rights

Under the No Hatchery Alternative, the Bogus Creek water diversion of up to 8.75 cfs to operate Iron Gate Hatchery, and the Fall Creek water diversion of up to 9.24 cfs to reopen and operate Fall Creek Hatchery (Section 2.7.6 *Hatchery Operations*), would not occur. However, since water proposed to be diverted for the Iron Gate and Fall Creek Hatcheries under the Proposed Project would be for non-consumptive uses, and therefore would not change the amount of water available for diversion downstream, the lack of these diversions under the No Hatchery Alternative would result in no difference relative to either the Proposed Project or existing conditions. Removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not otherwise affect the amount of surface water flow available for diversion compared to the Proposed Project; therefore, the effects of the No Hatchery Alternative on the amount of water available for diversion in the Klamath River would be the same as those described for the Proposed Project (Potential Impacts 3.8-1, 3.8-2, and 3.8-5) and there would be no significant impacts.

Under the No Hatchery Alternative, mobilization of reservoir sediment deposits during reservoir drawdown would occur as described for the Proposed Project, such that release of stored sediment could impact water intake pumps downstream from Iron Gate Dam (Potential Impact 3.8-3) and there would be a significant impact. Implementation of Mitigation Measure WSWR-1 would result in no significant impact.

The City of Yreka's municipal water supply pipeline would still need to be relocated following drawdown of Iron Gate Reservoir under the No Hatchery Alternative, and as described for the Proposed Project there would be potential for disruption to the City's water supply, which would be a significant impact. Implementation of Mitigation Measure WSWR-2 would result in no significant impact.

4.7.9 Air Quality

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to air pollutants as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Therefore, the No Hatchery Alternative would have the same short-term construction-related emissions of air pollutants (i.e., VOCs, CO, NOx, SOs, PM_{10}, $PM_{2.5}$) as those described for the Proposed Project (Potential Impacts 3.9-1 through 3.9-5). Like the Proposed Project, construction activities occurring under the No Hatchery Alternative would exceed the Siskiyou County Air Pollution Control District emissions thresholds and would result in a significant and unavoidable impact.

Note that analysis of the Proposed Project considers only construction-related air quality impacts because no changes in operational sources are part of the Proposed Project (Section 3.9.4 *[Air Quality] Impact Analysis Approach*). Under the Proposed Project, operational emissions for the reduced operation of Iron Gate Hatchery combined with the re-instated operation of Fall Creek Hatchery are assumed to be the same as existing operation conditions at Iron Gate Hatchery for eight years following dam removal, since the existing functions at the Iron Gate Hatchery that would be eliminated as part of dam removal activities, would be replaced by the reopening and operation of the Fall Creek Hatchery and by making improvements to the Iron Gate Hatchery (Section 2.7.6 *Hatchery Operations*). Thus, as a matter of general comparison, under the No Hatchery Alternative, operational emissions from the hatcheries would be lower (zero) than those under existing conditions. Since the existing operational emissions from Iron Gate Hatchery are not quantified, a beneficial significance determination may not be supported and the alteration in emissions under the No Hatchery Alternative would result in no significant impact.

4.7.10 Greenhouse Gas Emissions

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to greenhouse gas emissions as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Therefore, the No Hatchery Alternative would have the same short-term construction-related potential impacts on greenhouse gas emissions as those described for the Proposed Project (Potential Impacts 3.10-1 and 3.10-2) and would result in no significant impact on greenhouse gas levels relative to existing conditions.

Note that analysis of the Proposed Project assumes that energy use associated with the reduced operation of Iron Gate Hatchery combined with the re-instated operation of Fall Creek Hatchery would be the same as existing conditions operations at Iron Gate Hatchery for the eight years following dam removal, since the existing functions at the Iron Gate Hatchery that would be eliminated as part of dam removal activities would be replaced by the reopening and operation of the Fall Creek Hatchery and by making improvements to the Iron Gate Hatchery (Section 2.7.6 *Hatchery Operations*). Thus, as a matter of general comparison, under the No Hatchery Alternative, operational emissions from the hatcheries would be lower (zero) than those under existing conditions. Since the existing operational emissions from Iron Gate Hatchery are not quantified, a beneficial significance determination may not be supported and the alteration in emissions under the No Hatchery Alternative would result in no significant impact.

4.7.11 Geology, Soils, and Mineral Resources

Removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not affect geologic hazards, short-term soil disturbance, earthen dam embankment instability, or mineral resource availability relative to the Proposed Project. Therefore, the effects of the No Hatchery Alternative on geology and soils would be the same as those described for the Proposed Project (Potential Impacts 3.11-1, 3.11-2, and 3.11-4 through 3.11-8) and there would be no significant impacts relative to existing conditions. For reasons described in Section 3.11.5 *[Geology, Soils, and Mineral Resources] Potential Impacts and Mitigation*, Implementation of Recommended Measure GEO-1 would be necessary to reduce the potential impacts resulting from slope failure in reservoir rim areas at Copco No. 1 Reservoir (see Potential Impact 3.11-3). With implementation of Mitigation Measure GEO-1, there would be no significant impacts due to the potential for hillslope instability at Copco No. 1 Reservoir during drawdown and the year following drawdown.

4.7.12 Historical Resources and Tribal Cultural Resources

Since the Lower Klamath Project dams and associated facilities would be removed in the same manner under the No Hatchery Alternative as the Proposed Project, potential impacts and associated mitigation measures under the No Hatchery Alternative would be the same as those described for the Proposed Project, Section 3.12.5 *[Historical Resources and Tribal Cultural Resources] Potential Impacts and Mitigation*, except for the differences discussed below.

Since the Iron Gate Hatchery would not be operated for eight years following dam removal, the portion of the Limits of Work containing the Iron Gate Hatchery footprint (Figure 2.7-4) would be returned to more natural conditions In the short term, which would be beneficial relative to existing conditions and the Proposed Project. Further, since construction/upgrading activities would not occur at Fall Creek Hatchery, there would be no pre-dam removal construction activities (Potential Impact 3.12-1) at the Fall

Creek site and thus no significant impacts to known or as yet unknown tribal cultural resources (Potential Impact 3.12-1) or historic-period archaeological resources (Potential Impact 3.12-12) relative to existing conditions, and fewer impacts relative to the Proposed Project.

Full removal of the Iron Gate Hatchery, which currently releases salmonid smolts and contributes to returning adults, and not reopening Fall Creek Hatchery, would reduce the amount of Fall-run Chinook and coho salmon present for California Native American tribes that currently use salmon in their diet and consider salmon to be an important part of their culture (Potential Impact 3.12-10). The elimination of hatchery produced fall-run Chinook salmon under this alternative would likely result in a reduction (averaging 35 percent, potentially ranging from 19 to 50 percent based on existing conditions) in adult returns in the fall beginning in post-dam removal year 3 and continuing for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal are realized (see Section 4.7.3 *Aquatic Resources*, Potential Impact 3.3-7). The elimination of hatchery produced coho salmon would likely result in a reduction in adult returns for a period of one to five years before the benefits of dam removal are realized (see Section 4.7.3 *Aquatic Resources*, Potential Impact 3.3-9). This potential impact to the fishery would be greater than under the Proposed Project, because under the Proposed Project the hatcheries would continue to supplement natural adult returns (albeit at a reduced rate of production) until after seven generations or cohorts of fish have been hatched with the benefit from expanded habitat and improved water quality conditions. However, the short term reduction in the fishery due to elimination of hatchery-produced fall-run Chinook and coho salmon under the No Hatchery Alternative would represent a material impairment of the Klamath Riverscape as a resource and a substantial restriction of tribal access to the fishery relative to existing conditions.

In the long term, increased adult returns for fall-run Chinook and coho salmon resulting from restored connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and creation of additional spawning and rearing habitat within the Hydroelectric Reach, as well as improved habitat quality (more natural flow regime and seasonal variation in water temperature, improved water quality, reduced likelihood of fish disease and algal toxins), would be beneficial for fall-run Chinook salmon and coho salmon and would offset reductions in adult returns due to cessation of hatchery operations under this alternative (Section 4.7.3 *Aquatic Resources*, Potential Impacts 3.3-7 and 3.3-9). Additionally, the populations of other salmonids are expected to benefit from expanded habitat, improved water quality, reduced disease factors and decreased competition from hatchery fish. The increased abundance and productivity of these salmon species would result in an increase in availability of salmon for California Native American tribes and would be beneficial in the long term.

4.7.13 Paleontologic Resources

Removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not affect downcutting or erosion of the Hornbrook Formation located downstream of Iron Gate Dam relative to the Proposed Project. Therefore, the effects of the No Hatchery Alternative on paleontologic resources would be the same as those described for the Proposed Project (Potential Impact 3.13-1) and there would be no significant impacts relative to existing conditions.

4.7.14 Land Use and Planning

Overall, under the No Hatchery Alternative, potential impacts on connectivity between areas of a community in California would be the same as those described for the Proposed Project in Section 3.14.5 *[Land use and Planning] Potential Impacts and Mitigation*. The California dam removal actions and California land transfer and management for public interest purposes would occur in the same manner under both the No Hatchery Alternative and under the Proposed Project.

4.7.15 Agriculture and Forestry Resources

Fully removing Iron Gate Hatchery and not reopening Fall Creek Hatchery under the No Hatchery Alternative would not affect agriculture and forestry management relative to the Proposed Project or to the existing condition. Therefore, effects of the No Hatchery Alternative on agriculture and forestry resources would be the same as those described for the Proposed Project (Potential Impact 3.15-1 through 3.15-3), and there would be no significant impacts relative to existing conditions.

4.7.16 Population and Housing

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to population and housing as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Construction activities are the only part of the Proposed Project and this alternative that merit analysis for potential impacts on population and housing. The number of construction workers in California would be the same as those described for the Proposed Project and would not result in a substantial influx of population (Potential Impact 3.16-1), nor would there be a need to displace existing residents or build replacement housing elsewhere (Potential Impact 3.16-2), and there would be no significant impacts relative to existing conditions.

4.7.17 Public Services

Overall, under the No Hatchery Alternative, potential impacts on public services in California would be the same as those described for the Proposed Project. The California dam removal actions and California land transfer and management for public interest purposes would occur in the same manner under both the No Hatchery Alternative and under the Proposed Project. Thus, for reasons described in Section 3.17.5 *[Public Services] Potential Impacts and Mitigation*, impacts and associated mitigation measures from increased public service response times for emergency fire, police, and medical services due to construction and demolition activities, elimination of a long-term water source for wildfire services substantially increasing the response time for suppressing wildfires, and potential effects on schools services and facilities would be the same under the No Hatchery Alternative as those described for the Proposed Project (Potential Impacts 3.5-1 through 3.5-3).

4.7.18 Utilities and Service Systems

Full removal of the Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to utilities and services systems as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Construction activities are the only part of the Proposed Project and this alternative that merit analysis for potential impacts on utilities and service systems. For reasons described in Section 3.18.5 *[Utilities and Service Systems] Potential Impacts and Mitigation Measures*, there would be no significant impacts on utilities and service systems related to this degree of construction under the Proposed Project or this alternative. Construction-related activity in California would still require the need for onsite wastewater treatment, stormwater drainage, and/or solid waste disposal facilities at the same level as the Proposed Project (Potential Impacts 3.18-1 through 3.18-4) and would result in no significant impacts relative to existing conditions.

4.7.19 Aesthetics

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to aesthetics as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Short-term and long-term impacts on aesthetic resources, including a loss of open water and lake vistas in favor of more natural river, canyon, and valley vistas (Potential Impact 3.19-1) and changes in river flows, channel morphology, and visual water quality (Potential Impact 3.19-2 and 3.19-3) would be the same as described for the Proposed Project. Short-term visual changes resulting from reservoir drawdown would be the same as described for the Project (Potential Impact 3.19-4).

Under the No Hatchery Alternative, visual changes resulting from the removal of the Lower Klamath Project dams and associated facilities would be the same as the Proposed Project (Potential Impact 3.19-5) with the exception of the portions of the Limits of Work that contain the Iron Gate Hatchery and Fall Creek Hatchery footprints. Since Iron Gate Hatchery would not be operated for eight years following dam removal, the portion of the Limits of Work containing the Iron Gate Hatchery footprint (Figure 2.7-13) would be returned to more natural conditions in the short term. This would be beneficial relative to existing conditions and the Proposed Project. Since construction/upgrading activities would not occur at the Fall Creek Hatchery, there would be no impact (no change from existing conditions) and a small reduction in short-term impacts on aesthetic resources for the portion of the Limits of Work containing the Fall Creek Hatchery footprint (Figure 2.7-15) relative to the Proposed Project.

Other short-term visual impacts of construction activities (Potential Impact 3.19-6) and nighttime views during short-term construction activities (Potential Impact 3.19-7) would be the same as those described for the Proposed Project.

4.7.20 Recreation

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to recreation as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Thus, potential impacts would be the same as those described for the Proposed Project (Potential Impacts 3.20-1 through 3.20-3, 3.20-5) and there would be no significant impact. Loss of hatchery operations would not affect flows in the Hydroelectric Reach, such that the loss of whitewater boating opportunities in the Hell's Corner Reach (within the upper portion of the Hydroelectric Reach) would be the same as the Proposed Project (Proposed Impact 3.20-5) and would be significant and unavoidable. There would be no significant impact in the Middle and Lower Klamath River.

Full removal of the Iron Gate Hatchery, which currently releases salmonid smolts and contributes to returning adults, and not reopening Fall Creek Hatchery, would reduce the amount of salmon present for river-based recreational fishing in the short term (Potential Impact 3.20-6). The elimination of hatchery produced fall-run Chinook salmon under this alternative would likely result in a reduction (averaging 35 percent, potentially ranging from 19 to 50 percent based on existing conditions) in adult returns in the fall beginning in post-dam removal year 3 and continuing for an indeterminate period of perhaps one to five years (i.e., short-term), before the benefits of dam removal are realized (see Section 4.7.3 *Aquatic Resources*, Potential Impact 3.3-7). Most of the recreational river fishing access sites along the Middle Klamath River are rated as light usage (see Section 3.20.2.2 *Klamath River-based Recreation – Middle and Lower Klamath River – Fishing Opportunities*) and species caught by recreational fishers in the Middle and Lower Klamath River include steelhead and trout, in addition to Chinook salmon. Further, adult Chinook salmon returning to Klamath River tributaries (Table 3.20-2) (i.e., natural origin salmon) would still be available as a recreational fishing opportunity. Overall, the 35 percent reduction (on average) in available fall-run Chinook salmon beginning in post-dam removal year 3 and continuing for one to five years under this alternative would not result in changes to or loss of rare or unique recreational facilities affecting a large area or substantial number of people; therefore, the short-term impacts would be less than significant.

In the long term, increased adult returns for fall-run Chinook salmon resulting from restored connectivity to hundreds of miles of potentially usable habitat in the Upper Klamath Basin and creation of additional spawning and rearing habitat within the Hydroelectric Reach, as well as improved habitat quality (more natural flow regime and seasonal variation in water temperature, improved water quality, reduced likelihood of fish disease and algal toxins), would be beneficial for fall-run Chinook salmon and would offset reductions in adult returns due to cessation of hatchery operations under this alternative (Section 4.7.3 *Aquatic Resources*, Potential Impacts 3.3-7 and 3.3-9). The increased abundance and productivity of these salmon species would result in an increase in availability of salmon for river-based recreational fishing opportunities and would be beneficial. Since recreational fisheries would not be adversely impacted under this alternative, and for the reasons described for the Proposed Project, there would be long-term beneficial effects on the scenic quality, recreation, fisheries and wildlife of the California Klamath River wild and scenic river segment and to the resource values of the eligible and suitable wild and scenic river segment under the No Hatchery Alternative (Potential Impact 3.20-7).

4.7.21 Hazards and Hazardous Materials

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to hazards and hazardous materials as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. Thus, impacts and mitigation measures related to hazards and hazardous materials under the No Hatchery Alternative would be the same as those described in Section 3.21.5 *[Hazards and Hazardous Materials] Potential Impacts and Mitigation*, Potential Impacts 3.21-1 through 3.21-8.

4.7.22 Transportation and Traffic

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to transportation and traffic as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. However, since there would be no modifications to the Fall Creek Hatchery and no operations for managing the hatcheries, there would be slightly reduced traffic compared with that identified for the Proposed Project. The small degree of difference between the Proposed Project and this alternative would not be sufficient to change the assessment of potential transportation and traffic related impacts, and thus for the reasons described under the Proposed Project, Potential Impacts 3.22-1 through 3.22-5 would continue to be significant and unavoidable and Potential Impact 3.22-6 would be less than significant.

4.7.23 Noise

Full removal of Iron Gate Hatchery under the No Hatchery Alternative would result in a similar degree of construction activities and associated impacts related to noise as the Iron Gate Hatchery modifications (i.e., relocation of fish trapping and holding facilities, relocation of the cold-water supply) and Fall Creek Hatchery upgrades are included under the Proposed Project. However, since there would be no modifications to the Fall Creek Hatchery and no operations for managing the hatcheries, there would be slightly reduced noise compared with that identified under the Proposed Project. The small degree of difference between the Proposed Project and this alternative would not be sufficient to change the assessment of potential noise-related impacts. For the reasons described under the Proposed Project, short-term vibration from blasting at Copco No. 1, Copco No. 2, and Iron Gate dams, and noise from deconstruction activities at Copco No. 1 and Iron Gate dams and restoration activities in the reservoir footprints, would result in significant and unavoidable impacts (Potential Impact 3.23-1 through 3.23-2 and 3.23-4 through 3.23-6). Noise-related impacts at Copco No 2. Dam due to construction-related activities (Potential Impact 3.23-3), traffic noise along haul routes (Potential Impact 3.23-7), moving or elevating structures with flood risk and modification of downstream water intakes (as needed) (Potential Impact 3.23-8), construction associated with modifying water intakes (Potential Impact 3.23-9), and construction activities related to deepening or replacement of existing groundwater wells (Potential Impact 3.23-10) would result in no significant impacts relative to existing conditions, as described for the Proposed Project.

5 OTHER REQUIRED CEQA DISCUSSION AND CONSIDERATION OF SOCIAL AND ECONOMIC FACTORS

CEQA also requires consideration and discussion of several other enumerated factors, including irreversible and irretrievable commitment of resources, growth inducing impacts, and areas of controversy. Additionally, CEQA provides guidance regarding how to assess potential economic and social changes resulting from a project within the context of determining physical effects on the environment. Each of these topics is considered below.

5.1 Irreversible and Irretrievable Commitment of Resources

CEQA requires a discussion of any significant effect on the environment that would be irreversible if the project were implemented or would result in an irretrievable commitment of resources (CEQA Guidelines Section 15126(c)).

Dam removal, deconstruction, construction, and restoration activities under the Proposed Project and the other dam removal alternatives would involve the consumption of nonrenewable natural resources. These nonrenewable natural resources would consist of fuels necessary to operate equipment used during deconstruction activities. The Proposed Project would include removal of four dams and all power generation facilities. This would result in the generation of waste from the concrete, mechanical, and electrical items at the dams and power facilities. Petroleum-fueled transportation equipment would be used to haul these materials to disposal sites in the project area. In addition to fuels used in transportation, the use of the disposal sites would constitute an irreversible and irretrievable commitment of resources. Concrete and earthen materials would be used as backfill to bury dam structures, backfill the excavated tailrace channels, and restore the river to its pre-dam appearance. These materials would be permanently committed during implementation of the Proposed Project and the other dam removal alternatives. Construction activities necessary for implementation of the Proposed Project would require the use of nonrenewable natural resources including petroleum for fuels and other construction materials.

5.2 Growth Inducing Impacts

CEQA Guidelines Section 15126.2(d) requires an environmental document to:

> *"Discuss the ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth…."*

Direct growth-inducing impacts generally stem from the construction of new housing, businesses, or infrastructure. Indirect growth inducement could result if a project establishes substantial new permanent employment opportunities or if it would remove obstacles hindering population growth, such as the expansion or the provision of urban services and infrastructure in an undeveloped area. Under CEQA, growth inducement may not necessarily be considered detrimental, beneficial, or of insignificant consequence. Induced growth is considered a significant impact only if it directly (or indirectly) affects the ability of agencies to provide needed public services, or if it can be demonstrated that the potential growth significantly affects the environment.

The Proposed Project would not result in the construction of new housing either directly or indirectly. The Proposed Project would not provide new water, wastewater, sewer, electricity, or natural gas infrastructure or facilities and would not require or create any new public services such as schools, public services, or public roads that could support increased growth in the Klamath Basin.

The Proposed Project and the other dam removal alternatives would likely bring in construction workers to the project vicinity during the construction work period. Any Project-related employment required for the alternatives would be temporary and would be needed only during an approximate 17-month period encompassing demolition activities associated with Copco No. 1, Copco No. 2, and Iron Gate dam developments. Construction worker housing would be temporary during the construction period. See Section 3.16.5 *[Population and Housing] Potential Impacts and Mitigation* for a detailed discussion of this topic. Implementation of the Proposed Project would not generate any permanent employment opportunities that would attract a substantial number of people to the region or create the need for substantial amounts of new housing or services.

Restoration of the Klamath River fisheries is one of the main objectives of the Proposed Project. If the fish populations were to rebound back to pre-dam levels, this could result in an increase in recreational fishing in the region (see Section 3.20.5 *[Recreation] Potential Impacts and Mitigation* for a detailed discussion of this topic) and possibly an increase in overall tourism. Such a change in visitor numbers would likely occur slowly as fish populations rebound, but would be unlikely to result in permanent population growth.

As discussed below in Section 5.4.1.1 *Commercial Fishing*, benefits to the commercial ocean fishery and associated fleets that rely on that fishery could lead to increased regional employment, with ports along the Northern California and Southern Oregon coastlines likely to experience the highest increases. USBR (2012) estimated that under a dam removal scenario, up to 453 full time, part time, or temporary additional jobs would be created in the commercial fishing industry across the five management areas stretching along approximately 600 miles of coastline, from the San Francisco ocean commercial fishing management area to the Central Oregon ocean commercial fishing management area. Given that economic benefits related to increases in the commercial ocean fishery would come in the form of a rebound from historic lows in recent years to levels that previously existed, and estimated job creation would be spread across a region stretching from the San Francisco Bay Area to central Oregon, the increases should not reasonably necessitate new or additional permanent housing, utilities or services in the region. For additional comparative purposes, the Klamath-CA Management Zone, which includes Humboldt and Del Norte Counties, is expected to see an increase of 19 jobs due to the Proposed Project (USBR 2012), or approximately 1 percent of the population growth for that region that is projected to occur between 2020 and 2030 (1,921 people) (California Department of Transportation 2017, Humboldt County 2017).

The Proposed Project and the other dam removal alternatives would not result in new permanent housing, utilities, services, permanent employment, or other growth inducement in the region, nor would the Proposed Project result in any impacts that would require the provision of new permanent housing, utilities, services, or permanent employment. Therefore, the Proposed Project and the other dam removal alternatives would not create growth-inducing impacts.

5.3 Areas of Controversy and Issues Raised by Agencies and the Public

CEQA Guidelines Section 15123 requires disclosure of the controversial project issues known to the Lead Agency, including those raised by agencies and the public. Table ES-2 in the Executive Summary of this EIR presents a summary of controversies raised by agencies and the public during the scoping period and other forums. These are opinions and issues raised by agencies and members of the public and do not necessarily represent the position of the State Water Board.

5.4 Social and Economic Factors Under CEQA

Pursuant to CEQA, lead agencies must analyze potentially significant adverse impacts of a project to the physical environment. The term 'environment' means "*the physical conditions which exist within the area which will be affected by a proposed project including land, air, water, minerals, flora, fauna, ambient noise, and objects of historical or aesthetic significance… The "environment" includes both natural and man-made conditions"* (CEQA Guidelines Section 15360). Under CEQA, potential effects from implementing a project, such as reductions in property values, loss of property tax revenues, and increases in energy costs, that are solely social or economic in nature, would not constitute an effect (i.e., an impact) to the physical environment.

CEQA Guidelines Section 15131 states the following regarding consideration of economic or social factors as part of an EIR:

> *(a) Economic or social effects of a project shall not be treated as significant effects on the environment. An EIR may trace a chain of cause and effect from a proposed decision on a project through anticipated economic or social changes resulting from the project to physical changes caused in turn by the economic or social changes. The intermediate economic or social changes need not be analyzed in any detail greater than necessary to trace the chain of cause and effect. The focus of the analysis shall be on the physical changes.*
>
> *(b) Economic or social effects of a project may be used to determine the significance of physical changes caused by the project…. Where an EIR uses economic or social effects to determine that a physical change is significant, the EIR shall explain the reason for determining that the effect is significant.*
>
> *(c) Economic, social, and particularly housing factors shall be considered by public agencies together with technological and environmental factors in deciding whether changes in a project are feasible to reduce or avoid the significant effects on the environment identified in the EIR. If information on these factors is not contained in the EIR, the information must be added to the record in some other manner to allow the agency to consider the factors in reaching a decision on the project.*

5.4.1 Consideration of Economic Information for Resources Potentially Affected by Dam Removal

Economic studies completed in 2011−2012 by USBR (2012) and DOI (Real Estate Sub-team 2012) for removal of the four dams and alternatives considered likely costs and benefits for a number of topics, including the following:

- Hydroelectric energy costs
- Irrigated agriculture
- Commercial fishing
- In-river recreational fishing
- Ocean sport fishing
- Refuge recreation
- Nonuse values
- Real estate

The USBR/DOI economic studies determined direct dam removal costs from deconstruction, construction, operations, maintenance, and replacement, as well as forgone costs to hydropower, reservoir recreation, and whitewater recreation. Benefits were identified for irrigated agriculture, commercial fishing, ocean sport fishing, in-river sport fishing, tribal fisheries and cultural values, refuge recreation, nonuse values (e.g., desire to preserve ecosystems, altruism towards plants and animals), and real estate. Benefits to tribal fisheries and cultural values, the wildlife viewing component of refuge recreation, and real estate were not quantified in economic terms in USBR (2012). Potential economic impacts on real estate were discussed in a separate report (Real Estate Sub Team 2012).

Of the topics from the 2012 studies, several of the analyses are not relevant to the Proposed Project (i.e., irrigated agriculture, refuge recreation, nonuse values) because the prior studies related to implementation of the Klamath Basin Restoration Agreement (KBRA) (see Section 2.6.3 *Klamath Settlement Agreements*). Under the 2012 analysis, implementation of the KBRA was a “connected action” to dam removal and inclusion of the KBRA is an inherent assumption of the prior economic analyses. Other topics (i.e., hydroelectric energy costs [see Section 3.10 *Greenhouse Gas Emissions*], in-river recreational fishing [see Section 3.20 *Recreation*]) are analyzed in this EIR by focusing on physical changes that would occur as a result of the Proposed Project and the alternatives, and, consistent with CEQA Guidelines Section 15131(b), the results of the previous economic analyses are not required to determine if a physical change to the environment would be significant.

The prior economic studies of potential commercial fishing effects from dam removal is relevant to this EIR, since Proposed Project Objective 2 (see Section 2.1 *Project Objectives*) focuses on advancing the long-term restoration of the natural fish populations in the Klamath Basin, including commercial fisheries. The results of the USBR/DOI prior economic studies for commercial fishing are summarized below in Section 5.4.1.1 *Commercial Fishing*. Although this EIR focuses on the analysis of potential impacts to in-river recreational fishing under the Proposed Project (see Section 3.20 *Recreation*), the prior economic analysis of ocean sport fishing is summarized below in Section 5.4.1.2 *Ocean Sport Fishing* to provide broader context for possible increased recreational fishing opportunities given dam removal. Lastly, as noted in

Table ES-2, the State Water Board received several comments during the NOP public scoping process regarding the potential for regional economic impacts of the Proposed Project, including comments from the Pacific Coast Federation of Fishermen's associations and the Institute for Fisheries Resources, estimating economic benefits from restored fisheries, and comments from the Siskiyou County Assessor-Recorder regarding reductions in property values and the loss of property tax revenues. The results of the DOI's prior economic studies for real estate and the concerns from the Siskiyou County Assessor-Recorder are summarized below in Section 5.4.1.3 *Real Estate and Property Taxes*.

5.4.1.1 Commercial Fishing

The commercial ocean salmon fleets that rely on the affected ocean commercial fishery consist largely of small, independently owned and operated trollers[232] that land (i.e., catch) salmon south of Cape Falcon, Oregon. The fishery is a mixed stock fishery, where the commercial harvest includes salmon stocks from different rivers, including Southern Oregon/Northern California Coast (SONCC) coho and Klamath River fall- and spring-run Chinook salmon (see also Section 3.3.2.1 *Aquatic Species – Anadromous Salmonids*). The Pacific Fisheries Management Council (PFMC) manages the salmon fishery on the basis of "weak stock management," whereby regulations are designed to protect weaker stocks, even if that means foregoing some harvest of the healthier stocks that comingle with the weaker ones in the ocean commercial fishery. For purposes of this discussion the primary implications of weak stock management as it relates to SONCC coho and Klamath Chinook salmon are as follows (NMFS 2012).

- PFMC-managed ocean fisheries south of Cape Falcon are subject to consultation standards for two Chinook and four coho salmon Evolutionarily Significant Units (ESUs) listed under the Endangered Species Act (ESA), including the SONCC coho ESU (listed in 1997). To meet consultation standards for the coho ESUs, the PFMC has banned coho retention (i.e., catching and keeping or retaining individuals) in the troll fishery in Klamath Management Zone in California (KMZ-CA) and in Oregon (KMZ-OR) since 1990 and in all other management areas south of Cape Falcon since 1993 (with the exception of limited fisheries in 2007 and 2009 in Central and Northern Oregon).
- The major salmon stocks targeted by ocean fisheries south of Cape Falcon are Sacramento River fall Chinook and Klamath River fall Chinook salmon. For most of the past three decades, Klamath River fall Chinook has been more constraining on the troll fishery than Sacramento River fall Chinook. Because Sacramento River fall Chinook and Klamath River fall Chinook intermix in the troll harvest, regulations devised to limit harvest of Klamath River fall Chinook necessarily constrain Sacramento River fall Chinook harvest as well to levels below what would have been allowed in the absence of the Klamath River fall Chinook constraint.

Coastal ocean fishing-dependent communities have suffered severe economic impacts due to decreases in fish numbers and related harvest limitations. USBR (2012) identified that the removal of four dams and facilities would result in notable positive regional economic benefits to commercial troll fishing of SONCC coho and Klamath

[232] Trolling is a method of fishing where one or more fishing lines, baited with lures or bait fish, are drawn by a vessel through the ocean surface waters (or at a certain depth) to catch individual fish.

River fall- and spring-run Chinook salmon. The ocean migratory range of these species is mostly south of Cape Falcon, Oregon, and includes the Northern Oregon, Central Oregon, Klamath Management Zone (KMZ-OR and KMZ-CA), Fort Bragg, San Francisco, and Monterey management areas. The KMZ-CA (Oregon-California state line to Horse Mountain) falls within the Area of Analysis for aquatic resources in this EIR (Figure 3.3-1). Within these areas, USBR (2012) considered the effects on the SONCC coho ESU qualitatively through the increase in viability of the Klamath River coho populations. USBR (2012) reported that the removal of the dams and associated facilities would likely increase the viability of the SONCC coho ESU in the Klamath Basin, but would be unlikely to lead to de-listing of the ESU as a whole and thus they considered that coho retention would likely continue to be prohibited. Following dam removal, harvests would be larger because of increased abundance of salmon, which would, in turn, increase commercial fishing revenues.

The USBR (2012) quantitative economic analysis relied heavily on the Evaluation of Dam Removal and Restoration of Anadromy (EDRRA) model, using the average annual Klamath Chinook troll harvest for the period 2001 to 2005 (35,778 fish) as a measure of the existing condition, where this average was also applied by NMFS (2012) to assess the effects on fall- and spring-run Chinook salmon over fifty years. The EDRRA model accounted for the requirement to reserve 50 percent of the Klamath-Trinity River salmon for the Yurok and Hoopa Valley Tribes, where this requirement has been in effect since 1993 (DOI 1993), with the remaining 50 percent allocated to the in-river recreational fishery (7.5 percent), ocean sport fishery (8.5 percent), and ocean commercial fishery (34 percent) (NMFS 2012). The EDRRA model allowed for area-specific estimates of troll harvest and net revenue (gross revenue minus trip expenses) for various alternatives in the Klamath Basin, including a “No Project Alternative” and the removal of the four dams and facilities. In addition to the EDRRA model analysis of Chinook escapement and harvest, the following considerations were part of USBR’s (2012) economic evaluation, based on information from Hamilton et al. (2011), Lindley and Davis (2011), and Goodman et al. (2011):

- Partial or full dam and facilities removal would provide habitat (coldwater tributaries and thermal refugia) favorable to spring-run Chinook salmon;
- Viable populations of spring-run Chinook salmon in the Upper Klamath Basin would improve the sustainability of the ESU;
- Removal of the four dams and associated facilities offers greater potential for increased harvest and escapement of Klamath Chinook salmon than current conditions, and the potential for positive benefits is greater for the fall-run than for spring-run Chinook salmon.

Primarily using the EDRRA model, and dependent on the management area, dam and facilities removal was estimated by USBR (2012) to provide an additional 11 to 218 commercial fishing industry jobs within the five management areas, an increase of labor income between $0.06 million to $2.56 million, and an economic output of $0.13 million to $6.6 million (all 42 to 43 percent increases) for commercial fishing compared with the status quo (see Table V-4 in NMFS 2012). The average annual increase in net revenue for all areas modeled with removal of the dams and associated facilities would be $7.296 million (43 percent increase), and ocean commercial fishery benefits for 2012 to 2061 were estimated to be $134.5 million (discounted to 2012 value). The KMZ-CA portion of this annual net revenue benefit was estimated to be $267,131 (2012 dollars).

Overall, the prior economic studies concluded that commercial troll fishery harvests of SONCC coho and Klamath River fall- and spring-run Chinook salmon would increase over existing conditions due to an increased abundance of salmon resulting from dam removal. For the reasons discussed in this EIR in Section 3.3.5 *Aquatic Resource Impacts*, the KRRC's Proposed Project would be beneficial for populations of fall-run Chinook salmon (Potential Impact 3.3-7), spring-run Chinook salmon (Potential Impact 3.3-8), and coho salmon (Potential Impact 3.3-9). Although some aspects of the KRRC's Proposed Project are different from the dam removal scenarios analyzed in the USBR/DOI economic analyses, the primary assumptions regarding the effects of dam removal on coho and Chinook salmon have remained the same, such that the prior economic indication of the benefits of dam removal to commercial fisheries also informs consideration in this EIR that dam removal would advance the long-term restoration of natural fish populations in the Klamath Basin, including having a significant beneficial effect on commercial fisheries and an associated significant beneficial economic impact on the coastal commercial fishing industry.

5.4.1.2 Ocean Sport Fishing

In addition to providing in-river recreational fishing opportunities, salmon support an ocean sport fishery. Based on prior economic studies, sport fishing of the SONCC coho ESU and the Klamath River fall- and spring-run Chinook salmon could economically benefit from the removal of the four dams and associated facilities. Although there would be a substantial economic benefit to the SONCC coho ESU, USBR (2012) determined that it would be unlikely to lead to de-listing from 'threatened' under the ESA. Using the EDRRA model (described for commercial fisheries above), the average combined annual net economic value of the ocean recreational Chinook salmon harvest (all stocks) attributable to Klamath Chinook salmon was modeled to increase from $6.415 million under the "No Project Alternative" to $9.159 million following the removal of the four dams and associated facilities (43 percent increase). With the removal of the four dams and associated facilities, this would equate to an increase in the net economic value for the period 2012 to 2061 (discounted to present value) of $50.5 million in excess of the "No Project Alternative." Potential for increases in the harvest of spring- and fall-run Chinook salmon were also identified, with timing of migrations meaning that an increase in fall-run Chinook salmon abundance would be more likely to be advantageous to the ocean recreational fishery (USBR 2012). Overall, the prior economic studies concluded that ocean sport fishing of SONCC coho and Klamath River fall- and spring-run Chinook salmon would increase over existing conditions due to an increased abundance of salmon resulting from dam removal. This finding is generally consistent with the discussion in this EIR in Section 3.20.5 *[Recreation] Potential Impacts and Mitigation* that the KRRC's Proposed Project would benefit in-river recreational fishing opportunities in the long term (Potential Impact 3.20-6), although the aforementioned projected economic effects on ocean sport fishing are not required to support the significance determination for in-river recreational fishing.

5.4.1.3 Real Estate and Property Taxes

Removal of the four dams and their reservoirs could affect real estate values of parcels surrounding Copco No. 1 and Iron Gate reservoirs, and parcels adjacent to the Klamath River downstream of Iron Gate Dam. In prior studies, the outcome of the regional economic real estate analysis was complex indicating that there would be both positive and negative local value changes as a result of dam removal. Dam removal represented only one factor driving the value changes, while local circumstances and ongoing economic trends also had a major influence on predicted values (USBR 2012, Real Estate Sub-team 2012). USBR (2012) qualitatively assessed dam removal based on net economic benefits associated with various resources, and found that removal of the four dams and facilities could result in short-term declines in real estate values, which would be partially offset as the barren landscape is revegetated. USBR (2012) indicated that for some parcels that are currently adjacent to the reservoirs, loss of reservoir frontage may have a permanent adverse effect on their values. For other parcels downstream of Iron Gate Dam, USBR (2012) indicated that improvements of water quality could lead to increased real estate values in the long term. Additional details regarding the USBR (2012) and Real Estate Sub-team (2012) studies are provided below, along with a discussion of Siskiyou County Assessor-Recorder scoping comments on the Lower Klamath Project, as applicable.

The Siskiyou County Assessor-Recorder provided comments during the Lower Klamath Project scoping period (see Appendix A) expressing their view that the prior assessment on property values and tax revenues under a dam removal scenario was deficient. In their comment letter, the County Assessor-Recorder provided their assessment that PacifiCorp's assets (total $162.6 million) would be greatly reduced (by $32.5 million in value) by removal of the dams and associated infrastructure, resulting in a loss of approximately $370,000 per year in taxes for Siskiyou County, in addition to financial effects on the Hornbrook Elementary School District. While the assumptions used to arrive at the numbers in the USBR real estate reports are explained in the text of these reports, both viewpoints suggest that the County would lose some tax revenue from the removal of the dams.

The Siskiyou County Assessor-Recorder expressed concerns that while the USBR (2012) appraisal considered nearly 1,500 Potentially Impacted Parcels (PIPs) as part of their analysis, they determined that the number of parcels that could be impacted was only 700 Impacted Parcels (IPs). The County Assessor-Recorder also expressed their concern that the approach by USBR (2012) understates the reduction in appraised value and that structural and site improvements, the largest portion of a property's value, were excluded from the appraisals.

The Real Estate Sub-team (2012) Report provided the below reasoning for determining the numbers of PIPs and IPs:

> *"Based on the field inspection, it was determined that those parcels on the near side of the ridgeline were determined to have potential impacts and therefore were included in the parcel list. Those parcels on the far side (backside of the ridgeline) had limited to no views (no lake views), limited access to the reservoirs, and appeared to be larger parcels. It was concluded that these parcels would not be significantly impacted by the dam removals (any influence could not be reliably measured); therefore they were not included on the PIP list."*

The Real Estate Sub-team (2012) Report also stated that the purpose of the study was *"…to determine the impacts to the value of the real property of those parcels that align and/or are influenced by the reservoirs that have formed behind the three identified dams. This study is from a macro perspective, to wit, it is designed to look at the financial impacts, in the aggregate, it is not an analysis of an impact to any given parcel or property. It was determined that the primary value influences or enhancements to* *parcels attributable to the reservoirs include water-frontage and reservoir views. Since these value influences or enhancements are directly attributable to the land component of the real property interest and not to the improvement component it was determined that it would be unnecessary to evaluate the combined house/lot interest."*

Further, the Real Estate Sub-team (2012) Report stated the following:

> *"No building improvements are included in the analysis although approximately 12 percent of the parcels on the impacted parcel list, according to the assessor, have improvements."*

As reported in Real Estate Sub-team (2012), Figure 3.14-3 indicates the number of vacant properties (88 percent of the PIPs) that have not been developed since the surrounding subdivisions were recorded, noting that many of the lots are not ideal for building on and instead are used by owners for camping, and that the remoteness of location, limited access and high utility connection costs were also factored into the analysis. The remaining 12 percent "have land use indicating development (land is improved based on assessed value)". The Real Estate Sub Team (2012) identified 668 parcels that were likely to be negatively affected (i.e., de-valued) as a result of dam removal, and differentiated these parcels into the following three categories:

- Parcels with a view of Iron Gate Reservoir
- Parcels with a partial view of Copco Reservoir
- Parcels with Copco Reservoir Frontage/Access

Table 5.4-1 differentiates the 668 parcels by type of use, of which 127 parcels are used by single-family residences. Table 5.4-2 indicates that less than one-third of the single-family homes in the area are occupied by primary residents.

Table 5.4-1. Land Use Breakdown.

Land Use	No. of Impacted Parcels
Vacant Commercial	2
Commercial	5
Rural (20-acre minimum)	3
Vacant Rural Land (20-acre minimum)	13
Single Family Residence	127
Vacant Residential Land	518
Total Parcels	**668**

Source: Real Estate Sub-team 2012

Table 5.4-2. Single-family Homes on Copco No. 1 and Iron Gate Reservoirs.

	Single Family Residences (SRFs)	SRFs Serving as Primary Residences	Percent Primary Residents
Partial View of Copco Reservoir	40	11	28 percent
Partial View of Iron Gate Reservoir	13	5	38 percent
Copco Reservoir Frontage/Access	74	23	31 percent
Total	**127**	**39**	**31 percent**

With regard to concerns of diminishing property value as a result of the Proposed Project, confirmation of the property value effect is difficult because many variables, (including market conditions, number of distressed sales, buyer resistance) can affect the sale price of a residence (Bender and Rosenthal 2011). In the appraisal process, the Real Estate Sub-team (2012) looked at comparable units which had sold in a similar area of the development. The actual property value effect on housing units cannot be known until the first unit is sold after implementation of the Proposed Project, should this project occur. However, as described below, the Real Estate Sub Team (2012) Report notes that the effect of the Proposed Project on property values would not necessarily only be negative, but may be mixed.

Further, the amount of property tax that municipalities, school districts, and fire districts receive from the State fluctuates over time due to a number of factors in addition to property values. Some of the most significant factors that affect local revenue-raising include (ILG 2016):

- The allocation of local property tax among a county, and cities, special districts and school districts within each county is controlled by the Legislature.
- Property taxes may not be increased except with a two-thirds vote to fund a general obligation bond.
- Voter approval is required prior to enacting, increasing or extending any type of local tax.
- Assessments to pay for public facilities that benefit real property require property owner approval.

The Siskiyou County Assessor-Recorder scoping comments also expressed their view that the prior studies ignored the perception that with removal of the dams, property values for residents downstream of Iron Gate Dam would drop because people believe that they will be subject to additional flooding as a result of the removal of the dams. The County asserted in their comment letter that "*Perception is reality when it comes to property values*". The Real Estate Sub Team (2012) Report notes that dam removal would reduce or eliminate many of the effects of poor water quality in the river (e.g., extensive algae mats, odors and algal toxins), which could increase values for downstream properties located adjacent to the river, and that more robust runs of anadromous fish could also increase property value. The potential effects of the Proposed Project on flood risk, water quality, and fisheries, are robustly considered in this EIR by analyzing those specific resource topics in Section 3.6 *Flood Hydrology*, Section 3.2 *Water Quality*, and Section 3.3 *Aquatic Resources*.

Under CEQA, potential effects from implementing a project, such as reductions in property values, loss of property tax revenues, and increases in energy costs, that are solely social or economic in nature, would not constitute an effect (i.e., an impact) to the physical environment and are not further analyzed in this EIR. While Siskiyou County currently receives tax revenues from PacifiCorp for hydroelectric power generation at the Lower Klamath Project, it would be expected that these revenues would cease. This would result in a lowering of County tax revenues for operation of County government.

Under the Proposed Project, if Parcel B lands were operated as income-producing wildlife management areas after being transferred to the State then California Fish and Game Code section 1504 would apply. Subdivision (a) of section 1504 states:

> *When income is derived directly from real property acquired and operated by the State as wildlife management areas, and regardless of whether income is derived from property acquired after October 1, 1949, the department shall pay annually to the county in which the property is located an amount equal to the county taxes levied upon the property at the time title to the property was transferred to the State. The department shall also pay the assessments levied upon the property by any irrigation, drainage, or reclamation district.*

5.4.2 Consistency Under CEQA With Respect to Consideration of Economic or Social Factors

According to Section 15131(a), socioeconomic effects themselves are not required to be discussed under CEQA, but rather discussion should be focused on any physical changes that would occur as a result of such effects. If the resulting physical changes are reasonably foreseeable and significant, then the conclusion that there would be an impact is supported; otherwise it is speculative. Additionally, under Section 15131(b), economic or social effects may be used as a rationale to determine if any physical change to the environment is significant. The prior economic studies conducted by USBR and DOI for removal of the four dams and alternatives did not identify reasonably foreseeable physical impacts that could occur as a result of anticipated economic effects due to dam removal, nor did the 2012 KHSA EIS/EIR that relied upon those studies. Additionally, during scoping the public did not raise any substantial concerns that the potential economic or social changes resulting from the Proposed Project would, by themselves, result in significant adverse physical changes to the environment separate from any impacts already identified by the analyses. Based on subsequent review of the prior economic studies for preparation of this EIR (see Section 5.4.1 *Prior Economic Studies for the Klamath Basin Dam Removal*), there would be economic benefits to commercial fisheries that could lead to physical changes to the environment. While increased commercial fish catch could impact the ocean environment near the Klamath River mouth and result in the need for additional infrastructure onshore, because the potential environmental effects associated with a long-term increase in commercial harvests are speculative, and would be subject to local or other regulations, they are not considered further.

Additionally, the concerns and issues raised by the public during the NOP scoping process (Section 5.3 *Controversies and Issues Raised by Agencies and the Public*) do not provide substantial evidence that potential economic changes or social changes resulting from the Proposed Project would, by themselves, result in significant adverse physical changes to the environment separate from any impacts already identified by the analyses. Where the potential for socioeconomic effects has been raised, the effects have themselves been speculative, and while these remain speculative, so would the potential for any resulting physical impacts to the environment.

Having considered CEQA Guidelines Sections 15131(a) and (b), reasonably foreseeable physical environmental effects of the Proposed Project and alternatives (e.g., transformation of reservoirs into a free-flowing river, downstream transport of reservoir sediment deposits, alterations in the 100-year floodplain, changes in seasonal water temperatures in the Klamath River) have been rigorously assessed in this EIR using significance criteria that directly reflect the characteristics of the associated environmental resource being analyzed. Further, a number of potential environmental effects of the Proposed Project and alternatives that could have related socioeconomic effects (e.g., unplanned population growth, displacement of existing people or housing necessitating the construction of replacement housing, changes in connectivity between areas of a community, conversion of agricultural or forest lands) also have been rigorously assessed in this EIR using significance criteria that directly reflect the characteristics of the associated environmental resource being analyzed, such that a separate social or economic analysis is not required, consistent with Section 15131(b).

According to Section 15131(c), consideration of appropriate mitigation measures and/or alternatives to a project should include an assessment of whether there are any socioeconomic effects that would render the proposed measures or alternatives infeasible, such that they would not avoid significant adverse physical changes to the environment. Consideration of potential economic impacts of Lower Klamath Project mitigation measures and alternatives to the Proposed Project was undertaken throughout EIR preparation. For example, the physical removal of reservoir bottom sediments prior to drawdown (i.e., dredging) was deemed to be infeasible, in part due to the high cost of this approach (Lynch 2011) and thus cannot serve as mitigation for short-term increases in suspended sediment concentrations due to dam removal. Section 4 *Alternatives* also presents a discussion of the selection of feasible alternatives that includes consideration of the cost of implementing project alternatives.

Note that a number of impacts have been identified as significant and unavoidable under the Proposed Project, because mitigation is infeasible due to preemption of the Federal Power Act over state authority (see Section 2.8 *Intended Uses of the EIR*) rather than for socioeconomic reasons.

In summary, this EIR is consistent with CEQA Guidelines Section 15131 regarding consideration of economic or social factors associated with a project. The use of potential economic or social effects of the Proposed Project to determine the significance of physical changes caused by the project is unnecessary given that the significance criteria used in this EIR directly reflect the characteristics of the associated environmental resource being analyzed, and any other potential physical changes are speculative. Lastly, consideration of potential economic impacts of Lower Klamath Project mitigation measures and alternatives to the Proposed Project has been undertaken throughout this EIR.
